Singapore 2025
WORLD SLEEP
September 5-10

World Sleep Society is pleased to share the abstracts presented at the 18th World Sleep congress, which was held in Singapore over September 5 – 10, 2025. Researchers from over 80 countries gathered in Singapore to present the 1700+ abstracts now published in this supplement. We thank the World Sleep community for its contributions to the World Sleep 2025 scientific program and to the advancement of sleep health.

Age-related Changes in Sleep Characteristics and Chronotype, and Their Associations with Physical Frailty: A Longitudinal Study

J. Wei¹, H. Wu¹, X. Tan^{1,2}

¹Zhejiang University, Department of Big Data in Health Science, Zhejiang University School of Public Health, Hangzhou, China, ²Karolinska Institutet, Department of Clinical Neuroscience, Stockholm, Sweden

Introduction: Sleep phenotypes and circadian manifestations are closely linked with physical frailty. However, the associations between sleep traits, chronotype, and the impact of chronological changes in these factors on frailty remain underexplored.

Materials and methods: A total of 292,940 UK Biobank participants were included for association analysis. Among, 34,157 participants were used for transition analysis. Self-reported continuous sleep duration (short (≤ 6 h) and long (≥ 9 h) sleep durations), insomnia, and chronotype were treated as exposures. Physical frailty was assessed by Fried five criteria, including weight loss, exhaustion, low physical activity, slow walking speed, and low grip strength. Multinomial logistic regression (MLM) and Two-stage regression (2SLS) were applied to analyze the associations. Transition analysis examined the effect of changes in sleep traits and chronotype on frailty risk.

Results: In both MLM and 2SLS models, each additional hour of sleep was associated with a lower risk of frailty (MLM: OR 0.92, 95% CI 0.91-0.94; 2SLS: OR 0.58, 95% CI 0.45-0.73). Short sleep duration (MLM: OR 1.96, 95% CI 1.88-2.05; 2SLS: OR 5.89, 95% CI 2.84-12.18) and insomnia (MLM: OR 2.72, 95% CI 2.61-2.83; 2SLS: OR 2.44, 95% CI 1.37-4.36) were associated with increased frailty risk. Morning chronotype was linked to a lower risk of pre-frailty (MLM: OR 0.94, 95% CI 0.93-0.94; 2SLS: OR 0.93, 95% CI 0.90-0.97). Transition analysis revealed that maintaining healthy sleep patterns (7-8 hours of sleep, no insomnia, and morning chronotype), along with improvements in insomnia and chronotype shifts, were associated with reduced frailty risk.

Conclusions: Multiple sleep and circadian phenotypes including short sleep duration, insomnia, and late chronotype may predispose physical frailty, and improvements in these factors overtime can reduce frailty risk. This underscores the need for widespread attention to sleep and circadian health.

Age related changes in sleep quantitative EEG brain activity and longitudinal relationship to cognitive function

E. Stumbles^{1,2}, B. Yee^{1,2}, S. Appleton^{3,4}, R. Adams^{3,4}, J. Parker^{3,4}, A. Vakulin^{1,3}, G. Wittert^{5,6}, N. Marshall^{1,7}, A. D'Rozario^{1,7}

¹Woolcock Institute of Medical Research, Sydney, Australia, ²University of Sydney, Sydney, Australia, ³Flinders Health and Medical Research Institute, Adelaide, Australia, ⁴Flinders University, Adelaide, Australia, ⁵Australian Institute of Family Studies, Melbourne, Australia, ⁶Freemasons Centre for Male Health and Wellbeing, Adelaide Medical School, Adelaide, Australia, ⁷Macquarie University, Sydney, Australia

Introduction: Sleep microarchitecture including spindle characteristics evolves with normal ageing, and cognition declines with age. Sleep disturbance is a risk factor for cognitive impairment, however the underlying pathophysiology remains incompletely understood. Altered sleep spindle metrics have been shown to be associated with an increased risk of mild cognitive impairment in cross-sectional studies, however the longitudinal relationship between sleep neurophysiology and cognition in middle-to-late life is unclear. This study examined sleep microarchitecture measured by single channel (F4-M1) EEG and cognitive performance assessed with the trail-making test (TMT) part A and B and mini-mental state examination (MMSE) in a cohort of community dwelling men from the Florey Adelaide Male Ageing Study (FAMAS) over an 8-year period. The objectives of the study were to examine changes in sleep microarchitecture, and changes in cognition over eight years, and to investigate the longitudinal relationship between sleep microarchitecture and cognition.

Materials and methods: Participants from the FAMAS with no reported previous diagnosis of OSA underwent home-based PSG and cognitive testing at baseline and at follow-up, approximately eight

years apart. Power spectral analysis of EEG recordings was performed. Baseline and follow-up sleep parameters including sleep spindle characteristics and power spectra, and baseline and follow-up cognition were compared using paired t-tests, and associations were examined using Pearson's correlation.

Results: NREM (267.6 vs 299.2 minutes) sleep was higher during follow up PSG compared to baseline ($p < .001$). NREM spindle events (257.5 vs 351.7) and density (0.95 vs 1.17 events/ minute) were higher at follow up ($p < .001$). TMT performance declined (TMT-A: 15.4 vs. 38.7 seconds, TMT-B: 74.9 vs. 93.7 seconds, $p < .001$). There was no change in MMSE. The change in sleep spindle metrics and cognition were not correlated.

Conclusions: In this community-dwelling cohort of men, significant differences were observed in sleep spindle metrics and cognitive function at follow-up compared to baseline. No longitudinal relationship between sleep microarchitecture and cognitive function was observed.

Amplitude fluctuations of cerebrovascular oscillations and CSF movement desynchronize during NREM3 sleep

V. Vijayakrishnan Nair¹, B. Kish¹, H. Oshima¹, A. Wright², Q. Wen², Y. Tong¹, A.J. Schwichtenberg³
¹Purdue University, Weldon School of Biomedical Engineering, West Lafayette, United States, ²Indiana University School of Medicine, Department of Radiology and Imaging Sciences, Indianapolis, United States, ³Purdue University, Human Development and Family Science, West Lafayette, United States

Introduction: Sleep is a natural, reversible, and repeating neuro-behavioral state characterized by distinct coordinated cellular, circuit, and system level changes intended to optimize physiology, behaviour, and health. In mammals, sleep is broadly divided into different states – non-rapid eye movement (NREM) and rapid eye movement (REM) sleep with NREM sleep further divided into NREM1, NREM2 (collectively called light sleep), and NREM3 (deep sleep). During sleep, an individual cycles between these states which are characterized by distinct patterns of neural activity, muscle tone, breathing, and systemic physiology - including cerebrospinal fluid (CSF) movement.

Fluctuations in cerebral blood volume (CBV) are a dominant mechanism aiding CSF movement in the brain during wakefulness and non-rapid eye movement (NREM) sleep. However, it is unclear if the amplitudes of CBV oscillations also change in proportion to the changes in amplitude of CSF movement across specific NREM sleep states. It is also not known if the coupling strength between them varies between NREM sleep states. To investigate these relationships, we measured cerebral hemodynamics and cranial CSF movement at the fourth ventricle simultaneously during wakefulness and NREM sleep states using concurrent Electroencephalography and functional Magnetic Resonance Imaging.

Materials and methods: Ten healthy participants (6 females) aged 19 – 24 (20.90 ± 1.59) years were included in this study. The wake/sleep cycles were continuously monitored via actigraphy for a minimum of four days prior to the experimental session to ensure that they maintained regular habitual sleep schedules. In addition, they were also asked to listen to sound recordings from the MR scanner to acclimate to the sound. Further, on the day of the scan, participants were asked to wake 3 hours earlier than usual and the scan sessions were initiated an hour past their typical bedtime to build homeostatic and circadian sleep pressure. All participants' structural and functional MRI data were acquired using a 3T SIEMENS MRI scanner with a 64-channel head coil. 32-channel Electroencephalography (EEG) was concurrently acquired to allow for sleep stage scoring.

Results: We found that the amplitude fluctuations of cerebral hemodynamics and CSF oscillations desynchronize from one another only during deep NREM3 state, despite the strong mechanical coupling between CBV changes and CSF movement, which was consistent across all states. Deep NREM3 sleep marked a period of significant reduction in the amplitude fluctuations of only the cerebral hemodynamics, without any similar reductions in CSF inflow to the brain compared to light sleep. Interestingly, we also found the coupling between cerebral hemodynamic changes and CSF inflow continues to remain strong during NREM3 sleep, despite a significant reduction in cerebral hemodynamic fluctuations.

Conclusions: Our results suggests the existence of a different mechanism, linked to the cortical interstitial volume/resistance change, that regulates the NREM3 CSF inflow into the brain.

An integrated analysis of rhythmic ageing markers, targets of anti-ageing compounds, and metabolic pathways for unraveling the circadian impact on ageing

S. Banerjee¹, S. Saha¹, R. Ghana¹, S. E H¹, S. Ray¹

¹India Institute of Technology, Biotechnology, Hyderabad, India

Introduction: Circadian rhythms have pronounced impacts on human health, diurnally synchronising physiological and behavioural processes. Circadian dysfunction can cause a multitude of physiological and metabolic irregularities, neurodegeneration, oxidative damage, and reduced lifespan. Ageing enhances these disruptions, leading to diverse chronic diseases. Therefore, it is crucial to investigate the molecular underpinnings and markers of ageing and their effects on circadian dysregulations. Also, compounds with evidence of prolonging lifespan are now well-reported; however, the effects of geroprotectors on circadian behavior remain poorly understood from a clock-controlled perspective. Our study addresses these gaps by a) creating a comprehensive map of circadian ageing markers across the mammalian system, b) identifying chrono-geriatric targets for ageing attenuation, and c) elucidating the effects of geroprotectors on circadian behavior across different aged *Drosophila*.

Materials and methods: In this study, we performed an *in-silico* analysis from a circadian perspective to identify ageing markers and chrono-geriatric targets for ageing attenuation. We curated a comprehensive map of human ageing markers (besides homologs in mice and *Drosophila*) from the Human Aging Genomic Resources, Aging Atlas, and Digital Aging Atlas databases. Another aspect of our study was curating anti-ageing drugs utilising the DrugAge and Ageing Atlas databases and their targets from Drugbank. We identified 24-hour rhythmic transcripts using CircaDB at the transcriptome level across the mammalian system for both the ageing markers and targets of anti-ageing pharmacological compounds (<http://circadb.hogeneschlab.org/>). Using the DAVID (<https://david.ncifcrf.gov/>) resource system, we conducted a functional analysis of the ageing-related rhythmic transcripts and robustly rhythmic compound targets (Period 24±3 hr, JTKQ < 0.1) to map the enriched pathways (FDR<0.01). On examining compounds with secondary clock targets and evidence of lifespan extension, we selected resveratrol as a candidate compound. The effects of resveratrol were investigated in different age groups of *Drosophila*.

Results: 50% of ageing genes investigated across the mammalian systems exhibit 24-hour rhythmic oscillation at the transcriptome level. The key physiological pathways associated with prevalent rhythmic genes were the longevity-regulating pathway, the AGE-RAGE signaling pathway, and pancreatic cancer in humans. The convergent biological process corresponding to oscillating targets of anti-ageing compounds was lipid metabolism. Resveratrol treatment was found to enhance locomotor activity with ageing, besides its sleep-altering effects when administered early in life.

Conclusions: The robustly rhythmic molecular components associated with the Absorption, distribution, metabolism, and excretion (ADME) process of geroprotectors converged to the biological process of lipid metabolism, a potential target for future chrono-geriatric treatments. Additionally, our investigations portray anti-ageing compounds' role in altering clock-controlled behavioural rhythms.

Association Between Functional Dyspepsia and Sleep Architecture Disruption in Geriatric Patients: A Comprehensive Cohort Study

W. Qi¹, X. Gao², J. Wang³, J. Zhang¹, Y. Liu³

¹Shijiazhuang People's Hospital, Shijiazhuang, China, ²Hebei Medical University, Shijiazhuang, China,

³Peking University People's Hospital, Beijing, China

Introduction: Sleep disorders and functional dyspepsia are prevalent comorbidities in patients with geriatric syndrome. The co-occurrence of functional dyspepsia and sleep disturbances demonstrates significant epidemiological overlap, with sleep disruptions frequently triggering emotional disturbances

and exacerbating gastrointestinal symptoms. Further investigation into the bidirectional pathophysiological interplay between these conditions is warranted to advance clinical risk stratification and therapeutic decision-making.

Materials and methods: A cohort of 400 elderly patients (aged ≥ 65 years) treated in Shijiazhuang People's Hospital, Hebei Province, P. R. China, from January 2022 to December 2023 was prospectively analyzed. Participants were stratified into sleep disorder ($n=281$, PSQI ≥ 8) and normal sleep groups ($n=119$, PSQI ≤ 7) using Pittsburgh Sleep Quality Index (PSQI) criteria. Comparative analysis of clinical characteristics was performed, followed by multivariate logistic regression to identify sleep quality determinants. The sleep disorder cohort was further subclassified by functional dyspepsia (FD) status into FD group ($n=224$) and non-FD group ($n=57$), with FD severity stratified into mild and moderate-severe subgroups. Polysomnography (PSG)-derived sleep architecture parameters were compared across groups. Spearman's rank correlation analyzed FD severity-PSQI associations.

Results: Significant intergroup differences emerged in marital status, smoking history, chronic gastrointestinal disorders, SDS scores (≥ 53), SAS scores (≥ 50), and FD prevalence (all $P<0.05$). Multivariate analysis identified SDS ≥ 53 (OR=2.41, 95%CI 1.62-3.58), SAS ≥ 50 (OR=1.97, 95%CI 1.28-3.04), chronic gastrointestinal comorbidity (OR=3.12, 95%CI 1.89-5.15), and FD diagnosis (OR=4.05, 95%CI 2.47-6.63) as independent risk factors for sleep disorders. The FD subgroup demonstrated elevated PSQI scores (14.3 ± 3.2 vs 8.1 ± 2.7 , $P<0.01$) and increased N1+N2 sleep stage proportion ($68.4\%\pm 9.1$ vs $59.2\%\pm 8.3$, $P<0.001$) compared to non-FD counterparts. PSG analysis revealed obstructive sleep apnea (OSA) severity stratification: no OSA (4.2%), mild OSA (13.9%), moderate OSA (22.1%), and severe OSA (59.8%), with significant PSQI elevation in moderate-severe OSA groups ($P<0.05$). Strong positive correlation emerged between FD severity and PSQI scores ($r=0.625$, $P=0.021$).

Conclusions: Progressive sleep architecture disruption in elderly patients demonstrates significant associations with FD severity, modulated by psychological parameters (SDS/SAS thresholds) and gastrointestinal comorbidity. These findings advocate integrated sleep-gut axis evaluation in geriatric care protocols.

Association Between Sleep Duration and Sarcopenia in Korean Older Adults: Evidence from the 2022 KNHANES

J. Yim¹, Y. Her²

¹Kangwon National University Hospital, Family Medicine, Chuncheon-si, Korea, Republic of, ²Kangwon National University School of Medicine, Department of Dermatology, Chuncheon-si, Korea, Republic of

Introduction: Sarcopenia, defined as the combined loss of muscle mass and strength, is a significant health problem among older individuals, and is associated with impaired mobility, falls, and increased mortality. Although there is growing evidence that sleep duration is associated with reduced risk for sarcopenia, the evidence has been inconsistent, and there has been a lack of studies examining the relationship between sleep duration and risk for sarcopenia in Asian populations, including Korean older adults. Here, we utilize nationwide representative data from Korea to analyze the relationship between sleep duration and sarcopenia.

Materials and methods: We used the 2022 Korea National Health and Nutrition Examination Survey (KNHANES) data, consisting of a total of 2,544 adult subjects 65 years of age and older. Sarcopenia was defined based on the 2019 Asian Working Group for Sarcopenia (AWGS) definitions: low grip strength (≤ 28 kg in men and ≤ 18 kg in women) and low appendicular skeletal muscle mass index ($ASM/height^2 \leq 7.0$ kg/m² for men, ≤ 5.0 kg/m² for women). The sleep duration was performance into four categories: ≤ 5 hours, 5–7 hours, 7–9 hours (reference), and ≥ 9 hours. Multivariable logistic regression models were applied to assess the relationship between sleep duration and sarcopenia overall, while adjusting for sociodemographic, lifestyle, and clinical factors.

Results: The odds ratio of sarcopenia was 1.75 (95% CI: 1.02–2.99, $p=0.041$) in a participant who had 9 h or more sleep independent of reference group (7–9 h sleep). No such relations were found in the ≤ 5 h or 5–7 h groups. The sub-cohort analysis of men showed a similar trend (aOR=1.60) but it also did

not reach significance. For women, no significant relationship was observed between sleep duration and sarcopenia. U-type association between sleep duration and the risk of sarcopenia.

Conclusions: This is one of the first studies to examine the relationship between sleep duration and sarcopenia among Korean older adults based on nationally representative data. We found that long sleep (≥ 9 hours) was associated with an increased risk of sarcopenia, similar to those of previous studies for CHARLS and NHANES populations, respectively. These findings emphasize the need to consider sleep duration as a modifiable lifestyle factor in the prevention of sarcopenia and strategies for healthy aging among Korean older adults.

Associations between obstructive sleep apnoea risk and fall-related physical performance

R. Khanal¹, K.Sv. Schooten^{2,3}, R. Piovezan^{4,5}, R. Adams¹, K. Sansom^{1,6}, A. Vakulin¹

¹Flinders University, Flinders Health and Medical Research Institute Sleep Health, Adelaide, Australia,

²Falls, Balance and Injury Research Centre, Neuroscience Research Australia, Sydney, Australia,

³University of New South Wales, School of Population Health, Sydney, Australia, ⁴University of Adelaide, Adelaide, South Australia, Australia, Adelaide Geriatrics Training and Research with Aged Care (GTRAC) Centre, Adelaide, Australia, ⁵SA Health, Aged Care, Rehabilitation and Palliative Care Division, AdelaideAusta, Australia, ⁶Murdoch University, Centre for Healthy Ageing, Health Futures Institute, Perth, Australia

Introduction: Falls are a leading cause of injury, loss of independence and mortality in older people. Measures of physical performance, including balance, gait speed, and handgrip strength are significant predictors of falls. Emerging evidence suggests that obstructive sleep apnoea (OSA), a common sleep-related breathing disorder, may impair physical and cognitive performance in older adults, potentially through mechanisms including nocturnal hypoxemia, excessive daytime sleepiness, and impaired vasoreactivity. However, associations between the risk of OSA and fall-related physical performance remain unclear.

Materials and methods: Cross-sectional data from the 2016 Health and Retirement Study was analysed. OSA risk was derived using survey items aligned with the STOP-Bang questionnaire. Poor balance was defined as the inability to hold a semi-tandem stance for 10 seconds. Slow gait speed was defined as walking <0.8 m/s over 2.5 meters. Weak handgrip strength (HGS) was defined as HGS divided by body mass index (BMI) of <1.00 kg/BMI for males and <0.56 kg/BMI for females. Binomial logistic regression models were used to examine associations between high-risk OSA and physical performance measures. Potential confounders adjusted in the models include age, sex, BMI, physical activity, alcohol consumption, comorbidity burden, ethnicity, and treatment for sleep/snoring problems.

Results: Data from 6,911 participants (mean age 66 ± 11 years; 57% female) were analysed. The prevalence of high-risk OSA, poor balance, slow gait speed and weak HGS was 36%, 32%, 63% and 15%, respectively. High-risk OSA was significantly associated with higher odds of poor balance (OR: 1.23, 95% bootstrapped confidence interval (BCI): 1.07-1.39, $p=0.002$), slow gait speed (OR: 1.29, BCI: 1.06-1.56, $p=0.009$), and weak HGS (OR: 2.20, BCI: 1.86-2.60, $p=0.001$).

Conclusions: High-risk OSA is associated with higher odds of poor balance, slow gait speed and weak relative HGS, which are key predictors of falls. Co-screening of OSA and poor fall-related physical performance may support early detection and preventative strategies to improve safety and maintain functional independence in older adults.

Acknowledgments: All participants of the health and retirement study.

Associations Between Sleep Patterns and Estimated Pulse Wave Velocity From a Wearable Smart Ring in 500,000 Free-Living Adults

A. Rantanen¹, M. Valkonen¹, P. Ohukainen¹

¹Oura Health, Oulu, Finland

Introduction:

Pulse wave velocity (PWV) is a well-established marker of arterial stiffness and a predictor of cardiovascular risk. Although conventionally assessed using tonometry or oscillometric techniques, recent evidence indicates that features derived from photoplethysmography (PPG)—a signal commonly

captured by consumer wearables such as smart rings—correlate strongly with PWV. This advancement supports the potential for continuous, passive vascular monitoring in real-world settings.

Sleep duration has shown a U-shaped association with arterial stiffness, with both short and long sleep linked to higher PWV. Beyond duration, lower sleep regularity, quantified by the Sleep Regularity Index (SRI), has been associated with increased PWV.

To address the need for validated wearable estimated PWV (ePWV) metrics, this study evaluates the accuracy of smart ring PPG-based estimates against a reference device and examines the relationship between ePWV and long-term sleep patterns in a large free-living cohort.

Materials and methods:

Carotid-femoral PWV (cf-PWV) was measured using the SphygmoCor XCEL system in a reference cohort of 300 healthy individuals. A model was trained on 200 participants using wearable-derived features and validated on the remaining 100.

We analysed anonymised and de-identified data from 500,000 Oura Ring Gen3 users with ≥ 14 days of valid recordings in September 2024. Daily sleep and ePWV estimates were averaged to produce monthly aggregates. ePWV delta was calculated as the difference between each user's estimated PWV and the age- and sex-specific average within the dataset.

Sleep metrics included total sleep time, awake time, sleep stage durations (light, deep, REM), and sleep onset and wake times, used to calculate the SRI. The difference between ePWV delta in binned sleep metric groups was evaluated using Kruskal–Wallis test.

Results: ePWV showed good agreement with cf-PWV ($R = .76$, mean difference = $.210$ m/s, $SD = .999$ m/s), meeting acceptable validation criteria (mean $\pm$ SD between 1.0 – 1.5 m/s). ePWV delta differed across total sleep duration groups, lowest at 7–9 hours; long sleep (>9 h) showed a greater increase than short sleep (<7 h). Kruskal–Wallis tests showed significant differences ($p < .001$) across all metrics. Increased deep and REM sleep were linked to lower ePWV delta, while increased awake time was tied to higher values. Light sleep duration showed a U-shaped pattern in ePWV delta. Higher SRI corresponded to lower ePWV delta.

Conclusions:

PWV estimates from a smart ring demonstrate acceptable agreement based on recommended validation guidelines. 7–9h sleep duration, regular timing, and more deep/REM sleep are linked to lower arterial stiffness (ePWV). In contrast, 4–7h and 9–11h sleep duration, irregular timing and more awake time are linked to higher ePWV. These findings demonstrate that PPG-based ePWV produces results consistent with prior research and provide a foundation for future large-scale studies investigating the complex relationship between sleep and arterial stiffness.

Acknowledgments: The authors are employed by Oura Health, the wearable device manufacturer.

Benzodiazepine Burden and associated Health Risks in geriatric Patients with Hearing impairment: A Population-Based Cohort Study

H. Choi¹, H. Song², J.-H. Nam³, J.-Y. Shin^{4,5}, J.-H. Seo⁶, W.S. Jeong⁷

¹Veterans Health Service medical center, Department of Psychiatry, Seoul, Korea, Republic of,

²Sungkyunkwan University, School of Pharmacy, Suwon, Korea, Republic of, ³Korea University Sejong Campus, Division of Big Data Science, Sejong, Korea, Republic of, ⁴Sungkyunkwan University, Department of Clinical Research Design & Evaluation, Samsung Advanced Institute for Health Sciences & Technology (SAIHST), Seoul, Korea, Republic of, ⁵Sungkyunkwan University, Department of Biohealth Regulatory Science, Seoul, Korea, Republic of, ⁶Korea University Sejong Campus, Department of Big Data Science, Sejong, Korea, Republic of, ⁷Korea University Sejong Campus, Department of Applied Statistics, Sejong, Korea, Republic of

Introduction: Benzodiazepine derivatives (BDZs) are commonly utilized as sedatives, hypnotics, muscle relaxants, and anticonvulsants. In South Korea, orexin receptor antagonists have not yet been introduced into clinical practice; thus, BDZs, along with Z-drugs, are prescribed in certain cases for the management of insomnia. Hearing loss is prevalent among older adults and is associated with an increased risk of falls, cognitive impairment, and mortality. BDZs may worsen these risks owing to their adverse effects to this age group with hearing loss. This study aims to investigate the association between prolonged BDZs use and the subsequent risks of falls, fractures, emergency department (ED) visits, dementia, and mortality in older adults with hearing loss in Korea.

Materials and methods: This population-based retrospective cohort study utilized data from the Korean National Health Insurance Database spanning 2018 to 2021. Participants included individuals aged 65 years or older who were diagnosed with hearing loss in the previous year, excluding those with cancer, genetic hearing loss, fractures, or dementia. The benzodiazepine burden was assessed using the approximate equivalent dose of 10 mg of diazepam (EDD10) and total standardized daily doses (TSDD). Cox regression analysis estimated hazard ratios (HRs) for falls, fractures, ED visits, dementia, and mortality, adjusting for covariates. The models used were as follows: Model 1 was unadjusted; Model 2 adjusted for age and sex; Model 3 further adjusted for alcohol consumption, smoking, and BMI; and Model 4 included adjustments for comorbid diseases associated with falls, fractures, and dementia.

Results: The final cohort consisted of 598,152 individuals. The group with a high benzodiazepine burden (TSDD $\geq$ 30, n=85,614) exhibited significantly increased risks for dementia (adjusted HR 1.197, 95% CI 1.162-1.215), ED visits (adjusted HR 1.051, 95% CI 1.016-1.079), and mortality (adjusted HR 1.127, 95% CI 1.09-1.164) compared to the group with no benzodiazepine burden (TSDD=0, n=370,665) after adjusting age, sex, alcohol use, smoking use, body mass index, comorbid diseases related to falls, fractures, and dementia. When the outcomes were falls and fractures, a significantly increased risk was observed in the group with a high benzodiazepine burden after adjusting for age, sex, alcohol use, smoking status, and body mass index. However, this association was no longer significant after further adjustment for comorbid conditions related to falls, fractures, and dementia. The Kaplan–Meier curves indicated a higher incidence of all outcomes, except mortality, in the high benzodiazepine burden group compared to the no burden group at all observed time points.

Conclusions: Prolonged benzodiazepine use in older adults with hearing loss is associated with an elevated risk of adverse outcomes, including dementia, ED visits, and mortality. When prescribing to this vulnerable population, the risk-benefit balance should be carefully considered and monitoring this population to mitigate potential harms. Further research is warranted to explore alternative therapeutic options and the underlying mechanisms contributing to these risks.

Acknowledgments: The authors thank the National Health Insurance Service (NHIS) for their cooperation in providing access to the National Health Insurance Database.

Cerebral and Peripheral Hemodynamics across wakefulness and NREM Sleep

V. Nair¹, B. Kish¹, H. Oshima¹, Q. Wen², Y. Tong¹, A.J. Schwichtenberg³

¹Purdue University, Weldon School of Biomedical Engineering, West Lafayette, United States, ²Indiana University School of Medicine, Department of Radiology and Imaging Sciences, Indianapolis, United States, ³Purdue University, Human Development and Family Science, West Lafayette, United States

Introduction: Wake/sleep state-related changes in cerebral hemodynamic oscillations are well established. However, similar changes in peripheral hemodynamics are vastly understudied. Importantly, the inter-relationships between cerebral and peripheral hemodynamics may change with wake/sleep states, given the fact that these oscillations in the low-frequency range are strongly coupled during wakefulness. The current study therefore investigates the temporal and spectral variations in cerebral and peripheral hemodynamics as well as the coupling between them in the low-frequency range across sleep-wake states.

Materials and methods: To study these, we concurrently measured cerebral hemodynamics and peripheral hemodynamics respectively using functional Magnetic Resonance Imaging of the brain and Near-infrared spectroscopy of the fingertips during wakefulness and non-rapid eye-movement sleep. This study included 10 healthy participants (6 females) aged 19 – 24 (20.90 $\pm$ 1.59) years. Actigraphy

was used to track each participant's sleep-wake cycles for at least four days before the experiment to ensure they adhered to their usual sleep schedules. Additionally, to allow for sound acclimation, they were instructed to listen to sound recordings from the MR scanner at bedtime for two to three nights before their scheduled bedtime scan. To capitalize on elevated homeostatic and circadian sleep pressures, participants were asked to wake up three hours earlier than usual the morning of their scan, and the scan sessions began roughly one hour after their usual sleep onset time. All MRI data were acquired using a 3T SIEMENS MRI scanner with a 64-channel head coil. Peripheral hemodynamics were recorded from two fingertips (fourth finger of both arms) using a Continuous Wave (CW) NIRS system with two laser sources, each combining two wavelengths (785 and 830 nm) and MRI-compatible NIRS probes with 10 m long optical fibers. For sleep scoring, a 32-channel Electroencephalography (EEG) was also simultaneously acquired using an MRI-compatible EEG system.

Results: Overall findings from the present study are twofold. First, hemodynamics in the brain remarkably differ in both oscillation amplitude and spectral power from peripheral hemodynamics during NREM sleep stages. Second, the LF coupling between cerebral and peripheral hemodynamics become desynchronized during NREM3 sleep.

Conclusions: Our data demonstrate the amplitude fluctuations of cerebral hemodynamics significantly increase during light NREM sleep (NREM1 and NREM2) and then decrease significantly during deep sleep (NREM3). Fluctuation levels of peripheral hemodynamics however stays the same from wake to NREM3. To our knowledge, this is the first study to report this discrepancy in hemodynamic fluctuation levels between brain and periphery during NREM sleep.

Clinical Characteristics of pediatric Obstructive Sleep Apnea Hypopnea Syndrome After SARS-CoV-2 Exposure

L. Sun¹, G. Yin², J. Ye²

¹Beijing Tsinghua Changgung Hospital, Otorhinolaryngology-Head and Neck Surgery, Beijing, China,

²Beijing Tsinghua Changgung Hospital, Beijing, China

Introduction: Pediatric obstructive sleep apnea (OSA) is a prevalent sleep disorder characterized by recurrent episodes of partial upper airway obstruction, leading to oxygen desaturation and sleep disruption. Recent studies published between 2016 and 2023 have reported higher prevalence rates, ranging from 12.8% to 20.4%. Studies have demonstrated that persistent viral RNA can be detected in the tonsillar and adenoid tissues of children for weeks to months following acute SARS-CoV-2 infection. To investigate the incidence trends and clinical characteristics of pediatric obstructive sleep apnea (OSA) following exposure to SARS-CoV-2.

Materials and methods: This study enrolled a consecutive cohort of pediatric patients with polysomnography (PSG) recordings from the Sleep Medical Center of Beijing Tsinghua Changgung Hospital between January 2021 and November 2024. Patients who had severe concomitant pulmonary, neurologic, cardiovascular, or psychiatric disorders were excluded. The demographic and PSG characteristics were compared.

Results: 1. A total of 1,377 children were included in the study; a notable upward trend in the incidence of pediatric OSA was observed following exposure to SARS-CoV-2, with the pre-SARS-CoV-2 Exposure Group (pre-SCE) (n=496) and the post-SARS-CoV-2 Exposure Group (post-SCE) (n=881). After stratification by age, the incidence rose 1.06-fold in children <6 years and 2.09-fold in those aged 6-8 years. Strikingly, children > 8 years exhibited the most pronounced increase, with a 3.94-fold surge in the prevalence of OSA.

2. Pediatric OSA showed significant disease progression after SARS-CoV-2 exposure. The post-SCE group exhibited higher median values for the apnea-hypopnea index (AHI: 5.500 [2.750, 13.000] vs. 3.800 [1.900, 7.700]), hypopnea index (HI: 3.500 [1.400, 8.400] vs. 1.800 [0.600, 4.850]), and obstructive apnea-hypopnea index (OAHl: 4.150 [1.400, 10.675] vs. 2.000 [0.697-6.400]), $P < 0.001$.

3. PSG analysis indicated significant sleep architecture modifications post-SCE, with the arousal index increasing from 7.500 [5.100, 10.700] to 11.900 [8.700, 16.700], $P < 0.001$.

4. A comparative analysis of tonsillar and adenoid dimensions before and after viral exposure revealed a statistically significant rise in the proportion of grade 3 (36.49% vs 43.47%) and grade 4 (12.10% vs

14.42%) ($p < 0.05$) tonsillar enlargement following SARS-CoV-2 exposure. Within the age > 8 years group, the prevalence of adenoid tissue obstruction $> 75\%$ following SARS-CoV-2 exposure increased significantly from 11.90% to 22.05%, despite this age group typically exhibiting physiological adenoid involution.

5. Multivariate regression analysis revealed that children with grade 4 tonsillar hypertrophy demonstrated a significantly greater increase in the OAHl scores following exposure to SARS-CoV-2 compared to the pre-pandemic period ($\beta=3.40$, $p<0.001$).

Conclusions: Following exposure to SARS-CoV-2, there has been a notable increase in the incidence of pediatric OSA and the severity of the disease, which is associated with significant tonsillar hypertrophy and delayed adenoid regression.

Clinical Trial: Efficacy of Metered-dose Negative-Pressure Breathing Training in OSA Patients

S.-L. Lin¹

¹Children Center Clinic, New Taipei, Taiwan

Introduction: Oliven et al (J Sleeping Res. 2018) found pharyngeal muscles response linearly to airway negative pressure change. We use that as a “dumbbell” load for exercise prescription. This study aims to assess the effectiveness of a resistance mask device (GST) for negative pressure breathing training in patients with obstructive sleep apnea (OSA).

The study plans to enroll 10 participants to assess the device's impact on respiratory muscle strength and sleep apnea symptoms.

One of the main contributors to sleep apnea is the collapse of upper airway muscles during sleep, resulting in breathing difficulties. Strengthening these muscles through targeted exercises could potentially alleviate symptoms and improve quality of life for patients with sleep apnea.

Materials and methods: * Participants diagnosed with sleep apnea will be recruited for the trial and provided with the mask device for daily use. The device GST utilizes resistance inspiration negative pressure with 10-40 hpa depending on the patient's condition to enhance the strength of upper respiratory dilator muscles during breathing exercises. Assessments of 4% ODI, questionnaire and visual analogue score will be conducted before and after using the device. Data analysis will focus on comparing pre- and post-treatment measurements to determine the device's efficacy in improving respiratory muscle function and alleviating sleep apnea symptoms. This study aims to provide valuable insights into the role of targeted muscle strengthening in managing sleep apnea and enhancing respiratory health.

Recruitment Criteria:

>Inclusion Criteria:

OSA patients aged 18-65, willing to participate, with a confirmed OSA diagnosis, and able to comply with the study protocol.

>Exclusion Criteria:

Abnormal PFT, acute illnesses, cardiovascular diseases, and uncontrolled allergic rhinitis or nasal obstruction diseases, BMI >30 , will be excluded

Results: 6 patients complete the trial

4% ODI: Decreased by an average of 29%

minSpO₂: Improved by 2%

Snoring Score: Totally reduced by 22%, very loud by 76%

Morning Symptoms: Headache and dizziness frequency dropped by 28%

Adherence: 100%

Training Load: 10–30 hPa, tailored per subject

Temporal Trends:

- ODI improvement occurred between Day 10–26

- Symptom relief noted after Day 32–40

- Snoring decreased after Day 7-25

Conclusions: Preliminary findings suggest GST is a promising adjunct to conventional OSA therapy, especially in enhancing patient tolerance and respiratory muscle endurance. GST's adaptability and high adherence rate support its feasibility. The initial clinical response appears temporally progressive and responsive to upper airway events, implying a muscle-based mechanism.

Metered-dose negative-pressure respiratory muscle training using the GST device shows early effectiveness in improving oxygenation, reducing snoring, and alleviating OSA-related symptoms. This pilot supports the rationale for broader trials and potential integration into multimodal OSA management.

Future Directions

- Expansion to full cohort with subgroup analysis
- Long-term follow-up on muscle strength and AHI
- Combination therapy with CPAP/APAP
- AI-guided personalization of pressure dosing

Acknowledgments: Thanks for the contribution of Julian Chen, Sam Wu.

Daytime Sleepiness is Associated with Poorer Driving Outcomes in Older Adults with SCD or MCI

T. Lo¹, J. Manousakis^{2,1}, M. Jackson¹, M. Woodward³, S. Naismith⁴, C. Anderson^{5,1}

¹Monash University, School of Psychological Sciences, Melbourne, Australia, ²Austin Health, Institute for Breathing and Sleep, Melbourne, Australia, ³Austin Health, Aged and Continuing Care Services, Melbourne, Australia, ⁴University of Sydney, School of Psychology, Sydney, Australia, ⁵University of Birmingham, School of Psychology, Birmingham, United Kingdom

Introduction: Daytime sleepiness increases the risk of cognitive decline in older adults and separately has important implications for driving safety. To date, no research has investigated the association between sleepiness and driving behaviours in older adults with early stage cognitive decline: that is, subjective cognitive decline (SCD) and mild cognitive impairment (MCI). This study investigated how prodromal stages of dementia (cognitively healthy, SCD, and MCI) are associated with daytime sleepiness, self-reported driving behaviours, and the relationship between sleepiness and driving across the cognitive stages.

Materials and methods: Fifty-eight participants (mean age 71.34 ± 5.72 years) completed a neuropsychological assessment and were classified as cognitively healthy ($n = 21$), SCD ($n = 24$) or MCI ($n = 13$). The Geriatric Depression Scale (GDS), Epworth Sleepiness Scale (ESS) and the Manchester Driving Behaviours Questionnaire (DBQ) were also completed. The DBQ is categorised into lapses, aggressive violations, violations, and errors. Additionally, participants completed a driving diary for trips that were 15 minutes or longer, for two continuous weeks. This included the Karolinska Sleepiness Scale (KSS), Sleepiness Symptoms Questionnaire (SSQ) for sleepiness symptoms specific to driving, and any adverse driving events (i.e., sleep-related, inattention, hazardous, or violations).

Results: Relative to cognitively healthy participants, ESS scores were significantly elevated in SCD (156% increase, $p < .001$) and MCI (137% increase, $p = .014$) groups, adjusted for age, sex, and GDS. Similarly, driving diaries indicated that the SCD group reported 1.09x higher rates of sleepiness symptoms on the SSQ ($p = .004$) compared to cognitively healthy participants. For driving behaviours, the SCD group reported 2.77x more violations on the DBQ compared to the MCI group ($p = .032$), but did not differ to healthy controls. The SCD group also reported 7.51x greater inattention events on driving diaries compared to cognitively healthy participants ($p = .011$), adjusted for drive duration. Within group analyses showed that each unit increase in SSQ was associated with 1.34x more inattention events in the SCD group ($p = .004$) and 2.32x more inattention events in the MCI group ($p = .018$). Further analysis of specific SSQ items within the SCD group identified that "Reactions are slow" predicted 5.07x greater inattention events ($p < .001$), and "Difficulty keeping to the middle of the road" predicted 4.04x more inattention events ($p = .016$).

Conclusions: This was the first study to examine the relationship between sleepiness and driving in older adults at various prodromal stages of dementia. We show older adults with SCD and MCI report greater daytime sleepiness than those who are cognitively healthy, with sleepiness symptoms associated with more inattention driving events for both groups. These results suggest that daytime sleepiness may be early consequence of cognitive decline with implications for driver safety. Future work should examine whether targeting daytime sleepiness may improve driving outcome for those at

the early stages of cognitive decline, especially at SCD, which could prolong safe driving to preserve independence and social connectedness in older drivers.

Effect of sex hormones on sleep architecture in older women

M. Varma¹

¹California University of Science and Medicine, Medical Education, Colton, United States

Introduction: Sleep in post menopausal elderly women is lacking in data as to how hormones effect their various stages of sleep. It has been shown that sex steroids Testosterone (T) and Estrone (E) increase with age with steady decline in DHEA. Sex hormones have been implicated in development of age related chronic diseases, including cancer, impacting overall longevity and quality of life. It has been established that decreasing levels of estrogen with increased testosterone levels affect development of cardiovascular diseases. Estrone is the major circulating estrone in post menopausal women. Post menopausal women have disturbed night time sleep with episodes of hot flashes that disrupt their sleep and leaves them tired and fatigued. they often complain of frequent awakenings, difficulty falling asleep, and poor overall quality of sleep. Each decade of post menopausal life has varying amounts of circulating sex hormones. Specifically in the seventh decade there is most significant changes observed in level of Estrone and testosterone. We hypothesized that changes in sleep architecture affected by circulating hormones will be observed in this age group of women.

Materials and methods: Twenty two post menopausal women between the ages of 55-79 were divided into two groups 55-69 and 70-79 underwent overnight polysomnography as indicated by their physicians. Data was collected on their age, BMI, chronic illnesses use of medications. Sleep stages of N1, N2, N3 and REM were measured and expressed in percentage of sleep. Total sleep time and time in bed was also measured. Data was collected and measured in percentage of sleep, Data analyzed as mean $\pm$ Std dev and t test conducted with $p < 0.05$ taken as significant.

Results: All twenty two postmenopausal women were diagnosed with sleep apnea. of the thirteen women in the 70-79 group, Eleven of these women were also diagnosed with diabetes and one was current smoker. Average BMI in the group was 32.1, Further N2 sleep was 60% and N3 and REM sleep were significantly reduced compared to women in the 55-69 age group, to 11% and 3 % of total sleep time with $p < 0.05$,

Conclusions: Post menopausal women have significant alterations in circulating sex hormones which among other things also significantly impacts their sleep architecture. Instead of putting all post menopausal women under one umbrella it would be helpful to cluster them in each decade of life and hence provide more appropriate supportive therapy as indicated by symptoms and circulating hormone levels. This study specifically looked at women in the seventh decade of life as literature shows that in this decade Estrone is the predominant circulating estrogen and levels of testosterone are not significantly different from premenopausal levels. So, could estrone be impacting sleep outcome, this needs further evaluation.

Elder Abuse, Age Discrimination, and Insomnia Among Frail Older Adults in India

M. Thalil¹, W. Ali²

¹Pennsylvania State University, Department of Human Health & Family Studies, Pennsylvania, United States, ²Sultan Qaboos University, Department of Geography, Muscat, Oman

Introduction:

Elder abuse and age discrimination are growing public health concerns in India, particularly amid shifting family dynamics, changing caregiving roles, and persistent social stigma around aging. Insomnia is also highly prevalent among older adults, especially those who are frail, due to diminished physiological resilience and heightened vulnerability to psychosocial stressors. This study examined the associations of elder abuse and age discrimination with insomnia symptoms in a nationally representative sample of frail older adults in India.

Materials and methods: We analyzed data from the Longitudinal Aging Study in India (LASI), focusing on a sample of 8,901 older adults identified as frail. Frailty was measured using a modified version of the Fried Frailty Phenotype. To examine the association between elder abuse, age discrimination and

insomnia symptoms among frail older adults, we employed multivariable linear and logistic regression models.

Results: After adjusting for sociodemographic and health variables, including chronic conditions, both elder abuse (β : 0.35, 95% CI: 0.12, 0.57) and age discrimination (β : 0.23, 95% CI: 0.10, 0.36) were significantly associated with higher levels of insomnia symptoms among frail older adults. Specifically, elder abuse was associated with increased odds of difficulty initiating sleep (AOR: 1.57, 95% CI: 1.11, 2.22), difficulty maintaining sleep (AOR: 1.74, 95% CI: 1.28, 2.37), and early morning awakening (AOR: 1.44, 95% CI: 1.02, 2.03), though not with daytime unrested feeling. In contrast, age discrimination was significantly associated with difficulty maintaining sleep (AOR: 1.35, 95% CI: 1.11, 1.63), early morning awakening (AOR: 1.43, 95% CI: 1.17, 1.74), and daytime unrested feeling (AOR: 1.37, 95% CI: 1.13, 1.66), but not with difficulty initiating sleep.

Conclusions: Our findings highlight both elder abuse and age discrimination as significant risk factors for insomnia symptoms among frail older adults in India. Elder abuse was particularly associated with difficulties in sleep initiation and maintenance, while age discrimination was more strongly linked to difficulty maintaining sleep, early morning awakening, and daytime unrested feeling. These results underscore the need for policies and interventions that address elder mistreatment and age-based discrimination not only to safeguard the dignity and well-being of older adults but also to promote healthier sleep and overall quality of life in later life.

Enlarged perivascular spaces is associated with cognitive impairment in older adults with obstructive sleep apnoea

S. Kong¹, B. Sinclair², N. Espinosa¹, A. Lam¹, V. Vidal¹, M. Law², S. Naismith¹

¹University of Sydney, School of Psychology, Sydney, Australia, ²Monash University, Department of neuroscience, Melbourne, Australia

Introduction: Obstructive sleep apnoea (OSA) is prevalent among older adults and is often linked to cognitive impairment when untreated. It is posited that the underlying pathology of OSA is connected to glymphatic dysfunction - a perivascular network in the brain responsible for metabolic waste removal. Although various methods have been proposed to index the perivascular spaces (PVS) as a promising imaging marker for the glymphatic system, these methods are often developed and tested on homogeneous datasets with high resolution scans, limiting its generalizability. Therefore, using a newly developed automated PVS segmentation method, this study aimed to determine (1) if PVS differs across OSA groups, and (2) if PVS is associated with cognitive impairment.

Materials and methods: Participants aged 50-80 with new onset cognitive or mood concerns underwent clinical and neuropsychological profiling at a memory clinic. Domain specific cognitive composites (i.e., verbal learning, verbal memory, executive function, processing speed and language) were created from neuropsychological tests, with age and education (where possible) adjusted. From polysomnography, apnea hypopnea index (AHI) was derived. Participants were categorized into normal (AHI<5; n=83), mild (AHI=5-14; n=92), moderate and severe (AHI≥15, n=111) OSA groups. PVS clusters and volumes were derived from a deep learning algorithm - Perivascular space Identification NnUNet for Generalised Usage (PINGU). Regions of interests (ROIs) included the Basal Ganglia, frontal lobe and Thalamus due to their functional relevance for sleep and cognition. One-way analysis of variance (ANOVA) and Spearman's rho were used to estimate group differences and correlations, adjusted for age, sex and body mass index.

Results: After adjusting for covariates, PVS clusters and volumes in all ROIs showed no differences among the three OSA groups. Across the whole sample, PVS was not associated with cognitive outcomes. However, in the mild OSA group, enlarged PVS in the Basal Ganglia was associated with impaired language ability (Clusters, $r=-.227$, $p=.042$; Volumes, $r=-.25$, $p=.023$). Enlarged PVS in the Thalamus was associated with lower performance in verbal learning (Clusters, $r=-.285$, $p=.010$; Volumes, $r=-.289$, $p=.009$), verbal memory (Clusters, $r=-.221$, $p=.049$; Volumes, $r=-.225$, $p=.043$), executive function (Volumes, $r=-.283$, $p=.012$) and processing speed (Volumes, $r=-.231$, $p=.039$).

Conclusions: This study, utilizing a new model of PVS processing pipeline, indicates that while OSA severity alone does not globally correlate with PVS enlargement or broad cognitive deficits in older adults, localized PVS changes in specific brain regions may influence domain-specific cognitive impairments, particularly in mild OSA. Early-stage OSA might trigger glymphatic dysfunction in cognition-critical regions, potentially masked or compounded by other pathological mechanisms in

moderate/severe OSA. The Thalamus and Basal Ganglia, crucial for sleep regulation, memory, and executive function, appear susceptible to PVS-related changes, highlighting their role as neural hubs where glymphatic disruption may disproportionately impact cognition. The PINGU tool allowed detection of subtle, region-specific PVS-cognition relationships, emphasizing the value of advanced segmentation techniques in heterogeneous clinical populations.

Evaluating Sleep Architecture Variability in Older Adults with Cognitive Decline

D. Leventowski¹, C. Fischer², A. Galbiati³, C. Ma¹, C. Walsh⁴, T. Neylan⁴, C. Berka¹, E. St. Louis⁵

¹Advanced Brain Monitoring, Carlsbad, United States, ²St. Michael's Hospital, Toronto, Canada,

³Universita Vita-Salute San Raffaele, Milano, Italy, ⁴University of California, San Francisco, San

Francisco, United States, ⁵Mayo Clinic, College of Medicine and Sciences, Rochester, United States

Introduction: Neurodegenerative disorders are characterized by cognitive deficits and sleep disturbances with abnormal sleep architecture. The interpretation and clinical application of sleep biomarker quantification for use in subtyping neurodegenerative disorders requires an understanding of how variability might impact the findings. In this study we investigated two factors that could influence the in-home sleep biomarker variability in older adults with cognitive decline.

Materials and methods: 23 women and 12 men (ages 71.5±8.5 years, 30 diagnosed with mild cognitive impairment and 5 with Alzheimer's dementia) completed two-night in-home recordings with the Sleep Profiler™ with 4 women and 6 men repeating the procedure one-year later, for a total of 45 recordings. The studies were auto-staged and then edited using procedures developed to visually verify accuracy. Intra-class correlations (ICC) and Bland-Altman (BA) analyses were used to compare Night-1 versus Night-2 variability obtained with auto- and then edited staging, followed by comparison of auto- versus edited staging by night.

Results: The consistency between Nights-1 versus Night-2 sleep times were poor for both auto- and edited-staging (ICC=0.39 and 0.31, $p<0.025$), and fair for recording times (ICC=0.50 and 0.40, $p<0.005$) and sleep efficiencies (ICC=0.46 and 0.47, $p<0.001$).

Between-night variability was exacerbated after the auto-staging was edited for REM time (ICC=0.55 and 0.47, $p<0.001$) and N1 time (ICC=0.59 and 0.49, $p<0.0005$), while pre- and post-edited consistencies were equivalent for %REM (ICC=0.54 and 0.55, $p<0.0001$) and %N1 (ICC=0.55 and 0.54, $p<0.0001$).

Between-night consistencies were good for auto- and edited times in stage N2 (ICC=0.68 and 0.69, $p<0.0001$), and increased to excellent for %N2 (ICC=0.80 and 0.80, $p<0.0001$). For stage N3, the variabilities were similar based on time (ICC=0.74 and 0.77, $p<0.0001$) and percent-time (0.74 and 0.74, $p<0.0001$).

Auto-staging biases resulting from detection of lower sleep efficiencies, decreased %REM, and increased %N2 on Night-1 (Bias=-2.38, -1.50, and 1.81%) were reduced after editing (Bias= -1.43, -0.72%, and 0.67%). These edits, however, contributed to an increased stage %N3 bias (Bias=0.03 and 0.59%).

The auto- versus edited recording times were excellent for Night-1 (ICC=0.84) and good for Night-2 (ICC=0.67). Sleep efficiency concordances were equivalent when auto- versus edited-staging were compared for Nights-1 and -2 (ICC=0.93 and 0.92, $p<0.0001$), however the bias on Night-1 was almost two-times greater than Night-2 (Bias=-0.92 to -0.49).

With the exception of Stage N1, the auto- versus edited consistencies were excellent across all stages, (all ICCs > 0.84, $p<0.0001$). Concordances were fair for time N1 and good for %N1 on Night-1 (ICC=0.53 and 0.69, $p<0.0001$) and excellent on Night-2 (ICC=0.78 and 0.91, $p<0.0001$).

The number of epochs edited from stage N2 to REM were greater on Night-1 and resulting in biases of -1.23% and 0.67%, respectively, versus 0.09 and -0.17 during Night-2.

Conclusions: Important night-to-night variability was observed in all sleep architecture measures except %N2. These findings point to a first night effect and suggest multiple nights would be useful in evaluating patients with cognitive impairment in their home. Technical edits to the auto-staging most prominently impact stages N1 and REM, primarily during Night-1.

Evaluation of the effect of sleep apnea syndrome, as well as its therapeutic interventions, on hearing level

Z. Kalentakis¹, P. Vlastarakos^{1,2}, T. Nikolopoulos^{1,2}

¹National and Kapodistrian University of Athens, Medical School, Athens, Greece, ²Attikon University Hospital of Athens, Otorhinolaryngology, Athens, Greece

Introduction: Obstructive sleep apnea (OSA) is one of the most common respiratory disorders characterized by intermittent upper airway obstruction during sleep resulting in episodes of apnea and/or hypopnea and awakenings associated with a respiratory event (RERA). While, the sense of hearing is based on the transmission of sound through the auditory pathway. It is a complex and quite sensitive pathway that begins from the external ear and ends in the auditory cortex of the brain, mediated by structures very sensitive to vascular insufficiency and hypoxemia such as the hair cells of the cochlea.

Materials and methods: In this prospective study we measured the hearing level of individuals with a new onset OSAS. For the purposes of the study, patients who, after a sleep study, will receive a diagnosis of sleep apnea syndrome will undergo a thorough ENT clinical examination and audiological examination. The participating patients will be re-evaluated three and six months after the initial diagnosis, a period that will coincide with the start of appropriate treatment (CPAP or surgery). Based on the results of the audiological tests at months 0, 3 and 6, we will attempt to test the correlation between treatment (CPAP or surgery) and prevention or improvement of the hearing threshold. In addition, the goal is to find the parameter that can best predict the degree of hearing loss in relation to the severity of sleep apnea. In this direction, we will look for the existence of a correlation between the degree of hearing loss and each of the following parameters of the sleep study: 1) Mean Spo2 of the study, 2) $\Delta\text{SpO}_2 = \text{resting} - \text{min sleep}$, 3) Total apnea time (minutes of sleep with saturation <90%), 4) Noise caused by snoring (dB), 5) AHI (apnea-hypopnea index) and 6) OSA questionnaires (Epworth Sleepiness Scale, Stop-Bang Questionnaire, OSA50, Berlin Questionnaire)

Results: Twenty two participants, (16 men, 6 women) with a mean age of 50.8 years old were included in the study. These individuals did not refer previous otologic history or any systematic disease associated with hearing problems. Clinical examination, otoscopy and tympanometry were normal. The pure tone audiogram revealed a slight sensorineural hearing impairment in both ears. A gradual deterioration was observed in high frequencies. The mean hearing level for 4kHz was 35dB for the right ear and 40dB for the left ear, while the hearing level for 8kHz was 45dB for both sides.

Conclusions: A few studies, with inconsistent results, have examined the possibility that nocturnal obstructive apnea-hypopnea affects the auditory pathway, however literature lacks consistency regarding the relationship between sleep apnea and hearing loss. Our study for correlation between OSAS and hearing loss was held at a clinical and not an experimental level. Audiological data are primarily based on subjective measurements of the pure tone audiogram. This fact decreases the degree of objectivity of the findings, however it allows speed, convenience and zero cost in data collection.

Lights Out, Waste Out: Dynamic Changes in Slow Wave Sleep Drive Peripheral Clearance of AD Biomarkers in Older Adults

C. Diep^{1,2}, J.E Manousakis^{2,3}, S.A Miles^{2,3}, E. Hodgman², P. Maruff⁴, M. Dresler⁵, C. Anderson^{1,2}

¹Centre for Human Brain Health, University of Birmingham, Psychology, Birmingham, United Kingdom, ²School of Psychological Sciences, Monash University, Psychology, Clayton, Australia, ³Institute for Breathing and Sleep, Austin Health, Heidelberg, Australia, ⁴The Florey Institute of Neuroscience and Mental Health, The University of Melbourne, Parkville, Australia, ⁵Radboud University Medical Center, Donders Institute for Brain, Cognition, and Behavior, Nijmegen, Netherlands

Introduction: There are currently 50 million people worldwide with dementia, with Alzheimer's Disease making up 60-80% of all cases. Convergent evidence suggests that slow wave sleep (SWS) is critical for brain health and cognition, and plays a potential role in neurodegeneration: for instance, SWS is associated with memory consolidation and frontal 'executive' function and shows a consistent decline with age, which is exacerbated in those with AD. Moreover, in a non-human model, SWS has been shown to clear AD-related waste products such as amyloid via the glymphatic system. More recently, dynamic changes in SWS across the night have been linked to plasma amyloid levels in providing evidence of SWS-related clearance of AD-related proteins in a human model. We aimed to extend this work by examining the association between SWS and other plasma biomarkers of AD in a cohort of older adults.

Materials and methods: Twenty-four cognitively intact older adults aged 60-76y (13 female) were recruited from the community and a large existing cohort (AIBL). Participants underwent simultaneous overnight polysomnography and blood sampling, whereby blood samples were collected every 30min remotely without awakening the participant, across an 8h sleep opportunity and for 1h post-wake. Plasma levels of AB40, AB42, pTau181, pTau217, GFAP and NfL were quantified using a SIMOA-HD, and modelled with slow oscillations (0.5-1Hz), slow wave activity (0.5-4Hz), and slow wave sleep minutes and proportion per 30min interval, across time lags of 0-120min.

Results: Linear mixed models revealed AB40, AB42, and pTau181 were significantly associated with several slow wave sleep dynamics at lags of 90-120 min. Moreover, repeated measures correlations show positive association between these markers and slow wave dynamics across the night, particularly at 120min lag. While pTau217 trended toward significance (for mixed models and correlations), overall plasma levels were extremely low, with less variability between participants or samples. In contrast, plasma GFAP and NFL levels were not significantly associated with slow wave dynamics. These results remained stable after accounting for baseline plasma levels, associated with cortical amyloid burden.

Conclusions: Slow wave sleep dynamics were significantly associated with peripheral levels of amyloid and p-Tau181 (p-Tau217 less consistent), but not GFAP and NfL. Given the established link between slow wave and glymphatic clearance, these peripheral markers *may* indicate glymphatic clearance, which in humans remains difficult to capture. These are preliminary data and further work is needed to establish (a) the causal role of slow wave on glymphatic clearance and (b) the use of this approach as a measure of glymphatic clearance.

Acknowledgments: This study was separately funded by the Dementia Australia Research Foundation and Takeda Pharmaceuticals. The content is solely the responsibility of the authors and does not necessarily represent the official views of the funding bodies.

Multi-organ sleep age derived from polysomnography and risk of dementia and mortality

C. Cavallès¹, S. Milton², Y. Fang², X. Chen³, Y. Wang³, R. Gao³, W. Huang⁴, W. Chen⁵, R.J. Thomas⁶, M.B. Westover⁷, H. Yi⁴, S. Yin⁴, Y. Leng²

¹Université Paris Cité, INSERM U1153, Epidemiology of Ageing and Neurodegenerative diseases, Paris, France, ²University of California San Francisco, Department of Psychiatry and Behavioral Sciences, San Francisco, United States, ³Beijing Five Seasons Medical Technology Co., Ltd, Beijing, China, ⁴Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Department of Otorhinolaryngology-Head & Neck Surgery, Shanghai, China, ⁵Sir Run Run Shaw Hospital, Zhejiang University School of Medicine, Department of Psychiatry, Hangzhou, Zhejiang, China, ⁶Beth Israel Deaconess Medical Center, Division of Pulmonary, Critical Care and Sleep Medicine, Department of Medicine, Boston, United States, ⁷Beth Israel Deaconess Medical Center, Harvard Medical School, Department of Neurology, Boston, United States

Introduction: Chronological age is a major risk factor for dementia and mortality, but may not capture differential biological aging across organ systems. Multimodal physiological signals obtained from polysomnography (PSG) probe widespread physiological networks, and provide a unique opportunity to evaluate organ-specific ages: the electroencephalogram (EEG), electrocardiogram (ECG), and respiratory effort signals can serve as proxies for the sleep-derived ages of the brain, heart, and lungs, respectively. Given complexity of such data, artificial intelligence (AI)-derived multi-organ ages generated from PSG signals could predict dementia or mortality risk.

Materials and methods: We trained deep neural networks on 60,968 PSG recordings to predict chronological age and applied them to an independent test set of 3,110 recordings. Data were drawn from the National Sleep Research Resource cohorts and from the Massachusetts General Hospital (MGH), Sir Run Run Shaw Hospital, and Shanghai Sixth People's Hospital. We estimated brain, heart, and lung age from the EEG, ECG, and abdominal belt-derived respiratory effort signals, and computed brain age index (BAI), heart age index (HAI), and lung age index (LAI) as the difference between each organ's AI-predicted age (derived from its corresponding PSG modality) and chronological age. We examined associations between the three age metrics and the risk of dementia and mortality, using data from 7,395 MGH patients who underwent in-laboratory PSG. Dementia was identified using ICD-9 and -10 codes and mortality from the Massachusetts death registry and MGH electronic health records. For the dementia analysis, individuals with prevalent dementia at the time of PSG were excluded, resulting in a sample of 7,384 participants. Multivariate Cox regression models were performed. Death was treated as a competing risk in the dementia analysis using the Fine-Gray subdistribution hazard models.

Results: Participants had a mean chronological age of 50.3 (± 15.7) years, 50.8% were women, and 18.8% were non-White. Brain, heart, and lung ages were estimated with mean absolute errors of 4.41, 5.01, and 5.43 years, and corresponding Pearson correlation coefficients of 0.97, 0.96, and 0.96. HAI correlated moderately with LAI ($r = 0.26$), whereas BAI showed weaker correlations with both HAI ($r = 0.13$) and LAI ($r = 0.15$); all $p < 0.001$. Over a median follow-up of 9.5 years [range: 0.02–16.1], 182 participants developed dementia and 207 died. After controlling for sociodemographics, sleep medications, apnea-hypopnea index, and health covariates, each 10-year increase in BAI, HAI, and LAI were associated with a higher risk of dementia of 172% (Hazard ratio (HR)=2.72, 95% confidence interval (CI)= 2.0-3.94), 32% (HR=1.32, 95% CI=0.98-1.75), and 32% (HR=1.32, 95% CI=1.04-1.65), respectively. Similarly, higher BAI, HAI, and LAI were associated with increased mortality risks of 87% (HR=1.87, 95% CI=1.43-2.43), 59% (HR= 1.59, 95% CI=1.26-2.00), and 38% (HR=1.38, 95% CI=1.09-1.75), respectively.

Conclusions: Accelerated brain, heart, and lung age, as captured from PSG, are associated with increased risks of dementia and mortality over 10 years. Brain age showed the strongest association with both outcomes, while heart age was especially predictive of mortality. These organ-specific age metrics may serve as early markers of vulnerability to aging-related disease and potential targets for intervention.

Nocturnal Hypoxic Burden Is Associated with Brain Structural Alterations in Older Adults with OSA

N. Akhtar¹, D. Vats¹, J. Joy¹

¹All India Institute of Medical Sciences, New Delhi, Physiology, New Delhi, India

Introduction: Intermittent hypoxia in obstructive sleep apnea (OSA) is often underestimated by the conventional apnea-hypopnea index (AHI), which quantifies discrete respiratory events without quantifying their physiological severity. Hypoxia burden, defined as the area under the oxygen desaturation curve offers a more accurate measure of the intensity and duration of hypoxic stress. However, the association between hypoxia burden and brain structural changes has not been thoroughly investigated in older adults with OSA. The aim of the study was to study the association between hypoxia burden and brain structural changes in older adults with OSA

Materials and methods: This study analyses data from SOLACE cohort. A subpopulation of 55 older adults (aged 51-80 years) with obstructive sleep apnea and without dementia were selected based on the availability of brain MRI scans. Flow events and oxygen saturation values were extracted from overnight polysomnography, and hypoxia burden was computed using a custom MATLAB script. brain structure volumes were assessed using voxel-based morphometry on 3T MRI scans.

Results: The final sample included 55 participants (mean age 64.98 ± 7.21 years; 83.6% male, median AHI 17.10 (3-.23-13.13). Hypoxia burden was significantly correlated with left hippocampus volume, $r(53) = -.2788$, $p = 0.039$ and left amygdala, $r(53) = -.324$, $p = 0.036$.

Conclusions: In older adults with OSA, greater hypoxia burden is significantly associated with reduced volumes of the left hippocampus and left amygdala, suggesting a potential link between nocturnal hypoxemic stress and brain structural alterations.

Orexin receptor antagonism rescues sleep and improves anxiety in tau-transgenic mice, but only improves cognition sex-dependently

J. Kron^{1,2}, H. Daykin¹, Y. Potts^{1,2,3}, J. Metha^{1,2}, R. Keenan⁴, D. Hoyer^{1,2,5}, L. Jacobson^{2,1}

¹The University of Melbourne, Melbourne, Australia, ²The Florey Institute of Neuroscience and Mental Health, Melbourne, Australia, ³KU Leuven, Leuven, Belgium, ⁴Monash University, Monash Institute of Pharmaceutical Sciences, Melbourne, Australia, ⁵The Scripps Research Institute, La Jolla, United States

Introduction: Alzheimer's disease (AD) is one of the largest public health issues facing societies with aging populations, affecting females more than males. Disordered sleep is a well-known AD risk factor, symptom and bidirectional pathological contributor to disease progression. Dual orexin receptor antagonists (DORAs) block signalling of both orexin 1 (Ox1R) and 2 (Ox2R) receptors, and are the only hypnotics approved for use in AD. Yet, preclinical evidence indicates a blunted response to selective Ox2R antagonists (2-SORAs) in female rodents with tauopathy. Therefore, we aimed to compare the effects of DORAs and 2-SORAs on sleep, cognition, and anxiety in tau-transgenic PS19 male and female mice.

Materials and methods: We performed two experiments in PS19 mice. Experiment 1 assessed the baseline relationship between sleep and behaviour. Mice underwent monthly polysomnographic EEG recordings and locomotor assays at 7, 8 and 9 months of age, and Barnes maze cognitive testing at 7 and 9 months. Experiment 2 assessed the effects of the DORA "DORA-22" (100 mg/kg) and 2-SORA "MK-1064" (40 mg/kg) after 6 weeks of chronic, oral dosing. Sleep, via polysomnographic EEG recordings, cognition via Barnes maze, and anxiety/agitation via locomotor and stress-induced hyperthermia (SIH) assays were assessed after 6 weeks of dosing.

Results: Experiment 1 revealed tau-transgenics were awake for 154.8 minutes more than WT, with loss in NREM and REM sleep. Tau-transgenics spent an average of 118.7cm in outer region of locomotor cells; indicating increased anxiety. This phenotype was significantly more pronounced in tau-transgenic males. PS19s demonstrated similar learning effects to WT in Barnes maze probe trial performance. Experiment 2 revealed the relationship between sleep and cognition differed markedly between genotype and sex. Vehicle-treated PS19s lost 82.9 and 135.9 minutes of TST in females and males (respectively) compared to WT. DORA-22 treatment rescued 71.4 and 73.8 minutes of TST in females and males, respectively. MK-1064 rescued 86.9 and 42.9 minutes of TST in females and males, respectively. Both treatments reduced numerous locomotor hyperarousal measures manifesting in females, alongside anxiety measures in SIH. Lastly, treatment with either DORA-22 or MK-1064 rescued Barnes Maze cognitive performance to WT-levels in male tau-transgenic animals, but did not improve female cognitive performance.

Conclusions: DORAs and 2-SORAs improved sleep and neuropsychological outcomes in tau transgenic mice. Initial research emerging from the clinical sector parallels these findings. However, cognition was only rescued in male tauopathic mice; demonstrating a tau-dependent disconnect between sleep and cognition in females. The present data support ORAs as a non-invasive AD therapeutic with relatively minimal side effects. However, ORAs appear less/ineffective for cognitive rescue in female tauopathic mice. This may have clinical translational implications and potentially hints to an understudied mechanism of female vulnerability to AD tau pathology. Overall, the potential of ORAs for improving the wellbeing of AD patients is growing and is supported by the current studies.

Polygenic scores for sleep traits and dementia incidence: Findings from the Swedish Twin Registry

M.S. Näsholm¹, M. Goodman², H. Wang², S. Sindi¹, I. Karlsson³

¹Karolinska Institutet, Department of Neurobiology, Care Sciences and Society (NVS), Solna, Sweden,

²Brigham and Women's Hospital, Division of Sleep and Circadian Disorders, Boston, United States,

³Karolinska Institutet, Department of Medical Epidemiology and Biostatistics (MEB), Solna, Sweden

Introduction: There is evidence that poor sleep is related to an increased risk of dementia. But findings might be influenced by reverse causation. This study aimed to examine the association between genetically predicted sleep traits and incident dementia to explore the role of genetic background in this association.

Materials and methods: We used cohort data from Swedish twins born before 1958 or earlier (Screening Across the Lifespan Twin Study (SALT study)) who had participated in data collections (1998/2002) including genotyping. Participants who had diagnosis of dementia at baseline were excluded. Of the 44,919 twins who participated in the SALT study, 17,284 had genotyping data available for the construction of polygenic scores (PGS) for sleep traits (sleep duration, insomnia symptoms, chronotype, snoring, daytime sleepiness, additive sleep health score, daytime napping). PGSs were computed using Plink 2.0. Prior to analysis, the PGS for sleep traits were adjusted for genetic ancestry by regressing out the first five principal components from the score, and standardized. Tertile of PGSs were used to categorize the genetically predicted low, middle, or high sleep trait. Cox proportional hazard models were used to examine the association between the genetically predicted sleep traits and incident dementia. Age was used as timescale.

Results: In the Swedish Twin Registry, 16,397 dementia-free twin individuals (mean age = 55.4 [standard deviation (SD) = 8.0] years) at baseline were followed for average of 16.0 (SD = 2.0) years. A total of 689 cases of dementia were detected. There was no association between PGS for sleep duration, insomnia, chronotype, snoring, daytime sleepiness, additive sleep health score and dementia. Compared to participants in the low PGS category for daytime napping, those in the high category was associated with 30% increased risk of dementia (Hazard ratio: 1.30, 95% Confidence Interval: 1.03 - 1.64), independently of sociodemographic, lifestyle -and health-related factors. While analyzing the PGS for daytime napping as a continuous variable, the association was in the same direction, but weaker.

Conclusions: These findings indicate that genetic predisposition to daytime napping day might be related to higher risk of all-cause dementia.

Predictive factors of sleep-related accidents in a large population of retired regular highway drivers

A. Chanteclair¹, J. Coelho², B. Moreau³, J. Taillard², J.-A. Micoulaud-Franchi², N. Salles¹, P. Philip², P. Sagaspe²

¹UMR CNRS 6033 SANPSY, University of Bordeaux, Department of Clinical Gerontology, University Hospital Bordeaux, Bordeaux, France, ²UMR CNRS 6033 SANPSY, University of Bordeaux, University Hospital Bordeaux, Bordeaux, France, ³Fondation VINCI Autoroutes, Nanterre, France

Introduction: Sleepiness at the wheel is a well-known risk factor for traffic accidents. The aim of this study is to explore the prevalence of sleepiness at the wheel and the risk factors associated with driving near misses and road accidents in regular French highway users who declared they were retired.

Materials and methods: Regular French highway users were invited to participate in an internet survey between April-May and October-November, 2024. A total of 14,046 retired drivers (mean age: 69.9 ± 6.2 years, 25.1% female) answered questions on socio-demographic characteristics, sleep behaviors, sleep disorders, lifestyle and health, substance use, driving habits, and near-accident and accident conditions.

Results: 14.9% reported at least one near-miss accident, and 4.5% reported at least one accident in the previous year. More than one out of three drivers (22.3%) experienced at least one episode of severe drowsiness at the wheel during the previous year (i.e., making driving difficult or forcing the driver to stop driving). Among these sleepy drivers, 26.6% reported at least one near-miss accident and 6.0% an accident in the past year. 67.2% of near-misses or accidents linked to sleepiness occurred on highways, and 68.7% on trips of over 2 hours. 67.2% of sleep-related near-misses and accidents occurred in a monotonous context (low traffic).

After adjustment for age, gender, mileage exposure and self-reported psychiatric disorders, the best predictive factors for accidents were: being widowed or divorced [adjusted OR 1.7, 95% CI, 1.3-2.2, P <.001], reporting at least one episode of severe sleepiness at the wheel in the past year [adjusted odds ratio (OR) 1.4, 95% confidence interval (CI) 1.1-1.8, P<.01], an Epworth score ≥11 [adjusted OR 1.5, 95% CI, 1.1-2.0, P <.01], being treated with hypnotics [adjusted OR 2.0, 95% CI, 1.1-3.7, P<.001] and having ever reported a near miss within the year [adjusted OR 6.6, 95% CI, 5.3-8.1, P<.001].

Conclusions: Occurrence of sleepiness at the wheel still constitute a major risk factor for near misses and accidents on highway in retired drivers. Having pathological excessive daytime sleepiness, being treated with hypnotics, reporting episodes of severe sleepiness at the wheel in the past year, and the reporting of a near miss in the past year, are major risk factors for near misses and road accidents in retired drivers.

Quantitative EEG Analysis Reveals Early and Progressive Sleep Dysfunction in Premanifest and Manifest Huntington's Disease

M. Malhotra¹, Z.J. Voysey¹, R.A. Barker¹

¹University of Cambridge, Department of Clinical Neurosciences, Cambridge, United Kingdom

Introduction: Sleep disturbances are common in Huntington's disease (HD) and have recently been recognized by our group to precede manifest disease onset. Quantitative EEG (qEEG) analyses provide sensitive tools for detecting subtle changes in brain oscillatory dynamics, which can reflect underlying neuropathological processes. This study is the first to longitudinally investigate sleep qEEG changes from premanifest to early manifest stages of HD, exploring their association with disease progression and cognitive impairment.

Materials and methods: Participants included 13 HD gene carriers and 9 age- and sex-matched healthy controls who underwent polysomnographic assessments at two points over a 12-year interval. 8 HD gene carriers developed manifest disease and 5 remained premanifest. qEEG analysis included spectral analysis using Welch's method to compute frequency band-specific relative power. Automated detection of sleep microstructures utilized an MNE-Python toolbox 'YASA' to identify sleep spindles, slow waves, and sigma-slow-oscillation phase-amplitude coupling and circular mean phase. Exploratory tests included topographical tests, coherence analysis and aperiodic PSD metrics such as spectral slope. Statistical analyses included ANCOVA with backward covariate selection to measure cross-sectional group differences. Longitudinal group differences were calculated by conducting repeated measures general linear models to identify significant group*time interactions.

Results: Cross-sectionally at follow-up, HD patients showed pronounced reductions in theta power, decreased slow-wave amplitude, and increased spindle density and amplitude, including the emergence of "giant" spindles. Theta power loss and slow-wave amplitude reduction were progressive-highest in controls, intermediate in premanifest HD, and most pronounced in early manifest HD-suggesting stepwise deterioration with disease advancement. Longitudinally, loss of theta power and slow wave amplitude were steepest in individuals who converted to manifest HD, compared to both controls and those who remained premanifest. Increased spindle density and amplitude were already evident at baseline in gene carriers, particularly in those who converted to manifest HD, indicating that heightened spindle activity may serve as an early electrophysiological marker of dysfunction. Over time, spindle density and amplitude declined at rates similar to controls, but remained consistently higher in HD patients. Theta loss correlated significantly with deficits in psychomotor speed, attention, executive function, and increased depression and impulsivity scores. Elevated spindle density was associated with better performance in attention and executive domains and lower disease burden, whereas increased spindle amplitude correlated with worse cognitive performance. Supplementary analyses showed decreased coherence in the delta band and spectral slope flattening, reflecting a shift toward higher-frequency "noise" and reduced low-frequency synchrony.

Conclusions: HD is associated with early alterations in sleep EEG microarchitecture, including increased spindle density and amplitude and decreased slow-wave amplitude and theta power, detectable even in premanifest stages. The combination of these results suggest dysfunction in overlapping hippocampal-entorhinal cortex circuits and thalamocortical systems affected by HD pathology. These findings support sleep qEEG markers as sensitive indicators of compensatory and progressive network dysfunction. The association between electrophysiological changes and cognitive outcomes suggests that modulating sleep physiology may represent a potential strategy to improve cognitive function in HD. Sleep EEG may thus serve as a valuable non-invasive biomarker for early detection, monitoring, and therapeutic intervention in Huntington's disease.

Sleep and care burden of informal caregivers of people with dementia: an interim exploratory analysis of the ICare.IT-AvereCura study

A. Berardi¹, Y. Druda¹, P. Di Florio¹, M. Sicbaldi¹, F. Palmese², F. Zanasì¹, E. Bei¹, I. Chirico¹, S. Trolese¹, E. Capulli¹, F. Ingravallo¹, M. Albertini¹, M. Domenicali^{1,2}, A. Silvani¹

¹University of Bologna, Bologna, Italy, ²Santa Maria Delle Croci Hospital, AUSL Romagna, Ravenna, Italy

Introduction: Although informal caregivers of people with dementia play a crucial role in maintaining the well-being and residual autonomy of their care-receivers, their own well-being is relatively understudied and often neglected. In particular, the links between sleep and the care burden perceived by family caregivers of people with dementia remain insufficiently understood. ICare.IT-AvereCura is a longitudinal study aimed at monitoring the the well-being of family caregivers of people with dementia, focusing on psychological, physiological, socio-relational, and occupational aspects. The study combines self-administration of online questionnaires with the use of wearable sensors to monitor physical activity, sleep, and heart rate for one-week periods at baseline and after 6 and 12 months.

Materials and methods: We aimed to perform an interim exploratory analysis of the ICare.IT-AvereCura study results. The analysis included data at baseline from the first 68 consecutively recruited caregivers. The caregivers' sleep was assessed subjectively, with the Pittsburgh Sleep Quality Index (PSQI) and a sleep diary recording the time spent in bed (TIB) with lights out, and objectively, with data from an accelerometer (GeneActive, Activinsights, UK) on the non-dominant wrist analyzed with a validated algorithm in the GGIR R package. The perceived care burden was assessed with the Zarit Burden Interview (ZBI). The caregivers' anxiety and depression were evaluated with the Hospital Anxiety and Depression Scale subscales (HADS-A and -D, respectively). Data are reported as median (interquartile range, IQR) and analyzed with Spearman's correlations (ρ).

Results: The recruited caregivers (75% females) were aged 59 (14) years, perceived moderate care burden (ZBI: 39 (21)), mild levels of anxiety (HADS-A: 8 (3)) and depression (HADS-D: 8 (7)), and poor sleep quality (PSQI: 10 (5)). They reported a TIB of 7.4 (1.3) hours, while their total sleep duration (TST) estimated with sleep actigraphy aided by sleep log was 6.2 (1.3) hours. The ZBI score correlated positively and significantly with PSQI score ($\rho = 0.42$, $p = 0.005$), HADS-A, and HADS-D ($\rho = 0.49$, $p < 0.001$) and, marginally, with age ($\rho = 0.28$, $p = 0.052$), but not with TIB or TST ($\rho = -0.09/-0.16$, $p = 0.522/0.291$). The PSQI score correlated significantly with HADS-A ($\rho = 0.49$, $p < 0.001$) and marginally with HADS-D ($\rho = 0.31$, $p = 0.043$).

Conclusions: These interim exploratory results of the iCARE-IT-AvereCura study suggest that higher care burden perceived by family caregivers of people with dementia may be associated with worse subjective sleep quality and symptoms of anxiety and depression, but not with reduced objective sleep time.

Sleep EEG-Based Brain Age Index as a Biomarker of Cognitive Function

H.R. Park¹, S. Yook², H. Kim², E.Y. Joo¹

¹Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Neurology, Seoul, Korea, Republic of, ²USC Stevens Neuroimaging and Informatics Institute, Keck School of Medicine of USC, University of Southern California, Los Angeles, United States

Introduction: Sleep quality and architecture are known to influence cognitive processing, and growing evidence links sleep disruption to neurodegenerative diseases and cognitive decline. Our group recently introduced the brain age index (BAI), a novel biomarker derived from sleep EEG, which has shown associations with cortical thinning. This study examines whether the sleep EEG-based BAI can serve as an indicator of brain health, specifically by evaluating its association with cognitive function

Materials and methods: We retrospectively analyzed polysomnography (PSG) data from 128 individuals (89 with obstructive sleep apnea [OSA], 39 healthy sleepers) who also completed neuropsychological assessments. Sleep EEG data were transformed into scalograms and input into a 3D deep learning model to predict brain age. BAI was calculated as the difference between predicted and

chronological age. We performed correlation and mediation analyses to evaluate the role of BAI in linking sleep features and cognitive outcomes.

Results: BAI showed negative correlation with attention and executive function in both overall subjects and the OSA subgroup. Mediation analysis revealed that BAI significantly mediated the relationship between sleep EEG microstructure and attention/executive function, as well as between sleep macrostructure (N3%, sleep efficiency) and attention/executive function.

Conclusions: This study demonstrated that sleep EEG based-BAI could be a promising biomarker for assessing cognitive impairment in patients with sleep disorders. Furthermore, BAI may serve as a mediator in the relationship between sleep and cognitive function, offering novel insights into the pathophysiology of neurodegenerative diseases.

Sleep micro-architecture predicts magnetic resonance imaging markers of brain aging in the general population

Introduction: Sleep micro-architecture is a time-resolved assessment believed to underlie the beneficial processes of sleep on cognitive functions. We hypothesise that polysomnography (PSG) sleep micro-architectural features could be a valuable biomarker of one's cognitive health and brain aging, quantified by magnetic resonance imaging (MRI) measurements.

Materials and methods: 747 individuals from the Study of Health of Pomerania-Trend baseline, a population cohort, had PSG and MRI measurements, alongside other demographic and health variables assessed. Extracted micro-architecture consists of spindles, slow oscillations (SO) and spindle-SO coupling features. Brain structural measures included an individualised Alzheimer's disease score (AD score), mean cortical thickness (CT) and brain volume (BV), as proxies of brain aging. Regional associations of segmented CT, white matter (WM) area and subcortical areas using the Desikan-Killiany atlas were also evaluated. 476 individuals further underwent a 7-year follow-up MRI assessment on whom we performed longitudinal analysis of the same outcome variables.

Results: Exploratory findings across all sleep micro-architecture and whole-brain structural outcome pairs revealed that fast and slow spindle (FS and SS) powers were strongly and positively associated with BV (FS: $3.5e4$ [$2.2e4$, $4.8e3$], $fdr=4.8e-6$; SS: $3.7e3$ [$2.3e3$, $5.1e3$], $4.8e-6$). SS frequency was associated with AD score (0.33 [0.12 , 0.54], $fdr=0.029$) and SS power was positively associated with CT (0.0052 [0.0016 , 0.0088], $fdr=0.046$). SO frequency was positively associated with BV ($3.5e4$ [$9.8e3$, $6.1e4$], $fdr=0.027$). Against our assumptions, slow oscillations (SO) density was positively associated with AD score (0.2 [0.083 , 0.32], $fdr=0.01$) and negatively associated with mean CT (-0.015 [-0.026 , 0.0051], $fdr=0.02$). SO frequency was associated with BV ($3.5e4$ [$9.8e4$, $6.1e4$], $fdr=0.027$), while SO amplitude was surprisingly positively associated with WHM (0.0021 [$3.9e-4$, 0.0038], $fdr=0.049$). FS-SO coupling density was positively associated with BV ($-8.2e3$ [$-1.2e4$, $4.2e3$], $fdr=0.0013$). Despite multiple cross-sectional associations, there were no significant whole-brain associations longitudinally. In the sensitivity analyses, metabolic factors modified the strengths of the relationships. Presence of diabetes modified the effect sizes of 4 (of 10) associations, and total cholesterol/HDL ratio negated the association between SO amplitude and WMH.

In the region-wide association, we observed multiple significant micro-architectural-brain region pairs both cross-sectionally and longitudinally. The 162 regional metrics (68 GM thicknesses, 68 WM volumes, 26 subcortical volumes), and 19 micro-architectural features yielded 3078 associations. Multiple testing corrections were applied within each micro-architecture feature, across the 162 regions. Fisher's exact test revealed that significant associations were more likely to occur in AD-

vulnerable regions (Odds ratio=1.78 [1.15, 2.7], $p=0.0072$), which were: entorhinal cortex, parahippocampal gyrus, hippocampus, posterior cingulate cortex, precuneus, fusiform gyrus, amygdala, middle temporal gyrus, inferior temporal gyrus and inferior parietal lobe. These regions were more highly enriched in the longitudinal MRI dataset (Odds ratio=2.76 [1.53, 4.92], $p=4.28e-4$).

Conclusions: Our findings demonstrated associations of sleep micro-architectural characteristics with general, whole-brain measures of brain aging and regional structural correlates. Longitudinal analysis revealed limited associations with general brain-aging metrics, but regional associations were more pronounced. While the interpretation of these results would rely on further understanding of underlying neurophysiology, our results indicate that micro-architecture could potentially explain structural brain correlates of brain aging and neurodegeneration.

Sleep-related Cerebrospinal Fluid Dynamics in Young and Mature Adults

A. Frels¹, M. West², B. Kish¹, V. Vijayakrishnan¹, H. Oshima¹, Y. Tong¹, A.J. Schwichtenberg²

¹Purdue University, Weldon School of Biomedical Engineering, West Lafayette, United States, ²Purdue University, Human Development and Family Science, West Lafayette, United States

Introduction: Cerebrospinal fluid (CSF) dynamics during sleep are a key portion of the glymphatic system (GS) and typical age-related data are needed to inform pathology development (i.e., neurodegeneration). CSF movement is directed both caudally (downward) and cranially (upward) building on the pulsatory nature of heart-rate and respiration. Using a developmental pathology approach, this study compared two groups of healthy adults (young and mature) to assess how CSF sleep-related dynamics change with age.

Materials and methods: In two groups of healthy adults, young ($n = 8$, age $M(SD) = 21(1.69)$ years) and mature ($n = 10$, age $M(SD) = 37.5(5.86)$ years), we measured CSF dynamics at the fourth ventricle during wakefulness and NREM sleep states using concurrent polysomnography (PSG) and functional magnetic resonance imaging (fMRI). Indices of average CSF movement, CSF fluctuation range, and CSF fluctuation standard deviations (across recorded 30 second epochs) were extracted from MR data and stratified by PSG-verified stages (Awake, NREM-N1, NREM-N2, NREM-N3). A series of ANOVAs were conducted to compare groups.

Results: A clear age effect emerged - total CSF movement decreased with age across all assessed stages (eta-squared range .49 - .46). There is some evidence of CSF fluctuation range increase with age during sleep - most notably during NREM-N2 (eta-squared = .30). CSF fluctuation SD did not vary by age or sleep stage.

Conclusions: Changes in CSF movement with age could reflect changes in cardiac or respiratory function - or change could reflect other, yet unknown, factors. Although sleep is highlighted by several recent papers as influential in CSF movement and ultimately GS function, the present data highlight that the impact of age may be more robust and considerations based on sleep stage alone may not be sufficient to capture meaningful differences.

Sleep spindles and slow oscillations predict neurofilament-light, neurogranin 36, Chitinase-3-like protein-1 and cognition in mild to moderate Alzheimer's Disease

A. Paez¹, S. Bakian Dogahneh², S.O. Gillman², A. Carnes³, F. Dakterzada⁴, F. Barbé⁵, T.T. Dang-Vu², G. Piñol Ripoll⁶

¹Concordia University, Sleep, Cognition, and Neuroimaging Laboratory, Montreal, Canada, ²Concordia University, Sleep, Cognition and Neuroimaging Laboratory, Montreal, Canada, ³Unitat de Trastorns Cognitius, Cognition and Behavior Study Group, Hospital Universitari Santa Maria Universitat de Lleida, Lleida, Spain, ⁴Universitat de Lleida, Hospital Universitari Santa Maria, Unitat de Trastorns Cognitius, Cognition and Behavior Study Group, Lleida, Spain, ⁵Biomedical Research Institute of Lleida, Translational Research in Respiratory Medicine (TRRM), Hospital Universitari Arnau de Vilanova-Santa Maria, Lleida, Spain, ⁶Universitat de Lleida, Unitat de Trastorns Cognitius, Cognition and Behavior Study Group, Hospital Universitari Santa Maria, Lleida, Spain

Introduction:

Sleep is essential for brain health, including the clearance of β -amyloid ($A\beta$) and tau-hallmarks of Alzheimer's disease (AD). Sleep physiology can predict levels of these biomarkers and cognitive decline in persons with mild-to-moderate AD (Paez, 2025). However, there is a need for complementary biomarkers of neurodegeneration and neuroinflammation that reflect distinct aspects of AD pathology and improve diagnosis, staging, and prognosis. These include neurofilament light (NfL), a marker of axonal damage; chitinase-3-like protein-1 (YKL-40), a marker of neuroinflammation; and neurogranin (NG-36), associated with synaptic dysfunction and brain atrophy specific to AD. While linked to AD progression, these biomarkers have primarily been studied in at-risk but cognitively unimpaired older adults, not in those with established AD. It remains unclear how sleep physiology (microarchitecture) relates to these biomarkers, which sleep characteristics predict them, and whether they, in turn, predict cognitive or neuropsychiatric decline.

Materials and methods: We analyzed data from our prospective cohort of persons with mild-to-moderate AD (n=60; mean age 74.7; 30 female) in Lleida, Spain. Baseline assessments included overnight polysomnography (PSG), cerebrospinal fluid (CSF) and blood sampling for $A\beta$ 42, phosphorylated tau (pTau-181), total tau, NfL, YKL-40, and NG-36, as well as cognitive and neuropsychological testing at baseline, 12, 24, and 36 months using the Mini-Mental Status Examination (MMSE), California verbal learning test (CVLT), Rey-Osterrieth Complex Figure Test (ROCF), Alzheimer's Disease Assessment Scale-Cognitive Subscale (ADAS-Cog), and Neuropsychiatric Inventory (NPI).

PSG was scored per AASM guidelines. Sleep spindles and slow oscillations (SO) were analyzed using in-house, validated open-source algorithms. Generalized linear models (False Discovery Rate-adjusted) tested associations between sleep parameters, AD biomarkers, cognition, and neuropsychiatric symptoms, controlling for age, sex, and apnea-hypopnea index (AHI).

Results:

We found previously unreported associations between spindle and SO characteristics, NfL, YKL-40, NG-36, NfL/ $A\beta$ 42 ($\beta=-.0029$, $p=0.001$), YKL-40/ $A\beta$ 42 ($\beta=0.0004$, $p=0.003$) and cognition in persons with AD. These biomarkers predicted worse cognitive performance (higher ADAS-cog [$\beta=2.28$, $p=0.004$], lower MMSE scores [$\beta=-2.42$, $p=0.01$]) from baseline to 36-months, and a significant increase in neuropsychiatric symptom severity (NPI $\beta=16.93$ $p<0.001$). CSF NfL/ $A\beta$ 42 also mediated the effects of spindle activity on cognitive performance on the ADAS-cog ($p=0.041$) and MMSE ($p=0.0019$), while NfL, YKL-40, NG-36, NfL/ $A\beta$ 42 also moderated the relationships between spindle and SO activity on cognition, and spindles and SO moderated the relationships between these biomarkers and cognition.

Conclusions: Our novel findings demonstrate that spindle and SO activity are robustly associated with NfL, YKL-40, and NG-36, and cognitive decline, constituting predictive, non-invasive biomarkers of neurodegeneration, cognition, and mental health in AD. NREM spindle and SO activity can act as complimentary, non-invasive markers of neurodegeneration and potential therapeutic targets for sleep-related interventions designed to monitor or slow AD symptom progression. They add further evidence for links between NfL, NG-36, YKL-40, sleep, and cognition, and their role as supplemental AD biomarkers and biomarkers of susceptibility to neurodegeneration in cognitively unimpaired persons at higher risk of AD. They also constitute potential targets for sleep-related interventions for cognition in the context of AD and other neurodegenerative disorders.

The effect of yoga on sleep quality and menopausal symptoms in menopausal women: a systematic review and meta-analysis

C. Segsarnviriya¹, P. Sugkraroek², N. Chirakalwasan³

¹Samitivej Thonburi Hospital, Otolaryngology, Bangkok, Thailand, ²Dhurakij Pundit University, Department of Anti-Aging and Regenerative Medicine, College of Integrative Medicine, Bangkok, Thailand, ³King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Excellence Center for Sleep Disorders, Bangkok, Thailand

Introduction: Menopausal women often experience sleep disturbances and menopausal symptoms that significantly affect their quality of life. Recent studies have suggested that yoga may also positively

affect sleep quality by promoting relaxation and reducing stress, making it an appealing option for managing menopausal symptoms. We conducted a systematic review and meta-analysis of menopausal women to assess the effect of yoga on sleep quality and menopausal symptoms.

Materials and methods: PubMed, Scopus, Ovid, The Cochrane Library, and Google Scholar were searched through July 2023. Randomized controlled trials (RCTs) that evaluated the effects of yoga in menopausal women and reported quantitative data on sleep quality and menopausal symptoms were included. The study protocol was registered on PROSPERO (CRD 42023464468).

Results: Thirteen RCTs (1649 patients) were eligible for meta-analysis. The meta-analysis of six RCTs (591 patients) did not demonstrate a statistically significant difference in the total score of the Pittsburgh Sleep Quality Index (PSQI) (mean difference -1.39; 95% CI (-3.69, 0.92); $P = 0.24$). On the contrary, the meta-analysis of eight RCTs (1065 patients) revealed a significant improvement in the total score of the Menopausal Rating Scale (MRS) (mean difference -7.10; 95% CI (-11.27, -2.93); $P = 0.0008$). There were significant differences in the subscale of each symptom including somatovegetative, psychological, and urogenital subscale (somatovegetative subscale: mean difference -2.64; 95% CI (-4.93, -0.35); $P = 0.02$, psychological subscale: mean difference -3.43; 95% CI (-5.76, -1.11); $P = 0.004$, urogenital subscale: mean difference -1.25; 95% CI (-2.30, -0.21); $P = 0.02$).

Conclusions: The pooled results did not demonstrate the significant benefits of yoga on sleep quality in menopausal women. Conversely, the remarkable advantages of yoga in relieving menopausal symptoms were illustrated. To further explain the benefit of yoga on sleep quality in menopausal women, additional, longer-duration yoga training or longer-term studies are required.

The Relationship Between Napping and Memory Varies as a Function of Genetic Risk for Alzheimer's Disease

C. Faucher^{1,2,3}, R. Thienel⁴, A. Behler¹, L. Gomez², J. Fripp³, M. Breakspear^{1,4}, M. Lupton^{2,5,6}

¹The University of Newcastle, School of Psychological Sciences, Newcastle, Australia, ²QIMR Berghofer, Brain and Mental Health, Brisbane, Australia, ³CSIRO, Australian eHealth Research Centre, Brisbane, Australia, ⁴The University of Newcastle, School of Public Health and Medicine, Newcastle, Australia, ⁵Queensland University of Technology, School of Biomedical Sciences, Brisbane, Australia, ⁶The University of Queensland, School of Biomedical Sciences, Brisbane, Australia

Introduction: Habitual daytime napping is a significant aspect of many older adults' sleep-wake cycle. Growing evidence links napping and cognitive abilities in the context of Alzheimer's Disease (AD), yet little is known about how genetic risk influences this relationship. This study investigates the interactions between genetic risk for AD and self-reported daytime napping on the cognitive performance of 1655 non-clinical middle-aged to older adults.

Materials and methods: Cognition was assessed using a self-administered online battery and reduced to three variables: memory, visuospatial abilities and executive function. Sleep parameters were obtained via self-reported questionnaires. Genetic risk was assessed with the presence of the apolipoprotein (APOE) $\epsilon 4$ allele, the strongest known genetic risk factor for AD, and with polygenic risk scores (PRS; excluding APOE), with a low score indicating a lower risk for AD. The interactions between habitual napping duration and genetic risk on cognitive performance were assessed using analyses of covariance, adjusting for age, sex, education and body mass index (BMI).

Results: Participants were aged between 42 and 75 years (70.2% female), with 31.2% being APOE $\epsilon 4$ carriers (i.e., with at least one $\epsilon 4$ allele). APOE $\epsilon 4$ carriers who reported habitual long naps ($M = 0.32$, $SE = 0.16$) demonstrated better memory performance ($p = .003$) than non-carriers who also reported long naps ($M = -0.27$, $SE = 0.12$). Among APOE $\epsilon 4$ carriers, those who napped for ≥ 1 hour ($M = 0.32$, $SE = 0.16$) performed better ($p = .048$) than those reporting shorter naps ($M = 0.09$, $SE = 0.05$). This was not the case for non-carriers. In a separate analysis, low PRS ($M = 0.12$, $SD = 0.06$) was related to better memory performance than high PRS ($M = -0.13$, $SD = 0.68$) among those who did not nap ($p = .007$). Within the low PRS group, participants who did not nap ($M = 0.12$, $SD = 0.06$) outperformed ($p = .049$) those who reported short naps ($M = -0.18$, $SD = 0.10$). These results remained significant after accounting for self-reported overnight sleep efficiency.

Conclusions: The results of this study suggest that the relationship between napping and memory varies as a function of genetic risk for AD. Notably, it is possible that for those at a higher genetic risk for AD, napping provides a compensatory mechanism to adjust for deficiencies in nocturnal sleep. As such, our findings do not support a one-size fit all approach to sleep advice that long naps may be

detrimental, including for cognitive abilities. The current results could inform future studies investigating personalised preventative treatment, such as behavioural interventions modifying the sleep wake cycle, based on genetic profiles.

The Sleep Detectives: a co-designed protocol for longitudinal tracking of sleep health, sleep neurophysiology and cognition in children and young people at risk of neurodevelopmental disorders

A. Saka¹, L. Berndt², M. Attwood¹, J. Haddon³, D. Brooks³, J. Rennie¹, A. Sorrentino¹, C. Dawson¹, C. Jarrold¹, N. Donnelly¹, J. Clayton¹, J. Hall³, A. Shaw², M. Van den Bree³, M. Jones⁴

¹University of Bristol, Bristol, United Kingdom, ²University of Exeter, Exeter, United Kingdom, ³Cardiff University, Cardiff, United Kingdom, ⁴University of Bristol, School of Physiology, Pharmacology & Neuroscience, Bristol, United Kingdom

Introduction: Several chromosomal deletions and duplications – including 22q11.2 and 1q21.1 deletion and 16p11.2 duplication – are associated with high risk of neurodevelopmental and psychiatric outcomes. Many people living with these copy number variants (CNV) present with insomnia and fragmented sleep, which are associated with symptoms including ADHD and anxiety. Sleep and circadian disruption are a key concern for children and their families/carers, and may present opportunities for early diagnosis and treatment, alongside offering insights into neurobiological mechanisms of psychiatric risk. However, harnessing these opportunities requires robust, longitudinal measures of sleep health, sleep neurophysiology (EEG) and rest-activity rhythms that are accessible and acceptable to children and young people.

Materials and methods: Working with a Lived Experience Advisory Panel of children and young people, parents, carers and support charities, we co-designed a protocol combining questionnaires, wrist-worn actigraphy (Fitbit Inspire 3), wearable EEG (Muse S headband) and gamified cognitive tasks (<https://osf.io/f78bq/>). The protocol was piloted with a representative sample of 28 school children (8-12 years) over 7 consecutive days/nights. We also report further analyses of cross-sectional data from wrist-worn actigraphy (Philips Actiwatch, 14 days/nights, 29 probands with 22q11.2 deletion syndrome [DS] and 22 siblings, 8-20 years) and/or high-density sleep EEG (60 channels, 1 night, 28 probands with 22q11.2DS and 17 siblings, 6-20 years) and polysomnography (PSG) in children and young people with 22q11.2 deletion syndrome (PMID: 31144615, 36039635).

We developed an open-source pipeline that uses the Fitbit Web API to extract, preprocess, and report longitudinal sleep and activity data (<https://github.com/sleepdetectives/fitbit-data-pipeline>). The pipeline facilitates derivation of Rest-Activity Rhythm metrics, an actigraphic proxy of circadian rhythms. EEG analyses leveraged computational modelling to infer the synaptic basis of sleep EEG alterations in 22q11.2DS using a Dynamic Causal Model (DCM) of thalamocortical circuits underpinning the hallmark oscillations of sleep EEG.

Results: Our pilot protocol was acceptable to school children and their families. The Muse S headband was well-tolerated and enabled characterization of spindle and slow-wave events, though signal quality tended to degrade over the course of each night.

Based on actigraphy and diaries, children with 22q11.2DS spent significantly longer in bed and asleep than siblings (total sleep time 517 vs. 475min, $p < 0.001$), but reported slightly reduced sleep quality ($p < 0.05$). These differences in sleep duration were not replicated with EEG/PSG. Rest-activity rhythms were altered in 22q11.2DS, with reduced amplitude and Midline Estimating Statistic of Rhythm ($p < 0.001$).

DCM showed that synaptic dysfunction in 22q11.2DS was most prominent during sleep, with constellations of parameters varying across non-REM and REM stages. Increased thalamo-cortical drive during N3 associated with reported sleep problems. Simulating increased NMDA receptor-mediated

gain showed potential to align 22q11.2DS EEG with neurotypical patterns. The largest effect sizes were particularly evident at slow-wave and spindle frequencies during non-REM.

Conclusions: Our multi-modal toolkit proved acceptable to children and young people, enabling integrated, multiscale analyses extending from qualitative descriptors of sleep quality to predictions of synaptic mechanisms. Using these approaches has allowed detection of potential biomarkers of thalamocortical network dysfunction in 22q11.2DS; current work is extending to other CNV.

Acknowledgments: Thanks to team Sleep Detectives and Wellcome (grant 226709/Z/22/Z).

Trait-Like Slow-Wave Activities Link to Cognition: Multi-Night At-Home Wireless EEG Study in Older Adults

S. Qin¹, J.L. Ong¹, K.F. Wong¹, T. Liang¹, E.K.K. Ng¹, W.-P. Koh², J.H. Zhou¹, M.W.L. Chee¹

¹National University of Singapore, Center for Sleep and Cognition, Singapore, Singapore, ²National University of Singapore, Healthy Longevity Translational Research Programme, Singapore, Singapore

Introduction: In-laboratory polysomnography remains the gold standard for studies examining associations between sleep and cognition. However, a single night of sleep – particularly in a new environment does not capture the extent of naturalistic night-to-night variability in sleep parameters and may contribute to inconsistent results across studies. In the present study, we computed variability across sleep stages and relative power spectra over multiple nights of sleep at home using a wireless headband to identify trait-like metrics that would be most reliably associated with cognitive function in older adults.

Materials and methods: A total of 49 free-living older adults (Age range: 71-80) with no self-reported sleep disorders. They wore a wireless sleep headband (Dreem Headband, Beacon Diagnostics, USA) over 4-8 nights of sleep. Night-to-night variability of sleep parameters was determined using the coefficient of variation (CV). Trait-likeness was defined as having CV under 20%. Cognition was assessed via a comprehensive neuropsychological battery. A composite global cognition score was computed from the battery. Correlation analyses examined the associations between trait-like sleep metrics and global cognition. Both the average across days and single nights of trait-like sleep metric were examined for correlation with cognition.

Results: Night-to-night variability in the current sample (n = 49; 302 nights) was high for N3% (CV=47%), medium for REM% (CV=22%), and low for N2% and relative power from all bands (CV=3-17%). Only relative Delta power (0.8- 4.5 Hz) was significantly associated with global cognition, both when considering average ($r=0.51$, $p<0.001$) and single night ($r=0.3-0.4$) assessments.

Conclusions: Delta band power demonstrated clear trait-likeness across nights and strong associations with cognition in free-living older adults. These results highlight the underestimation of night-to-night variability in objective sleep metrics when only using one assessment night and the importance of assessing slow-wave activity instead of N3% in examining sleep-cognition associations in older adults.

Tunable Lighting to Improve Sleep and Cognition Performance in Elderly Population in Nursing Homes

M. Boubekri¹, N. Sharp²

¹University of Illinois at Urbana-Champaign, Illinois School of Architecture, Champaign, United States,

²Arizona State University, The Design School, Herberger Institute for Design and the Arts, Tempe, United States

Introduction: Depression is a common symptom among older adults with an estimated prevalence of 5% - 15% among those who are community-dwelling. In older adults, depression is associated with cognitive impairment and could approximately double the risk of dementia [3]. Moreover, these depressive symptoms could place additional stress on caregivers in both institutional and home settings.

Materials and methods: Lighting interventions included two whole-day lighting schemes with varying illuminance levels and/or CCTs. Both lighting schemes were designed based on available research to

meet circadian lighting needs of older adults. We perceived from prior literature indicates that an optimum lighting solution for circadian entrainment should provide:

- High levels of bright blue illuminance (high intensity + high CCT (or blue-enriched spectrum)) early in the morning to phase advance the circadian clock.
- Medium to high levels of illuminance (medium to high intensity + medium CCT (neutral white)) in the afternoon to increase alertness without exerting substantial phase shifting effects on the circadian clock
- Dimmed illumination (low intensity + low CCT (yellowish white light)) in the evening to avoid disruption of circadian rhythms and unwanted phase delay.

Results: The patterns of the depression scores across the study are illustrated in Figure 1. The general pattern is similar for the two groups; namely, depression scores decrease with the L1 intervention, decrease even more with the L2 intervention, and start returning to baseline levels after the intervention has been discontinued. These general trends were assessed with an independent *t*-test statistical analysis to determine the effectiveness of the experimental whole-day lighting interventions on depression among older adults. Data were managed and analyzed using IBM SPSS 22.0 statistical software.

Baseline measurements revealed that the mean GDS score in group A was 4.71 points higher than group B. After 9 days of exposure to the L1 and L2 interventions, we observed more reduction from the baseline 1 in mean depression scores in group A compared to group B (Table 5). However, an independent *t*-test showed no significant difference in the mean GDS score between groups in baseline 1 ($t = 2.12, P = 0.05$), L1 ($t = 1.11, P = 0.29$), L2 ($t = -0.08, P = 0.94$), and baseline 2 ($t = 0.56, P = 0.58$).

Conclusions: During the L2 intervention, we added tuning spectrum quality to the ambient illumination with varying illuminance levels to provide a bright cool light in the morning and a dimmed warm light in the evening. L2 intervention reduced mean depression score in participants by 60% in group A and 30% in group B, which were significantly higher than L1 intervention in both groups. This supports the idea that adding tuning spectrum to the environmental lighting quality provides additional benefits to reduce depression in older adults and improve their mood and well-being; hence, the color of light also matters.

Acknowledgments: The study was funded by Jim H. McClung Lighting Research Foundation. The Authors would like to acknowledge Dave Meglio and Jared Ruhl of Meglio & Associates for their assistance with lighting setups.

Basic Research

A Bistable Stochastic Model Quantifies Performance Degradation And Individual Vulnerability To Sleep Deprivation

S. Raison¹, P. Sanz-Leon¹, C. Schmidt^{2,3}, V. Muto^{2,3,4}, S. Postnova¹

¹The University of Sydney, School of Physics, Sydney, Australia, ²University of Liège, GIGA-CRC in Vivo Imaging, Liège, Belgium, ³University of Liège, Psychology and Neurosciences of Cognition Research Unit, Liège, Belgium, ⁴University of Molise, Department of Humanities, Education and Social Sciences, Campobasso, Italy

Introduction: Sleep deprivation impairs vigilance, increasing the frequency of very long reaction times (> 500 ms) and slowing average response speed on the psychomotor vigilance task. Vulnerability of sustained attention impairment due to sleep deprivation is trait-like, with some individuals consistently more vulnerable than others. However, the mechanisms behind vulnerability traits are not known, and no gold-standard method exists for classifying individuals according to their vulnerability. The objectives of this study were to (i) characterise and quantify sustained attention impairment during sleep deprivation and (ii) develop a mathematical model that accounts for these characteristics, as a step towards a vulnerability classification system.

Materials and methods: Young, healthy, male participants ($N = 321$, age 22.1 ± 2.7) underwent 40 hours of sleep deprivation under a constant routine protocol (dim light < 5 lux, constant posture and meals) starting from their habitual wake time. Participants performed a 10-minute psychomotor vigilance task every 2 hours, and saliva melatonin was collected every hour. Reciprocal reaction time

data was referenced to dim light melatonin onset and aggregated over individuals in 2-hour bins (group-aggregated data). To characterise vulnerability, for each individual, data was aggregated across baseline (2 – 16 h since awakening) and sleep deprivation (18 – 40 h since awakening). In all cases, we analysed distributions of reciprocal reaction times. Our bistable stochastic model was fit to all aggregated datasets using the maximum likelihood method.

Results: We observed that group-aggregated reciprocal reaction time distributions exhibited (i) a primary peak centered at 3.05 s^{-1} , and (ii) a secondary peak centered at 0.16 s^{-1} emerging 6 h after and persisting until 22 h after dim light melatonin onset. The secondary peak corresponds to very long reaction times, which can be characterised as period of unresponsiveness. We proposed a bistable stochastic model that accurately reproduced the experimental group-aggregated data (Kolmogorov distance between model and data was 0.009 ± 0.003). Analysis of model fits to baseline and sleep deprivation distributions for each individual revealed heterogeneous responses to sleep deprivation, where effects on individuals' primary and secondary peaks were decoupled. We found that participants can be split into groups based on the presence of the secondary peak at baseline and during sleep deprivation. A typical resilient person does not demonstrate a second peak at either baseline or during sleep deprivation, while a typical vulnerable person develops a second peak during sleep deprivation. However, shifts in the primary peak were often substantial and led to large increases in the frequency of reaction times $> 500 \text{ ms}$ even when no secondary peak developed, indicating that susceptibility to critical response slowing is distinct from susceptibility to periods of unresponsiveness.

Conclusions: A secondary peak in the reciprocal reaction time distribution differentiates very long responses from average response speed, and is predicted by bistability in a mathematical model. Individual responses to sleep deprivation are heterogeneous, and both peaks must be accounted for in order to properly characterise individual vulnerability.

A Case Study---Improving Sleep Quality and Glycemic Biomarkers in Patients with Obstructive Sleep Apnea and Type 2 Diabetes through Long-Term Use of Continuous Positive Airway Pressure Therapy

P.-T. Huang¹, J.-W. Chen², C.-H. Yuan^{2,3,4,5}, H.-R. Lin^{4,6}, Y.-K. Lee^{2,4}

¹Kaohsiung Armed Forces General Hospital, Medical Education and Research Center, Kaohsiung City, Taiwan, ²Kaohsiung Armed Forces General Hospital, Medical Laboratory, Medical Education and Research Center, Kaohsiung City, Taiwan, ³Kaohsiung Armed Forces General Hospital, Department of Otolaryngology, Kaohsiung City, Taiwan, ⁴National Sun Yat-sen University, Institute of Medical Science and Technology, Kaohsiung City, Taiwan, ⁵National Defense Medical Center, Department of Otolaryngology, Taipei, Taiwan, ⁶Kaohsiung Armed Forces General Hospital, Nursing Department, Kaohsiung City, Taiwan

Introduction: Obstructive Sleep Apnea (OSA) and Type 2 Diabetes Mellitus (T2DM) frequently coexist and exacerbate each other. OSA leads to intermittent nocturnal hypoxia and sleep fragmentation, which can worsen insulin resistance and glycemic control. Studies have shown that long-term use of Continuous Positive Airway Pressure (CPAP) therapy significantly improves sleep quality, reduces hypoxic episodes, and helps stabilize key biochemical markers in T2DM patients, such as fasting glucose, HbA1c, and insulin sensitivity. As a non-invasive intervention, CPAP presents a promising adjunctive treatment for patients suffering from both OSA and T2DM.

Materials and methods: This single-case study involved a patient with type 2 diabetes and insomnia, diagnosed with severe obstructive sleep apnea (AHI > 100), a body mass index (BMI) over 40, and an HbA1c level above 10. The patient underwent a two-month intervention using a Continuous Positive Airway Pressure (CPAP) device, worn nightly. Sleep quality and type 2 diabetes-related biochemical markers—including fasting glucose, HbA1c, and insulin sensitivity—were regularly monitored to evaluate the clinical impact of sustained PAP therapy.

Results: Before intervention, the patient's AHI exceeded 100 and HbA1c was over 10. After two months of continuous positive airway pressure therapy, AHI dramatically decreased to below 20. HbA1c levels significantly dropped, BMI showed a downward trend, and sleep quality improved markedly. Additionally, glycemic control became more stable.

Conclusions: These findings suggest that continuous positive airway pressure therapy has beneficial clinical and metabolic effects in patients with severe obstructive sleep apnea combined with type 2 diabetes, offering a promising adjunctive treatment approach.

Acknowledgments: Key Word: Obstructive Sleep Apnea (OSA), Type 2 Diabetes Mellitus (T2DM), Continuous positive airway pressure (CPAP), Apnea-Hypopnea Index (AHI), Sleep Quality, Hemoglobin A1c (HbA1c)

Acetate improves neurocognition in sleep-deprived male Wistar rats via modulation of xanthine oxidase/uric acid-driven oxidative stress and NFkB-dependent inflammation, and caspase 3-mediated apoptosis

R. Akhigbe¹, O. Adepoju², C. Adegbola¹, A. Lasisi-Sholola¹, A. Oladipo¹, T. Akhigbe⁴

¹Ladoke Akintola University of Technology, Physiology, Ogbomoso, Nigeria, ²Hospital Samaritano, Neurology, Sao Paulo, Brazil, ³Osun state university, Agronomy, Ejigbo, Nigeria

Introduction: The global rise in sleep deprivation (SD) is alarming, as reports show that an increasing number of individuals suffer from SD in at least 3-4 days per week due to work shifts, stress, and anxiety. SD alters several biological processes, including neurocognition, via the induction of oxidative stress. However, acetate confers cellular protection by modulating oxidative stress-sensitive signaling. Notwithstanding, the effect of acetate on SD-induced neurocognitive deficit is still unknown. Therefore, this study investigated the effect of acetate on SD-induced neurocognitive deficit. Also, the roles of xanthine oxidase (XO)/uric acid (UA) and NFkB/caspase 3 pathways were probed.

Materials and methods: Forty 10-week-old male Wistar rats of similar weights were randomly allotted into four groups (n=10): vehicle-treated control (0.5 mL of water), sodium acetate (200 mg/kg), SD, and SD + acetate. SD was induced by exposing the rats to continuous SD for 72 hr using the modified multiple platform technique. Acetate treatment was *per os* and lasted for 72 h. After this period, biochemical and histopathological parameters were evaluated in the serum and hippocampal and cortical tissues.

Results: SD led to neurocognitive deficit (evidenced by impaired parameters from novel object recognition, Y maze, and open field tests). In addition, SD increased hippocampal and cortical XO, UA, and MDA levels but reduced GSH, SOD and catalase. SD also elevated TNF- α , IL-1 β , IL-6, NF-kB, and caspase-3 in these tissues. These alterations were accompanied by a rise in lactate, lactate dehydrogenase, and creatinine kinase, and distorted hippocampal and cortical histo-architecture (pyknosis and neurodegeneration). However, acetate administration attenuated SD-driven hippocampal and cortical biochemical and histological derangements.

Conclusions: In conclusion, these findings revealed that SD induced neurodegeneration and cognitive deficit via the upregulation of XO/UA and NFkB/caspase 3 signaling. More so, acetate ameliorated SD-induced hippocampal and cortical biochemical and histological derangements by downregulating UA generation, NFkB-mediated inflammation, and caspase 3-dependent apoptosis.

A cross-sectional observational study on sleep parameters in Indian males and females

R. Tripathi¹, H. Bano¹, S. Tiwary^{1,1}, A. Taru¹

¹All India Institute of Medical Sciences, Gorakhpur, Psychiatry, Gorakhpur, India

Introduction: Nearly all living organisms spend a fraction of their lives in a reversible, unconscious, coma-like state. It is still unclear why exactly organisms sleep but it is related to health and well-being. Disturbed sleep has negative effects on mental and physical health. Sleep has gender difference as well. The aim of the present study was to understand and compare sleep pattern of adult Indian males and females.

Materials and methods: A cross-sectional observational study was conducted on 301 participants presenting to a tertiary care centre in India. Participants were bystanders of patients representing the community and were not suffering from any known medical or psychiatric disorder. The participants were assessed on their socio-demographics, sleep profile and substance use profile with the help of Pittsburgh Sleep Quality Index (PSQI), Sleep -50, Epworth Sleepiness Scale (ESS), sleep Hygiene and The Alcohol Smoking and Substance involvement screening test (ASSIST).

Results: 187 males and 114 females participated in the study. Nearly half of the sample was married and nearly 60% of the sample were employed. Most of the sample belong to urban locality and middle socio-economic status. Only five percent of the sample reported lifetime use of tobacco and three percent reported current tobacco use. No participant reported use of any other substance. There was no difference in socio-demographics in males and females except for employment status as most of the females in our study were housewives. The mean age of the total sample was 31.2 (10.2) years. The mean subjective sleep latency and total sleep time of the sample were 30 (15,60) minutes and 417.3 (70.7) minutes. Near about 30 percent of the sample has PSQI>5. Females reported more sleep disturbance (n=37,33%) than males (n=53,28.8%) in terms of total PSQI score>5, however it was not statistically significant. The median PSQI score of the sample was 4(2,6). The median sleep latency was found to be same for males and females (30(15,60) minutes vs30 (15,30) minutes). The median ESS scores for males was 3.5 (0,7) and for females was 4 (1,9). The mean total sleep latency for males and females was 417.2 (73.7) minutes and 418.4 (67.1) minutes respectively. Most of the patients had normal day time sleepiness (n=268,89%). Only three percent of the participants (n=8) reported moderate to severe day time sleepiness. No significant difference was observed between subjective sleep latency, subjective total sleep time, total PSQI scores and total ESS scores between male and female participants. A significant negative correlation was observed between marital status and sleep latency in males but not in females. A significant positive correlation was observed between total ESS scores and type of employment in males but not in females.

Conclusions: The general adult population in India has a sleep of around seven hours. Females had more sleep disturbance than males although difference was not statistically significant. Married males had earlier onset of sleep.

Acute sleep deprivation causes rats' soleus muscle neuromuscular junction to undergo synaptic plasticity

T. Sengupta¹, B. Sharma², A. Roy³, A. Singh⁴, T.C. Nag⁵, R. Netam², N. Akhtar², H.N. Mallick⁶

Introduction: Sleep is crucial for both cognitive and physical performance. Sleep deprivation impairs not just brain function but also causes physical exhaustion. A good night's sleep cures the functional abnormalities produced by sleep deprivation. Sleep's influence on brain function has been thoroughly explored. However, its role in the functional anatomy of the neuromuscular junction or skeletal muscle morphology is poorly understood, although skeletal muscle atonia and suspended thermoregulation during rapid eye movement sleep may provide a favorable environment for muscle rest and repair, similar to slow-wave sleep for synaptic downscaling.

Materials and methods: The Institutional Animal Ethics Committee's rules were followed throughout the investigation. A total of 18 rats were randomly assigned to three groups: control, 24-hour sleep deprivation, and 24-hour recovery sleep. After 24 hours of sleep deprivation utilizing a modified multiple-platform approach, animals were euthanized, and tissues were collected and analyzed for neuromuscular junction architecture and neurochemistry using electron microscopy and immunohistochemistry in the rat soleus muscle. A similar analysis of the neuromuscular junction was done in rats after sleep recovery given to the rats exposed to 24-hour sleep deprivation.

Results: Acute sleep deprivation changed synaptic ultrastructures, including mitochondria, synaptic vesicles, synaptic proteins, basal lamina, and junctional folds required for neuromuscular transmission. Furthermore, acute sleep loss causes depletion of the neurotransmitter acetylcholine and overactivity of its degrading enzyme, acetylcholine esterase, at the neuromuscular junction. The effects of sleep deprivation on synaptic homeostasis in the brain have lately been widely studied. Interestingly, in the sleep recovery group, the altered parameters at the neuromuscular junction was brought back to near normalcy.

Conclusions: The data from our research provides important insights into how sleep affects the homeostasis and functionality of neuromuscular junctions.

Acknowledgments: Current data from our research provides new perspectives into how sleep affects neuromuscular junction homeostasis and function.

A Digital, Real-Time, History-Based Sleep-Management Tool to Enhance Alertness

Y.M. Song¹, S.J. Choi², D. Lim³, R.H. Wijaya³, H.J. Jang³, H.R. Park⁴, E.Y. Joo⁴, J.K. Kim³

¹Institute for Basic Science, Biomedical Mathematics Group, Daejeon, Korea, Republic of,

²Sungkyunkwan University, Seoul, Korea, Republic of, ³KAIST, Daejeon, Korea, Republic of, ⁴Samsung Medical Center, Seoul, Korea, Republic of

Introduction: Chronic sleep disruption and circadian misalignment have become pervasive in today's 24-hour society, contributing to impaired cognitive performance, increased risk of accidents, and long-term health consequences. Yet, most sleep management strategies rely on one-size-fits-all recommendations that overlook individual variability, resulting in suboptimal and/or impractical solutions.

Materials and methods: To address this gap, we developed a real-time, personalized sleep scheduling framework that tracks dynamic sleep pressure and circadian rhythms using a mathematical model. This framework was implemented as a mobile application, SleepWake, which delivers individualized sleep recommendations based on continuously updated sleep data. We evaluated its effectiveness through two studies: a retrospective analysis of 71 female shift workers from a previous clinical trial, followed by a prospective clinical study involving 19 male shift workers.

Results: The analysis revealed that greater adherence to SleepWake's recommendations was associated with significantly improved alertness, even when total sleep time was comparable. These benefits were driven by two key innovations: real-time supplemental sleep prescriptions informed by recent sleep history, and personalized sleep timing aligned with each individual's circadian rhythm.

Conclusions: This study provides the first direct evidence that continuously updated, personalized sleep schedules can enhance alertness and sleep health in real-world environments. By integrating sleep physiology with evidence-based mathematical modeling, SleepWake offers a scalable tool to promote health, safety, and well-being in shift-working populations and beyond.

Adiponectin ameliorates chronic intermittent hypoxia induced insulin resistance by modulating macrophage polarization in visceral white adipose tissue

X. Weng¹, W. Wang¹

¹The Second Affiliated Hospital of Nanjing Medical University, Respiratory Department, Nanjing, China

Introduction: Chronic intermittent hypoxia (CIH) caused by obstructive sleep apnea (OSA) is an independent risk factor for insulin resistance (IR) in non-obese individuals, yet its underlying mechanisms remain unclear. Visceral adipose tissue (vWAT) is a central driver of insulin resistance, and its dysfunction is closely associated with IR. Adiponectin (Ad), one of the key adipokines secreted by adipose tissue, playing a key role in metabolic regulation. This study investigated how IR was induced by CIH and ameliorated by Ad through modulating macrophage polarization in vWAT.

Materials and methods: This study successfully set up a lean murine CIH-IR model, C57BL/6J mice were divided into normoxic control (NC) group, CIH-exposed (CIH) group, and Ad-intervened CIH-exposed (CIH+Ad) group (10 mice / group) .

Glucose metabolic parameters were measured to evaluate systemic glucose homeostasis.

Subsequently, epididymal white adipose tissue (eWAT) was collected for comprehensive analysis. Macrophage infiltration and polarization status were assessed using a combination of immunofluorescence (IF) staining, flow cytometry, and ELISA. In parallel, RNA sequencing (RNA-seq) was conducted to identify differentially expressed genes in the adipose tissue, followed by Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment analysis to elucidate significantly altered biological pathways. To further investigate the pathway, Western blot (WB) analysis was performed to examine key proteins in the insulin signaling pathway.

Results: It was found that the serum Ad level was significantly reduced in CIH group compared with the NC group, while accompanied by clearly increased Homeostatic Model Assessment of Insulin Resistance (HOMA-IR). When Ad was administered to CIH mice twice a week for 10 weeks, we

observed reductions in HOMA-IR.

Transcriptomic sequencing identified the top 100 differentially expressed genes (DEGs) in eWAT among three groups. KEGG pathway enrichment analysis revealed significant alterations in the PI3K-AKT signaling pathway. Western Blot (WB) analysis demonstrated that p-PI3K and p-AKT protein expression was downregulated in the eWAT of CIH group, and improved by Ad complementation. The IF tests of F4/80 in mouse eWAT indicated that the proportion of F4/80-positive cells in the CIH group was significantly higher than that in the NC group and CIH+Ad group. Flow cytometry analysis revealed that the number of F4/80 and CD11b double-positive cells in the single-cell suspension of the stromal vascular fraction (SVF) from eWAT was remarkably increased in the CIH group compared to the NC group, while it was decreased after Ad intervention. Meanwhile, it showed a higher M1/M2 ratio in the CIH group compared to the NC group, while a reduced M1/M2 ratio was identified in the CIH+Ad group.

The levels of TNF- α , IL-6, and IL-1 β in the eWAT suspension of the CIH group were significantly higher compared to the NC group, whereas these inflammatory cytokines were lower in the CIH+Ad group.

Conclusions: CIH might impair insulin signaling pathways in mouse eWAT by promoting M1 polarization of eWAT macrophages, which is probably an important mechanism of CIH-induced insulin resistance. Furthermore, it is hypothesized that Ad alleviates CIH-induced insulin resistance in mice by regulating eWAT macrophage polarization and restoring insulin signaling pathways.

AI-Driven Contactless Sleep Monitoring Using Smart Mattress and Machine Learning to Predict Obstructive Sleep Apnea and Sleep Quality in Military Personnel

Y. Chien-Han^{1,2,3,4}, H.-R. Lin^{3,5}, B.-S. Chen¹, Y.-K. Lee^{1,3}

¹Kaohsiung Armed Forces General Hospital, Medical Laboratory, Medical Education and Research Center, Kaohsiung City, Taiwan, ²Kaohsiung Armed Forces General Hospital, Department of Otolaryngology, Kaohsiung City, Taiwan, ³National Sun Yat-sen University, Institute of Medical Science and Technology, Kaohsiung City, Taiwan, ⁴National Defense Medical Center, Department of Otolaryngology, Taipei City, Taiwan, ⁵Kaohsiung Armed Forces General Hospital, Kaohsiung, Nursing Department, Kaohsiung City, Taiwan

Introduction: Obstructive Sleep Apnea (OSA) significantly impairs sleep quality and daytime alertness, especially in military personnel who face high operational and cognitive demands. Polysomnography (PSG), while being the diagnostic gold standard, is impractical for large-scale or continuous monitoring. This study aims to develop and validate a contactless sleep monitoring system using AI-enhanced smart mattress data integrated with machine learning (ML) algorithms to classify OSA severity and estimate sleep quality among hospitalized military personnel.

Materials and methods: Sleep data from military inpatients will be collected using a smart mattress system (Huijia Health Life Corporation) that records physiological signals (heart rate, respiratory rate, body movement) simultaneously with PSG. Supervised ML models-random forest, support vector machines, and deep neural networks-will be trained to classify OSA severity and predict sleep quality. SHAP values will be applied to interpret model outputs and identify key contributing features.

Results: We expect to establish a high-performing and interpretable model capable of classifying OSA severity with high accuracy and estimating sleep quality non-invasively. The model may also uncover latent relationships between OSA and degraded sleep, enabling early intervention and clinical decision-making.

Conclusions: Integrating smart mattress technology with ML provides a novel, non-contact, and scalable solution for OSA risk detection and sleep quality assessment. This approach could transform sleep monitoring and enhance military healthcare strategies.

A Machine Learning-Derived Transcriptomic Risk Model Linking DEHP and Sleep-Disordered Breathing to Cancer Prognosis and Immune Dysregulation

C.-H. Chang¹, K.-F. Chang¹, B.-S. Chen¹, Y.-K. Lee²

¹Medical Laboratory, Medical Education and Research Center, Kaohsiung Armed Forces General Hospital, Kaohsiung, Taiwan, ²Kaohsiung Armed Forces General Hospital, Medical Education and Research Center, Kaohsiung, Taiwan, Kaohsiung, Taiwan

Introduction: Both sleep-disordered breathing (SDB) and exposure to environmental toxicants such as di(2-ethylhexyl) phthalate (DEHP) are associated with chronic inflammation, immune dysfunction, and tumor progression. However, their combined molecular impact remains poorly understood. Clarifying this relationship may uncover novel mechanisms linking environmental and physiological stress to cancer outcomes.

Materials and methods: Thirteen overlapping genes related to both DEHP and SDB were identified via transcriptomic analysis and literature mining. A DEHP-SDB score was developed using LASSO Cox regression in The Cancer Genome Atlas (TCGA) pan-cancer cohort. Risk groups were compared across survival endpoints (OS, PFI, DSS). Functional enrichment and immune microenvironment analyses were conducted to interpret the biological relevance of the score.

Results: The DEHP-SDB score was significantly associated with poor survival in multiple cancers (- LUAD, KIRC, COAD, and ACC). High-risk tumors showed activation of epithelial-mesenchymal transition, IL-17 signaling, and the p53 pathway. These tumors also had increased immune checkpoint expression and stromal activation. A prognostic nomogram incorporating the score achieved an AUC of 0.81 for 5-year survival prediction.

Conclusions: We propose a novel DEHP-SDB transcriptomic signature that integrates environmental and sleep-related stressors into a unified prognostic model. This risk score not only predicts survival outcomes but also reflects immune and inflammatory remodeling, offering new insights for cancer risk stratification in vulnerable populations.

Acknowledgments: We sincerely thank the Kaohsiung Armed Forces General Hospital for providing clinical resources and institutional support. We also acknowledge Huijia Health Life Corporation for supplying the smart mattress system used in this study. Special thanks to Bo-Sheng Chen for his technical expertise in AI model development and implementation.

Aperiodic EEG activity in rodents as a potential marker for human hyperarousal

J. Fischer¹, E. van Someren¹, A. Osorio-Forero¹

¹Netherlands Institute for Neuroscience, Sleep and Cognition, Amsterdam, Netherlands

Introduction: Insomnia and anxiety-related disorders account for one-third of the mental disorder burden in society. This situation is likely related to a limited understanding of the complex biological mechanisms underlying their symptoms, which in turn results in a poor prognosis and limited treatment effectiveness for these conditions. A common key marker of severity and treatment resistance in both disorder types is hyperarousal. Here, we aim to study potential electrophysiological markers of altered monoaminergic activity across sleep stages in rodents and study its relation to hyperarousal in humans.

Materials and methods: Our work employs a systems neuroscience approach in mouse sleep to investigate the aperiodic activity of mice across sleep stages, their spatial features, and their dependency on recording conditions. We study their alterations upon optogenetic manipulation of the Locus Coeruleus (LC) noradrenergic (NA) system, sleep restriction, and stress.

Results: The intercept and slope of aperiodic activity across sleep stages are highly dependent on the spectral band analyzed and the type of signal studied, specifically whether it is cortical EEG or high-impedance Local Field Potentials (LFP). Stimulation of LC activity significantly alters the aperiodic features of the EEG and LFP, rendering them more "wake-like" compared to sham manipulations. In contrast, inhibiting these cells has a negligible effect on aperiodic features. Interestingly, a stressful experience, resulting in increased LC activity, produces a more non-rapid-eye-movement sleep-like aperiodic features in comparison to baseline or gentle sleep deprivation.

Conclusions: This work focuses on the aperiodic activity of the EEG and LFP in mice upon artificial or behavioral manipulations of LC-NA activity. These experimental conditions are related to the theoretical mechanisms of the overlapping symptom of hyperarousal in humans. We demonstrate that LC-NA activity is linked to the aperiodic component of electrophysiological activity in the sleeping brain, and we highlight the importance of technical considerations when conducting this type of analysis, as it may have potential consequences for the study of hyperarousal in humans.

Acknowledgments: The Swiss National Science Foundation partially supports this project, grant P500PB_214403.

Aperiodic neural activity reflects subjective sleep depth

B. Schneider¹, A.M. Stephan², L. Salvesen³, R. Bódizs¹, F. Siclari², M. Dresler³, Y. Rosenblum³

¹Semmelweis University, Institute of Behavioural Sciences, Budapest, Hungary, ²Lausanne University Hospital, Center for Investigation and Research on Sleep, Lausanne, Switzerland, ³Radboud University Medical Centre, Donders Institute for Brain, Cognition and Behavior, Nijmegen, Netherlands

Introduction: The feeling of being well-rested is essential to proper everyday functioning, however, the neural correlates of subjective sleep depth are still being established. A serial awakenings experiment (Stephan et al., 2021) found that subjective sleep depth was lowest during the early NREM sleep, the time when slow wave activity is highest. Furthermore, subjective sleep depth inversely correlated with fast high-frequency EEG activity as measured by the conventional band-based spectral approach. We use a part of the same dataset and calculate the aperiodic component of the EEG signal, a strong marker of objective sleep depth and stages. We explore whether, similarly to objectively measured sleep, aperiodic spectrum steepens as subjective sleep depth increases.

Materials and methods: We re-analyzed a part of the data reported by Stephan et al., 2021, where serial awakenings were carried out in 20 healthy subjects during two night's sleep with high-density EEG. Two-minutes EEG epochs were extracted before awakening. Participants reported whether they felt asleep or awake and the depth of the experienced sleep. To control for the effect of time of night and sleep stages, only awakenings from the first two hours of the night were included (n = 146). The aperiodic component of spectral power was calculated using the Irregular Resampling Auto-Spectral Analysis method with 4-s windows. Then, a piecewise-defined linear regression was applied in the log-log domain in the fitting range of 1–30Hz, resulting in a pair of low and high bands separated by the breaking frequency that differed for each epoch. Aperiodic slopes and intercepts were calculated and compared between epochs corresponding to the reported feeling asleep vs feeling awake for N2 (33 asleep, 8 awake reports) and N3 (69 asleep, 26 awake reports) separately, using the permutation test with the correction for multiple comparisons. To keep the number of awake and asleep reports balanced, the equal number of asleep epochs were randomly selected for each stage. Likewise, we correlated aperiodic parameters with the reported sleep depth on a scale of 1–5 ("5" being the deepest sleep).

Results: Upon awakening from N3 but not N2, EEG segments associated with subjective reports of feeling asleep showed steeper aperiodic slopes and higher intercepts in the low (but not high) domain in the occipito-parietal region compared to reports of feeling awake with medium to large effect sizes (Cohen's d's = 0.5–1.3, p's < 0.005). Furthermore, in N3, deeper subjective sleep was associated with steeper aperiodic slopes.

Conclusions: Beyond being noticeably distinct in different sleep stages, aperiodic neural activity also reflects modulations in perceived sleep depth, where steeper aperiodic spectral decay corresponds to deeper subjective sleep during early N3 sleep.

Acknowledgments: Supported by the Ministry of Innovation and Technology, Hungary (TKP2021-EGA- 25 and TKP2021-NKTA- 47) and the Vidi grant by the Dutch Research Council (NWO).

Assessing sleep quality and sleepiness among nursing undergraduates: A cross-sectional survey

W.Y. Mak¹

¹Saint Francis University, S. K. Yee School of Health Sciences, Hong Kong, Hong Kong, SAR of China

Introduction: Background: Sleep quality is crucial for health and quality of life, especially for nursing students. Daytime sleepiness is uncontrollable tiredness and snoozing during the day. Poor sleep quality and excessive daytime sleepiness that might have negative impacts on nursing students in terms

of poor academic and clinical practicum performance, mental health problem e.g., insomnia and depression, and further affect patient care.

Aims: This study was to assess the sleep quality and daytime sleepiness among nursing undergraduates.

Materials and methods: A cross-sectional questionnaire study was employed to recruit year 2 to 5 nursing undergraduates studying in the Caritas Institute of Higher Education (CIHE), Hong Kong. Approval was granted from the Research and Ethics Committee of CIHE. A total of 129 nursing undergraduates were invited to complete an online questionnaire, including demographic variables, Sleep Quality Scale (SQS) and Epworth Sleepiness Scale (ESS) from 06 November 2023 to 30 December 2023. The collected data was analysed using Pearson chi-squared test and correlation tests to investigate the relationship between sleep quality and daytime sleepiness.

Results: This study revealed a significant relationship between sleep quality and daytime sleepiness with a significant score of $r = 0.264$ (1), $p = 0.003$. The Pearson Chi-Squared test coefficients for 6 factors of SQS (Daytime dysfunction, restoration after sleep, difficulty in falling sleep, difficulty in getting up, satisfaction with sleep and difficulty in maintaining sleep) and ESS (Daytime sleepiness) indicated non-significant results. Only year 5 students had scores of $r = 0.413$ (1), $p = 0.014$ showing a significant relationship between sleep quality and daytime sleepiness.

Conclusions: There was a significant positive correlation between sleep quality and daytime sleepiness, indicating that higher levels of daytime sleepiness were associated with poorer sleep quality. The findings highlight the need to address sleep hygiene and promote optimal sleep quality for overall student well-being and alertness in clinical practicum for patient safety especially for final year students. Further research and interventions are necessary to better understand and improve sleep health in academic settings to acknowledge the limitations of the study, including its reliance on self-reported measures. Future research should aim to incorporate objective measures and expand the participant pool to enhance generalizability of findings.

Acknowledgments: The authors (Dr. Wai Yee Mak, Mr. Wong Ho Yin) would like to offer our sincere thanks to the support provided by other Honour's project supervisors Mr. Raymond Leung, Dr. Gladys Hui, and our director of research office for ethical approval, Dr. Andrew Low Yiu Tsang, Prof. Lisa Low, and Ethics Reviewer, Ms. Szeto Jessica. Special thanks to other student project's members Ms. Chan Yu Lam, Mr. Cheung ka Kit, Mr. Cheung Wan To, Mr. Chik Wai Chak, Ms. Mutto Natalie, Mr. Yuen Chun Ming.

Assessment of sleep quality among heavy truck, shift work drivers in Erdenet Mining Company of Mongolia

D. Shuren¹, A. Otgonnasan²

¹Mongolian National University of Medical Sciences, neurology, Ulaanbaatar, Mongolia, ²Erdenet Mining Company, Safiet and Health department, Hygiene specialist, Orkhon, Mongolia

Introduction: The working conditions of truck and heavy vehicle drivers, such as shift work, long driving hours, and irregular sleep patterns, are among the highest risk factors for sleep deprivation. Shift workers are at increased risk for sleep disorders due to disrupted circadian rhythms and reduced sleep duration to less than 7 hours per 24-hour period.²¹ Shift work of more than 12 hours, early work start times before 6 am, and shifts that start at night have been shown to negatively impact sleep quality.

Objectives: To assess the sleep quality, and lifestyle using a questionnaire.

Materials and methods:

The study followed a cross-sectional, descriptive design. Demographic, anthropometric, and sleep questionnaire surveys were done on 300 drivers and shift workers from November 3, 2023, to December 5, 2023. From the 300 operators who participated in the survey, 20 operators at risk were selected and polysomnography was conducted.

Results: 88% of the mine operators were male with a sex ratio of 4:1, mean age 39.2, and 80% of the operators were aged 30-49. 87% of the respondents were smokers, and 50% had a history of alcohol consumption. 28% of the operators had worked in the mine for 5-10 years, and increasing age was directly related to increasing years of work. Anthropometric indicators showed that 74% were overweight or obese, with neck circumference and waist circumference 3-5 cm larger than the average

Mongolian, and an average of 1st-degree hypertension. Anthropometric indicators differed by the workshop, with overweight and hypertension being more common among drivers. 76% of all operators are at risk of having one or more sleep disorders, 44% are excessively sleepiness, and 38% have poor sleep quality. Sleep disorders, drowsiness, and poor sleep quality are directly related to having a high BMI, large neck and waist circumference, high blood pressure, and high heart rate, and are also associated with years of work. In polysomnography, 99% of all operators have sleep disorders or poor sleep quality, of which 10% have insomnia as the main diagnosis, 65% have sleep apnea, and 20% have periodic limb movement disorder. Noteworthy that 80% have two or more types of sleep disorders combined.

Conclusions: Obesity, alcohol consumption, and insufficient sleep and rest time among mining operators and workers are major risks to the normal functioning of the work-life balance. Therefore, increasing sleep time is not only important for safety but also for individual health, and has many benefits for improving labor productivity and stable work. We propose measures that include organizational and individual participation from the organization.

Assessment of sleep quality and its association with mental status and physical activity among medical undergraduates

B.M. Naik¹, A. Pallavi¹, K. Natarajan¹, R. Subhiksha¹

¹Jawaharlal Institute of Postgraduate Medical Education and Research (JIPMER), Puducherry, Physiology, Puducherry, India

Introduction:

Sleep is vital for overall health and well-being. Sleep improves cognition, learning and memory, and academic performance. It also brings behavioural and emotional control and fosters positivity, thus improving the overall quality of life (QoL). Chronic sleep deprivation worsens health and emotional well-being and leads to self-criticism, internalising symptoms and risk-taking behaviours escalating to mental illness, self-harm and suicidal tendencies if unattended. The majority of the young population, in their peak productive period, neglect sleep and suffer from insufficient sleep syndrome due to academic and work demands. Therefore, the present study was planned to assess sleep quality and its association with mental status and physical activity among medical undergraduate students.

Materials and methods:

Undergraduate Medical students (N=345) of either sex between the age group 18 and 25 years were recruited for the study. The data was collected online by Google form and self-reported questionnaires of the Pittsburgh Sleep Quality Index and Depression Anxiety Stress Scales, Epworth Sleepiness Score and International Physical Activity Questionnaire were used to measure the Sleep quality, Depression, Anxiety and Stress levels, Daytime sleepiness and Physical activity respectively

Results:

The average age of the Study participants (n=345) was 20.36 ± 1.135 years. Of the total, 184 (53.3%) were male and 161 (46.7%) were female. Sleep quality data revealed that 146 (42.3%) had good sleep, while 199 (57.7%) experienced poor sleep. Additionally, participants with poor sleep quality had significantly higher levels of depression ($p < 0.001$), anxiety ($p < 0.001$), stress ($p < 0.001$), and daytime sleepiness ($p < 0.001$), along with a significant decrease in physical activity ($p = 0.009$), compared to those with good sleep quality.

Conclusions:

Poor sleep quality is high among medical students and is significantly associated with depression, anxiety, and stress. However, structured physical activity of moderate to severe degree proves beneficial in improving sleep quality

Acknowledgments:

I express our gratitude to the Jawaharlal Institute of Postgraduate Medical Education and Research (JIPMER), Puducherry, for granting permission to conduct this study in medical undergraduates. This helped us to estimate the sleep quality and the determine the prevalence of poor sleep quality among medical undergraduates

Beyond Sleep Duration: The Critical Role of Sleep Stages in Cardiovascular Disease Risk: Insights from two community-based cohort study

J. Wang¹

¹Sun yat-sen university, School of public health, Guangzhou, China

Introduction:

While most studies have focused on conventional self-reported measures such as sleep duration and quality, emerging evidence highlights the physiological and clinical heterogeneity of sleep architecture. This study comprehensively investigated the linear and nonlinear associations between four polysomnography-derived sleep stages (N1, N2, N3/N4, REM) and long-term CVD incidence in two large independent cohort studies, focusing on effect modification by habitual sleep duration and obstructive sleep apnea (OSA) status, as well as the mediating pathways exploration.

Materials and methods: We recruited 5,804 middle-aged and elderly individuals from the Sleep Heart Health Study (SHHS) and 1,416 individuals from the Wisconsin Sleep Cohort (WSC). Sleep stages were assessed objectively using in-home polysomnography. Multivariable Cox regression models were employed to calculate hazard ratio (HR) for CVD, coronary heart disease (CHD), and stroke, adjusting for demographics and other sleep metrics. Subgroup analyses stratified by habitual sleep duration and OSA status were conducted. Mediation analysis was used to quantify the mediating effect of six modifiable cardiometabolic biomarkers.

Results: A total of 4,042 participants from SHHS and 600 participants from WSC were included in the analysis, with a mean follow-up of 11.0 (SD=2.7) and 8.8 (SD=2.6) years, respectively. During the follow-up time, 695 and 60 CVD cases occurred in SHHS and WSC. After adjustment for potential confounders, each standard deviation (SD) increase in N2% was associated with a 17% increase in CVD risk (adjusted hazard ratio (AHR)=1.17, 95% CI: 1.08–1.27), while each SD increase in REM% was associated with an 11% reduction in CVD risk (AHR=0.89, 95% CI: 0.83–0.96). Sleep duration shows a significant modification effect for REM% (P for interaction=0.008), while OSA status shows a significant modification effect for N2%, N3/4%, and REM% (All for interaction<0.05). Restricted cubic spline curves indicate U-shaped associations of N3/4% with CVDs (P for non-linearity<0.001). Mediation analysis shows BMI and SBP are the main mediators, accounting for 13.1% and 5.5% for N2% and 13.9% and 7.4% for REM% sleep.

Conclusions: Our study demonstrates that a higher proportion of N2 sleep and a lower proportion of REM sleep are associated with increased CVD risk, especially in individuals with short habitual sleep duration and non-OSA populations. The BMI reduction and SBP control for CVD prevention may warrant prioritization, targeting the adverse effects of unfavorable sleep stage proportion.

Bidirectional Relations of Insomnia with Anxiety and Depression symptom networks and Moderating Role of Fatigue

H. Xing^{1,2}, F. Meng^{1,2}, P. Wang^{1,2}, X. Ma^{1,2}, Z. Li^{2,1}

¹Beijing Anding Hospital, Beijing, China, ²Capital Medical University, Beijing, China

Introduction: Insomnia is closely associated with anxiety and depression, forming a complex bidirectional relationship. Although previous research has demonstrated that fatigue is a core and bridge symptom within this complex relationship, its potential moderating role in their interaction remains unexplored. This study employs symptom network analysis to explore the Moderating role of fatigue, aiming to identify core symptoms and their interactions.

Materials and methods: 544 participants (37.86 ± 11.41 , 210 males) diagnosed with chronic insomnia disorder were participated in the study. The Pittsburgh Sleep Quality Index (PSQI), Insomnia Severity Index (ISI), and Hamilton Anxiety and Depression Scales (HAMA and HAMD-17), were used to assess symptoms. Network analysis was conducted using hierarchical LASSO to estimate symptom networks, with O3(fatigue) as a moderating variable.

Results: Our study revealed significant bidirectional relationships among insomnia, depression, and anxiety symptoms, such as S5 with O2, and O4 with D2. Fatigue played a crucial moderating role, particularly in strengthening the relationships between sleep maintenance difficulties and circadian rhythm features, S2 (sleep satisfaction) and D2 (weight changes), A2 (somatic anxiety) and O1 (daytime dysfunction). Centrality analysis identified mental anxiety (A1), the impact of insomnia on quality of life (S6), and sleep interference with daytime function (S5) as core symptoms in the network.

Conclusions: We identified significant bidirectional relationships between the symptoms of insomnia, depression, and anxiety symptoms and interaction terms moderated by fatigue. These findings provide valuable theoretical and practical insights for breaking the cycle between symptoms of insomnia, depression, and anxiety through intervention with fatigue.

Bilateral thalamic stimulation via TES-TI Enhances Sleep Spindle Activity during a Daytime Sleep Episode

S. Bruno¹, B. Mat¹, E. Schaeffer^{1,2}, I. Haber^{1,3}, Z. Fan^{1,4}, T. Alauddin¹, R. Smith¹, S. Pahl¹, M. Wilcox¹, M. Loring¹, P. Achermann^{5,6}, S. Beerli⁶, M. Capstick⁶, E. Neufeld⁶, N. Kuster^{6,7}, L. Albantakis¹, S. Jones¹, C. Cirelli¹, M. Boly⁸, G. Tononi¹

¹University of Wisconsin - Madison, Department of Psychiatry, Madison, United States, ²University of Wisconsin - Madison, Medical Scientist Training Program, Madison, United States, ³University of Wisconsin - Madison, Department of Biomedical Engineering, Madison, United States, ⁴University of Tsukuba, Tsukuba Institute for Advanced Research, Tsukuba, Japan, ⁵University of Zurich, Institute of Pharmacology and Toxicology, Zurich, Switzerland, ⁶Foundation for Research on Information Technologies in Society, Zurich, Switzerland, ⁷Swiss Federal Institute of Technology, Department of Information Technology and Electrical Engineering, Zurich, Switzerland, ⁸University of Wisconsin - Madison, Department of Neurology, Madison, United States

Introduction: Sleep spindles are transient electroencephalographic (EEG) elements named after their typical waxing and waning morphology. They represent a defining characteristic of non-rapid eye movement sleep in mammals. The rhythmic interaction of the thalamic reticular nucleus with the thalamocortical relay neurons constitutes the core neurophysiological mechanism underlying spindle generation. Sleep spindles activity exhibits correlations with memory performance, while their deficit has been reported in patients affected by schizophrenia in association with decreased cognitive abilities. Here, we demonstrate Transcranial Electrical Stimulation with Temporal Interference (TES-TI) ability to enhance spindle activity bilaterally targeting the thalamus.

Materials and methods: 24 participants (age $27.2 \text{ ys} \pm 7.4 \text{ ys}$; 69.6% F) underwent thalamic TES-TI stimulation during daytime naps. Stimulation protocols were delivered during N2 sleep with the following parameters: three minutes duration, 15 kHz carrier frequency, 15 seconds ramping up/down periods. Three envelope frequencies were tested in random order: 10 Hz (TES-TI 10Hz), envelope frequency matched to each participant's sigma peak (TES-TI Peak), and 0 Hz (TES). Simultaneous 256-channel high-density EEG recordings were performed. Average spectral power in the sigma band (9-16 Hz) across all electrodes was compared before (PRE) and during the stimulation (STIM) using paired Wilcoxon test. Topographic patterns of sigma power modulation during the stimulation were assessed using a non-parametric cluster-based permutation test. Spindle density and power were quantified using an automated spindle detection algorithm and compared between STIM and PRE using paired Wilcoxon tests.

Results: TES-TI 10Hz stimulation was associated with a significant increase in sigma power ($\Delta\mu_{\text{STIM-PRE}} = 0.36 \log_{10}\mu\text{V}^2$, $p = 0.042$), but not TES ($\Delta\mu_{\text{STIM-PRE}} = -0.17 \log_{10}\mu\text{V}^2$, $p = 0.23$) and TES-TI Peak stimulation ($\Delta\mu_{\text{STIM-PRE}} = -0.047 \log_{10}\mu\text{V}^2$, $p = 0.47$). Cluster-based analysis localized the increase over two frontal and centro-parietal electrode clusters ($p = 0.027$). TES-TI 10Hz stimulation was also associated with a significant increase in spindle power ($\Delta\mu_{\text{STIM-PRE}} = 0.035 \log_{10}\mu\text{V}^2$, $p = 0.0093$) and a trend towards an increase in spindle density ($\Delta\mu_{\text{STIM-PRE}} = 1.96 \text{ spindle/s}$, $p = 0.092$). No significant change in spindle characteristics was observed during TES-TI Peak (power: $\Delta\mu_{\text{STIM-PRE}} = -0.0042$

$\log_{10}\mu V^2$, $p = 1$; density: $\Delta\mu_{\text{STIM-PRE}} = -2.45$ spindle/s, $p = 0.20$) and TES stimulation (power: $\Delta\mu_{\text{STIM-PRE}} = -0.012 \log_{10}\mu V^2$, $p = 0.49$; density: $\Delta\mu_{\text{STIM-PRE}} = -2.79$ spindle/s, $p = 0.16$).

Conclusions: This study presents the first evidence supporting the successful use of TES-TI during sleep to target the thalamus and enhance sleep spindle activity. Stimulation at a fixed envelope frequency of 10 Hz effectively increased sigma band power, whereas stimulation matched to each participant's individual sigma band peak did not produce a comparable enhancement. Sigma power increase followed a pattern consistent with typical spindle topography in healthy adults and was associated with an increase in power of individual spindles. Further research is needed to investigate the cognitive and clinical impact of TES-TI-induced spindle enhancement.

BTBD9 Controls Sleep via Ubiquitination of IMPDH2 and Adenosine Modulation in the Basal Forebrain

Z. Gao¹, F. Liu¹, S. Yin¹

¹Shanghai Jiao Tong University, Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China

Introduction: BTBD9 has been established as a critical sleep-regulating gene, whose genetic variants are associated with human insomnia and restless legs syndrome (RLS), while its loss-of-function leads to disrupted sleep architecture in both mice and *Drosophila*. However, its precise molecular mechanisms remain elusive.

Materials and methods: We employed an integrated multidisciplinary approach: 1) AAV-mediated Cre/loxP system with stereotaxic injection for basal forebrain (BF)-specific genetic manipulation; 2) Long-term sleep monitoring and deprivation experiments using synchronized electroencephalography/electromyography (EEG/EMG) recordings; 3) Quantitative proteomics, ubiquitinomics, and bioinformatic prediction to identify key substrates; 4) Structural analysis, in vitro ubiquitination assays, and site-directed mutagenesis to validate molecular interactions; 5) Fiber photometry and tissue metabolome for neurotransmitter dynamics assessment; 6) AAV-delivered competitive interfering peptides for in vivo functional rescue experiments.

Results: We discovered that BF-specific *Btbd9* knockout induces a previously-unexpected pro-sleep phenotype mediated by elevated adenosine levels. IMPDH2, the rate-limiting enzyme in *de novo* GTP biosynthesis, was identified as an evolutionarily conserved ubiquitination substrate of BTBD9, with lysine 195 (K195) being the critical modification site. BTBD9-mediated ubiquitination disrupts GTP-dependent feedback inhibition of IMPDH2, altering its enzymatic activity. Both pharmacological inhibition of IMPDH2 with MPA and conditional knockout in BF neurons recapitulated the sleep-promoting effects, increasing NREM sleep duration and slow-wave activity (SWA)—key markers of sleep pressure. Crucially, targeted disruption of the BTBD9-IMPDH2 interaction via AAV-delivered interfering peptides not only prolonged NREM sleep but also confirmed the druggability of this pathway.

Conclusions: Our study unveils the novel BTBD9-IMPDH2-adenosine axis in sleep regulation and proposes targeting this interaction as a promising therapeutic strategy for sleep disorders. These findings provide groundbreaking insights into the molecular pathogenesis of sleep disturbances.

Butyric Acid Suppresses Adipogenesis Triggered by Intermittent Hypoxia and Hypercapnia via sAC/cAMP/PKA Pathway Modulation

X. Su¹, A. Rukkaiya², Q.-L. Huang², A. Khalid², M.-H. Xu³, M.-S. Su²

¹School of Rehabilitation Medicine, Wenzhou Medical University, Wenzhou, China, ²The Second Affiliated Hospital and Yuying Children's Hospital of Wenzhou Medical University, Department of Respiratory Medicine, Wenzhou, China, ³Wenzhou Medical University, Laboratory Medical and Life Science College, Wenzhou, China

Introduction: To explore whether intermittent hypoxia and hypercapnia i.e., intermittent hypoxic-hypercapnia (IHH), the main characteristics of obstructive sleep apnea (OSA), induce adipogenesis, and assess the inhibitory effect of butyric acid, (BA) on intermittent hypoxia or hypercapnia accelerated adipogenesis.

Materials and methods: To determine the potential impact IHH on adipogenesis, cells were exposed to simultaneous transient hypoxic-hypercapnia (4% O₂, 10% CO₂) for 48 hours. Intracellular lipid and triglyceride accumulation of groups above was observed using an Oil Red O stain and triglyceride assay. To clarify the underlying mechanism, the expression level of the pro-adipogenic markers including peroxisome proliferator-activated receptor (PPAR) γ , CCAAT/enhancer binding protein (CEBP) α , CEBP β and cAMP Response Element-Binding Protein (CREB) were measured. And the protein expression of soluble adenylyl cyclase (sAC) cyclic adenosine monophosphate (cAMP) and protein kinase A (PKA) was also assessed.

Results: IHH accelerated lipid accumulation, triglyceride formation, and protein expression of PPAR γ , CEBP α , CEBP β and CREB which were inhibited by butyric acid. Additionally, butyric acid suppressed the sAC/cAMP/PKA pathway protein expression in IHH-induced adipogenesis.

Conclusions: This study reveals that OSA-induced adipogenesis results from the synergistic effort of hypoxia and hypercapnia, also butyric acid could inhibit adipogenesis induced by hypoxic-hypercapnia via the suppression of sAC-dependent cAMP production and PKA activation.

Acknowledgments: None

Can breaking up prolonged sitting with physical activity during simulated dayshifts and nightshifts improve sleep quality? A randomised controlled trial

C. Gupta¹, I. Vitanage¹, S. Ferguson¹, C. Vandelanotte^{1,1}, M. Duncan², D. Easton³, G. Tuckwell⁴, C. Ah Shay³, P. Tucker⁵, M. Lastella³, M. Zerella³, G. Vincent³

¹Central Queensland University, Adelaide, Australia, ²Central Queensland University, Rockhampton, Australia, ³University of Newcastle, Callaghan, Australia, ⁴University of Adelaide, Adelaide, Australia, ⁵Swansea University, Swansea, United Kingdom

Introduction: Inadequate sleep is a global problem and contributes to poor health outcomes. Physical activity has a positive impact on sleep outcomes, however the prevalence of physical inactivity is increasing worldwide, coupled with the rise of sedentary behaviour at work. Interventions that promote physical activity and reduce sedentary behaviour are essential, as they can improve sleep. The current study investigated the effects of breaking up prolonged sitting with physical activity during the day or night on sleep architecture during a 9 h or 5 h sleep opportunity.

Materials and methods: Participants (n=125, 51% male, 23.4 $\pm$ 4.8 years of age) completed an in-laboratory sleep study. Participants completed five simulated shifts during the day or night. During the simulated work shifts, participants in the breaking up sitting conditions completed a 3-minute light walk (3.2km/h) on a treadmill every 30 minutes. Sleep opportunities were either 9 h or 5 h following each shift. Participants were allocated to one of six conditions, 1) Sedentary during the day and 9 h sleep; 2) Breaking up sitting during the day and 9 h sleep opportunity; 3) Sedentary during the day and 5 h sleep opportunity; 4) Breaking up sitting during the day and 5 h sleep opportunity; 5) Sedentary during the night and 9 h sleep opportunity; 6) Breaking up sitting during the night and 9 h sleep opportunity. Sleep outcomes were recorded using polysomnography (total sleep time, sleep onset latency, sleep efficiency, wake after sleep onset and percentage of time spent in stage N1, N2, N3, NREM and REM).

Results: In the analysis of day shifts, mixed model ANOVAs demonstrated a significant physical activity condition by sleep opportunity interaction for total sleep time ($p < 0.001$), sleep onset latency ($p < 0.001$), time spent in N2 ($p < 0.001$) and N3 ($p = 0.03$). Post-hoc analyses revealed that participants in the 9 h sleep conditions had longer total sleep time, shorter sleep onset latency, and more slow-wave sleep (N3) during sleep opportunities 1-4 but not sleep opportunity 5. There were no significant differences in sleep architecture by physical activity condition for the nightshift conditions.

Conclusions: Better sleep quality was seen in the 9 h condition compared to the 5 h condition, and breaking up sitting did not affect sleep. Given the benefits of breaking up sitting on health, our findings suggest a breaking up sitting intervention can be promoted without detrimental impacts on sleep.

CD169⁺ Macrophages Mediated Downregulation of Endothelial CX43 Expression Underlies Obstructive Sleep Apnea Related Cognitive Impairment

M. Li^{1,1}, Q. Li²

¹Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Department of Respiratory and Critical Care Medicine, Shanghai, China, ²Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China

Introduction: Objective: Obstructive sleep apnea (OSA) is an independent risk factor for cognitive impairment, with chronic intermittent hypoxia (CIH)-induced blood-brain barrier (BBB) injury being a critical mechanism. However, the specific pathways remain unclear. Macrophages may regulate BBB damage by influencing endothelial cell function. Macrophages exhibit heterogeneity, and tissue-resident macrophages in the brain (CD169⁺ macrophages) play a pivotal role in the early stages of disease. This study investigates the molecular mechanism by which CD169⁺ macrophages mediate OSA-related cognitive dysfunction through interactions with endothelial cells.

Materials and methods: Methods: A CD169⁺ macrophage-depleted mouse model was generated by intraperitoneal injection of diphtheria toxin (DT) into CD169-DTR mice. These mice were then subjected to chronic intermittent hypoxia stimulation to mimic OSA-related pathological conditions. Changes in blood-brain barrier permeability were quantitatively analyzed using two-photon fluorescence imaging. Cognitive dysfunction was assessed through behavioral tests, including the Morris Water Maze and Novel Object Recognition assays. Immunofluorescence staining was employed to determine the spatial localization of CD169⁺ macrophages in specific brain regions of CIH-exposed mice. Additionally, an *in vitro* co-culture system of CD169⁺ macrophages and endothelial cells was established to investigate the downstream molecular mechanisms mediated by the CX43-Claudin 5 pathway. Sequencing and pathway analyses were conducted to identify key gene expression changes and signaling cascades underlying macrophage-endothelial interactions.

Results: Results: CIH impaired learning and memory in mice and increased BBB permeability to 10-kDa small molecules. These effects were alleviated after CD169⁺ macrophage depletion. Under CIH, CD169⁺ macrophages proliferated in the hippocampal region and exacerbated neuroinflammation. The expression of chemokines CXCL3 and CXCL5, as well as inflammatory factors IFN β and IL-6, was significantly elevated in CD169⁺ macrophages. Sequencing results from the *in vitro* co-culture system revealed that CD169⁺ macrophages downregulated endothelial *Gja1* (encoding connexin CX43) expression. Pathway analysis showed that CX43 inhibited the expression of p38 α in the MAPK signaling pathway, thereby suppressing *Cldn5* gene transcription. This led to reduced levels of the tight junction protein Claudin 5, resulting in disrupted BBB integrity and increased permeability.

Conclusions: Conclusion: In summary, CIH promotes BBB injury and neuroinflammation, contributing to cognitive dysfunction via interactions between CD169⁺ macrophages and endothelial cells. CD169⁺ macrophages downregulate connexin CX43 expression in endothelial cells, suppress the MAPK pathway, and reduce Claudin 5 levels, ultimately increasing BBB permeability. Targeting CD169⁺ macrophages may provide a theoretical foundation for understanding the immunological mechanisms and therapeutic strategies for OSA-related cognitive impairment.

Chronic Intermittent hypoxia exacerbates the progress of periodontal disease via promoting inflammatory and microbial dysbiosis

X. Wang¹, H. Chen², P. van der Stelt³, S. Ge¹

¹Shandong University, Department of Periodontics, Jinan, China, ²Shandong University, Department of Orthodontics, Jinan, China, ³Academic Centre for Dentistry Amsterdam (ACTA), Department of Oral Radiology, Amsterdam, Netherlands

Introduction: Obstructive sleep apnea (OSA) has been suggested to be independently associated with periodontitis; however, the causal relationship between OSA and periodontitis remains unclear. This study aimed to investigate the effects of chronic intermittent hypoxia (CIH), a hallmark of OSA, on periodontitis.

Materials and methods: Eight six-week-old male Wistar rats were randomly assigned to two groups: normoxic group and CIH group. A periodontitis model was induced in both groups by ligating the maxillary second molars. The CIH group was exposed to a chronic intermittent hypoxic environment simulating OSA for five weeks. Gingival crevicular fluid was collected, and the microbiome composition was analyzed via pyrosequencing and bioinformatic analyses of 16S rRNA. Micro-computed tomography (micro-CT) was used to evaluate the relative cemento-enamel junction (CEJ) to the alveolar bone crest (ABC) distance, bone volume fraction (BV/TV), and trabecular thickness (Tb.Th). Histological

evaluations were conducted using hematoxylin and eosin (HE) staining, Masson's trichrome staining and tartrate-resistant acid phosphatase (TRAP) staining. Inflammatory markers, including HIF-1 α and IL-1 β , were quantified using enzyme-linked immunosorbent assay (ELISA) and real-time quantitative PCR.

Results: Clinical parameters showed that probing depth (PD) and bleeding index (BI) were significantly higher in the CIH group than in the normoxic group. Micro-CT analysis revealed a greater distance from the CEJ to the ABC in the CIH group, along with reduced Tb.Th and BV/TV. Histological analysis showed increased attachment loss and inflammatory cell infiltration in the CIH group. TRAP staining demonstrated a higher number of activated osteoclasts in the CIH group. Inflammatory markers HIF-1 α and IL-1 β were significantly elevated in the CIH group. At the phylum level, 16S rRNA analysis revealed an increased relative abundance of Proteobacteria, Firmicutes, Bacteroidota, and Deinococcota, with decreased relative abundance of Actinobacteriota in the CIH group.

Conclusions: Chronic intermittent hypoxia (CIH) aggravates the progression of periodontitis by elevating inflammatory factor levels, changing the composition of the subgingival microbiota, and accelerating periodontal tissue destruction.

Acknowledgments: We extend our gratitude to all contributors and Shandong University for supporting this research.

Comparison between Ultrasound and CBCT Measurements of Airway Anatomy in Adults with and without Obstructive Sleep Apnea

E. Kim¹, H. Oh², A. Yoon³, H. Suh¹

¹University of the Pacific, Arthur A. Dugoni School of Dentistry, Orthodontics, San Francisco, United States, ²University of the Pacific, Arthur A. Dugoni School of Dentistry, San Francisco, United States, ³Stanford University/Sleep Medicine Center, Psychiatry, Redwood City, United States

Introduction: Obstructive sleep apnea (OSA) is a significant public health concern linked to adverse cardiovascular, metabolic, cognitive, and mental health outcomes. While polysomnography (PSG) remains the diagnostic gold standard, it primarily captures physiological sleep data and lacks direct anatomical insight, limiting its ability to guide precision treatment. Identifying patient-specific anatomical contributors to OSA is essential for developing targeted, etiology-based therapies. Backscattered ultrasound imaging (BUI), particularly submental ultrasound (US), has emerged as a promising modality due to its portability, cost-effectiveness, and radiation-free nature. Prior studies have demonstrated that ultrasound can visualize the pharyngeal airway and detect dynamic changes in the retropalatal transverse diameter, facilitating the identification of severe OSA. Incorporating ultrasonography into routine evaluation may enable longitudinal, anatomy-driven care in a more accessible and cost-effective manner.

Materials and methods: A retrospective analysis was conducted on eight patients (mean age 38.8 $\pm$ 12.1 years; 3 females, 5 males), with or without a diagnosis of obstructive sleep apnea (OSA), screened at the University of the Pacific's graduate orthodontics clinic. Upper airway ultrasound imaging was performed using the AmCAD-UO system (AmCAD BioMed Corporation), measuring airspace width at the velum, oropharynx, tongue base, and epiglottis during tidal and Müller breathing. The system also generated a risk assessment for moderate/severe OSA (low, medium, or high). CBCT scans were acquired for all patients using the i-CAT FLX system (Imaging Sciences International), and corresponding airway measurements were obtained using the CBCT Airway Evaluation module in Dolphin Imaging software. Additionally, three patients underwent overnight home sleep apnea testing (HSAT) using the WatchPAT One device (Itamar Medical Ltd.), dispensed through the Stanford Sleep Medicine Center.

Results: Airspace width measurements during tidal breathing obtained via ultrasound imaging (US) were compared to CBCT-derived measurements at four anatomical levels. At the velum, mean widths were 2.5 $\pm$ 0.9 cm (US) and 2.8 $\pm$ 0.6 cm (CBCT); at the oropharynx, 3.1 $\pm$ 1.0 cm (US) and 2.8 $\pm$ 0.7 cm (CBCT); at the tongue base, 3.0 $\pm$ 0.6 cm (US) and 3.0 $\pm$ 0.7 cm (CBCT); and at the epiglottis, 2.9 $\pm$ 0.5 cm (US) and 3.2 $\pm$ 0.3 cm (CBCT). No statistically significant differences were observed, suggesting strong agreement between US and CBCT measurements during tidal breathing. Among the three patients who underwent home sleep apnea testing, ultrasound-based risk assessments were consistent with sleep study results.

Conclusions: This study highlights the potential of ultrasound imaging as a valuable diagnostic tool for screening and evaluating patients with obstructive sleep apnea (OSA). When compared to CBCT and home sleep apnea testing (HSAT), ultrasound demonstrated strong diagnostic concordance. Its fast, radiation-free assessment of dynamic upper airway anatomy enables accurate identification of anatomic sites of restriction, offering a practical and informative approach to guiding treatment planning and evaluating therapeutic outcomes.

Comparison of epilepsy mouse models induced by kainic acid through different administration routes

S.-B. Li¹, L.-W. Xing², C. Yang², Y. Deng², W.-X. Tang², W.-X. Wang², J.-H. Guo², X.-Y. Wang², R.-C. Fang², J. Guan³, J. Cang⁴

¹Fudan University, Department of Anesthesiology, Zhongshan Hospital; Institute for Translational Brain Research, Shanghai, China, ²Fudan University, Institute for Translational Brain Research, Shanghai, China, ³Shanghai Jiao Tong University, Department of Otolaryngology Head and Neck Surgery, Shanghai Key Laboratory of Sleep Disordered Breathing, Shanghai, China, ⁴Fudan University, Department of Anesthesiology, Zhongshan Hospital, Shanghai, China

Introduction: Epilepsy is a debilitating neurological disorder driven by abnormal excessive or synchronous neuronal activity in the brain, affecting about 50 million people worldwide according to the World Health Organization Report 2024. Over the last decades, different epilepsy models have been developed including injection of chemoconvulsants, traumatic brain injury, electrical kindling, and optogenetic kindling established more recently. The most widely used epilepsy model is created with kainic acid (KA) due to its convenience and robust phenotype mimicking the clinical symptoms observed in patients bearing epilepsy. However, a side-by-side comparison of sleep/wake pattern, and the implicated brain regions in epilepsy mouse models with KA administration through different routes remains underexplored. In this study, we administered KA/saline intraperitoneally or intrahippocampally, and compared their seizures, isolated spikes, and c-Fos expression pattern spanning the entire mouse brain at different time points in a systematical manner.

Materials and methods: Epilepsy mouse models were created through intraperitoneal injection of KA (IPKA, 20mg/kg, saline (0.9% NaCl) as solvent, IPS), or locally to dorsal hippocampal CA1 region (IHKA, 150ng, saline as solvent, IHS). EEG and simultaneous EMG were sampled at various times to monitor the dynamic changes of sleep/wake architecture, and the development of epilepsy. A subgroup of mice was perfused at different times following drug administration, and their brains were collected for immunohistochemical analyses to determine the contribution of dynamic neuronal activity during the development of epileptogenesis.

Results: We observed a more severe disruption of sleep architecture perpetuating for a longer time associated with seizures in the IHKA group. IHKA induced a more robust epilepsy pattern during the acute phase. Both IPKA and IHKA increased the amount of wakefulness and decreased non-rapid eye movement (NREM) sleep within a few hours after injection. REM sleep was completely abolished during the initial 5 hours in the IHKA group, whereas the absence of REM in the IPKA group lasted for a shorter time. A chronic epilepsy model was developed as seizures were observed up to 4 weeks in the IHKA group, but not in the IPKA group. Reduction of REM sleep remained 4 weeks after treatment of IHKA. IHKA induced more isolated spikes overall, and stabilized at 3 weeks after drug administration. Both IPKA and IHKA induced increased c-Fos expression within 3 hours after the drug administration as compared to their controls. Pearson correlation analyses among different brain regions expressing c-Fos revealed that IHKA primarily affected forebrain and midbrain, but IPKA implicated subnuclei across the entire brain despite c-Fos+ cell counts were less than the IHKA group.

Conclusions: Our results demonstrate that the IHKA induced a more robust epilepsy mouse model, which exhibited acute and chronic disruption of sleep/wake architecture, perpetuating seizures, and more isolated spikes. c-Fos expression analysis revealed that the correlation pattern of brain regions expressing c-Fos in the IHKA group is distinct from the correlation pattern in the IPKA group at the acute phase.

Introduction: Poor sleep quality is consistently noted in patients of hypothyroidism. People complained of sleeplessness, excessive day-time sleepiness, snoring, arousals and breathlessness. Decrease in quantity and quality of sleep occurred in various degrees of severity. These facts provided an impetus to assess the correlation between T3,T4 levels and TSH and Total Sleep Time, Sleep efficiency, Sleep stage percentage, Sleep onset latency, Arousal index, Apnoea-Hypopnea index, Oxygen desaturation index, Snoring index and Epworth Sleepiness Scale score.

Materials and methods: This cross sectional study was conducted in thirty patients of hypothyroidism who were in ages between 30 and 50 years. Polysomnography was conducted on these patients for studying the sleep architecture.

Results: There was positive correlation between T3 and sleeps parameters including total sleep time, sleep efficiency, sleep onset latency, apnea-hypopnea index, arousal index, snoring index, oxygen desaturation index and Epworth Sleepiness Scale score. A significant negative correlation was found between T4 and AHI and T4 and ESS. A significant positive correlation was found TSH and ODI, TSH and AHI.

Conclusions: These fact reveals that hypothyroidism affect sleep architecture leading to poor sleep quality.

Daflon attenuates sleep deprivation-induced neurocognitive deficit in male Wistar rat by activating AMPK/Nrf2/HO-1 and downregulating Bax/Bcl-2/caspase 3 apoptotic signaling

R. Akhigbe¹, O. Adepoju², O. Adeleye³, C. Adegbola¹, A. Lasisi-Sholola¹, P. Ashonibare¹, T. Akhigbe⁴

¹Ladoke Akintola University of Technology, Physiology, Ogbomoso, Nigeria, ²Hospital Samaritano, Neurology, Sao Paulo, Brazil, ³Ladoke Akintola University of Technology, Anatomy, Ogbomoso, Nigeria, ⁴Osun state university, Agronomy, Ejigbo, Nigeria

Introduction: Sleep deprivation (SD) is a widespread global challenge, with recent surveys revealing that about one-third of individuals report difficulty falling or staying asleep multiple times per week, due to work shifts, anxiety, stress, and financial pressures. SD has been associated with neurocognitive deficit, which is mediated by oxidative stress signaling. On the other hand, daflon exerts antioxidant properties. However, the effect of daflon on SD-induced neurocognitive deficit has not been reported. Thus, this study investigated the effect of SD, with or without daflon, on neurocognition and the involvement of AMPK/Nrf2 and Bax/Bcl-2/caspase 3 apoptotic signaling as a possible mechanistic pathway.

Materials and methods: Thirty-two-week-old male Wistar rats weighing 200 ± 10 g were randomly allotted into vehicle-treated control (0.5 mL of water), daflon (100 mg/kg), SD, and SD + daflon. SD was induced by exposing the animals to continuous SD for 96 hr using the modified multiple platform technique, followed by a 72 hr recovery period (where they were allowed to sleep). This cycle continued for 4 weeks. Daflon treatment was daily and *per os*. Twenty-four hours after the experimental period, neurobehavioral studies such as Barnes', novel object recognition, Y maze, open field, and hanging wire tests were performed to evaluate cognition, motor function, and anxiety, while the cerebral cortex, hippocampus, and cerebellar cortex were excised for biochemical assays and histopathological examinations.

Results: Daflon improved cognition, motor function, and anxiety-like behaviour in SD rats. Also, daflon attenuated lipid peroxidation (MDA generation), and enhanced cellular antioxidant (GSH, SOD, and catalase), brain-derived neurotrophic factor (BDNF), dopamine, and acetylcholinesterase in SD rats. In addition, daflon upregulated AMPK, Nrf2, HO-1, and Bcl-2 but downregulated NF-kB, TNF- α , IL-1 β , IL-6, Bax, and caspase-3 in the brain tissues. Daflon also improved the histological alterations in the cerebral cortex, hippocampus, and cerebellar cortex, such as pyknotic neurons, vascular congestion, and inflammatory cell infiltration in SD rats.

Conclusions: In conclusion, this study revealed that daflon improves neurocognition in sleep-deprived rats by activating AMPK/Nrf2/HO-1 and downregulating Bax/Bcl-2/caspase 3 apoptotic signaling.

Acknowledgments: Authors are grateful to the staff members of Reproductive Biology and Toxicology Research Laboratory (ReBTReL), Oasis of Grace Hospital, Osogbo, Osun State, Nigeria, for their support in the course of the study.

Data-Driven Fatigue Management: Harmonising Predictive Models with Actual Pilot Data to Optimise Alertness and Performance

P. Kirby¹, I. Marando^{1,2}

¹Qantas, Flight Operations, Sydney, Australia, ²University of South Australia, Sleep and Chronobiology Laboratory, Adelaide, Australia

Introduction: Fatigue remains a significant risk to pilot performance and safety. To proactively manage fatigue, Qantas utilises a comprehensive Fatigue Risk Management System (FRMS), incorporating biomathematical modelling to predict sleep, fatigue, and performance. Biomathematical models, however, are based on population-level data and may not reflect individual variability or unique operational contexts. Therefore, this study aimed to explore the sleep/wake behaviours of A330 pilots and harmonise actual versus predicted sleep/wake behaviour using biomathematical modelling. Harmonising the biomathematical models refers to refining and improving the accuracy for a specific operation. Refining these models ensures they remain aligned with operational realities and contemporary sleep science, which is critical for optimising scheduling, crew alertness, and safety outcomes.

Materials and methods: Twenty-six Qantas A330 pilots (10 Captains, 8 First Officers, 8 Second Officers), aged 33-60 years (median= 48.5 years), participated between 1–3 month period. Data from 299 flight sectors, both domestic (e.g. Perth, Melbourne) and international (e.g. Haneda, Shanghai) were analysed. Objective sleep throughout flight patterns were recorded using Dreem 3 EEG headbands and MotionWatch 8 actigraphy. Cognitive performance was assessed via the Psychomotor Vigilance Task (PVT), and subjective fatigue and sleepiness were measured using the Samn-Perelli Fatigue Scale and Karolinska Sleepiness Scale, respectively. Sleep diaries provided additional subjective data. Cognitive performance and fatigue/ sleepiness measures were taken Pre-Flight, Top of Climb, Pre-Rest, Post-Rest, Top of Descent, and Post-Flight, as well as for sleep outside duty periods.

Results: Pilots achieved the American Academy of Sleep Medicine (AASM) recommendation of 7h of sleep when at home, with reduced sleep at layovers and recovery after a flight. Sleep efficiency was sufficiently above 80% across all sleep periods except for in-flight. There were high levels of Stage 3 sleep across all sleep periods, indicating deep, restorative sleep at all times, including during in-flight rest. Subjective sleepiness and PVT performance deteriorated with time into flight, especially upon waking up from in-flight rest, and after the flight. Harmonisation of the biomathematical modelling improved Minimum Sleep/Wake Accuracy from 81.5% to 86% and Total Daily Sleep Accuracy from 82.1% to 99.2%, confirming model reliability with minor adjustments.

Conclusions: This study provides novel insights into the real-world sleep patterns of A330 pilots. Despite limited sleep opportunities during in-flight rest, restorative deep sleep was achieved. Harmonisation of biomathematical modelling improved prediction accuracy and led to the development of a fleet specific biomathematical modelling setup. These refinements enhance operational confidence in fatigue prediction and support better rostering, countermeasures, and crew safety. The integration of EEG in the field represents a major advancement in aviation sleep science. Continued research and education are vital to further strengthen fatigue risk management and pilot wellbeing.

Day-time Napping: The Benefits of Well-Being and Productivity

C. Dawes^{1,2}, S. Motta¹, E. Calzolari², E. Maggioni², M. Obrist¹

¹University College London, Department of Computer Science, London, United Kingdom, ²Hynt Labs Limited, London, United Kingdom

Introduction: Short day-time naps are increasingly recognised as effective strategies for improving alertness and well-being in workplace settings. While nature-based sounds (e.g., forest rain) are widely acknowledged for their relaxation benefits, their potential to enhance nap-related outcomes remains understudied.

Materials and methods: In a repeated-measures crossover design, 22 healthy adults (mean age: 30.1 ± 10.9 years) completed two 20-minute naps in a MetroNaps® EnergyPod®, once while listening to forest rain sounds (music condition) and once with noise-cancelling headphones (control condition), on separate days. Participants rated subjective sleepiness (Karolinska Sleepiness Scale; Åkerstedt & Gillberg, 1990), relaxation, productivity readiness, valence, and arousal immediately before and after each nap, following a 5-minute adjustment period to mitigate sleep inertia. Working memory (N-BACK) and basic reaction time (PVT) tasks were also administered pre- and post-nap. Subjective evaluations continued post-nap via a short-burst experience-sampling protocol delivered by text message, achieving a 95% completion rate. This protocol included three hourly follow-ups and an additional bedtime reflection regarding the perceived impact of the nap on work and personal productivity.

Results: Outcomes across the six timepoints (pre-nap, post-nap, and four follow-ups) were analysed using Linear Mixed Effects models with fixed effects for condition, timepoint, and their interaction. Interactions were non-significant across all models and were removed ($p > .555$). Follow-up contrasts were Holm-corrected for multiple comparisons. Naps significantly improved self-reported relaxation (pre-nap: 5.9, 95% Confidence Intervals [5.4, 6.4] vs. post-nap: 7.2 [6.67, 7.64]; $p < .001$, $d = 1.15$) and reduced arousal (pre-nap: 48.8 [40.1, 57.5] vs. post-nap: 34.7 [26.0, 43.4]; $p < .001$, $d = 0.963$). Valence did not change significantly (pre-nap: 72.5 [66.7, 78.3] vs. post-nap: 76.5 [70.7, 82.4]; $p > .999$, $d = 0.32$). A modest, non-significant increase in sleepiness was observed post-nap, consistent with sleep inertia (pre-nap: 4.1 [3.56, 4.62] vs. post-nap: 4.8 [4.29, 5.35]; $p = .056$, $d = 0.57$). Evening reflections indicated participants perceived the nap as improving work ($p < .001$, $d = 1.37$) and personal productivity ($p < .001$, $d = 0.87$), with no significant differences between music and control conditions ($p > .600$, $d < .118$). No changes in cognitive task performance were observed ($p > .091$, $d < .11$). Outcome measures were not influenced by auditory context (all $p > .11$).

Conclusions: Brief workplace naps improve subjective relaxation and reduce arousal, offering perceived benefits to productivity later in the day—regardless of auditory context. The lack of added benefit from relaxing music may reflect the effectiveness of the noise-cancelling control, which likely created a similarly tranquil environment. Future studies should explore personalised auditory contexts, as effects may vary based on individual preference, familiarity, and situational fit. Although no immediate cognitive improvements were observed, extending measurement later into the day may reveal protective effects of day-time napping on cognitive fatigue. Incorporating longitudinal and biometric measurements could further enhance understanding of nap effects. Brief naps represent a low-cost, scalable intervention for enhancing well-being and sustaining perceived productivity in real-world work settings.

Differential histamine responses measured with biosensor in wild-type and orexin/ataxin-3 mice: genotype-specific pharmacological sensitivity

C.G. Hviid^{1,2}, G. Sørensen¹, B.R. Kornum², K.F. Herrik¹

¹H. Lundbeck A/S, Circuit Biology, Copenhagen, Denmark, ²University of Copenhagen, Department of Neuroscience, Copenhagen, Denmark

Introduction: The histaminergic and orexinergic systems are key regulators of wakefulness. Orexin/ataxin-3 mice, which lack orexin neurons, exhibit sleep-wake fragmentation, cataplexy, and excessive daytime sleepiness—features resembling human narcolepsy type 1. By modulating these systems using TAK-925 (an orexin receptor 2 agonist) and pitolisant (a histamine 3 receptor inverse agonist/antagonist), we aim to investigate acute, compound-specific effects on extracellular histamine in wild-type and orexin/ataxin-3 mice.

Materials and methods: Orexin/ataxin-3 and wild-type littermates were implanted with a GPCR-activation based (GRAB) - HA1h biosensor and optic fiber in lateral hypothalamus, along electroencephalography (EEG) and electromyography (EMG) electrodes. Furthermore, accelerometer (Acc) and video data were collected. Recordings began at ZT10, followed by subcutaneous injection of

TAK-925, pitolisant, or vehicle at ZT12 (lights off). We recorded 4 hours of biosensor data and 21 hours of EEG/EMG/Acc and video data post-injection.

Results: Administration of TAK-925 (10 mg/kg) or pitolisant (10 mg/kg) increased relative histamine levels extracellularly ($\Delta F/F$ normalized to baseline) in both genotypes. Pitolisant increased histamine similarly in both genotypes with similar progressions in normalized $\Delta F/F$ over time. TAK-925 increased normalized $\Delta F/F$ histamine levels extracellularly more in orexin/ataxin-3 mice than in wild-type littermates and remained higher over a longer time-course.

Conclusions: The GRAB-HA1h biosensor enables real-time detection of compound-induced changes in extracellular histamine. The effects of pitolisant appear independent of orexin signaling, showing similar profiles across genotypes. In contrast, TAK-925 elicits a genotype-dependent histaminergic response, suggesting heightened sensitivity in the absence of endogenous orexin. These findings underscore distinct mechanisms by which these compounds influence arousal circuits.

Acknowledgments: The authors would like to thank the animal facility at Lundbeck for taking good care of the mice and Innovationsfonden for funding parts of the research.

Dim light at night exacerbate Parkinson's disease through circadian rhythm related pathways in mice

B. Li¹, N. Zheng², Y. Fan², B. Lin², T. Luo², J. Zhang², H. Feng²

¹The Affiliated Brain Hospital of Guangzhou Medical University, Center for Sleep and Circadian Medicine, Guangzhou, China, ²The Affiliated Brain Hospital of Guangzhou Medical University, Guangzhou, China

Introduction: Growing evidence suggests that exposure to dim light at night (dLAN) can disrupt circadian rhythms. Circadian disruption has been implicated in the pathogenesis of various neurological disorders, including Parkinson's disease (PD)—a prevalent, progressive neurodegenerative condition with no cure and a high risk of disability. While studies have established a close association between circadian rhythms and PD, direct evidence linking dLAN exposure to the onset or progression of PD remains limited. Thus, we investigated whether dLAN could exacerbate Parkinsonism and circadian rhythms induced by 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine.

Materials and methods: MPTP-induced PD mice were housed in either a light-dark cycle (LD; 12 h of 200 lux:12 h of 0 lux) or a light-dLAN cycle (dLAN; 12 h of 200 lux:12 h of 5 lux) during the experimental periods. Motor function was assessed by the pole test and rotarod test. Substantia nigra transcript profiles were examined using multi-timepoint transcriptome analysis to assess the effects of dLAN exposure.

Results: First, we observed that dLAN exacerbated motor dysfunction in PD mice. Next, we found that dLAN decreased the levels of dopaminergic fibers and neurons in the striatum and the substantia nigra, respectively. In addition, dLAN reduced the amplitude of circadian rest-activity behaviors and nighttime activity levels in PD mice. Moreover, dLAN disrupted the expression of circadian genes in the substantia nigra, particularly *Npas2* in PD mice.

Conclusions: These findings reveal that dLAN exacerbated motor dysfunction and dopaminergic neuron loss in MPTP-induced PD mice, with disruptions in circadian rest-activity rhythms and rhythmic gene expression likely mediating the adverse effects of dLAN on these behaviors.

Does acute late sleep restriction impact placebo hypoalgesia?

M. Hołda¹, I.A. Łaska^{2,3}, E.A. Bajcar³, H. Bieniek^{2,3}, J. Brączyk^{2,3}, A. Budzisz³, A. Jankowska³, D. Rubanets^{2,3}, K. Szymanek¹, S. Szymański¹, P. Bąbel³

²Doctoral School in the Social Sciences, Jagiellonian University, Kraków, Poland, ³Jagiellonian University, Institute of Psychology, Pain Research Group, Kraków, Poland

Introduction: Sleep plays a critical role in regulating physiological and cognitive functions, including pain processing and affective learning. Experimental sleep restriction has been shown to impair emotional regulation and stress reactivity. However, little is known about whether sleep loss can potentially impair the ability to induce placebo effects. The placebo effect is a psychobiological phenomenon that produces clinical benefits attributed to a wide range of neurobiological mechanisms. The relationship between sleep and placebo effects, especially placebo effects in pain, has received very little attention. This study aims to investigate if acute late sleep restriction affects the formation of observationally induced placebo effect.

Materials and methods: 20 healthy volunteers were randomly assigned to either a sleep restriction group or a control group with habitual sleep. The experimental setup took place in a controlled laboratory environment, where participants were required to sleep. Participants in the sleep restriction group had their natural night sleep shortened by 60% due to early wake-up, while those in the control group maintained their standard sleep duration. All participants underwent an overnight PSG recording. During the 7 days preceding the study, participants' sleep-wake cycle was monitored using wrist actigraphy combined with a sleep log. The start time of the study and the required sleep duration in both sleep restriction group and control group were determined individually and adjusted to each participant's circadian rhythm, based on the sleep log and actigraphy recordings.

In the morning participants from both groups underwent placebo hypoalgesia induction via observational learning. Participants were presented with a video depicting a model experiencing pain stimuli and rating them as less intense when applied with the placebo. The sham TENS device attached to the forearm was used as a placebo. Thermal pain stimuli of medium intensity were delivered to the participants' forearm before and after the observational learning phase to test learning effects. Pain intensity was rated on an 11-point Numeric Rating Scale (NRS), ranging from 'no pain' to 'the most intense pain tolerable', and recorded after each stimulus.

Results: Data collection is ongoing, the results will be presented on the poster.

These findings come from a pilot study conducted with 20 healthy participants. The results indicate that observational learning successfully induced placebo hypoalgesia in both sleep conditions. Participants in the sleep restriction group reported significantly lower pain during placebo trials ($M = 3.97$, $SD = 1.37$) compared to control trials ($M = 4.90$, $SD = 1.43$), $p < .001$. A similar effect was observed in the habitual sleep group (placebo: $M = 3.42$, $SD = 1.05$; control: $M = 4.14$, $SD = 1.13$), $p < .001$. No significant between-group differences were found, $t(18) = 1.27$, $p = .22$.

Conclusions:

Observational learning is effective in inducing placebo hypoalgesia. However, we found no evidence that acute late sleep restriction affects the placebo hypoalgesia. As a pilot study, these findings are preliminary and will be continued in a larger sample. Importantly, this is the first study to investigate the role of sleep restriction in the formation of placebo hypoalgesia through observational learning.

Effect of sleep irregularity on driving simulator performance during extended wakefulness

A. Montero¹, C. Dunbar¹, H. Scott¹, A. Guyett¹, D.P. Nguyen¹, K. Nguyen¹, K. Bickley¹, N. Lovato¹, A. Reynolds¹, L. Lack¹, P. Catcheside¹, R. Adams¹, J. Cori², M.E. Howard², C. Anderson³, A. Vakulin¹

¹Flinders University, FHMRI Sleep Health, Bedford Park, Australia, ²Institute for Breathing and Sleep, Heidelberg, Australia, ³University of Birmingham, Birmingham, United Kingdom

Introduction: Insufficient and irregular sleep are now well-established risk factors for adverse health outcomes. While the impact of insufficient sleep on driving performance is known to be substantial, the degree to which irregular sleep, independent of sleep duration, affects driving performance is far less understood. We examined whether habitual sleep irregularity in the lead up to acute sleep loss influences subsequent driving simulator performance during extended wakefulness.

Materials and methods: Thirty-eight healthy sleepers (23 females and 15 males, aged 31.0 ± 11.6 y) completed two weeks of sleep/wake monitoring (GENEActiv activity monitors) prior to undergoing 29 h laboratory extended wakefulness study. Five 60-minute driving simulator (AusEd) tests were completed: 1, 7, 13 h of wakefulness determined baseline rested performance, while 19 and 25 h determined performance while sleep deprived. Sleep irregularity prior to the laboratory was calculated using the standard deviation (SD) of sleep midpoint time and total sleep time, used to split participants into irregular ($n=11$) or regular ($n=27$) sleeper groups using two-step cluster analysis. Linear mixed

model analysis was used to test the effects of time awake (rested vs sleep deprived) and sleep irregularity (regular vs irregular) on driving simulator steering deviation. Binary logistic regression was used to examine the association between continuous sleep irregularity measures and incidence of driving crashes.

Results: Steering deviation significantly deteriorated throughout extended wakefulness (Mean $\pm$ SD, rested vs sleep deprived, 45.1 $\pm$ 27.9 vs 69.1 $\pm$ 37.5 cm, $F(1, 30.45) = 17.03$, $p < .001$), but there was no interaction ($F(1, 30.5) = 0.19$, $p = .665$) or main effect of sleep irregularity group ($F(1, 35.5) = 0.02$, $p = .901$). Binary logistic regressions revealed that when rested (i.e., 1, 7, and 13 hours after waking), neither irregularity in total sleep time (OR=1.85 [95% CI:0.67, 9.34], $p = .458$) nor irregularity in sleep midpoint timing (OR=0.59 [95% CI:0.14, 2.47], $p = .467$) were associated with crash incidence. However, when sleep deprived (i.e., 19 and 25 hours after waking), irregularity in total sleep time (OR=9.97 [95% CI:1.20, 85.67], $p = .033$) but not irregularity in sleep midpoint timing (OR=0.42 [95% CI:0.07, 2.40], $p = .325$) was associated with crashing events on the driving simulator.

Conclusions: These findings suggest that although sleep irregularity does not impact steering stability. Driving simulator crash events are indicative of alertness and performance failure, and hence our findings suggest that irregular sleep duration may predispose drivers to adverse effects of sleep loss by increasing the risk of a crash. Further studies are warranted to determine the relative impacts of habitual sleep irregularity, independent of sleep duration, to better understand impacts on road safety.

Effects of chronic intermittent hypoxia during sleep on intraoral pain via hypoxia inducible factor-1 α in ovariectomized rats

S. Katsura^{1,2}, A. Katagiri¹, N. Uzawa², T. Kato^{1,3}

¹The University of Osaka, Department of Oral Physiology, Graduate School of Dentistry, Osaka, Japan,

²The University of Osaka, Department of Oral & Maxillofacial Oncology and Surgery, Graduate School of Dentistry, Osaka, Japan, ³The University of Osaka Hospital, Sleep Medicine Center, Osaka, Japan

Introduction: Burning mouth syndrome (BMS) is a chronic pain condition characterized by a burning sensation or discomfort in oral mucosa without any visible lesions. In BMS, capsaicin, an agonist of transient receptor potential cation channel subfamily V member 1 (TRPV1), can exacerbate pain in the tongue and the oral mucosa. The etiology of BMS is thought to involve a complex interplay of multiple factors. The risk of developing BMS increases after menopause, a trend also observed in obstructive sleep apnea (OSA). Moreover, OSA has been reported as a potential risk factor for BMS. Therefore, we propose that there is a link between OSA and the development of BMS, with OSA-induced hypoxia serving as a contributing factor. Hypoxia-inducible factors (HIFs) serve as a sensor of hypoxia; under hypoxic conditions, HIF-1 α accumulates and is translocated to the nucleus, where it functions as a transcription factor that regulates genes related to the cellular responses to hypoxia. The HIF pathway has been implicated in various physiological and pathophysiological processes. Based on these, we hypothesized that hypoxia by OSA contributes to the accumulation of HIF, which then promotes TRPV1 expression in the trigeminal ganglion (TG), then enhancing the sensitivity to capsaicin and contributing to the development of BMS.

Materials and methods: Ovariectomized (OVX) rats were exposed to chronic intermittent hypoxia (CIH) (nadir O₂ 5%, 6-min cycles, 6 h/day, 14 days). Intraoral pain was assessed using a two-bottle preference drinking test with a capsaicin solution. Immunohistochemical staining was used to assess changes in the proportion of TRPV1-positive and HIF-1 α -positive cells in the ophthalmic, maxillary, and mandibular nerve branches of the TG. Additionally, a HIF-1 α inhibitor was administered to the TG to determine the effects on capsaicin sensitivity and the proportion of TRPV1-positive and HIF-1 α -positive cells.

Results: Capsaicin consumption was significantly lower in the OVX-CIH group than that in the control group. OVX-CIH rats showed a significantly higher number of TRPV1-positive, HIF-1 α -positive, and TRPV1+HIF-1 α co-positive cells in all branches of the TG. Furthermore, the administration of an HIF-1 α inhibitor to the TG of OVX-CIH rats alleviated intraoral sensitivity to capsaicin. The increase in the number of TRPV1-positive cells in the OVX-CIH group was suppressed by the HIF-1 α inhibitor administration.

Conclusions: These findings suggest that the CIH-induced stabilization of HIF-1 α in the trigeminal ganglion contributes to BMS-like intraoral pain by upregulating TRPV1.

Effects of Chronobiologically Effective Lighting on Attention, Mood and Daytime Sleepiness

A. Seiger¹, L. Luding¹, K. Lederer², I. Fietze¹, A. Leder³, C. Vandahl⁴, J. Krajewski⁵, M. Glos¹

¹Charité – Universitätsmedizin Berlin, Interdisciplinary Center of Sleep Medicine, Berlin, Germany,

²Advanced Sleep Research GmbH, Berlin, Germany, ³jetlite GmbH, Hamburg, Germany, ⁴Technische Universität Ilmenau, Lighting Engineering Group, Ilmenau, Germany, ⁵ixp - Institute of Experimental Psychophysiology, Dusseldorf, Germany

Introduction: Light plays a crucial role in regulating the circadian rhythm, influencing sleep-wake cycles and various physiological processes. Research suggests that melanopically equivalent daylight illuminance (MEDI) levels exceeding 250 lx may enhance daytime functions, including mood, alertness, and reduce sleepiness. This study investigates the effects of different daytime lighting scenarios, applied under standardized conditions, on mood, alertness, and sleepiness.

Materials and methods: A randomized crossover design was employed with two 1-day sessions per participant, separated by a 1-week interval.

Data collection was conducted from June to November 2024. 20 healthy subjects (18–35 years) participated in the study and were exposed to two lighting Scenarios (under controlled laboratory conditions): Scenario 1: Reference Lighting (RL) = E: 123 lux | MEDI: 58 lx | T_c: 2816 K; Scenario 2: Chronobiologically Effective Lighting (CEL) = E: 739 lux | MEDI: 594 lx | T_c: 5422 K

Participants completed a neurocognitive test battery before and after 1 hour of light exposure. The tests included:

- Karolinska Sleepiness Scale (KSS)
- Profile of Mood States (ASTS)
- d2-R Attention and Concentration Test

Results: Prospective statistical analysis will test the following hypothesis:

Higher alertness and lower sleepiness under the CEL condition compared to the RL condition. Mixed linear regression analysis considering: (1) sequence of light scenarios and (2) time of day (morning, midday, afternoon)

Descriptive statistical analysis revealed the following: N = 20, mean age: 24 $\pm$ 3 year, ESS: 7 $\pm$ 2, ISI: 4 $\pm$ 2, PSQI: 4 $\pm$ 1, Chronotype (MCTQ): Mild late chronotype (MSF)

Conclusions: This study contributes to the development of individually adaptive lighting scenarios designed to support daily life, particularly in professional and social contexts. These scenarios aim to improve attention, enhance mood, and reduce sleepiness, offering potential benefits for managing challenges such as jet lag.

The research is part of a collaborative project to establish an Internet of Things (IoT) standard for individualized, adaptive, and chronobiologically effective lighting solutions, applicable in both mobility and everyday situations. For more information, visit www.chronolite.de.

Effects of Combined Chronic Intermittent Hypoxia and Hypercapnia Exposure on Blood Pressure, Systemic Inflammation, and Oxidative Stress Levels in Rats

J. Zhang¹, Y. Yin¹, C. Zhang², G. Yin¹, J. Ye¹

¹Beijing Tsinghua Changgung Hospital, Otolaryngology, Head and Neck Surgery, Sleep Medicine Center, Beijing, China, ²Beijing Friendship Hospital, Otolaryngology, Head and Neck Surgery, Beijing, China

Introduction: Chronic Intermittent Hypoxia (CIH), the most characteristic pathophysiological feature of obstructive sleep apnea (OSA), has been extensively documented in animal studies to induce multiple

OSA-associated adverse outcomes. Intermittent hypercapnia, another hallmark pathophysiological trait of OSA, however, has rarely been incorporated into OSA animal modeling paradigms. The purpose of this study is to investigate the effects of combined chronic intermittent hypoxia with hypercapnia (CIHHC) exposure on blood pressure, systemic inflammation, and oxidative stress (OS) levels in Sprague-Dawley (SD) rats, compared to chronic intermittent hypoxia (CIH) alone and chronic intermittent hypercapnia (CIHC) alone.

Materials and methods: Forty 6-week-old male SD rats were randomly divided into four groups (n=10 per group) and exposed for 8 hours daily to specific oxygen (O₂) or carbon dioxide (CO₂) partial pressure conditions: (1) Control group (O₂: 21%, CO₂: 0.3%); (2) CIH group (O₂ cycled every 60 seconds between 5% and 21%, CO₂: 0.3%); (3) CIHC group (O₂: 21%, CO₂ cycled every 60 seconds between 0.3% and 5%); and (4) CIHHC group (O₂ cycled between 5% and 21%, CO₂ cycled between 0.3% and 5% every 60 seconds). Tail artery systolic blood pressure (SBP) was measured pre- and post-30-day exposure. Post-exposure peripheral serum samples were collected to quantify levels of inflammatory biomarkers [tumor necrosis factor- α (TNF- α), interleukin-6 (IL-6)] and OS markers [superoxide dismutase (SOD), malondialdehyde (MDA)].

Results: No significant differences in pre-exposure SBP (pre-SBP) were observed among the four groups. While post-exposure SBP (post-SBP) differed significantly ($P=0.002$), with the order CIH > CIHC > CIHHC > Control. Post-SBP increased significantly in all experimental groups but not the control group compared to their respective pre-SBP (all $p<0.05$). Post-exposure serum levels of TNF- α , IL-6, SOD, and MDA also differed significantly among groups (all $P<0.05$). TNF- α , IL-6, and MDA levels followed the order CIH > CIHC > CIHHC > Control, while SOD levels ranked Control > CIHHC > CIHC > CIH.

Conclusions: Both CIH and CIHC exposure significantly elevated blood pressure, systemic inflammation, and OS levels in rats. However, combined CIHHC exposure induced significantly milder effects compared to CIH or CIHC alone, suggesting that intermittent hypercapnia concurrent with CIH may exert a protective or ameliorative influence on these pathological processes.

Effects of Sleep Deprivation on Cognitive Performance and Neurovascular Coupling: A Functional Transcranial Doppler Study

K. Ladthavorlaphatt^{1,2}, A. Pugongchai^{1,2}, C. Tepwimonpetkun^{2,3}, S. Muengtaweepongsa⁴

¹Thammasat University Hospital, Medical Diagnostics Unit, Khlong Luang District, Thailand,

²Thammasat University Hospital, Sleep Centre of Thammasat, Khlong Luang District, Thailand,

³Thammasat University, Pulmonary and critical care medicine, Department of internal medicine, Faculty of Medicine, Khlong Luang District, Thailand, ⁴Thammasat University, Centre of Excellence in Stroke, Faculty of Medicine, Khlong Luang District, Thailand

Introduction: Sleep deprivation (SD) disrupts neural homeostasis and compromises cognitive abilities, particularly attention and verbal fluency. Neurovascular coupling (NVC), the mechanism that ensures cerebral blood flow (CBF) matches neural metabolic demands, is crucial for sustaining cognitive functions. This study aimed to explore how 32 hours of total sleep deprivation affects cognitive performance across various task difficulties and the corresponding changes in cerebral blood velocity (CBv).

Materials and methods: Fourteen healthy participants, aged between 26 and 47 years, underwent functional transcranial Doppler (fTCD) assessments, during which bilateral cerebral blood velocity (CBv) in the middle cerebral arteries was continuously recorded. Measurements were obtained both during resting conditions and while performing two categories of cognitive tasks: Thai word-naming (NW), divided into easy (k/ sound), moderate (ph/ sound), and hard (f/ sound) levels, and serial subtraction (SS) tasks involving sequences such as 100–2, 100–7, and 1000–17. Each cognitive task was administered for 60 seconds, with CBv signals normalized against a 60-second resting baseline recorded before task initiation. According to data distribution, pre- and post-task comparisons were analyzed using either paired t-tests or Wilcoxon signed-rank tests. Furthermore, a two-way ANOVA was employed to examine interactions between task complexity and time segments under normal and sleep-deprived conditions, with multiple comparisons adjusted using Tukey's post hoc procedure.

Results: Resting CBv, mean arterial pressure, and heart rate showed no significant differences between the pre- and post-SD conditions ($p > 0.05$). At the start of all cognitive tasks, a significant bilateral increase in CBv was observed ($p < 0.001$). Post-SD, the CBv responses in the left hemisphere were

significantly influenced by the complexity levels of the NW tasks (interaction $p = 0.038$), with a notable increase particularly observed during the T3 phase ($p < 0.05$). Pre-SD, a clear dominance of the left hemisphere was evident during NW tasks; however, this lateralization effect diminished during SS tasks post-SD ($p > 0.05$). Additionally, no significant differences were found in CBv responses across the complexities of the SS tasks, pre- and post-SD ($p > 0.078$).

Conclusions: Thirty-two hours of SD selectively impaired NVC responses during verbal fluency tasks. This was indicated by noticeable increases in CBv in the left hemisphere, depending on the task complexity. These findings suggest that the brain employs compensatory hemodynamic strategies to maintain verbal fluency performance despite SD. However, attention-related tasks, such as SS, appeared less affected by the NVC disruptions caused by SD. Functional TCD provides a valuable, non-invasive method for detecting subtle changes in cerebral hemodynamics related to sleep loss, which has significant implications for monitoring cognitive health in clinical and research contexts.

Acknowledgments: The authors gratefully acknowledged the research fund provided by Thammasat University Hospital. We are also appreciative of the participants for their participation in the study.

Efficacy and feasibility of light therapy glasses to mitigate fatigue in patients with multiple sclerosis: a randomised, placebo-controlled, crossover field study

J. Ottersbach^{1,2}, M. Canazei³, S.K. Bauer^{1,2}, C. Hfalek^{1,2}, C. Berggold^{1,2}, T.C. Wetter¹, D.-H. Lee⁴, R.A. Linker⁵, R.F. Popp¹

¹University of Regensburg, Department of Psychiatry and Psychotherapy, Center of Sleep Medicine, Regensburg, Germany, ²University of Regensburg, Department of Experimental Psychology, Regensburg, Germany, ³University of Innsbruck, Department of Psychology, Innsbruck, Austria, ⁴University of Regensburg, Department of Neurology, Regensburg, Germany, ⁵University of Regensburg, Department of Neurology, Regensburg, Germany

Introduction: Fatigue is a highly prevalent, clinically significant, persistent symptom in multiple sclerosis (MS), highlighting the need for effective countermeasures.

The objective of the present study was to evaluate the feasibility and short-term efficacy of light therapy in reducing MS-related fatigue.

Materials and methods: This single-blind, randomized, placebo-controlled crossover study included 20 patients with MS with high levels of fatigue (Fatigue Severity Scale [FSS] >36). Participants used active blue-enriched bright light (BL) glasses or placebo dim red light (DRL) glasses for 20 minutes daily after waking up. Each intervention lasted 1 week, separated by a 6-day washout period. Fatigue was the primary outcome (Visual Analogue Scale for Fatigue [VAS_F], immediately before and after each intervention, and at 13:00). Two additional fatigue measures (the FSS and the Daily Fatigue Impact Scale [DFIS]) and one quality of life measure (Multicultural Quality of Life Inventory [MQLI]) were rated four times per intervention week. Feasibility was evaluated using self-reported variables related to comfort, side effects, and sleep parameters.

Results: Both interventions significantly reduced fatigue ratings (VAS_F) immediately after the intervention and at 13:00 on the same day, with BL showing significantly more reduction compared to DRL (all $p < 0.05$). FSS scores significantly decreased on the sixth and seventh intervention days (follow-up) during both interventions (all $p < 0.05$), with BL inducing a clinically significant reduction on the sixth day. D-FIS and MQLI scores remained unchanged. Patients reported greater comfort and improved fitness, well-being, and reduced fatigue with BL (all $p < 0.05$). Both interventions showed low levels of side effects and no effects on subjective sleep parameters.

Conclusions: The findings of the present study provide initial evidence for blue-enriched bright light therapy administered via glasses as a feasible and immediately effective intervention for MS-related fatigue.

Acknowledgments: We are grateful to all patients who were interested in, willing to participate, and who did participate in our study.

Enhancing Pilot Performance and Alertness: A Survey of Fatigue Risk in Short-Haul Flight Operations

I. Marando^{1,2}, P. Kirby¹

¹Qantas, Flight Operations, Sydney, Australia, ²University of South Australia, Sleep and Chronobiology Laboratory, Adelaide, Australia

Introduction: Fatigue within aviation presents a serious risk to pilot performance, safety, and wellbeing. While most research focuses on long-haul or ultra-long haul flying, critical gaps remain in understanding fatigue in short-haul contexts. Short-haul pilots face unique stressors including consecutive early starts, short turnarounds between multiple flights, and minimal rest periods between flying duties. Of particular focus are back of clock (BOC) operations, defined as flying for at least 2 hours between 01:00-04:59, which disrupt sleep and circadian rhythms. Controlled rest (brief, in-cockpit sleep) is a proposed fatigue countermeasure used by Qantas. The effectiveness of controlled rest, however, is limited by stigma, regulatory inconsistencies, and sleep inertia. This survey addresses the literature gap by exploring the fatigue experiences of Qantas B737 short-haul pilots, with a focus on BOC operations, use of controlled rest, and operational workload. The research aims to inform fatigue risk management strategies to enhance in-flight alertness, particularly considering the evolving aircraft fleets and flight schedules.

Materials and methods: A total of 124 Qantas B737 pilots (14.19% of all B737 Qantas pilots; 71 Captains, 53 First Officers), aged 26-69 years (median=45 years) completed an online survey via Survey Monkey. The survey took approximately 30 minutes to complete and included a total of 55 questions with both multiple-choice and open-ended questions on general operations, BOC duties, controlled rest, and workload. A thematic analysis was conducted on qualitative responses using Delve. Transcripts were first read for familiarity, then systematically coded. Codes were then organised into broader themes through iterative refinement and were supported by participant quotes to ensure accurate representation.

Results: Thematic analysis revealed several key contributors to fatigue in short-haul operations. The sleep opportunity is variable and mainly impacted by rostering and suboptimal sleep environments. Scheduling design, including the swapping between early to late starts and late to early starts, extended duties, and limited recovery is a source of fatigue. Circadian disruption persists during BOC operations, with pilots frequently reporting misaligned sleep with their circadian timing. In-flight rest is also hindered by cockpit discomfort, operational requirements, and cabin noise and distractions. Lifestyle factors, including exercise and personal routines, influenced fatigue resilience but are often compromised by work demands. Fatigue management strategies include caffeine use, strategic napping, and controlled rest. Uptake, however, was hindered by operational constraints and perceived stigma.

Conclusions: This study provides novel insights into the fatigue challenges specific to short-haul pilots, particularly during BOC operations. Key fatigue drivers included insufficient rest opportunities, underutilisation of controlled rest, and high workload. The findings support several actionable recommendations, including optimised rostering, improved controlled rest protocols, enhanced cockpit conditions, and enhanced fatigue education. These strategies aim to improve pilot alertness, reduce fatigue-related risk, and support safer, more sustainable short-haul operations.

Esketamine and Dexmedetomidine Co-Administration: A Novel Approach to Alleviating Depression and Insomnia in chronic restraint stress Mouse Models

Introduction: Depression is often accompanied by insomnia, and conventional antidepressants have limited efficacy in addressing sleep disorder. This study investigates the therapeutic potential of combining esketamine and dexmedetomidine in a chronic restraint stress (CRS) mouse model of depression.

Materials and methods: We confirmed depression-like symptoms with behavioral tests and used functional magnetic resonance imaging (fMRI) to assess changes in brain activity, transmission electron microscopy to observe the ultrastructure of the brain, and combined with molecular biology to detect protein changes in the CA1 region of the hippocampus.

Results: The results showed that the functional connections of amygdala, hippocampus and lateral habenular nucleus were significantly changed after combination therapy, and demyelination changes

were reduced compared with the model group. In addition, combination therapy significantly upregulated the levels of brain-derived neurotrophic factor and its receptor TrkB in hippocampus. **Conclusions:** These findings suggest that the combination of esketamine and dexmedetomidine can alleviate depressive symptoms, improve brain functional connectivity, and repair ultrastructural damage, providing valuable insights into treatment strategies for sleep disorders associated with mood disorders.

Exercise improves sleep deprivation-induced cognitive impairment by upregulating brain-derived neurotrophic factor and restoring hippocampal synaptic plasticity

Y. Wen^{1,2,3,4}, X. He^{1,2,3,4}, H. Huang^{1,2,3,5}, W. Wei^{1,2,3,6}, Q. Zhong^{1,2,3}, M. Zhao^{1,2,3,4,6,5}

Introduction: Sleep deprivation (SD) impairs hippocampal synaptic plasticity, reducing brain-derived neurotrophic factor (BDNF) and affecting cognitive and motor functions vital for neurorehabilitation. Exercise mitigates these deficits remains unclear. This study evaluates whether exercise alleviates SD-induced behavioral and synaptic deficits in rats.

Materials and methods: Eighteen male Wistar rats were divided into normal control (NC, n=6), sleep deprivation (SD, n=6), or SD with exercise (SD+Ex, n=6) groups. NC rats were housed under standard conditions, while SD and SD+Ex groups underwent 31-day SD using the multiple platform method. SD+Ex rats received an 5-day treadmill exercise intervention during SD. Behavioral, structural, and molecular outcomes in the hippocampus were assessed using the Morris Water Maze (MWM), Open Field Test (OFT), ELISA, Golgi staining, and Western blot.

Results: SD induced cognitive and motor deficits, with prolonged MWM escape latency ($P<0.05$), reduced reversal learning and locomotor activity ($P<0.05$), and decreased BDNF ($P<0.0001$), dendritic spine density ($P<0.05$), and synaptic function markers Synapsin ($P<0.05$) versus NC. Exercise restored hippocampal dendritic spine density ($P<0.05$) versus SD, significantly upregulated BDNF ($P<0.05$), increased LTP-related molecules NMDAR ($P<0.0001$) and CaMKIV ($P<0.05$), elevated synaptic function markers PSD-95, tyrosine hydroxylase ($P<0.05$), and enhanced reversal learning ($P<0.05$) and locomotor activity ($P<0.01$) versus SD.

Conclusions: Exercise mitigates SD-induced cognitive and synaptic deficits by enhancing BDNF-mediated synaptic plasticity and dendritic spine restoration, providing a potential non-pharmacological neurorehabilitation strategy for individuals with sleep disorders.

EXPERT SYSTEM FOR SLEEPINESS MONITORING

Z. Markovics¹, M. Erins¹, N. Limba²

¹Riga Technical University / Institute of Applied Computer Systems, Faculty of Computer Science, Information Technology and Energy, Riga, Latvia, ²Riga Stradins University / Faculty of Medicine, Department of Human Physiology and Biochemistry, Riga, Latvia

Introduction: The purpose of the monitoring system is to determine the level of human sleepiness without interfering with the performance of actions, give recommendations for further action so that prevent falling asleep. The secondary objectives of the study are to orientate in the development of sleepiness, optimize the set of measured parameters, develop expert decision rules in a situation where most parameters are absent numerical value, but are verbal assessments given by experts.

Materials and methods: To achieve the goals, the monitoring system (MS) is designed as an expert a system that works with decision trees, production laws.

For understanding the development (pathogenesis) of sleepiness and the parameters to be measured

the topological method of functioning systems is used to select an optimized set modeling (TM). Subjective information is an input evaluated by expert ratings on point scales without a numerical equivalent. Decision making applies fuzzy logic and linguistic variable theory. Anticipatory alarm is realized by EEG signals.

Results: The MS “Non-intrusive human fatigue assessment” of sleepiness has been developed. The MS consists of 3 blocks: sleepiness determination, recommendations, anticipatory alarm. Blocks evaluate the objective and subjective information using the fuzzy set and the linguistic variable theory. Anticipatory alarm block that prevents a person from falling asleep, receives an EEG signal from 1 electrode in the forehead area. A single electrode EEG lead provides monitoring application of the system in practice. Realized MS interface system for the user (operator or driver) in the form of a mobile Application, where the user is supposed to enter questionnaire data, interactively perform fatigue detection test activities and visualize fatigue assessment, recommendations and alarm warnings. On the other hand, the implemented Expert system visualization interface is intended for direct interaction with each of the modules of the ES complex.

Conclusions: The application of topological modeling is justified by choosing a set of parameters optimized for sleepiness by their informativeness and detection options. Theory of expert systems with decision trees and product laws allow the level of sleepiness to be determined. Linguistic variables theory allows the evaluation of subjective information that does not contain numeric assessments. Adaptation of the system to the field of use is discussed by creating specific recommendations for car drivers and for the work of operators. Recommendations for reducing mental fatigue and alarming state assessments during monitoring and for a pre-flight survey tailored to operators or performing risky work are separately provided. On the other hand, monitoring for the detection of drowsiness has been implemented for the use of drivers, which is based on the data of wearable sensors with the possibility of providing a preventive alarm signal.

Exploration of Physiological Markers Sensitive to Sleep Restriction during the Maintenance of Wakefulness Test

Y.H. Dzen¹, T. Noguchi¹, T. Abe²

¹Ph.D. Program in Humanics, University of Tsukuba, Ibaraki, Japan, ²International Institute for Integrative Sleep Medicine (WPI-IIS), Tsukuba Institute for Advanced Research (TIAR), University of Tsukuba, Ibaraki, Japan

Introduction: Sleepiness resulting from sleep deprivation or sleep disorders is known to impair neurobehavioral performance, increasing the risk of traffic and occupational accidents. Objective assessments of sleepiness, such as the Maintenance of Wakefulness Test (MWT), are essential for identifying individuals with excessive daytime sleepiness. However, current assessment methods are limited by the need for specialized facilities, extended testing durations, and high cost. Therefore, there is a pressing need to develop more accessible and efficient approaches to assess sleepiness.

Objective:

This study aimed to identify electroencephalogram (EEG) and ocular markers that are sensitive to sleep restriction during the MWT, with the goal of contributing to the development of simpler and more practical sleepiness detection methods.

Materials and methods: This study was approved by the Ethics Committee of the Faculty of Medicine, University of Tsukuba (No. 2053). Healthy adults (target N = 20) participated in two sleep conditions: 8-hour (normal) or 4-hour (restricted) sleep, following an adaptation night. On the test day, participants completed four MWT sessions at 2-hour intervals. High-density EEG and ocular data were collected during each session. EEG analyses included microsleep frequency, microsleep latency, and Hori's EEG stages (Hori et al., 1994). Ocular indicators included the PERcent time of slow eyelid CLOSures (PERCLOS) and estimated response speed in the Psychomotor Vigilance Test (PVT), inferred from eyelid opening degree (Noguchi et al., 2024). Data from 19 participants (11 females; mean age = 25.4 ± 4.5 years; 136 trials) were analyzed. Hori's EEG stage data analyses were available for 15 participants (9 females; mean age = 25.5 ± 4.8 years; 120 trials).

Results: MWT sleep latency was significantly reduced following sleep restriction ($p = 0.002$, $d = 0.85$), and microsleep frequency significantly increased ($p = 0.003$, $d = 1.03$). Percentages of Hori's EEG stages 2 and 3 were significantly higher after sleep deprivation ($p = 0.004$ and 0.0006 ; $d = 1.13$ and 1.09 ,

respectively). Estimated PVT response speed also significantly declined following sleep restriction ($p = 0.02$, $d = 0.85$), whereas PERCLOS showed no significant change ($p = 0.48$).

Conclusions: Multiple physiological markers were sensitive to sleep restriction during the MWT. Among these, percentages of Hori's EEG stages 2 and 3 emerged as the most sensitive markers. A device that detects Hori's EEG stages holds promise for more practical and accessible methods for sleepiness detection in real-world settings.

Glucose homeostasis during recurrent periods of sleep restriction and recovery in healthy young adults

T. Tan¹, Y.Y.Y. Cheung¹, T. Koa¹, C.M. Khoo², J. Lo^{2,1,3}

¹National University of Singapore, Centre for Sleep and Cognition, Yong Loo Lin School of Medicine, Singapore, Singapore, ²National University of Singapore, Department of Medicine, Singapore, Singapore, ³National University of Singapore, Human Potential Translational Research Programme, Yong Loo Lin School of Medicine, Singapore, Singapore

Introduction: Short sleep has been shown to impair glucose metabolism as indicated by increased plasma glucose concentrations and reduced insulin sensitivity; however, most existing studies do not consider that sleep curtailment typically occurs on weekdays, and have not examined how glucose homeostasis is altered during multiple weeks of sleep curtailment with intervening weekend recovery sleep. Furthermore, recovery sleep does not only take place on weekends, but can also occur on weekdays, thereby increasing intraindividual variability in weekday sleep duration. Therefore, this study aimed to investigate glucose homeostasis during recurrent periods of sleep restriction on weekdays and recovery on weekends – a typical sleep pattern among adults in many countries, and whether among sleep restricted individuals, glucose homeostasis would depend on the variability in sleep duration across weeknights.

Materials and methods: In this 15-night lab-based study, 48 healthy young adults (age: 21-28y; 24 males) underwent two baseline nights of 8-h time-in-bed (TIB), followed by two cycles of "weekday" sleep opportunity manipulation (control group's TIB: 8-h/night; stable short sleep group: 6-h/night; variable short sleep group: 8-, 4-, 8-, 4-, and 6-h from the first to the fifth night) and "weekend" recovery (all groups: 8 h). OGTTs were performed at the end of baseline and each manipulation period. Plasma glucose and insulin concentrations during fasting (0 min) and OGTT (15, 30, 60 and 120 min after 75g glucose solution consumption) were measured.

Results: At 2-h post-glucose load, the control group's glucose levels remained stable across the three OGTTs (mean $\pm$ SEM: between 5.28 ± 0.32 and 5.93 ± 0.32 mmol/L, $p > .08$), although their insulin levels increased from baseline (from 48.40 ± 13.61 to 81.19 ± 13.61 mIU/L, $p = .02$ and 93.92 ± 13.61 mIU/L, $p = .003$) probably due to the sedentary lifestyle in the laboratory. The stable short sleep group also showed increased insulin levels in the first week (from 69.06 ± 12.98 to 102.07 ± 12.42 mIU/L, $p = .02$), but their glucose levels still increased from baseline (from 5.68 ± 0.31 to 6.58 ± 0.29 mIU/L, $p = .02$). Importantly, in both weeks of sleep restriction, the variable short sleep group failed to elevate their insulin levels (between 64.09 ± 13.61 and 77.45 ± 13.61 mmol/L, $p > .30$); hence, their glucose was above baseline (baseline: 5.12 ± 0.32 ; week 1: 6.20 ± 0.34 mIU/L, $p = .01$; week 2: 6.49 ± 0.32 mmol/L, $p = .0005$).

Conclusions: Glucose homeostasis in healthy young adults is hampered during multiple nights of sleep restriction on weekdays despite weekend catch-up sleep, which may increase the risk of type 2 diabetes. Stable and variable short sleep schedules may cause such impairment through insulin resistance and impeding pancreatic beta-cell functions respectively.

Acknowledgments: This study was supported by a grant from the National University of Singapore awarded to Dr June Lo (NUHSRO/2021/078/NUSMed/05).

Hippocampal Activity Associated with Central Sleep Apnea Episodes

A. Limanskaya¹, E. Levichkina^{1,2}

¹IITP RAS, Laboratory of Sensory Information Processing, Moscow, Russian Federation, ²The University of Melbourne, Department of Optometry and Vision Sciences, Melbourne, Australia

Introduction: Breathing is primarily controlled by brainstem respiratory centers, but higher-order brain structures such as the amygdala, hypothalamus, and hippocampus also contribute to its regulation. These suprapontine areas can influence autonomic breathing during both wakefulness and sleep. Central sleep apnea (CA) is a temporary cessation of breathing during sleep due to a lack of central respiratory drive. CA can occur in healthy people and animals, as well as in association with neurological and cardiopulmonary disorders. Recent studies suggested a bidirectional relationship between hippocampal dysfunction and sleep-disordered breathing. We hypothesized that hippocampal activity may contribute to the initiation or modulation of CA episodes. In this case, hippocampal activity was expected to change not just during CA, but also before the onset of CA.

Materials and methods: Chronic electrophysiological recordings were performed in two adult cats across multiple natural sleep-wake cycles. We recorded single-neuron activity and local field potentials (LFPs) of the dorsal hippocampus along with EEG, ECG, eye movements, nasal airflow, and thoracic muscle activity, and identified naturally occurring CA episodes (duration > 3 sec). Neuronal spike rates (single- and multi-unit activities) were analyzed for the intervals before, during, and after apnea episodes, using sleep-stage-matched control periods for statistical comparisons (Wilcoxon rank-sum test). LFP segments for the analysis were selected based on EEG-defined sleep stability. Baseline neuronal activity was compared to the "pre-apnea" period, defined as the stable or transitional sleep phase preceding apnea onset based on EEG delta amplitude, and the "post-apnea" period, spanning from the last breath to the first recovery breath. These segments captured consistent physiological states for comparison with apnea-related changes.

Results: We recorded 71 CA episodes across all sleep stages. The majority occurred during transitions between sleep stages: 30 during slow wave sleep (SWS) to rapid eye movement (REM) transitions, 24 from REM to SWS, 12 within REM sleep, and 5 within stable SWS. Of the 238 recorded neurons, 88 (38%) exhibited significant ($p < 0.05$) changes in their firing rates related to CA episodes. Among them, 45% changed activity both before and after apnea, 22% only before, and 31% only after it. Most neurons showed increased activity prior to apnea onset and reduced activity following it. Multi-unit activity changed significantly in 19 of 27 recordings both before and after apnea. LFP analysis revealed consistent spectral changes as well. Before and during apnea, beta and gamma power increased, suggesting heightened local network excitability or arousal. Hippocampal delta power decreased both before and during apnea, while global EEG changed only after CA. Notably, theta power increased during apnea in both hippocampal LFPs and global EEG. Since hippocampal theta is associated with REM sleep, this may reflect a functional shift in brain state during respiratory arrest.

Conclusions: Our findings demonstrate that hippocampal activity reliably changes in association with CA episodes. Changes preceding CA suggest that the hippocampus may play a role in initiating or modulating these events, rather than merely responding to them. This supports our hypothesis and highlights the role of the hippocampus as a potential upstream modulator of brainstem respiratory centers.

Impact of Acute Sleep Restriction on the Resting Ventilatory Response to Normobaric Hypoxia and Its Relationship with Blood Cytokine Levels in Healthy Men

M. Chennaoui¹, L. David², J. Touron¹, A. Pontiggia¹, V. Beauchamps³, C. Malle¹, O. Nespoulous⁴, F. Sauvet¹, N. Koulmann⁵, D. Gomez-Merino¹, P. Fabries⁶

¹Institut de Recherche Biomédicale des Armées - Université Paris cité, UMR 7330, Bretigny/Orge, France, ²École du Val-de-Grâce, Hôpital Régional d'Instruction des Armées Clermont-Tonnerre, Paris, France, ³École du Val-de-Grâce - Institut de Recherche Biomédicale des Armées - Université Paris cité, UMR 7330, Bretigny/Orge, France, ⁴Institut de Recherche Biomédicale des Armées, Bretigny/Orge, France, ⁵École du Val-de-Grâce - UNIVERSITE EVRY, LBEPs, Paris, France, ⁶Institut de Recherche Biomédicale des Armées - Université EVRY (LBEPs), US Army Research Institute of Environmental Medicine, Bretigny/Orge, France

Introduction: Exposure to the combined stressors of hypoxia and sleep restriction can occur in various contexts, such as during operational missions, trekking expeditions, and similar situations. This combination of stressors is also observed in obstructive sleep apnea. While the effects of hypoxia on

sleep have been previously investigated, the impact of sleep restriction on physiological responses to hypoxia remains unknown. This study aimed to evaluate the effects of acute sleep restriction on (i) the resting ventilatory response to normobaric hypoxia, (ii) plasma levels of pro- and anti-inflammatory cytokines, and (iii) their potential relationship. Interindividual differences related to genetics were assessed on the cardiac response.

Materials and methods: Seventeen healthy men were exposed to 5 hours of normobaric hypoxia ($F_{iO_2}=13.6\%$, $\sim 3,500$ m) in a crossover design, following either habitual sleep (HS HY, Total sleep time (TST) > 6 hours) or restricted sleep (SR HY, TST < 3 hours). Ventilatory parameters were measured after 1.5 hours (Quark CPET, Cosmed® device), and blood cytokine levels (TNF- α and IL-10) were assessed at 1.5 (BS +1h30) and 5 hours (BS +5h00) (Simoa® CorPlex™ Cytokine Panel-1 5-Plex Kit, ref.85-0353, Quanterix). Genotyping for the rs228697_PER3 C>G polymorphism was performed on blood cells using the LAMP-MC method

Results: Sleep restriction led to increased tidal volume (0.68 ± 0.36 vs. 0.63 ± 0.36 L, $p < 0.05$) and ventilatory equivalent for CO₂ (36.30 ± 5.93 vs. 34.40 ± 4.33 , $p < 0.05$). TNF- α concentrations were elevated following sleep restriction (0.98 ± 0.38 vs. 0.86 ± 0.41 pg·mL⁻¹ at BS+1h30; 1.00 ± 0.45 vs. 0.79 ± 0.35 pg·mL⁻¹ at BS+5h00; $p < 0.001$). IL-10 levels were significantly higher after 5 hours of hypoxia after sleep restriction (0.94 ± 0.65 vs. 0.83 ± 0.61 pg·mL⁻¹, $p < 0.05$), and exceeded those measured under habitual sleep (0.94 ± 0.65 vs. 0.78 ± 0.73 pg·mL⁻¹, $p < 0.05$). IL-10 concentrations positively correlated with ventilatory responses, regardless of sleep condition or exposure duration. Carriers of the C/G mutated genotype of the rs228697_PER3 polymorphism showed higher heart rates under hypoxia, independent of sleep condition.

Conclusions: This is the first study to isolate the impact of sleep restriction on ventilatory and cytokine responses to normobaric hypoxia. It highlights IL-10's potential role in hypoxic ventilatory regulation and suggests that sleep duration influences the ventilatory response. Given these sleep-related differences, future hypoxia studies should, at minimum, quantify sleep duration to enable proper control and comparison of physiological outcomes and cytokines responses.

Investigating the Effects of Sedative-Hypnotic Drugs on Sleep and Autonomic Nervous System Function in Wild-type and Alzheimer's Disease Transgenic Mice

T.-Y. Chen¹, C.-W. Chen², T.B. Kuo³, C.C. Yang³

¹Tri-Service General Hospital, Psychiatry, Taipei, Taiwan, ²National Cheng Chi University, Institute of Neuroscience, Taipei, Taiwan, ³National Yang Ming Chiao Tung University, Institute of Brain Science, Taipei, Taiwan

Introduction: Patients with Alzheimer's disease (AD) often experience insomnia, and clinical management frequently involves the use of sedative-hypnotic drugs to alleviate sleep disturbances. However, previous studies have indicated potential negative consequences of long-term sedative use in patients. This study aims to explore the effects of single dose and long-term administration of sedative-hypnotic drugs on sleep patterns and autonomic nervous system function in APP/PS1 transgenic mice, a model of AD, during the pre-symptomatic stage.

Materials and methods: In this experiment, both pre-symptomatic APP/PS1 mice (17-18 weeks old) and wild-type (WT) control mice were orally administered different doses of Lorazepam (1, 2, and 4 mg/kg) and Zolpidem (5, 7.5, and 10 mg/kg) for a single dose. After one week, the mice were further administered Lorazepam (2 mg/kg) and Zolpidem (7.5 mg/kg) daily, along with a vehicle control, for two weeks. Each group consisted of 9 mice, and physiological signals such as EEG, EMG, and ECG were recorded continuously for 24 hours each week.

Results: Prior to drug administration, assessment revealed that APP/PS1 mice, compared to WT mice, exhibited poorer performance in quiet sleep (QS) duration (similar to human Non-REM sleep), sleep disturbances, and heart rate variability (HRV) parameters, including RR interval (RR), total power (TP), high frequency (HF), and normalized low frequency (LF%). Single-dose administration of Lorazepam and Zolpidem increased QS duration while reducing paradoxical sleep (PS) duration in both APP/PS1 and WT mice. Long-term drug use for two weeks showed that neither Lorazepam nor Zolpidem had a sustained effect on QS duration, and Lorazepam reduced PS duration in WT mice, while Zolpidem

reduced both QS and PS durations in APP/PS1 mice, along with an increase in awake time. Lorazepam significantly decreased HRV parameters (TP, HF, and LF%) during PS in APP/PS1 mice after a single dose, whereas Zolpidem had a smaller impact on HRV. However, after two weeks of continuous use, Zolpidem exhibited significant effects, particularly on PS sleep in APP/PS1 mice, approaching the impact observed with Lorazepam. Regardless of single or long-term administration, HRV in WT mice was less affected.

Conclusions: A single dose of Lorazepam and Zolpidem increased QS sleep in both WT and APP/PS1 mice, but this effect disappeared after two weeks of continuous administration, showing a trend of worsening sleep quality. Lorazepam, whether administered acutely or chronically, affected HRV during sleep in APP/PS1 mice, while Zolpidem had a minor impact with acute use, becoming more pronounced after two weeks of continuous administration, especially during PS sleep in APP/PS1 mice.

Investigating the impact of night-duty on sleep architecture and mental well-being in the security personnel: A quasi-experimental study

D.P. K¹, D.V. Daulatabad¹, D.N. John¹

¹All India Institute of Medical Sciences, Bibinagar, Physiology, Hyderabad, India

Introduction: In a world that never sleeps, the role of security personnel is vital in maintaining order, safety, and peace. While the responsibilities of security professionals are diverse and multifaceted, one aspect of their job that often remains hidden in the darkness is the relentless demand for night-duty shifts. This research delves into the often-overlooked consequences of night-duty shifts on security personnel. The study aims to investigate impact of night shifts on the physical health, psychological well-being of security professionals. By exploring the disruptions to sleep architecture, such as stages of sleep (N2), sleep efficiency, and the potential mental health implications like mental well-being, the research seeks to enhance understanding of the physiological changes in these dedicated professionals

Materials and methods: Using a novel quasi-experimental design approach, the study was conducted in AIIMS Bibinagar. Polysomnography (PSG) was used to monitor and analyze the sleep patterns of security personnel on night-duty shifts compared to off-duty periods. Additionally, mental well-being was assessed through validated mini state mental examination scores as psychological questionnaire

Results: PSG parameters like sleep time have significantly decreased, sleep efficiency along with duration of sleep stages of N2 has significantly decreased. There is a notable rise in systolic blood pressure which can be correlated to a decrease in the sleep's efficiency and total sleep time. These changes attributed to physiological changes due to sleep deprivation for the security personnel post night-duty shifts.

Conclusions: In conclusion, the reviewed literature and our current study clearly demonstrates the detrimental impact of night-duty on sleep architecture and mental well-being among security personnel. This study aims to provide the necessary evidence to develop and implement interventions that ultimately enhancing both personal and public safety.

Acknowledgments: Prof. Dr. Vikas Bhatia (Executive Director) for his constant support and guidance.

Investigation of the Role and Mechanism of the Der p1-IL-21 Axis in Adenoid Germinal Center Responses

B. Wang¹

¹Tsinghua University, Beijing, China

Introduction: Adenoid hypertrophy is a key etiological factor in obstructive sleep apnea-hypopnea syndrome (OSAHS), often associated with excessive germinal center (GC) proliferation. House dust mite (HDM) colonization, particularly by the allergen Der p1, has been implicated in this pathology, but its mechanistic role remains poorly understood.

Materials and methods: To investigate this, we established an innovative adenoid organoid model and utilized IL-21^{-/-} mice to evaluate the effects of Der p1 on GC responses.

Results: Our findings demonstrate that Der p1 stimulation significantly increased IL-21⁺ T follicular helper (Tfh) cells, which in turn enhanced GC responses. Notably, IL-21^{-/-} mice showed markedly reduced GC formation in the spleen.

Conclusions: These results suggest that the Der p1-IL-21 axis plays a critical role in promoting GC proliferation in adenoid hypertrophy, offering new insights into the pathogenesis of OSAHS and potential therapeutic targets.

I-SLEEPS: A Simplified and Accurate Approach to Sleep Disorder Prediction with Body Composition Metrics

O. Cawiding^{1,2}, H. Bae³, E.Y. Joo⁴, J.K. Kim^{1,2}

¹Korea Advanced Institute of Science and Technology, Department of Mathematical Sciences, Daejeon, Korea, Republic of, ²Institute for Basic Science, Biomedical Mathematics Group, Daejeon, Korea, Republic of, ³Inje University College of Medicine, Ilsan Paik Hospital, Department of Neurology, Inje University College of Medicine, Ilsan Paik Hospital, Goyang, Korea, Republic of, ⁴Samsung Medical Center, Sungkyunkwan University of School of Medicine, Department of Neurology, Neuroscience Center, Seoul, Korea, Republic of

Introduction: Accurately predicting the risk of sleep disorders such as insomnia, obstructive sleep apnea (OSA), and comorbid insomnia and sleep apnea (COMISA) typically requires a costly and time-consuming process involving multiple questionnaires and polysomnography tests. As a simpler alternative for sleep disorder prediction, the SLEEPS algorithm uses only nine questions, which includes the body mass index (BMI) as a key feature. However, BMI alone fails to capture differences in body composition, as individuals with identical BMI values can exhibit significant variations in muscle and fat distribution. We aim to develop a machine learning algorithm that can accurately predict the risk of insomnia, OSA, and COMISA using body composition metrics.

Materials and methods: We applied a tree-based machine learning algorithm to a dataset of 3291 patients. Demographic data, sleep-related questions, and body composition metrics were evaluated as potential features for the model. The final feature selection was based on feature importance calculated by Shapley additive explanations (SHAP) method. Using the selected features, we developed a new machine learning algorithm for predicting insomnia, OSA, and COMISA, named I-SLEEPS (InBody-based Simple questionnaire Predicting Sleep disorders). The accuracy of the algorithm was evaluated using the area under the receiver operating characteristics curve (AUROC).

Results: A total of 10 features were selected to construct I-SLEEPS, including skeletal muscle index (SMI) and fat-free mass index (FFMI) instead of BMI, along with the original SLEEPS questionnaire items. I-SLEEPS achieved superior predictive accuracy (AUROC > 0.93 for OSA, COMISA and insomnia) compared to SLEEPS (AUROC > 0.90). Additionally, our approach significantly enhanced AUPRC values, which is critical for addressing the imbalanced datasets of COMISA and insomnia. Furthermore, our analysis revealed distinct relationships between muscle mass indices (SMI and FFMI) and the risks of OSA, insomnia, and COMISA, providing new insights into the role of body composition in sleep disorders.

Conclusions: By leveraging the accessibility of InBody analysis, I-SLEEPS offers a practical, non-invasive alternative for diagnosing and managing sleep disorders, improving upon traditional screening methods such as polysomnography.

Acknowledgments: We thank the following organizations for their support of this study: Institute for Basic Science (to J.K.K.), Samsung Medical Center (to E.Y.J.), and Hyundai Motor's Chung Mong-Koo Global Scholarship (to O.R.C.).

KLF9 Regulates Sleep Architecture via B-Mediated Excitability of VTA Dopaminergic Neurons

F. Liu¹, N. Li¹, S. Yin¹

¹Shanghai Jiao Tong University, Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China

Introduction: Sleep is a fundamental physiological process essential for physical and mental recovery, representing a state of comprehensive brain rest. In mammals, sleep is tightly regulated by a complex network of deep brain nuclei. However, the genetic and molecular mechanisms underlying this intricate regulatory network remain largely unknown. Genome-wide association studies have identified a significant association between genetic polymorphisms in Krüppel-like factor 9 (KLF9) and alterations in sleep architecture in patients with obstructive sleep apnea. Nevertheless, whether KLF9 plays a functional role in sleep regulation and the nature of its downstream mechanisms remain unclear and warrant further investigation.

Materials and methods: To investigate the role of *Klf9* in sleep regulation, we employed a combination of genetic, neurophysiological, and multi-omics approaches. A *Klf9* knockout mouse model was generated using CRISPR/Cas9 technology, while whole-brain neuronal overexpression of *Klf9* was achieved through retro-orbital injection of AAV-hsyn-*Klf9*. Sleep parameters were assessed using EEG/EMG recordings to evaluate the impact of *Klf9* manipulation on sleep architecture. To trace the spatial expression of KLF9 protein in the brain, we constructed an in-frame *Klf9*-HA knock-in mouse model for in situ labeling. Region- and cell-type-specific overexpression or deletion of *Klf9* was further accomplished via stereotactic injection of AAV vectors combined with the Cre-loxP system, enabling precise dissection of its function in specific brain regions and neuronal populations. To uncover the transcriptional network downstream of *Klf9*, we integrated single-nucleus RNA sequencing (snRNA-seq) with CUT&Tag profiling. The regulatory relationships between *Klf9* and its target genes were subsequently validated through molecular biology, epigenetic, and electrophysiological analyses. Finally, rescue experiments were conducted in *Klf9*-deficient mice by restoring the expression of downstream gene, confirming the mechanistic role of the *Klf9* signaling in modulating sleep.

Results: *Klf9* knockout mice exhibited a significantly reduced total wake duration, increased frequency of microarousals, and shortened average wake episode length, indicative of a fragmented sleep phenotype. In contrast, overexpression of *Klf9* in whole-brain neurons led to opposing effects on sleep architecture, suggesting a regulatory role for *Klf9* in maintaining stable sleep-wake states. In situ protein tracing revealed that KLF9 is highly expressed in the subthalamic nucleus (STN), substantia nigra (SN), and ventral tegmental area (VTA). Region- and cell-type-specific genetic manipulation further demonstrated that KLF9 is essential for wake maintenance and sleep structure stability

specifically in dopaminergic neurons of the VTA. Integrated multi-omics analysis identified B as a direct downstream transcriptional target of KLF9. Loss of *Klf9* resulted in markedly altered B expression and decreased excitability of dopaminergic neurons. Notably, in situ restoration of B expression in *Klf9*-deficient mice effectively rescued the observed sleep abnormalities, confirming the functional relevance of the KLF9-B regulatory axis in sleep regulation.

Conclusions:

This study is the first to demonstrate the critical role of KLF9 in maintaining wakefulness and stabilizing sleep architecture.

Living with OSA & CPAP: Preliminary Report of a Multicenter Italian Study (Apulia Region)

E. Resta¹, V. Gnani², V.A. Falcone³, V.N. Quaranta⁴, M.D. Toraldo⁵, R. Sabato⁶, E. Capozza⁷, A. Pinto⁸, A. Laricchiuta⁹, A.R. Tusino¹⁰, C. Santomasi¹¹, M.F. Grimaldi¹², T. Campanino¹², D. Margiotta¹³, G. Mansueto¹⁴, E. Rollo², E. Di Perna¹⁵, A. D'Ambrosio¹⁵, D. Lacedonia¹⁴, P. Tondo¹⁴

Cesario Hospital, Lecce, Italy, ⁶Foggia Polyclinic University-Hospital, Foggia, Italy, ⁷Hospital of Terlizzi, Terlizzi, Italy, ⁸Hospital of Trani, Trani, Italy, ⁹Hospital of Putignano, Putignano, Italy, ¹⁰Masselli Mascia Hospital of San Severo, San Severo, Italy, ¹¹Polyclinic of Bari, Bari, Italy, ¹²Hospital of Ostuni, Ostuni, Italy, ¹³Hospital of Barletta, Barletta, Italy, ¹⁴University of Foggia, Foggia, Italy, ¹⁵Universo Salute Opera Don Uva, Bisceglie, Italy

Introduction: Obstructive sleep apnea (OSA) is a highly prevalent chronic respiratory disorder, associated with significant cardiovascular and metabolic complications. Although CPAP represents the first-line treatment, suboptimal adherence and the persistence of daytime symptoms often limit its clinical effectiveness. This multicentre study involved all Sleep Centres in the Apulia Region and aimed to describe the clinical characteristics of patients with OSA, as well as their self-reported symptoms, adherence to CPAP therapy, and residual complaints despite treatment, in a real-world setting.

Materials and methods: A shared regional database was created, including 1,396 consecutive patients diagnosed with OSA, enrolled from all specialized centres in Apulia. Clinical, demographic, and polysomnographic data were collected. In addition, patients underwent a comprehensive assessment on subjective sleep quality and disturbances cognitive symptoms, depression, anxiety, and quality of life. Adherence to CPAP therapy was evaluated, with adequate adherence defined as a minimum of 4 hours of use per night on at least 70% of nights.

Results: Preliminary analysis of the data showed a mean age of 60.4 ± 12.6 years, with a male predominance. The mean BMI was 34.04 kg/m^2 , indicative of class I obesity. The mean apnea-hypopnea index (AHI) was 39.3 events/hour, and the mean oxygen desaturation index (ODI) was 38.6/h. The average ESS score was 9.5 ± 5.3 , suggesting moderate sleepiness. A good adherence to CPAP was observed in 72% of patients. However, approximately 44% reported persistent cognitive symptoms and attention difficulties despite treatment.

Conclusions: Preliminary findings from this multicenter study reveal that, despite generally good adherence to CPAP therapy, a substantial proportion of patients continue to report residual symptoms such as cognitive difficulties, sleep disturbances, and daytime fatigue. These results underscore the need for more personalized follow-up and targeted therapeutic strategies that go beyond respiratory parameters alone. Moreover, this study highlights the importance of regional cooperation among Sleep Centers in generating a comprehensive, real-world understanding of OSA management and patient-reported outcomes.

LncRNA NONMMUT009018 drives tumorigenesis and progression by modulating the miR-8100/Col1a2/Thbs1 axis under intermittent hypoxia

Y. Bao¹, Q. Yao¹

¹Xinjiang Medical University, School of Basic Medical Sciences, Urumq, China

Introduction: This study aims to investigate the mechanism by which LncRNA NONMMUT009018/miR-8100/Col1a2/Thbs1 in promoting tumor proliferation, invasion, metastasis mediated by obstructive sleep apnea hypopnea syndrome (OSAHS)-related intermittent hypoxia (IH). To provide a theoretical foundation and potential therapeutic targets for the clinical prevention and treatment of OSAHS-associated tumors.

Materials and methods: Affymetrix Clariom D microarray and bioinformatics analysis, RIP, and dual-luciferase reporter assays were used to confirm binding interactions within the ceRNA network. DMOG was used to stabilize HIF-1 α expression in tumor cells, and C57BL/6J mouse tumor-bearing models were subjected to IH mimicking OSAHS for 28 days in vivo. Lentiviral and mimic transfection techniques were applied to modulate LncRNA NONMMUT009018 and miR-8100 expression in LLC and B16F10 melanoma cells, influencing downstream target genes *Col1a2* and *Thbs1*. CCK-8, transwell chamber, scratch wound healing assays, in vivo imaging, tumor weight/volume measurements, HE staining, RT-qPCR, and western blot were conducted to explore the role of the LncRNA NONMMUT009018/miR-8100/*Col1a2*/*Thbs1* regulatory axis in tumor growth, invasion and metastasis.

Results: Compared to the normoxic group, IH significantly upregulated the expression of LncRNA NONMMUT009018, *Col1a2*, and *Thbs1* in tumor tissues ($P < 0.05$), while miR-8100 expression was markedly downregulated ($P < 0.01$). RIP, MS2/AGO2-RIP and dual-luciferase reporter assays demonstrated direct binding of HIF-1 α to LncRNA NONMMUT009018, LncRNA NONMMUT009018 to miR-8100, and miR-8100 to *Col1a2* and *Thbs1*. Knockdown of LncRNA NONMMUT009018 and overexpression of miR-8100 significantly reduced *Col1a2* and *Thbs1* mRNA expression by RT-qPCR ($P < 0.01$). CCK-8 assays, transwell invasion and migration assays, scratch wound healing experiment, and EMT-related marker proteins E-cadherin, N-cadherin and MMP9 revealed that knockdown of LncRNA NONMMUT009018 or overexpression of miR-8100 can significantly inhibit HIF-1 α -mediated proliferation, invasion and metastasis of LLC and B16F10 tumor cells. However, overexpressing LncRNA NONMMUT009018 or inhibiting miR-8100 restored proliferation, invasion, migration of tumor cells. Similar phenotypic characteristics were found in IH-mediated tumor tissues.

Conclusions: This study established the LncRNA NONMMUT009018/miR-8100/*Col1a2*/*Thbs1* ceRNA network driving IH-associated tumor progression. HIF-1 α activation upregulated LncRNA NONMMUT009018, which sponged miR-8100 to derepress *Col1a2*/*Thbs1*, promoting tumor proliferation, invasion, migration, and EMT. Targeting this axis may offer novel strategies for OSAHS-related cancer prevention and therapy.

Deeply grateful to my supervisor, Professor Qiaoling Yao, for her invaluable mentorship. Extend my appreciation to my fellow lab members, Alimujiang, Qi Deng, Zhenlian Zhang.

Massai sleep in high altitude, kenya

F.X. Wallner¹

¹Passau, Numerical Analysis, Passau, Germany

Introduction: The massai tribe live in the south part of kenya and the north part of tanzania around the mt kilemanjaro. This tribe of 2 million people live as nomads on a strong social order. They eat and drink water, tea, milk, worm blood, and meat. Fruits only from forest small fields.

Materials and methods: we interviewed 62 persons in a manyata about the sleep duration, sleep disturbances in the village. the questionnaire was adapted on PSQI, We talked with 24 female and 38 male persons. All persons are wake up with sunrise and go to sleep at 8:30 pm. the teenagers dance often in moonshine much longer. the range was between 24-76 years. But no worrier was in the study. The massai are tall mean value 190 cm for men and 175 for female. The BMI of all members was under 24. We measured sleep with the Apple watch, O2 saturation, heart beat, Snoring, breathing/ min.

Results: We interviewed 62 persons, sleep disturbances are reported like crying animals, kids, cold temperature, but no snoring in this village. not one O2- desaturation during sleep.

Conclusions: To live in the massai tribe is combined with a sportive living. a massai walk every day 10-20 km a day. women are used for cooking, water fetching. man as cattleman and worriers. To be a massai in kenya protects you from breathing disorders in sleep.

Acknowledgments: This study is financed by
Dr. Franz Xaver Wallner.

Maternal sleep disordered breathing impacts cortisol regulation in pregnancy

M. Bublitz¹, G. Bourjeily², R. Butler³, C. Marsit⁴, K. Kelsey³

¹Brown University Health, Psychiatry, Providence, United States, ²Brown University, Medicine, Providence, United States, ³Brown University, Center for Environmental Health and Technology, Providence, United States, ⁴Emory University, Department of Environmental Health, Atlanta, United States

Introduction: Maternal sleep disordered breathing (SDB) is arguably the most common respiratory condition in pregnancy, and is an independent risk factor for adverse perinatal outcomes. While epidemiologic data link the condition to various adverse outcomes in pregnancy, mechanistic data examining the association are scarce. Therefore, in this study we examined if de-novo maternal SDB impacts maternal cortisol secretion and fetal cortisol exposure via placental gene methylation in pregnant women at risk.

Materials and methods: Pregnant women at risk for SDB who screened negative for SDB by in-home sleep apnea testing in early pregnancy, were enrolled and had repeat sleep apnea testing in the third trimester of pregnancy. Women had wake, 30 minutes post wake, and bedtime salivary cortisol collected at the two time points in pregnancy. A subset of consecutive women who agreed to have placental tissue collected at the time of delivery had quantitative pyrosequencing performed to assess DNA methylation of 11 β -hydroxysteroid dehydrogenase-1 (11 β HSD-1) and 11 β HSD-2.

Results: Seventy-five women with average BMI 35 ± 5 Kg/m², and 43% developed SDB by third trimester. 29% were primigravida, self-reported race/ethnicity was as follows: 26% Hispanic, 67% White, 11% Black, 3% Asian, 1% Native American, and 11% multiracial. After adjusting for maternal age, BMI, and stress symptoms (symptoms of depression and perceived stress as measured by the Patient Health Questionnaire-9 and Perceived Stress Scale), third trimester apnea hypopnea index (AHI) and oxygen desaturation index (ODI) were significantly associated with cortisol area-under-the-curve, (B= -2.69, p= 0.010) and (B= -0.32, p= 0.035), respectively. One-way ANOVA revealed that women with SDB displayed a significantly lower cortisol area-under-the-curve in third trimester (F= 4.41, p=0.040). Third trimester AHI was significantly associated with placental 11 β HSD1 methylation (B= -2.80, p= 0.019). A convenience sample of cord blood cortisol showed higher -but non-statistically significant- cord blood cortisol levels in women with SDB in third trimester compared to women without SDB.

Conclusions: This study demonstrates that SDB is associated with significant alterations in cortisol regulation in pregnancy to include reduced maternal cortisol output and reduced DNA methylation of 11 β HSD1. Our limited sample suggests overexposure of the fetus to cortisol; however, this finding needs to be confirmed in larger studies.

Modelling Amyloid-beta clearance dynamics across sleep-wake cycles in healthy conditions

S. Sangeet¹, A. D'Rozario², C. Phillips^{3,4}, C. Hoyos⁵, S. Postnova^{1,3}

¹University of Sydney, School of Physics, Sydney, Australia, ²Macquarie University, School of Psychological Sciences, Faculty of Medicine, Sydney, Australia, ³Woolcock Institute of Medical Research, Center for Sleep and Chronobiology, Sydney, Australia, ⁴Macquarie University, Macquarie Medical School, Faculty of Medicine, Health and Human Sciences, Sydney, Australia, ⁵Macquarie University, Department of Health Sciences, Faculty of Medicine, Health and Human Sciences, Sydney, Australia

Introduction: Understanding the fundamental mechanism of brain waste clearance is essential to elucidate physiological neurometabolite dynamics in healthy individuals. Sleep, particularly slow-wave sleep, is critical for the clearance of neurometabolites that accumulate in the brain during wakefulness. One of these neurometabolites is amyloid beta (A β), whose clearance increases approximately twofold

during sleep compared to wakefulness, and whose accumulation has been linked to Alzheimer's Disease. Clearance of neurometabolites is proposed to take place via complex interaction between the brain, cerebrospinal fluid and plasma, including the glymphatic system and the blood-brain barrier. Mathematical modelling is a useful tool to quantify and to better understand this complex system, especially since some of its dynamics are hard to measure experimentally. Successful models include microglial phagocytosis, glymphatic flow, and blood-brain barrier transport in rodents or in pathological states. However, they have not yet accounted for the effects of the sleep-wake cycles on the clearance dynamics. The objective of this study was to (i) develop a multi-compartment model of A β clearance dynamics across the brain, CSF, and plasma along the sleep-wake cycles in healthy individuals, and (ii) apply this model to explain experimental data.

Materials and methods: A three-compartment model, employing ordinary differential equations (ODEs), was developed to simulate A β dynamics across the brain, CSF and plasma, integrating production, and sleep-enhanced glymphatic clearance modulated by the sleep-wake cycle. The model was calibrated with human CSF and plasma data from studies of healthy individuals under normal sleep conditions. Model parameters were identified from experimental data where possible. The remaining parameters were found by fitting the model to data using the normalised root mean square error (NRMSE).

Results: Our three-compartment model predicts 24-hour A β oscillations during healthy sleep-wake cycles and achieves good agreement with experimental values for CSF and plasma A β concentration (NRMSE: 0.156–0.217). The default parameter set thus corresponds to a group average normal sleep-wake cycle in healthy people. With CSF A β concentration in the model ranging from 650 to 800 pg/ml, and plasma A β concentration from 15 to 19 pg/ml, the model predicts brain concentration of A β to range between 320 and 390 pg/ml. These CSF and plasma ranges align closely with experimental measurements, while concentration in the brain is yet to be measured experimentally. Application of the model to CSF data obtained with invasive CSF sampling over a 36-hour protocol predicts that such a procedure disrupts brain-to-CSF clearance dynamics with brain-to-CSF flux increasing by 1.25–25% during wake, while sleep-related glymphatic clearance decreases by 14.29–89.55%.

Conclusions: Our three-compartment model successfully reproduced the sleep-wake dynamics of A β concentration in CSF and plasma, and predicted A β dynamics in the brain. By applying the model to data, we were able to predict the potential mechanisms behind experimental observations of elevated CSF A β levels during normal sleep-wake cycles. Further model validation should be done against sleep disruption experiments.

mPFC activation drives phasic REM population dynamics in the pons

E. Pickup¹, J. Hong¹, M. Kim¹, S. Chung¹, F. Weber¹

¹University of Pennsylvania, Neuroscience, Philadelphia, United States

Introduction: Rapid eye movement (REM) sleep is a heterogeneous state consisting of tonic and phasic substates. Phasic REM sleep is characterized by rapid eye movements and pontine waves (p-waves), which are brief events generated in the pons. P-waves are linked to coordinated activity across many brain areas and may play a role in memory and plasticity. However, much about the neural expression of p-waves and how p-waves are triggered or regulated remains poorly understood. In this study, we tested whether the medial prefrontal cortex (mPFC) may regulate p-waves during REM sleep. We then used Neuropixels recordings and dynamical systems analysis to examine how mPFC activation drives neural population dynamics in the pons.

Materials and methods: We used chronic EEG/EMG recordings for sleep staging in mice, combined with fiber photometry and optogenetics to measure and manipulate mPFC activity. Pupil movements were tracked during REM sleep using video oculography in head-fixed animals. To assess downstream responses in the brainstem, we recorded single-unit activity using Neuropixels probes.

Results: Our results show that mPFC activity increases around the time of spontaneous p-waves, as measured by fiber photometry, suggesting that cortical activation may contribute to their occurrence. To test this, we optogenetically stimulated the mPFC using brief pulses delivered across sleep and wake states and found that mPFC activation triggered p-waves reliably only during REM sleep.

Stimulation induced additional phasic REM features, such as rapid eye movements and muscle twitches. To examine downstream effects of cortical input, we recorded population activity in the brainstem. In the pons, spontaneous activity showed a biphasic pattern, with periods of coordinated high firing followed by relative quiescence. During mPFC stimulation, we observed broad activation of brainstem neurons during laser-triggered p-waves, but not when stimulation failed to evoke a p-wave. **Conclusions:** Our findings show that activity in the pons is biphasic, alternating between tonic and phasic substates. mPFC stimulation shifts this local activity from the tonic to the phasic state, promoting the generation of p-waves and other features of phasic REM sleep. This suggests that the mPFC may contribute to initiating or coordinating phasic REM events through top-down modulation of brainstem circuits, offering a new perspective on cortical involvement in REM sleep regulation.

Multi-Person Sleep Monitoring Based on mmWave Radar

D. Kim¹, J. Ha¹, E. Jung¹, Y. Cho¹, E.Y. Joo²

¹Samsung electronics, Seoul, Korea, Republic of, ²Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Neurology, Seoul, Korea, Republic of

Introduction: The 60GHz mmWave radar enables non-contact detection of subtle thoracic respiratory movements, facilitating the estimation of sleep stages. In this study, we extend the application of this technology from single-subject monitoring to multi-person environments by developing a real-time sleep monitoring system capable of simultaneously assessing multiple individuals. The proposed multi-person sleep staging algorithm achieved a classification accuracy of 76% (Cohen's kappa: 0.61), comparable to the 78% accuracy (Cohen's kappa: 0.64) of our previously validated single-subject model. These results demonstrate the system's ability to overcome the limitations of single-user monitoring, highlighting its feasibility for real-world deployment in shared living environments.

Materials and methods: In this study, we implemented a real-time multi-person sleep monitoring system using a 60GHz mmWave radar. The radar captures reflected signals from transmitted waves to extract distance, velocity, and angle information, which is then mapped into a three-dimensional coordinate system to generate a point cloud.

The sequentially acquired point cloud data were processed using the DBSCAN (Density-Based Spatial Clustering of Applications with Noise) algorithm, a density-based clustering method. This approach enabled the formation of distinct clusters based on spatial density, allowing for independent identification and tracking of multiple individuals within the radar's sensing range by assigning unique IDs to each cluster.

Once individuals were detected to have entered a stable posture with minimal movement, spatial zones were defined based on their positions. Sleep stages were then independently estimated for each person, enabling simultaneous multi-subject sleep analysis.

Results: In our previous study (presented at *Sleep* 2024), we achieved a sleep stage classification accuracy of 78% (Cohen's kappa: 0.64) using a CNN and Transformer-based model in a single-subject setting, validated through a clinical trial involving 340 participants (200 for training and 140 for validation).

To evaluate the performance of the newly developed multi-person algorithm, we conducted a clinical trial in an environment where two individuals slept simultaneously. The system performed real-time tracking and spatial separation, allowing for individual sleep stage estimation. Due to limitations of the PSG device, sleep stage accuracy could only be validated for one participant at a time. A total of 20 subjects participated in the trial.

The results showed that the multi-person system achieved a classification accuracy of 76% with a Cohen's kappa of 0.61, indicating a slight decrease in accuracy compared to the single-subject model, yet maintaining comparable performance under multi-occupant conditions.

Conclusions: This study extends conventional single-person sleep analysis to a multi-person setting using point cloud-based techniques. The results demonstrate that mmWave radar-based sleep monitoring can maintain a comparable level of accuracy in estimating sleep stages for multiple individuals, similar to that observed in single-subject scenarios. These findings validate the feasibility of applying mmWave radar for real-world, non-contact sleep monitoring in environments with multiple occupants.

The significance of this work lies in its demonstration of the practical potential of non-contact sensor

technologies for multi-person sleep monitoring, marking a step forward in scalable, unobtrusive sleep assessment systems.

Neural Adaptations Across Daily Torpor and Sleep: Ultrastructural, Molecular, and Behavioural Changes in Djungarian Hamsters (*Phodopus sungorus*)

X. Zhou¹, D. Bannerman², A. Hoerder-Suabedissen¹, Z. Molnar¹, E. Becker³, D. Bodalia¹, M. Vu¹, L. McKillop¹, M. Bellesi⁴, L. de Vivo⁵, V.V. Vyazovskiy¹

¹University of Oxford, Department of Physiology, Anatomy and Genetics, Oxford, United Kingdom,

²University of Oxford, Department of Experimental Psychology, Oxford, United Kingdom, ³University of Oxford, Nuffield Department of Clinical Neurosciences, Oxford, United Kingdom, ⁴University of Camerino, School of Bioscience, Camerino, Italy, ⁵University of Camerino, School of Pharmacy, Camerino, Italy

Introduction: Torpor is a controlled and reversible state characterised by a lowered metabolic rate and body temperature. In golden-mantled ground squirrels (*Spermophilus lateralis*), torpor induces dendritic spine retraction and the re-localisation of synaptic proteins, which are restored within two hours upon arousal (von der Ohe et al., 2007). Emergence from torpor is followed by increased slow-wave activity (SWA), a well-established marker of sleep pressure. Our study aims to elucidate the structural, molecular, and behavioural effects of torpor and subsequent sleep in Djungarian hamsters (*Phodopus sungorus*), a species that exhibits daily torpor in response to a shortened photoperiod.

Materials and methods: Animals (n = 5–6 per group; sex-balanced) were sampled at various stages: euthermia, mid-torpor, arousal, two hours post-torpor, and two hours of sleep deprivation after torpor. The occurrence of torpor was confirmed using continuous, non-invasive thermal imaging.

To examine neural changes across states, three approaches were employed. First, serial block-face scanning electron microscopy (SBEM) was used to assess changes in the synaptic ultrastructure of layer 2 pyramidal neurons in the primary motor cortex. Second, novel object recognition (NOR) testing was conducted to evaluate novelty detection in animals that underwent daily torpor compared to non-torpor controls. Third, Western blotting and immunohistochemistry were used to quantify and localise synaptic and cytoskeletal protein markers across the torpor–euthermia cycle.

Ultrastructural and behavioural data were analysed using linear mixed-effects models to account for inter-individual and stage-related variability.

Results: Our preliminary SBEM data revealed that the area of the axon-spine interface (ASI), an indicator of synaptic strength, did not differ significantly between the mid-torpor and euthermia groups (t = 0.277, P = 0.785; linear mixed-effects model), suggesting that daily torpor does not compromise synaptic strength. However, a significantly lower proportion of synapses containing presynaptic mitochondria was observed in the mid-torpor group compared to the euthermia group (p = 0.0389; generalised linear mixed model).

In our behavioural experiments (n = 12), novel object recognition performance did not differ significantly between torpor and non-torpor groups (p = 0.61; linear mixed-effects model), indicating that torpor does not impair this form of learning immediately after arousal.

Our pilot Western blot data (n = 2) revealed synapse-specific differences in the localisation of plasticity-related proteins, such as NMDAR1 and CaMKII α , between the mid-torpor and euthermic states. These differences may reflect molecular mechanisms underlying the rapid synaptic recovery observed after torpor.

Conclusions: Our preliminary findings suggest that daily torpor in Djungarian hamsters preserves synaptic strength and cognitive function, as evidenced by comparable axon-spine interface size and novel object recognition performance between torpor and euthermic states. However, changes in mitochondrial distribution at synapses and the localisation of plasticity-related proteins indicate that torpor induces specific molecular and structural adaptations. These results highlight the brain's resilience and dynamic plasticity during naturally occurring hypometabolic states.

Acknowledgments: This research was supported by AMED (JP21zf0127005) and the Wellcome Trust (204826/Z/16/Z).

Neural correlates of sleep depth and sleep-wake perception during NREM sleep

K. Fehér^{1,2}, C.L. Schneider^{1,2}, E. Hertenstein^{1,2}, C. Mikutta³, C. Nissen^{1,2,4}

¹University of Geneva, Department of Psychiatry, Geneva, Switzerland, ²University of Bern, University Hospital of Psychiatry and Psychotherapy, Bern, Switzerland, ³Privatklinik Meiringen, Meiringen, Switzerland, ⁴Geneva University Hospitals (HUG), Department of Psychiatry, Geneva, Switzerland

Introduction: How do we perceive sleep? Serial awakenings in humans – our best proxy of sleep-wake perception during sleep – have shown that we frequently perceive sleep as wake. But is this “misperception”? And how does perception relate to objective sleep depth? The primary aim of this study was to explore neural correlates of sleep depth and sleep-wake perception during NREM sleep in healthy sleep. In addition, we included patients with insomnia disorder as a potential model of altered sleep depth and perception.

Materials and methods: Thirty healthy participants (21 female, 9 male, 36±13 years) and 30 patients with insomnia disorder (21 female, 9 male, 39±15 years) were tested across three nights in the sleep laboratory with high density EEG. After an adaptation and baseline night, up to 12 successful awakenings per participant were performed out of non-rapid eye movement (NREM) sleep in night three. A gentle awakening protocol was used through a vibrating bracelet. Waking response was used as an index of sleep depth. Upon successful awakening, participants reported on their sleep-wake perception through an automatized interview.

Results: We performed a total of 750 awakening attempts out of NREM sleep (405 in controls, 346 in patients), of which both controls and patients showed around one third no awakenings, sleep reports upon awakening and wake reports upon awakening, respectively. There were no significant differences in the percentages of these events between controls and patients (small effect sizes). Analyzing high density EEG in the 2 minutes prior to the awakening signal, no-awakenings were mainly predicted by increased slow wave activity (SWA), while wake as compared to sleep reports were predicted by increased fast spindle and beta activity. No differences between groups were observed.

Conclusions: Our results suggest general mechanisms of sleep depth and its perception, with slow wave activity predicting sleep depth and high frequency activity wake perception, in line with concepts of fluid sleep-wake dynamics (sleep-wake continuum). Our results also indicate that fundamentals of sleep-wake regulation and direct sleep-wake perception are intact in patients with insomnia disorder. This suggests that the clinical symptomatology emerges post-sleep, from “downstream” cognitive, emotional and behavioral mechanisms.

Nighttime Administration of 0.25-Hz Binaural Beats Reduce Stage 1 Sleep in Individuals with Self-Reported Difficulty Initiating Sleep

A. Hirayama¹, Z. Fan², Y. Suzuki², Y. Suzuki², T. Watanabe³, T. Abe²

¹Doctoral Program in Neuroscience, Degree Programs in Comprehensive Human Sciences, Graduate School of Comprehensive Human Sciences, University of Tsukuba, Tsukuba, Japan, ²International Institute for Integrative Sleep Medicine (WPI-IIIS), Tsukuba Institute for Advanced Research (TIAR), University of Tsukuba, Tsukuba, Japan, ³KYOCERA Corporation, Kyoto, Japan

Introduction: Pharmacological and cognitive behavioral therapies are effective for insomnia, but occasionally involve side effects, tolerance, dependence, and limited accessibility. This study investigated a non-pharmacological and non-invasive approach using binaural beats (BB). BB are auditory stimuli generated by presenting two slightly different frequencies to each ear. A previous daytime nap study reported that 0.25-Hz BB significantly reduced the latency of N2 and slow-wave sleep compared to silence (Fan et al., 2024). This study examined whether similar effects occur during nocturnal sleep in individuals with difficulty initiating sleep.

Materials and methods: Fourteen adults (mean age: 36.9 ± 14.0 years; 10 women) with self-reported difficulty initiating sleep and who could perceive BB participated in a randomized, counterbalanced, within-participant crossover study. To minimize the first-night effects, participants completed an

adaptation night in a sleep laboratory. Subsequently, participants underwent two overnight sessions (8 hours in bed): one with 0.25-Hz BB and one sham (silence), both delivered continuously via earphones. Sleep was recorded via polysomnography and scored into stages W, N1, N2, N3, and REM according to the AASM criteria. To investigate whether BB effects varied across the night, sleep cycles were identified using the “SleepCycles” R package (Blume & Cajochen, 2021) and visually confirmed. The analysis focused on the first four cycles. To detect EEG changes during sleep onset that were not reflected in the AASM staging, data were segmented into 5-second epochs and scored into nine stages based on Hori’s stages (Hori et al., 1994).

Results: In contrast to previous nap studies, BB did not significantly affect the latency to any sleep stage. However, it significantly decreased the proportion of N1 and increased the proportion of N2 (both $p < 0.05$). Arousal and the arousal index showed non-significant reductions (both $p < 0.1$). No other parameters differed significantly (all $p > 0.05$). These results suggest that BB may reduce light sleep without affecting latency. The sleep cycle analysis showed that BB increased the proportion of N2 across cycles ($p < 0.05$), with no condition $\times$ cycle interaction, suggesting a consistent effect. The proportions of W and N1 did not differ (both $p > 0.05$). The proportions of N2, N3, and REM varied by cycle (all $p < 0.05$), reflecting typical sleep architecture. In the Hori’s stages analysis, latency, mean duration, proportional duration, and total transitions showed no between-condition differences (all $p > 0.05$). However, a significant condition $\times$ Hori stage interaction was observed in stage-specific transition counts ($p < 0.05$); BB increased transitions in H1 and H2 and decreased them in H4 (all $p < 0.05$).

Conclusions: The 0.25-Hz BB did not facilitate sleep onset, but consistently reduced N1 and increased N2 without inducing arousal. The increase in N2 persisted across sleep cycles, suggesting the potential of BB for continuous nocturnal use. Although BB induced instability during the early phase of sleep onset, this did not persist in the mid phase. These findings suggest that 0.25-Hz BB is a potentially simple, non-pharmacological, and non-invasive approach for improving sleep.

Night-Time Internet Use and Its Association with Poor Sleep Quality and Autonomic Dysregulation in Medical Students

S. Kuppusamy¹, A. Nayak², J. Fredrick³, M. Ramachandran⁴, S.K. Subramanian⁵

¹JIPMER, Department of Physiology, Pondicherry, India, ²JIPMER, PONDICHERRY, India, ³AIIMS Kalyani, Kolkatta, India, ⁴Saveetha Medical College & Hospital, Chennai, India, ⁵AIIMS Madurai, Tamil Nadu, India

Introduction: High-quality sleep supports cognitive performance, emotional resilience, and cardiovascular health—critical for young adults in demanding academic settings. However, prevalent night-time internet use among medical students challenges sleep health. Beyond discomfort, poor sleep quality is linked to autonomic dysregulation marked by increased sympathetic activity and reduced parasympathetic tone, early indicators of cardiovascular risk. This study assessed the prevalence of poor sleep quality in undergraduate medical students and its association with internet addiction and cardiovascular autonomic modulation.

Materials and methods: In this cross-sectional analytical study, 148 undergraduate medical students aged 18–24 years were assessed. Sleep quality over the past month was measured using the Pittsburgh Sleep Quality Index (PSQI), with scores ≥ 5 indicating poor sleep. Internet addiction was evaluated using Young’s Internet Addiction Test (YIAT-20), categorizing participants as normal, mild, moderate, or severe users. Baseline cardiovascular parameters - heart rate (HR) and blood pressure (BP) were recorded. Autonomic function was assessed by heart rate response to deep breathing (E:I ratio, reflecting parasympathetic tone) and diastolic BP rise during isometric handgrip (Δ DBPiHg, indicating sympathetic reactivity). Statistical analyses included t-tests, ANOVA, Pearson’s correlation, and logistic regression; significance was set at $p < 0.05$.

Results: A concerning 66.9% of students reported poor sleep quality (mean PSQI score 5.6 ± 2.5). Internet addiction was prevalent in 87.2% of participants, with 73.6% classified as mildly addicted and 13.5% as moderate to severe. Notably, 82.4% preferred internet use at night. Students with poor sleep quality had significantly higher PSQI component scores—including sleep latency, duration, efficiency, disturbances, and daytime dysfunction—compared to good sleepers

($p < 0.001$). Logistic regression showed internet addiction independently tripled the odds of poor sleep (OR: 3.29; $p = 0.018$), even after adjusting for BMI and waist-hip ratio. Furthermore, total PSQI scores positively correlated with internet addiction severity ($r = 0.224$; $p < 0.05$), suggesting a dose-response relationship.

In physiological measures, students with poor sleep quality exhibited greater sympathetic reactivity, as indicated by a higher diastolic BP rise during handgrip (21.5 ± 8.7 vs. 17.3 ± 4.1 mmHg; $p < 0.001$). Internet-addicted students also showed elevated resting heart rates (86.7 ± 11.0 vs. 79.4 ± 12.9 bpm; $p = 0.019$), suggesting autonomic imbalance.

Conclusions: This study highlights poor sleep quality as a widespread issue among medical students, closely linked to excessive, predominantly night-time internet use. Importantly, poor sleep quality was associated with objective signs of heightened sympathetic activity—an established risk factor for future cardiovascular disease. These findings underscore the need to promote healthy digital habits and prioritize sleep health in medical education to safeguard both immediate well-being and long-term autonomic and cardiovascular health.

Acknowledgments: We thank the students who participated in this study. We acknowledge the Indian Council of Medical Research (ICMR) for supporting this work under the Short Term Studentship (STS) program (Ref no – 2018-02790).

Noninvasive Sleep Metrics Provide Early Diagnosis of Traumatic Brain Injury in Mice

G.S. Mannino¹, T.R. Green¹, S.M. Murphy², M.R. Opp¹, R.K. Rowe¹

¹University of Colorado Boulder, Integrative Physiology, Boulder, United States, ²Cumberland Biological and Ecological Researchers, Longmont, United States

Introduction: Accurately diagnosing traumatic brain injury (TBI), particularly in the acute phase, remains a major clinical challenge, with current tools often lacking sensitivity to functional brain disruption. Sleep-wake disturbances are among the most common and persistent consequences of TBI yet are rarely leveraged for diagnostic purposes. Because sleep regulation depends on widespread and highly integrated neural networks, early post-injury changes may offer a sensitive window into diffuse neurophysiological dysfunction. Advances in noninvasive sleep monitoring now enable real-time, scalable assessment of sleep behavior, presenting new opportunities to incorporate functional biomarkers into clinical TBI workflows. In this study, we evaluated whether acute sleep metrics could distinguish TBI from sham injury and differentiate among injury mechanisms in a mouse model, with direct relevance to scalable diagnostic applications.

Materials and methods: Adult male and female C57BL/6J mice ($n = 111$) were randomized to receive one of three injuries: midline fluid percussion injury (mFPI), closed-head impact (CHI), or controlled cortical impact (CCI), or respective sham surgeries. Noninvasive piezoelectric sensors recorded physiological parameters used to determine sleep for 72 hours post-injury. Key sleep metrics included total minutes slept and number of sleep-wake transitions. Data were modeled using generalized linear mixed models (GLMMs) with fixed effects of injury model, sex, and time. Righting reflex was used to standardize injury severity. Random forest classifiers were trained on summary sleep features (mean, SD, range) to predict injury. Model performance was assessed by ROC curve analysis and principal component analysis (PCA).

Results: Acute post-injury sleep behavior served as a highly accurate behavioral biomarker for TBI diagnosis. Within the first 24 hours, injured mice exhibited significantly increased total sleep and more frequent sleep-wake transitions compared to sham controls ($p < 0.01$). These sleep disruptions varied by injury type and sex: diffuse injuries (mFPI, CHI) produced earlier and more fragmented sleep than focal injury (CCI), and males showed greater disruption than females. Righting reflex time, a proxy for acute injury severity, also significantly predicted the extent of post-injury sleep disturbances, particularly in male and MFPI-injured mice, indicating that early neurological suppression is coupled to both increased sleep need and altered sleep architecture. Using only noninvasive sleep data collected

over 72 hours, a random forest classifier identified TBI with 94.4% accuracy (AUC = 0.944, 95% CI: 0.89–0.99), supporting the diagnostic potential of early sleep profiles. Sleep metrics also enabled classification of injury mechanism with 83.3% accuracy (AUCs: CHI = 0.93, CCI = 0.81, mFPI = 0.80). PCA revealed distinct clustering by injury type, particularly among females (PC1 ANOVA, $p < 0.01$). Among all features tested, the frequency and variability of sleep-wake transitions were the strongest contributors to model performance, reinforcing their value as functional, noninvasive biomarkers of brain injury.

Conclusions: Noninvasive measures of sleep quantity and quality reliably detect early TBI-induced changes and accurately classify injury type in mice. These results support the use of sleep-wake metrics as behavioral biomarkers of brain injury and demonstrate their promise as scalable, translational tools for early diagnosis in both research and clinical settings.

Non-noxious cooling stimulation of trunk skin inhibits melatonin secretion from the pineal gland in urethane-anesthetized rats

N. Watanabe¹, M. Moriya¹, H. Hotta¹

¹Tokyo Metropolitan Institute for Geriatrics and Gerontology, Department of Autonomic Neuroscience, Tokyo, Japan

Introduction: Melatonin, secreted from the pineal gland primarily under sympathetic control, plays key roles in regulating the sleep-wake cycle and other physiological functions. Thermal stimulation of the skin can elicit reflexive autonomic nerve responses and thereby influence visceral and endocrine functions. Although photostimulation is a well-known regulator of melatonin secretion, the effect of skin thermal stimulation remains unclear. In this study, we investigated whether non-noxious cooling stimulation of the skin alters melatonin secretion from the pineal gland.

Materials and methods: The experiments were conducted on Fischer rats (5-8 months of age) that were housed with a 12-h light-dark cycle (lights on at 8:00 h). Animals were anesthetized with urethane, artificially ventilated, and maintained at a constant rectal temperature using heating pad and lamp during experiment. Using *in vivo* microdialysis, pineal perfusate was collected every 20 min and melatonin concentrations were measured using ELISA. Perfusate collection was completed during the light phase. Intermittent cooling stimulation was applied to the trunk skin using a Peltier-based contact thermode by alternating the temperature between 30 °C and 15 °C (15 °C/s) for 20 min. To assess the involvement of the cervical sympathetic nerves in the effect of skin stimulation, bilateral cervical sympathetic trunks were surgically transected.

Results: Without cooling stimulation, melatonin concentrations in the pineal perfusate remained stable over 100 min. Cooling stimulation had no effect on melatonin concentrations during application, however, reduced melatonin for 40 min after the stimulation ended. This suppression was abolished in rats with bilateral cervical sympathetic nerve transection.

Conclusions: These findings suggest that non-noxious cooling stimulation of the skin suppresses pineal melatonin secretion via cervical sympathetic nerves. This transient suppression may offer novel insights into non-photoc modulation of melatonin secretion.

Pilot Study: Severity of Cyclical Intermittent Hypoxia Varies Lung Adenocarcinoma Progression via Different Mechanisms

D. Lim¹, E. Kim¹, E. Kim¹, S. Guo¹, M. Wangpaichitr², C.-B. Chen²

¹Miami VA, Medicine, Miami, United States, ²University of Pennsylvania, Philadelphia, United States

Introduction: Background

Systemic cyclical intermittent hypoxia (CIH) is a major underlying pathological consequence of OSA, and severe CIH is associated with increased cancer incidence and mortality. However, the mechanisms of how mild, moderate and severe CIH might affect natural cancer progression is not known.

Objective

To determine whether CIH reduces the "killing" immune response or increases the "suppression" immune response in the setting of cancer, compared to Local Tumor Hypoxia (LTH).

To determine whether CIH increases angiogenesis in potential metastatic sites such as the brain.

Materials and methods: Mouse model of CIH: The Hycon system (Figure 1) was developed with the engineer to mirror patients with OSA (Figure 2A) specifically the SpO₂ (Figure 2B) desaturation-resaturation time.

Importance of studying mild, moderate and severe CIH: We analyzed data from 4 public databases (Figure 2C) and most patients have mild OSA, so it is important to study all severities.

Mice with lung adenocarcinoma exposed to mild, moderate and severe CIH underwent uCT scans to calculate tumor rate increase/day (Figure 2D) as well as survival compared to Sham (room air, which represents LTH).

Mice without cancer exposed to moderate (CIH10) and severe (CIH5) CIH to calculate angiogenesis in the hippocampus (Figure 3B-D) and genes including TIE2, VEGFA, HIF1 α , and GLUT1 (Figure 3E).

Mice with lung adenocarcinoma exposed to severe CIH (CIH6) compared to Sham were harvested at early-stage cancer and evaluated for immune cells (Figure 4) in left lung (primary tumor), right lung (no sign of metastases yet), bone marrow, thymus, spleen and mediastinal lymph nodes.

Results: 1. In the setting of lung cancer, severe (CIH6) decreases survival and mice have larger metastatic tumors; moderate (CIH10) increases survival and mice have larger primary tumors; mild (CIH15) has no effect on survival, has the lowest combined tumor volume; LTH increases "Suppression" immune cells.

2. In the setting of no lung cancer, CIH (1) increases angiogenesis and increases VEGFA and GLUT1 transporters; there is no increase in HIF1 α ; (2) decreases "Killing" immune cells.

Conclusions: 1. CIH is a likely underlying pathophysiology that effects cancer progression in a mouse model of lung adenocarcinoma.

2. Implication for the sleep field: More attention should be placed on evaluating systemic intermittent hypoxia in the setting of lung cancer.

Preliminary analysis of intestinal flora characteristics in children with obstructive sleep apnea hypopnea syndrome

Y. Wang¹, Z. Wang¹, M. Lv¹, Z. Zhang¹, F. Wang¹, S. Wang¹

¹Children's hospital of Soochow University, Respiratory medicine, Suzhou, China

Introduction: Obstructive sleep apnea-hypopnea syndrome (OSAHS) has attracted increasing attention due to its high prevalence and serious long-term complications. A growing number of studies demonstrate a link between OSAHS and gut microbiota. We speculate that OSAHS can probably lead to changes in the abundance and composition of gut microbiota.

Materials and methods: Children diagnosed with primary snoring and OSAHS by PSG were enrolled in the study group. Nonsnoring children undergoing elective surgery were selected as the control group. Stool, sleep monitoring data and medical history data were collected. 16S rRNA high-throughput sequencing technology was used to analyze the composition of the intestinal flora.

Results: A total of 62 OSAHS patients (42 mild OSAHS and 20 moderate to severe OSAHS), 16 primary snoring patients and 46 controls were enrolled in this study. There were differences in some intestinal flora at the phylum, class, order, family, genus and species levels between the control group and OSAHS group. The predictive model for OSAHS diagnosis established by the receiver operating characteristic (ROC) curve showed that the area under the curve (AUC) of Firmicutes and the abundance ratio between Firmicutes and Bacteroidetes (F/B) were more than 50%. At the genus level, Akkermansia, Dialister, Escherichia-Shigella and Faecalibacterium was correlated with some PSG indicators.

Conclusions: The intestinal flora of children with OSAHS is slightly different at the phylum, class, order, family, genus and species levels. The F/B and Firmicutes abundance detection have auxiliary value for the diagnosis of OSAHS. At the genus level, some gut microbiota were correlated with PSG indicators.

Acknowledgments: We thank Jun Han and Nina Xiong for their contributions to full-night polysomnography in this study.

Reducing complement activation during sleep deprivation yields cognitive improvement by dexmedetomidine

Q. Zhai¹

¹The First Affiliated Hospital of Xi'an Jiaotong University, Department of Anaesthesiology, Xi'an, China

Introduction: Sleep loss and its associated conditions (e.g. cognitive deficits) represent a large societal burden, but the underlying mechanisms of these cognitive deficits remain unknown.

Neuronal synapse formation and pruning, which are critical for cognitive function, are regulated by glia during sleep. Microglia were reported to modulate synaptic connectivity in the healthy and diseased brain. Complement activation was reported to aberrantly stimulate synapse loss in demyelinating disease. Recent studies have revealed that synaptic function is enhanced during sleep, and microglia appear to selectively eliminate opsonised synapses through phagocytosis during each sleep phase. However, the causal relationship between the complement system and synaptic function during sleep deprivation and the underlying molecular mechanisms remain unknown.

Dexmedetomidine (DEX) is a highly selective agonist of α_2 adrenoceptors located both presynaptically and postsynaptically in the brain and peripheral tissues. It is commonly used clinically for sedation in the intensive care unit and as an adjunct to general anaesthesia in the operating room. DEX was found to induce a state mimicking natural sleep, and modestly improve subjective sleep quality in patients with chronic intractable insomnia. Previous studies have indicated that sleep loss can reduce spine density and attenuate synaptic efficacy, reduce the synthesis of proteins associated with neuroplasticity in the hippocampus, and impair hippocampal neurogenesis. Although DEX was reported to ameliorate the incidence of delirium and postoperative cognitive dysfunction, the effect of DEX on cognitive deficits induced by sleep deprivation remains unknown.

In this study, we aimed to explore whether DEX ameliorates cognitive deficits in mice subjected to chronic sleep restriction (CSR) and to explore the underlying mechanisms with a focus on complement proteins (C1q, C3, and C3aR), microglial activation, and associated synaptic and molecular changes.

Materials and methods: C57BL/6 mice were subjected to chronic sleep restriction (CSR) for 20 h (5 pm-1 pm the next day) daily for 7 days, and cognitive tests were subsequently carried out. The neuromolecular and cellular changes that occurred in the presence and absence of DEX (100 $\mu\text{g kg}^{-1}$, i.v., at 1 pm and 3 pm every day) were also investigated.

Results: CSR mice displayed a decline in learning and memory by 12% ($P<0.05$) in the Y-maze and by 18% ($P<0.01$) in the novel object recognition test; these changes were associated with increases in microglial activation, CD68+ microglial phagosome counts, astrocyte-derived complement C3 secretion, and microglial C3a receptor expression (all $P<0.05$). Synapse elimination, as indicated by a 66% decrease in synaptophysin expression ($P=0.0004$) and a 45% decrease in postsynaptic density protein-95 expression ($P=0.0003$), was associated with the occurrence of cognitive deficits. DEX activated astrocytic α_{2A} adrenoceptors and inhibited astrocytic complement C3 release to attenuate synapse elimination through microglial phagocytosis. DEX restored synaptic connections and reversed cognitive deficits induced by CSR.

Conclusions: The results demonstrate that complement pathway activation associated with synapse elimination contributes to sleep loss-related cognitive deficits and that dexmedetomidine protects against sleep deprivation-induced complement activation. Dexmedetomidine holds potential for preventing cognitive deficits associated with sleep loss, which warrants further study.

Acknowledgments: We would like to acknowledge the support provided by Feng Zhu for this project.

Relationship between circadian sleep parameters and self-perceived quality of life in patients on the liver transplant waiting list

L. Martínez Alarcón¹, M. Jover², J. Sáez³, P. Ramírez Romero⁴, G. Ramis Vidal⁵

¹Hospital Clínico Universitario Virgen de la Arrixaca, UDICA, Murcia, Spain, ²Instituto Murciano de Investigación en Biomedicina (IMIB), El Palmar-Murcia, Spain, ³Hospital Clínico Universitario Virgen de la Arrixaca, Intensive Care Unit, Murcia, Spain, ⁴Hospital Clínico Universitario Virgen de la Arrixaca, Surgery Service, Murcia, Spain, ⁵Universidad de Murcia, Departamento de Producción Animal, Murcia, Spain

Introduction: Sleep should be one of the health factors studied in patients on the waiting list for liver transplantation, but it is not usually given much attention. On the other hand, there are different ways of assessing sleep; on the one hand, self-perceived quality questionnaires such as the Pittsburgh or Epworth scales, and on the other hand, objective methods such as actigraphy or polysomnography. In this study, we compared self-perceived quality using the aforementioned questionnaires with the parameters obtained through actigraphy.

Materials and methods: Fifty patients on the waiting list for liver transplantation at the Virgen de la Arrixaca University Hospital (Murcia, Spain) completed the Pittsburgh questionnaire, which ultimately provide an index called PSQI, which reaches 21 points for poor sleep quality; the Epworth questionnaire (EI), which provides an indication of daytime sleepiness, and the Munich questionnaire. On the other hand, the parameters were monitored using a Kronowise K6 device and the data were analysed using Kronowise 100 software (both from Kronohealth, Murcia, Spain). The patients wore the device on their non-dominant wrist for at least 7 days before the transplant. Forty-two parameters of sleep quality or circadian rhythm were calculated.

Results: Correlations have been found between the PSQI and various parameters such as WASO ($r=0.396$; $P=0.006$), sleep efficiency ($r=-0.417$; $P=0.004$), total time in bed ($r=0.438$; $P=0.002$), average activity during sleep ($r=0.415$; $P=0.004$), total light ($r=0.357$; $P=0.014$) and blue light ($r=0.376$; $P=0.009$) received during sleep, nap frequency ($r=0.440$; $P=0.002$) and nap duration ($r=0.355$; $P=0.014$). The overall score on the Epworth questionnaire correlated with light received during sleep ($r=0.431$, $P=0.002$), blue light received during sleep ($r=0.425$; $P=0.003$), total light ($r=0.463$; $P=0.001$) and blue light received 2 hours before sleep ($r=0.377$; $P=0.009$). The Munich questionnaire correlated the time of waking during the week with blue light received 2 hours before sleep ($r=0.325$; $P=0.034$), the time of waking with total light received during the 2 hours before sleep, and the reported latency with the objective onset of sleep ($r=0.443$; $P=0.008$) and with the average temperature 2 hours before sleep ($r=0.349$; $P=0.043$).

Conclusions: It seems clear that self-perception of sleep correlates significantly with numerous objective sleep parameters, especially the PSQI, which correlates with up to 14 objective sleep parameters. Interestingly, the Epworth daytime sleepiness index is significantly related to the amount of light the patient receives two hours before bedtime and during sleep, which marks a point of intervention for sleep quality in these patients to reduce such sleepiness. These data corroborate that initial assessment of patients using self-perception questionnaires, in the absence of objective data such as actigraphy or polysomnography, is useful in evaluating sleep health in patients on the waiting list for liver transplantation.

Acknowledgments: The authors would like to thank the entire liver transplant team for granting access to patients. And, of course, the patients who participated in the study.

Restoring proteostasis rescues cognitive performance and improves sleep in Alzheimer's disease and Down syndrome mouse models

W. Duncan¹, K. Sengupta¹, E. Strus¹, P. Fenik¹, N. Naidoo¹

¹Perelman School of Medicine, University of Pennsylvania, Sleep Medicine, Philadelphia, United States

Introduction: Cognitive impairment and sleep disruption are hallmark features of both Alzheimer's disease (AD) and Down syndrome (DS). A shared molecular contributor is the amyloid precursor protein (APP), implicated in familial AD and triplicated in DS. APP overexpression leads to elevated amyloid- β ($A\beta$) production and proteotoxic stress, which contribute to early AD pathology, particularly in individuals with DS. Given that AD pathology involves misfolded protein aggregates, proteostasis pathways—including the unfolded protein response (UPR)—are key modulators of disease progression. Impaired proteostasis and aberrant UPR activation are observed in AD, sleep disruption, and DS. Previous work has shown that alleviating proteostatic stress with chaperones improves cognition and sleep in aged *Drosophila* and mice. Based on these findings, we hypothesized that restoring proteostasis through chaperone therapy would improve cognitive and sleep outcomes in mouse models of AD and DS.

Materials and methods: AD models used in this study included transgenic 3xTg and knock-in APP^{NLGF} mice. DS models included Ts65Dn and TsY66ah mice. Mice received either intraperitoneal (I.P.) injections of the chemical chaperone 4-phenylbutyrate (PBA) weekly for 10–12 weeks or hippocampal

injections of AAV-mediated BiP (an endogenous ER chaperone). Control groups received saline or AAV-mCherry. Cognitive function was assessed using the Spatial Object Recognition (SOR), Y-maze, and Novel Object Recognition (NOR) tasks. A subset of mice were instrumented for EEG recordings and sleep assessment. Brain tissues were collected post-perfusion for immunohistochemistry and biochemical analysis.

Results: PBA treatment improved both short- and long-term memory in hippocampal-dependent tasks in TsY66ah and Ts65Dn mice. In the NOR test, PBA-treated TsY66ah mice significantly outperformed vehicle-treated controls. Similar cognitive benefits were observed in both AD models. AAV-mediated BiP expression in the hippocampus led to significant improvements in spatial memory across both male and female AD model mice. However, only female 3xTg mice showed enhanced working memory following BiP overexpression. Preliminary sleep analyses revealed that PBA treatment in APP_{NLGF} mice increased NREM sleep and improved sleep and wake consolidation. Ongoing analysis of sleep data from 3xTg and Ts65Dn mice will further elucidate these effects. Molecular analyses demonstrated that both PBA and BiP attenuate PERK activation and enhance protein synthesis, processes critical for learning and memory.

Conclusions: Pharmacological and genetic restoration of proteostasis via chaperone administration significantly improves cognitive performance in AD and DS mouse models. Early findings also suggest beneficial effects on sleep architecture. These results highlight the therapeutic potential of targeting proteostasis mechanisms to alleviate cognitive and sleep dysfunction in neurodegenerative and neurodevelopmental disorders such as AD and DS.

Roll, Pitch and Yawn: When Rotational Vestibular Stimulation Modulates Sleep Macroarchitecture

A. Subramaniam¹, A. Eberhard-Moscicka^{2,1}, M. Ertl^{1,3,4}, F. Mast¹

¹University of Bern, Department of Psychology, Bern, Switzerland, ²University of Bern, Gerontology and Rehabilitation, ARTORG Center, Bern, Switzerland, ³Luzerner Kantonsspital, Clinic for Neurology and Neurorehabilitation, Lucerne, Switzerland, ⁴University of Lucerne, Faculty of Behavioural Sciences and Psychology, Lucerne, Switzerland

Introduction: Rocking devices are receiving increasing attention as a non-pharmacological modulator of sleep. In rodent models, changes in sleep architecture were attributed primarily to vestibular input, rather than proprioceptive or visual cues. While these findings suggest a key role for vestibular stimulation, studies in humans yielded contradictory results, particularly concerning sleep microarchitecture. To date, most human studies focused on manipulating motion frequency or stimulation duration, with little attention given to the motion pattern itself. Despite the vestibular system's sensitivity to rotational (angular) and translational (linear) acceleration, prior work primarily focused on translational stimulation. To extend this work, we examined whether passive rotational vestibular stimulation could modulate human sleep macro- and microarchitecture.

Materials and methods: Forty-one healthy participants (mean age = 23.2, range 18-36) completed four consecutive overnight sleep sessions in a within-subject, randomized design: one adaptation night and one stationary baseline night and two motion nights with rotational vestibular stimulation on a motion platform that generated sinusoidal movements at 12.34°/s² - above the perception threshold - to ensure vestibular engagement, switching between yaw, pitch, and roll every 3 minutes. Sleep was recorded using a 256-channel EEG over an 8-hour 10-minute period each night.

Results: Condition effects were assessed using linear mixed-effects models (LMMs), with significant results followed by post-hoc *t*-tests. For N2, the LMM revealed a significant main effect of motion ($F(2, 75.766) = 5.985, p = .004, R^2 = .43$), with post-hoc comparisons confirming significantly higher proportion of N2 sleep during both the first ($t(74.5) = 2.943, p = .012$) and the second motion night ($t(75.9) = 2.995, p = .01$), compared to the stationary night. We found no main effect for sleep onset latency, but a significantly lower arousal index in the second motion compared to the stationary night ($t(74.9) = 2.48, p = .04$). Furthermore, a post-hoc comparison indicated significantly higher REM in the stationary night compared to the second motion night ($t(77) = 3.501, p = .002$). Proportions of wake, N1, and N3 did not significantly differ between the stationary and the second motion night.

Conclusions: Rotational passive vestibular stimulation increased N2 sleep without impairing sleep continuity. Effects were most consistent after a night of adapting to the motion. The observed gain in N2 may reflect engagement of thalamocortical circuits involved in sensory processing and sleep spindle

generation, potentially at the cost of REM. The ongoing analyses will examine microarchitectural markers such as sleep spindles and slow oscillations. These findings highlight the potential of rotational vestibular stimulation as a novel, non-invasive method to support sleep quality.

Acknowledgments: Technology Platform of the Human Science Faculty and the IRC Decoding Sleep of the University of Bern.

Shared genetic architecture between sleep apnea related sleep traits and cardiometabolic diseases

S. Jian¹, H. Ouyang¹, B. Tang², X. Su³, M. Yi¹, Y. Zhang³

¹Central South University, School of Life Sciences, Changsha, China, ²Central South University, Department of Neurology, Xiangya Hospital, Changsha, China, ³Central South University, Department of Respiratory & Sleep Medicine, Xiangya Hospital, Changsha, China

Introduction: Sleep apnea related sleep traits show high comorbidities with cardiometabolic diseases (CMDs). Although genetic relationships between them have been widely reported, it is still unknown whether a small number of loci or the whole genome would be responsible for the overall genetic association. Genome-wide association studies (GWAS) have identified single nucleotide polymorphisms (SNPs) associated with either sleep apnea or cardiometabolic diseases. These findings provide a foundation for subsequent analysis of pleiotropic SNPs exhibiting cross-traits associations, which might aid in the understanding of potential shared genetic architectures underlying these comorbid conditions. The purpose of this study was to find shared genomic regions, genes, and pathways between sleep apnea and associated sleep traits (insomnia, sleepiness and snoring) and seven cardiometabolic diseases (atrial fibrillation, coronary artery disease, heart failure, hypertension, stroke, type 2 diabetes and venous thromboembolism).

Materials and methods: Using GWAS summary statistics from publicly available data sources, we calculated genetic correlation between two traits using linkage disequilibrium (LD) score regression (LDSC) and high-definition likelihood (HDL) analysis. Furthermore, PLACO, a pleiotropic analysis under a composite null hypothesis, was used to identify genetic variants that influence risk of two traits. And causal variants were identified by FM-summary, a Bayesian fine-mapping method. Colocalized association signals between trait pairs or among multiple traits were determined by the R packages coloc or HyprColoc. ANNOVAR program were used to identify nearest genes of causal variants and MAGMA was used to detect potential pleiotropic genes. Phenotype enrichment analysis and over-representation enrichment analysis were performed to characterize the phenotype and pathway specificity of these pleiotropic genes. Two-sample and multivariable mendelian randomization (MR) were used to identify causal associations between these traits and potential factors mediating causal relationships.

Results: Among 28 trait pairs between four sleep traits and seven cardiometabolic traits, 23 showed significant genetic connections. Pleiotropic analysis identified 720 (678 unique) pleiotropic causal SNPs in 23 trait pairs, with 92 (85 unique) colocalized loci. 73 nearest genes of colocalized loci were annotated with ANNOVAR program and gene-based analysis verified 48 of them. Shared genes were highly enriched in aging, liver/biliary system, muscle and endocrine/exocrine gland phenotypes. Furthermore, pathway enrichment analysis highlighted biological pathways including Cushing syndrome, an endocrine and metabolic disease characterized by too much cortisol in the body, and signal transduction like cAMP, Rap1 and cGMP-PKG signaling pathway. Vertical pleiotropy was further demonstrated across 14 trait pairs using MR analysis. Adjusting triglyceride, total cholesterol and glycemic traits, genetically predicted snoring was associated with higher risk of atrial fibrillation and heart failure. And genetically predicted sleep apnea was independently related with heart failure and type 2 diabetes, after adjusting blood pressure. Particularly, some pleiotropic loci were identified to be shared among multiple traits, such as 3q27.1 (ECE2), 4p12 (GNPDA2) and 17q21.31 (ACBD4).

Conclusions: This study not only supported the observed comorbidity of sleep apnea related sleep traits and CMDs, but also indicated shared genetic determinants underlying these trait pairs, might facilitating treatment and management of comorbid sleep apnea and CMDs.

SIMILARITIES AND DIFFERENCES BETWEEN FATIGUE AND DROWSINESS

N. Limba¹, Z. Markovičs², M. Erins²

¹Rīga Stradiņš University, Department of Human Physiology and Biochemistry, Riga, Latvia, ²Rīga Technical University, Faculty of Computer Science, Information Technology and Energy, Riga, Latvia

Introduction: In addressing the issue of human fatigue and reduced work capacity, particularly with the aim of reducing the number of accidents in specific application areas, new uncertainties arise regarding concepts such as fatigue and drowsiness. These states are not sufficiently studied, and there is no answer to the question of whether they are identical. If not, what characteristics are different and which are similar? It is clear only that drowsiness is much more dangerous than fatigue, as its end state is falling asleep, which leads to accidents. The aim of the study is to develop a monitoring system to determine the severity of these states.

Materials and methods: To solve this problem, in addition to physiological experiments in laboratory conditions, it is proposed to analyze the topological functional models (TFM) of these states, developed by scientists at Riga Technical University and used in computerized disease diagnostics tasks. TFM is a directed graph consisting of cause-effect chains, which in turn consist of vertices and directed arcs. The vertices represent functional parameters, and the arcs represent the links between them.

Results: The TFM created by the expert team, with 69 vertices and 74 arcs for the mental component of fatigue and drowsiness, provides several significant results. Mental fatigue is associated with energy imbalance parameters, while drowsiness is related to changes in nervous system functions. The sets of parameters that cause and maintain fatigue or drowsiness are also different. Drowsiness can depend on fatigue, but not vice versa. Drowsiness can occur without fatigue and fatigue without drowsiness. Severe fatigue can even lead to insomnia.

Conclusions: Fatigue, including its mental component, and drowsiness are not identical concepts, but their parameters and links can overlap. It has been confirmed that drowsiness is more dangerous than fatigue in many application areas. The parameters of drowsiness are easier to determine than those of fatigue, especially for determining the extreme state of drowsiness, i.e., falling asleep. Fatigue does not have such a clearly defined extreme state. The results of the study have made it possible to develop a monitoring system that not only determines the level of drowsiness during work but also, with a preemptive alert system, prevents the final state of drowsiness – falling asleep.

Sleep architectural changes during recurrent cycles of sleep restriction: comparing stable and variable short sleep schedules

T.B. Koa¹, J.L. Ong¹, J.C. Lo¹

¹National University of Singapore, Centre for Sleep and Cognition and Human Potential Translational Research Programme, Yong Loo Lin School of Medicine, Singapore, Singapore

Introduction: While several studies have investigated the effects of sleep restriction on sleep architecture, they have largely been limited to a single cycle of sleep loss and recovery and do not address the effects of re-exposure to subsequent cycles of sleep restriction. Sleep restriction implemented in previous studies are typically also evenly distributed across nights, limiting the generalisability of their findings to short sleep schedules with more night-to-night variability in sleep duration. To address these limitations, we tracked sleep architecture changes over recurrent cycles of “weekday” sleep restriction and “weekend” recovery in young adults, and investigated whether short sleep schedules with differing sleep duration variability on weekdays would lead to different sleep architectural responses.

Materials and methods: Fifty-two healthy young adults (25 males, age: 21-28) participated in this 15-night laboratory-based study. They were randomly assigned to three sleep schedules: stable short sleep, variable short sleep, or control. The participants started with two baseline nights of 8-h time-in-bed (TIB), followed by two cycles of “weekday” sleep opportunity manipulation and “weekend” recovery (8-h TIB). For each manipulation period, the control group received 8-h TIBs nightly, the stable short sleep group received 6-h TIBs nightly, while the variable short sleep group received 8-h, 4-h, 8-h, 4-h, and 6-h TIBs from the first to the fifth night (thereby receiving the same total TIB of 30 h as the stable short sleep group across the five nights). Participants kept to the same wake times throughout the protocol. Polysomnography was conducted every night. Group and night effects on sleep parameters (TIB, total sleep time [TST], N1, N2, slow wave sleep [SWS], rapid eye movement

[REM], sleep efficiency, wake after sleep onset [WASO], N2 latency and mean slow wave activity [SWA]) were analysed using mixed models. Average values across each period of sleep manipulation and recovery were also derived and compared using mixed models.

Results: Significant group x night interactions were found for all sleep parameters ($p < .03$). For both short sleep schedules, changes in sleep architecture resulting from sleep restriction returned to baseline levels by the first or second recovery night, and were mostly similar between corresponding nights of the first and second sleep restriction periods. There were no significant differences observed between the two short sleep groups for any of the sleep parameters averaged across each sleep restriction or recovery period ($p > .25$).

Conclusions: The similar sleep architectural responses observed in the two sleep restriction periods suggest that in young adults, sleep architecture does not adapt to recurrent weeks of moderate partial sleep loss. Furthermore, unlike with some neurobehavioural functions, such sleep patterns did not have compounding effects on sleep architecture. Additionally, overall, increasing night-to-night variability in sleep duration did not have much additional impact on sleep physiological responses relative to a stable short sleep schedule, suggesting that sleep duration variability may be a negligible factor for human sleep physiology as compared to overall sleep duration.

Sleep depth is reflected in the spectral characteristics of the human wrist actigraphy

C. G. Horváth¹, B. Maczák², S. Kim¹, K.P. Komáromi², G. Vadai², R. Bódizs¹

¹Semmelweis University, Institute of Behavioral Sciences, Budapest, Hungary, ²University of Szeged, Department of Technical Informatics, Szeged, Hungary

Introduction: Previous studies have demonstrated that the spectral characteristics of human activity show a power-law ($1/f^\alpha$) trend both during wakefulness (with $\alpha \sim 1$) and sleep (with α below 1) with different spectral exponents. However, a recent finding proposes that preprocessing methods of the acceleration signal and deterministic measurement errors can substantially influence the results of such analyses. Furthermore, to our best knowledge, there is no study on whether analysing human activity provides an insight about sleep pressure. The present study aims to fill this gap by comparing the slope (α exponents) of the power spectral density (PSD) derived from calibrated triaxial raw acceleration, unfiltered magnitude of acceleration (UFM), magnitude of acceleration after separating the gravitational component (UFNM, and ENMO), and minutely activity data derived from them using traditional methods (e.g., PIM). These comparisons are made between sleep and wakefulness on both weekdays and weekends, as well as between habitual and sleep-deprived sleep.

Materials and methods: The sample consists of two datasets with $N=35$ (D1 dataset) and $N=65$ (D2 dataset) healthy participants, both containing raw triaxial acceleration signals derived from the wrist. D1 is a 35-hour long sleep deprivation dataset including acceleration signals during the participants' baseline and recovery sleep periods. D2 contains 4-7-day wrist actigraphy recordings collected during habitual sleep and wake periods including at least one weekend sleep period. The PSD is calculated using the Discrete Fourier Transform, and spectral slope (α exponent) is estimated by applying least squares linear regression to log-transformed spectra in the 10^{-4} to 10^{-2} Hz frequency range.

Results: Our results show that the spectral exponent of calibrated wrist data derived from the three axes (UFX, UFY, UFZ) significantly differed between sleep and wakefulness, with a steeper slope observed during sleep (e.g. UFY: $t=29.8$, $p<10^{-6}$). Furthermore, increased sleep depth due to sleep deprivation has a significant effect on UFM-derived spectral slope resulting in steeper slope in recovery sleep. However, there is no significant difference between weekend and weekday sleep slope.

Conclusions: These preliminary results suggest that sleep depth may be inferred from the spectral characteristics of acceleration signals, particularly the slope of the power spectral density. While the spectral slope derived from triaxial raw acceleration shows a clear distinction between sleep and wakefulness, the spectral slope derived from calibrated UFM reliably reflects changes in sleep depth due to sleep deprivation. However, further investigation is needed to validate and refine this approach, as both calibration and the actigraphic methodology used largely influence the PSD slope during sleep. Furthermore, this metric responded only to substantial interventions, like sleep deprivation, and did not capture differences between weekday and weekend sleep.

Sleep fragmentation and mental health: understanding anxiety and depression upon experimental sleep modulation

D. Hrnčić¹, Z. Grubac¹, N. Sutulovic¹, D. Jerotic¹, E. Djuric¹, N. Puskas¹, M. Veskovc¹, D. Mladenovic¹, N. Ezgin¹, A. Grozdic Miladinovic¹, M. Sikiras¹, Y. Dodurga², T. Simic³, A. Rasic-Markovic¹, O. Stanojlovic¹

Introduction: Sleep is essential for mental health and disruption of sleep quality are related to mental health, emotional status, cognitive performances, as well as somatic health status. Obstructive sleep apnea (OSA), a prevalent sleep breathing disorder, is accompanied intermittent hypoxia and sleep fragmentation. Depression and anxiety has been more prevalent in OSA patients comparing to general population. The specific impact of sleep fragmentation, without reduced total sleep time, remains under-explored in this context related on mental health. Therefore, the aim of our study was to investigate the effects of sleep fragmentation mimicking OSA on depression- and anxiety like behavior, as well as on redox status and hippocampal plasticity in a rat model.

Materials and methods: Experiments were performed using adult male Wistar albino rats and were approved by relevant ethical committees. Rats were randomized into three groups (n=8 in each): sleep fragmentation (SF), activity control (AC) and treadmill control (TC). SF was induced via treadmill protocol (30sON/90sOFF) during the first 6h of the light phase for 14 consecutive days. Behavioral assessments were performed on days 1, 7 and 14 using Forced Swimming Test (FST) to explore depression – like behavior; Elevated Plus Maze (EPM) and Light Dark Box (LDB) tests to evaluate anxiety – like behavior. Redox status via oxidative stress markers and anti-oxidative enzyme activity were determined in the hippocampus via ELISA. Immunohistochemically analysis of hippocampal neurogenesis (DCX, Ki67) and astrocyte activity (GFAP) was performed.

Results: Sleep fragmentation significantly ($p<0.05$) increased malondialdehyde level (MDA), while reducing ($p<0.05$) the activity of superoxide dismutase and glutathione peroxidase in the hippocampus compared to controls. In the FST, SF rats showed increased floating and reduced swimming and struggling time, indicating depression –like behavior which was duration dependent and correlated with indicators of oxidative stress in the hippocampus. In the EPM and LD test, significantly decreased ($p<0.05$) number of transitions and time in the open arms and light compartment, respectively, were recorded in rats from SF group comparing to controls. Despite behavioral and redox status changes, immunohistochemistry did not reveal any significant difference in DCX, Ki67 or GFAP expression in the dentate gyrus among the groups ($p>0.05$).

Conclusions: Sleep fragmentation, mimicking severe OSA without reducing sleep duration, induced behavioral changes in rats which pattern is consistent with depressive-like and anxiety-like states. These effects are probably mediated by oxidative stress, rather than changes in hippocampal neurogenesis and astrocyte activation. Our findings indicate mechanistic link between sleep fragmentation and mental health and support the hypothesis that disrupted sleep architecture alone may contribute to psychiatric comorbidities in OSA.

Sleep in South African ambulance emergency care personnel

L. Motaung¹, K. Scheuermaier¹, J. Davimes¹

¹University of the Witwatersrand, School of Biomedical Sciences, Johannesburg, South Africa

Introduction: Ambulance emergency care personnel (ECPs) are a vital frontline workforce who operate in rotating shifts and are subjected to long and challenging working hours with high levels of trauma and stress. Shiftwork can cause both mental and physical health problems with sleep disturbances being especially prevalent. Those disturbances include circadian misalignment, poor sleep quality, increased sleepiness, daytime dysfunction, burnout and fatigue. Very limited research has investigated ECP sleep in settings where resources are limited and trauma exposure is above average, like that within South Africa. In this study, we investigated sleep quality in ECPs, and examined the effects of sex and shift (night vs day vs nonwork) on sleep.

Materials and methods: We collected the Patient Health Questionnaire-2 (PHQ-2), Pittsburgh Sleep Quality Index (PSQI), and Shift Work Disorder Questionnaire (SWDQ). Participants were given sleep and work diaries that included daily stress and sleepiness scores, as well as an actigraphy device (Actigraph wGT3X-BT). Two shift structures were investigated including the '4on4off' and 'long/short week' shift, both typical within South Africa and frontline professions globally.

Results: A total of 60 ambulance ECPs (33.6 ± 8.4 years; 58.5% male; 8.7 ± 6.8 years of shift work experience; 57% 'long/short week' shift) participated in the questionnaire component of the study, of which 43 (66%) also completed the actigraphy component. Mean PHQ-2 score was 1.50 ± 1.4 , with 21.5% ($n=14$) at risk for major depressive disorder. Mean PSQI total score was 7.8 ± 3.7 , with 70.8% ($n=46$) classified as poor sleepers ($PSQI > 5$). Poor sleepers had higher PHQ-2 depression risk scores ($p < 0.05$). Risk for SWD was present in 40% ($n=24$) and was associated with higher PHQ-2 depression risk scores and PSQI poor sleep scores ($p < 0.05$). Female ECPs had significantly higher global PSQI scores than males ($p < 0.05$) and were more likely to be poor sleepers (92.6 vs 55.3%, $p = 0.001$) even when adjusting for age and shift type (β (SE) = 1.92 (0.89); $p = 0.036$). Female ECPs had higher odds of reporting a high risk for developing SWD compared to males (OR = 3.69, 95% Wald CI 1.09-12.49). No significant differences were found between shift structures for all questionnaire variables. Using actigraphy, we found longer total sleep time on nonwork days (7.4 ± 1.9 hours), compared to post-day shifts (6.9 ± 1.8), and post-night shifts (4.2 ± 2.0). Additionally, wake after sleep onset (WASO) was high overall: nonwork, 71 ± 46 mins; post-day shift, 61 ± 39 ; post-night shift, 37 ± 36 . WASO was significantly higher for participants working the 'long/short week' compared to the '4on4off' shift for sleep on nonwork days and post-day shifts ($p < 0.05$).

Conclusions: Sleep quality, measured both objectively and through self-reported sleep questionnaires, is poor in South African ambulance ECPs. Sleep quality was poorer in females and after night shifts and was associated with higher depression symptoms. This study also suggests that the 'long/short week' shift structure may be more detrimental than the '4on4off'. Further investigation and potential intervention are required to reduce the effects on such a critical, yet vulnerable group of frontline workers.

Acknowledgments: The authors wish to thank all the participants and the South African National Research Foundation for funding.

Sleep pressure causes birds to trade asymmetric for symmetric sleep

D. Martinez-Gonzalez¹, S.J. van Hasselt², G.-J. Mekenkamp², A.L. Vyssotski³, S. Verhulst², G.J.L. Beckers⁴, P. Meerlo², N.C. Rattenborg¹

Introduction: Sleep is a dangerous part of an animal's life. Nonetheless, following sleep loss, mammals and birds sleep longer and deeper, as reflected by increased EEG slow-wave activity during NREM sleep. Stimulating a brain region during wakefulness also causes that region to sleep deeper afterwards, indicating that NREM sleep is a local, use-dependent, homeostatically-regulated process. Birds and some marine mammals can keep one eye open during NREM sleep. Unilateral eye closure is associated with lighter sleep or wakefulness in the hemisphere opposite the open eye – states called asymmetric and unihemispheric NREM sleep, respectively. Closure of both eyes is associated with symmetric NREM or REM sleep. Birds sleep with one eye open to mitigate the simultaneous need for sleep and ecological demands for wakefulness. However, as sleeping with one hemisphere at a time doubles the time required for both hemispheres to fulfill their need for NREM sleep, increased sleep pressure might cause birds to engage in symmetric sleep at the expense of asymmetric sleep. Using high-density EEG recordings of European jackdaws, we investigated intra- and inter-hemispheric asymmetries during normal sleep and following sleep deprivation.

Materials and methods: Epidural electroencephalogram electrodes were surgically implanted in hand-raised, 10-month-old jackdaws ($N=9$). The 28 electrodes spanned the dorsal surface of both cerebral hemispheres. A head-mounted data logger recorded the signals at 250 Hz. A 3-axis accelerometer recorded changes in head position related to wakefulness (frequent, rapid movements) and REM sleep

(head still or dropping). The 3 days recordings (12:12 photoperiod, 21°C, food and water *ad libitum*) consisted of a baseline day, 4-or 8-h sleep deprivation starting at lights out, and an additional recovery day. The recordings were scored in 4-s epochs using standard criteria. A state was scored when the majority of the signals exhibited that state for the majority of the epoch. Aside from occasional periods of asymmetrical NREM sleep, switches between states were largely synchronous.

Results: Jackdaws exhibited little (<0.1%) unihemispheric sleep, but over 20–30% of NREM sleep was classified as asymmetric. The proportion of asymmetric sleep was lower early in the sleep period and following sleep deprivation – periods of increased sleep pressure.

Conclusions: Our findings demonstrate a trade-off between the benefits of sleep and vigilance, and indicate that a bird's utilization of asymmetric sleep is constrained by temporal dynamics in their need for sleep.

Slow oscillatory responses to 300 ms closed-loop auditory stimuli during sleep: effects of timing and stimulus type

J. Koprivova^{1,2}, F. Černý^{1,3}, V. Piorecká^{1,3}, D. Dudysová¹, M. Piorecký^{1,3}

¹National Institute of Mental Health, Sleep and Chronobiology Research Center, Klecany, Czech Republic, ²Third Faculty of Medicine, Charles University, Prague, Czech Republic, ³Faculty of Biomedical Engineering, Czech Technical University in Prague, Prague, Czech Republic

Introduction: Closed-loop targeted memory reactivation (CL-TMR) is a novel method for precise targeting and reactivation of selective memories consolidated during sleep. The method has also been shown to enhance slow oscillations (SOs) and is currently being investigated as a tool to improve sleep quality. However, the impact of stimulation parameters—including timing, duration, and type of the sound stimulus—remains poorly understood. This study investigated the effect of 300 ms auditory stimuli on SOs characteristics, with the aim to determine: 1) whether the timing of stimulus phase of stimulation (upstate vs. downstate) modulates the evoked SO, 2) whether the topographic properties of evoked and spontaneous SOs differ, 3) and whether different types of sounds elicit distinct spectral EEG responses.

Materials and methods: Data were collected from 25 healthy adults (aged 20–29 years) during full-night polysomnography using a CL-TMR protocol. Auditory stimuli were delivered 330 ms after detection of a SO trough at the AFz electrode referenced to the pooled mastoids with a minimum interval of 2.5 seconds between two successive stimuli; one-third of the stimulation tags represented a sham condition (no sounds played). Prior to the analyses, trials were categorized into upstate and downstate. EEG responses were analyzed using event-related potentials (ERPs), topographical mapping, Hjorth parameters (activity, mobility, complexity), and spectral entropy. Data-driven analyses were used to evaluate brain responses to different sounds.

Results: Auditory stimuli of 300 ms duration reliably evoked slow oscillations during both upstate and downstate phases of endogenous SOs. Stimuli delivered during the upstate phase were associated with stronger ERP components, especially around the P300 latency, and more pronounced differences in frontal and occipital topography, suggesting increased cortical engagement. At 300 ms following stimulus onset, upstate stimulation produced larger scalp topography differences than downstate stimulation (compared to sham). There were no differences in EEG response to distinct sounds.

Conclusions: These findings suggest that both upstate and downstate phase stimulation with long (300 ms) auditory stimuli successfully elicits slow oscillatory activity during NREM 3 sleep. Although upstate stimulation may enhance certain aspects of cortical response (e.g., frontal amplitude, cognitive processing components), the consistent EEG responses observed for both timing conditions indicate a high level of robustness. Importantly, the brain's response remained stable across a variety of naturalistic sounds. These findings suggest that longer auditory stimuli may tolerate less precise timing while maintaining efficacy—an important prerequisite for real-world, home-based CLAS applications targeting sleep improvement in individuals with insomnia.

Spectral and network investigation reveals distinct power and connectivity patterns between phasic and tonic REM sleep

T. Avigdor¹, L. Peter-Derex², A. Ho³, K. Schiller¹, Y. Wang¹, C. Abdallah¹, E. Delaire⁴, K. Jaber^{3,5}, V. Travnicek⁶, C. Grova⁴, B. Frauscher⁷

¹McGill University, Neurology and Neurosurgery, Montreal, Canada, ²Lyon University, Center for Sleep Medicine, Lyon, France, ³Duke University, Neurology, Durham, United States, ⁴Concordia University, Physics, Montreal, Canada, ⁵Duke University, Neurology, Durham, United States, ⁶Czech Academy of Sciences, Institute of Scientific Instruments, Brno, Czech Republic, ⁷Duke University, Neurology, Durham, Canada

Introduction: Although rapid eye movement (REM) sleep is often thought of as a singular state, it consists of two substates, phasic and tonic REM, defined by the presence (respectively absence) of bursts of rapid eye movements. These two substates have distinct EEG signatures and functional properties. However, whether they exhibit regional specificities remains unknown.

Materials and methods: Using intracranial EEG recordings from 31 patients, we analyzed expert labeled segments from tonic and phasic REM and contrasted them with wakefulness segments. We assessed the spectral and connectivity content of these segments using Welch's method to estimate power spectral density and the phase locking value to assess functional connectivity.

Results: We found a widespread power gradient between low and high frequencies ($p < 0.05$, Cohen's $d = 0.17 \pm 0.20$), with tonic REM being dominated by lower frequencies ($p < 0.01$, $d = 0.18 \pm 0.08$), and phasic REM by higher frequencies ($p < 0.01$, $d = 0.18 \pm 0.19$). However, some regions such as the occipito-temporal areas as well as medial frontal regions exhibit opposite trends. Connectivity was overall higher in all bands except in the low and high ripple frequency band in most networks during tonic REM ($p < 0.01$, $d = 0.08 \pm 0.09$) compared to phasic REM. Yet, functional connections involving the visual network were always stronger during phasic REM when compared to tonic REM.

Conclusions: Phasic and tonic REM sleep display distinct and heterogeneous activation patterns depending on the region, network, and frequency band examined. Consistent with findings that sleep and wakefulness are local phenomena, we demonstrate that phasic and tonic REM also show region-specific electroencephalographic properties

Subcortical connectivity patterns during the introduction of NREMS and isoflurane-induced loss of responsiveness are partly different along the sleep/wake promoting pathway in mice

L. Joyce¹, R. Nuttall¹, M. Vadkertiova¹, S. Rahimi², M. Kreuzer¹, G. Rammes¹, G. Schneider¹, T. Fenzl¹

¹TUM University Hospital, School of Medicine and Health, Technical University Munich, Clinic for Anesthesiology and Intensive Care, Munich, Germany, ²Medical University Innsbruck, Institute for Pharmacology, Innsbruck, Austria

Introduction: NREMS and general anesthesia (GA) are often seen as two separate states, however, they share some neurophysiological similarities. Identifying common mechanisms may increase our understanding of these states and may help to develop even safer anesthetic regimes. This study focused on functional connectivity between the ventrolateral preoptic nucleus (VLPO) and locus coeruleus (LC) – two major nuclei along the sleep/wake-promoting pathway. Transitions between NREMS and wakefulness (WAKE), as well as loss (LOR) and return (ROR) of responsiveness during GA were recorded electrophysiologically *in vivo* and analyzed. Similar patterns in functional connectivity during natural NREMS/WAKE transitions and GA-induced transitions would point to a possible involvement of the sleep/wake-promoting pathway in isoflurane-induced GA.

Materials and methods: Twelve male C57Bl6/N mice were implanted with local field potential (LFP) electrodes in the VLPO and LC to record their activity, as well as with EEG electrodes to monitor vigilance states. Chronic recordings included two baseline days and LFP/EEG recordings during GA. Functional connectivity was calculated using coherence, inter-site phase clustering (ISPC), and Granger

causality (GC) analyses for frequencies between 0.5–40 Hz. Significance was set at 95% (Wilcoxon signed rank test). Parallel, we trained a support vector machine (SVM) using the consensus of 8 experts on WAKE/NREMS and LOR/ROR transitions to automatically identify all transitions detected manually.

Results: Coherence analysis revealed an increase at WAKE/NREMS transitions and a decrease at NREMS/WAKE transitions. During GA, coherence decreased after LOR; no significant changes at ROR could be detected. ISPC showed a similar trend with an increase during NREMS and a decrease during WAKE; no significant changes during LOR and ROR could be found. GC index from VLPO to LC increased during NREMS and decreased during WAKE. Also, it increased after LOR, with no significant changes at ROR. GC from LC to VLPO decreased during NREMS; there were no significant changes upon transition to WAKE. GC did not change significantly during LOR, but increased after ROR. The trained SVM model could predict transitions with high precision within the expert range and was used to pinpoint transitions between WAKE, NREM and ROR. In contrast, LOR showed very low consensus among experts. Therefore, an anomaly detection approach (semi-supervised) was used to identify the time point at which the EEG exhibited sharp changes after LOR.

Conclusions: This study supports findings from literature about functional connectivity between VLPO and LC during WAKE/NREMS/WAKE transitions. Their functional connectivity pattern at GA transitions suggests at least a less prominent role during LOR and ROR. However, their involvement in LOR and ROR is still not fully understood. Current research in our lab uses targeted inhibition of VLPO and LC to gain a deeper understanding of their role in GA. For these experiments, the newly developed SVM model will be applied to automatically detect WAKE/NREMS and LOR/ROR transitions.

Temporal effects of chronic intermittent hypoxia on genioglossus electromyography and ultrastructure in a rat OSA model

D. Li¹, J. Xiao¹, G. Yin¹

¹Beijing Tsinghua Changgung Hospital, School of Clinical Medicine, Tsinghua University, Otorhinolaryngology–Head and Neck Surgery, Beijing, China

Introduction: This study established a chronic intermittent hypoxia (CIH) rat model simulating obstructive sleep apnea (OSA) to evaluate the temporal impact of CIH on genioglossus (GG) electromyography (EMG), mitochondrial morphology, and neuromuscular junction (NMJ) integrity.

Materials and methods: Forty healthy male Sprague-Dawley rats (7-week-old) were randomized into three groups: normal control (NC, n=10), CIH (4-week hypoxia, n=15), and prolonged CIH (8-week hypoxia, n=15). CIH groups underwent daily 8-hour cycles of alternating hypoxia (90s at 7% O₂) and normoxia (90s at 21% O₂). Serial measurements of GG-EMG activity were performed at baseline and weekly intervals, complemented by repetitive nerve stimulation (RNS) assessments during weeks 4-8. Histopathological evaluation through H&E staining and transmission electron microscopy (TEM) quantified myofibrillar architecture and subcellular organelle integrity.

Results: In the CIH group, the GG-EMG showed a gradually increasing trend from the first week of CIH to the end of the fourth week ($P < 0.05$). And the multiple comparisons of GG-EMG between the groups during 1-4 weeks of CIH were statistically significant ($P < 0.05$). Meanwhile, the GG-EMG in most CIH prolonged groups showed a decreasing trend around 6 weeks of CIH. At 4 weeks of CIH, 15% of the rats showed decreased RNS high-frequency (20Hz) stimulation, and with the extension of hypoxia time, up to 8 weeks of CIH, 60% of the rats showed decreased RNS high-frequency stimulation ($P < 0.05$). Compared with the NC group, the CIH group had disordered arrangement of GG fibers, irregular and swollen fibers. TEM showed that the damage of GG muscle fibers and mitochondria was not obvious two weeks before CIH, and the damage of GG mitochondria was earlier than that of GG muscle fibers. With the prolongation of CIH exposure, the damage of GG muscle fibers and mitochondria was further aggravated.

Conclusions: CIH induces time-dependent GG neuromuscular dysfunction: Early compensatory EMG enhancement (≤ 4 weeks) transitions to decompensation (≥ 6 weeks). Mitochondrial vulnerability manifests earlier than myofibril damage. Progressive NMJ impairment correlates with RNS-detected abnormalities. These findings highlight critical phases of hypoxic adaptation in OSA-related upper airway dysfunction.

THC and CBD in insomnia associated to neuropathic pain: effect on sleep architecture and descending anti-nociceptive pathways

M. Lopez-Canul¹, A. Oveisì¹, A. Farina¹, A. Teggin¹, J. Enns¹, M.L. Vigano¹, L. Posa¹, D. de Gregorio², H. He¹, S. Yin¹, G. Gobbi¹

¹McGill University, Psychiatry, Montreal, Canada, ²Vita-Salute San Raffaele University, Pharmacology, Milan, Italy

Introduction: Neuropathic pain (NP) is a chronic pain condition caused by a lesion on the somatosensory system and affects 7-10% of the population. Additionally, up to 48 % of the patients who suffer from NP experience sleep disturbances. Preclinical and clinical studies indicate that delta-9-tetrahydrocannabinol (THC) and cannabidiol (CBD) possess both analgesic and hypnotic effects; however, the mechanisms of action in models of NP are not fully understood. Here, we examined the effects of THC and CBD on the sleep-wake cycle (EEG/EMG) in NP condition and explored their possible mechanism of action, examining the neurons of the descending anti-nociceptive pathway.

Materials and methods: We induced NP in Wistar rats; 14 days later, rats were evaluated for allodynia using von-Frey filament. To assess mechanical allodynia, NP animals were treated with THC (1, 1.5, 2, 2.5 and 5 mg/kg, i.p.) or CBD (5, 10 and 20 mg/kg, i.p.) or respective vehicle, and allodynia was measured during 7 h. Next, to evaluate the effect on sleep, NP rats were implanted with six stainless-steel wire electrodes in the skull and EEG/EMG was recorded for a period of 6 h (from 6 AM to 12 PM) with a single injection of THC (5 mg/kg, i.p.) or CBD (20 mg/kg, i.p.). To investigate the involvement of CB1 and 5-HT1A receptors in the pro-hypnotic effect of THC and CBD, rimonabant (1 mg/kg) and WAY 100635 (2 mg/kg) were injected 10 min before an effective dose of THC (5 mg/kg) and CBD (20 mg/kg), respectively. Next, the effects of microinjection of CBD (1 µg) and THC (10 µg) into the ventrolateral periaqueductal gray (PAG) were assessed by recordings of ON (pro-nociceptive) and OFF (antinociceptive) cells in the rostral ventral medulla (RVM) in NP rats.

Results: CBD (10 and 20 mg/kg, i.p.) and THC (2.5 and 5 mg/kg, i.p.) decreased mechanical allodynia in rats with NP vs VEH treated rats ($p < 0.001$) 1h after administration, reaching an antiallodynic peak of 7 (CBD) and 6 (THC) grams. NP rats developed insomnia characterized by decreased duration of NREM (-41.2%) and REM (-73.3%) during the inactive phase. CBD (20 mg/kg, i.p.) and THC (5 mg/kg, i.p.) were able to increase NREM ($p < 0.01$) and REM sleep ($p < 0.001$) in NP rats. Additionally, the pre-administration of rimonabant (1 mg/kg) was able to block the effect on sleep of THC (5 mg/kg) and WAY 100635 (2 mg/kg) the effect of CBD (20 mg/kg). On the other hand, microinjection of THC (10 µg) decreased the firing activity of ON cells and activated the firing of OFF cells in the RVM. Unlike THC, CBD reduced the activity of both ON and OFF neurons in NP rats.

Conclusions: The findings suggest that THC and CBD have a moderate acute analgesic effect, but significantly recovered the sleep disruption in NP rats by modulating the neural nociceptive pathway. Therefore, THC and CBD have potential in the treatment of neuropathic pain and comorbid insomnia.

The Association among the Sleep Spindle and Category-Induced False Recognition

K. Verma¹, N. Kashyap²

¹Sleep Cognition and Psychology Laboratory, Indian Institute of Technology Indore, School of Humanities and Social Sciences, Indore, India, ²Sleep and Cognition Lab, Indian Institute of Technology Guwahati, Department of Humanities and Social Sciences, Guwahati, India

Introduction: Research investigating sleep and memory suggests clear benefits of sleep on true memories; however, sleep's role in false memories is still unclear. Electrophysiological activities of the sleeping brain have been linked with information processing and memory management. One such electrophysiological marker is spindle activity in the 12-15 Hz range, which is believed to be generated by thermocortical activity occurring during memory processing in sleep. False memories belong to the larger umbrella of memory, distinguishing only in terms of content from true memories. The present study is an attempt to investigate the link between sleep spindle activity and false memories induced through category associates.

Materials and methods: The study involved eleven healthy participants (all male; mean age 19.07 ± 1.07 years) without any known medical issues. Participants performed category-associated tasks before engaging in sleep or deprivation in the sleep laboratory. On a later old/new recognition test, participants performed a recognition on lists containing targets and distractors. Spindle activity was extracted using the standard protocol mentioned elsewhere (Verma, Pandey & Kashyap, 2025). The Pearson correlation coefficient (r) was used to determine the relationship between sleep spindles and false memory formation.

Results: Significant positive correlation between sensitivity of critical lures and spindles on central [(C₃: $r_{(11)} = .711$, $p = .01$); (C₄: $r_{(11)} = .652$, $p = .03$)], and occipital [(O₁: $r_{(11)} = .645$, $p = .03$); (O₂: $r_{(11)} = .598$, $p = .05$)] channels were found. All other results were non-significant.

Conclusions: These results emphasise a strong positive relation between the sensitivity of high-frequency category-associated critical lures and spindle activity, indicating that sleep spindle activity may contribute to the retrieval mechanisms of high-frequency category-associated false memory formation. These findings highlight the relevance of studying the connection between sleep spindle activity and memory sensitivity to examine the cognitive process underlying memory consolidation and distortion.

Acknowledgments: We sincerely thank all participants for their valuable time and contribution to this study.

The Effect of L-alanine on Sleep in *Drosophila melanogaster*

R. Garibagaoglu¹, R. Kobayashi², J. Tomita¹, K. Kume¹

¹Nagoya City University, Nagoya, Japan, ²Nagoya University, Nagoya, Japan

Introduction: Sleep and nutrition are vital for survival. In fruit flies (*Drosophila melanogaster*), sweetness alone can promote sleep. Amino acids are essential nutrients involved in diverse physiological functions. The L- form of amino acids are the prominent form, and they are involved in sleep regulation. However, their sleep regulation mechanisms have been less explored by their taste. L-ala was shown to be attractive to flies and promotes feeding (Aryal et al., 2022; Yang et al., 2018) Yang we examined how its taste affects sleep by comparing sucrose-based (sweet) and sorbitol-based (non-sweet) foods.

Materials and methods: Wild type (w^{1118}) male flies were fed with food based on either 5% sucrose (sweet, nutritive) or 5% sorbitol (non-sweet, nutritive) supplemented with amino acids. Sleep was measured using DAM5 (single-beam) and DAM5H (multi-beam) *Drosophila* Activity Monitoring systems. Feeding behavior was assessed by food intake assays using blue dye and attractiveness was assessed by proboscis extension response (PER) tests. We examined both young and aged flies.

Results: We examined how amino acids, specifically L-alanine (L-ala), influence sleep via taste mechanisms, comparing sweet (sucrose) and non-sweet (sorbitol) base diets. We found that L-ala supplementation significantly enhanced sleep when given in sorbitol (non-sweet), but not in sucrose (sweet) food, indicating a taste-dependent effect. The sleep-promoting effects of L-ala in sorbitol were comparable to those of sucralose, an artificial sweetener. Furthermore, combining L-ala with low-dose sorbitol significantly extended lifespan, highlighting its role as a feeding promoter under nutrient-limited conditions. The concentration-dependent effects of L-ala supplemented in sorbitol was more prominent than in sucrose. By performing proboscis extension response (PER) assays, we confirmed that L-ala was attractive to flies. Importantly, aged flies supplemented with L-ala in sorbitol food doubled sleep duration compared to sorbitol alone. In addition, L-ala supplementation increased survival, with fewer flies dying (22/32 survived sorbitol alone; 30/32 with L-ala).

Conclusions: Our study demonstrates that L-alanine modulates sleep and survival in *Drosophila melanogaster* depending on sugar context and sweetness. Behavioral assays showed flies found L-ala attractive, increasing consumption of sorbitol food containing L-ala. However, higher L-ala concentrations reduced proboscis extension responses, possibly due to aversion. Nonetheless, flies still consumed L-ala food, suggesting a feeding-promoting effect. L-ala increased sleep even under nutrient restriction, but it only enhanced longevity when paired with minimal dietary sugars. Therefore, we show that sorbitol is an effective base sugar to examine taste-driven effects. L-ala addition to sorbitol food extends both sleep amount and lifespan suggesting its potential use for promoting lifespan.

The effects of environmental factor-related alterations on post-arousal hypersynchrony

Y. Suzuki^{1,2}, N. Ding³, A. Hirayama⁴, Z. Fan^{1,5}, C. Suzuki¹, K. Sato³, Z. Wang³, Y. Suzuki¹, Y. Oiwa⁶, T. Kanbayashi^{1,7}, T. Watanabe⁸, T. Penzel², T. Abe¹

¹International Institute for Integrative Sleep Medicine (WPI-IIS), Tsukuba Institute for Advanced Research (TIAR), University of Tsukuba, Tsukuba, Japan, ²Interdisciplinary Sleep Medicine Centre, Charité University Hospital, Berlin, Germany, ³Neuroscience Degree Programme, Graduate School of Comprehensive Human Sciences, University of Tsukuba, Tsukuba, Japan, ⁴Doctoral Program in Neuroscience, Degree Programs in Comprehensive Human Sciences, Graduate School of Comprehensive Human Sciences, University of Tsukuba, Tsukuba, Japan, ⁵Department of Psychiatry, University of Wisconsin–Madison, Madison, Wisconsin, United States, ⁶College of Medical Sciences, University of Tsukuba, Tsukuba, Japan, ⁷Ibaraki Prefectural Mental Health Centre, Kasama, Japan, ⁸KYOCERA Corporation, Kyoto, Japan

Introduction: Post-arousal hypersynchrony (PAH) denotes a delta burst followed by arousal, hypothetically functioning to antagonize arousal, because it shares similar characteristics with K-complexes and correlates with arousal numbers (Suzuki et al., 2021). Meanwhile, external environmental factors including sound and first-night effects (FNE), can induce sleep-related changes. Closed-loop auditory stimulation (CLAS) has been used to enhance slow oscillations (Ngo et al., 2013) via a mechanism that could involve auditory evoked potentials, such as the K-complex. Using 0.25-Hz binaural beats (BB), sleep structure-related alterations have been described in healthy adults with insomnia symptoms, characterized by a %N1 decrease and a %N2 increase, suggesting sleep stabilization (Hirayama et al., 2024). FNE promote wakefulness, including an increment in the number of arousals (Boulos et al., 2019). We hypothesized that external factors may increase the occurrence of PAHs, and examining PAH-related changes during sleep altered by these factors may help clarify the function of PAHs.

Materials and methods: In Experiment 1, 16 healthy adults with high anxiety (State-Trait Anxiety Inventory trait scores of 45-80) participated in the CLAS study (23.9±3.7 [mean±standard deviation] years, six females) (Suzuki et al., 2024). In Experiment 2, 14 healthy adults (36.9±14.0 years, 10 females) with insomnia symptoms (Insomnia Severity Index score >7) who could discriminate 0.25-Hz BB were enrolled in the study using 0.25-Hz BB (Hirayama et al., 2024). Both experiments were crossover study designs, with and without sound conditions. In Experiment 3, we examined four non-consecutive nights of PSG in 15 healthy adults (21.7±1.6 years, five females) who had not undergone PSG previously (Suzuki et al., 2025). In each experiment, PAH and sleep variables were assessed by a scorer and compared across conditions.

Results: In Experiments 1 and 2, the occurrence of PAHs remained unchanged between conditions (sound vs. no sound: 2.4±2.0 vs. 2.8±2.7 times and 0.5±0.7 vs. 0.4±0.8 times, respectively). In Experiment 3, the increase was observed during the first night (5.1±3.3 times) compared to the fourth night (2.7±1.8 times), while sleep variables showed no change in measurement number. As PAH was unexpectedly low in Experiment 2, we additionally compared it and sleep variables with three groups for Experiments 1 and 2 under no sound conditions and Experiment 3 on the second night, all recorded in the same sleep lab. PAH decreased in participants with insomnia symptoms compared with the other groups. Compared with healthy adults in Experiment 3, %N1 increased in the other groups and %N3 decreased in those with insomnia symptoms.

Conclusions: PAH was unaffected by CLAS and 0.25-Hz BB. It was acutely affected by FNE and could potentially contribute to sleep stabilization. Surprisingly, in those with insomnia symptoms, PAH incidence and %N3 were lower, and %N1 was higher. PAH might be influenced not only by the external environmental factor FNE, but also by insomnia symptoms with decreased objective sleep quality.

The Effects of Latitude on Sleep and Blood Pressure at an Altitude of 4300 m

C. Jung¹, R. Wehling¹

¹University of Alaska Anchorage, Biological Sciences, Anchorage, United States

Introduction: Over 140 million people live above 2400 m worldwide. Additionally, even more visit high altitudes (HA) every year for recreation, military and religious reasons. Exposure to HA is associated with hypoxia-related cognitive impairments and sleep disruptions and can cause negative impacts on physiology such as an increase in blood pressure. Additionally, latitude could cause additional negative impacts. Because of the Earth's rotation, there is a slight bulge at the equator, which causes both barometric pressure and the partial pressure of oxygen to be greater at the equator than at the poles. The additive effects of latitude and high altitude have yet to be studied. Thus, the aim of the current study was to determine if latitude has an impact on sleep and blood pressure at ~4,300 m.

Materials and methods: Similar testing protocols were utilized at ~4,300m at "Camp 14" on Denali at a latitude of ~63° (Alaska, USA) and at 4,300 m along the Everest Basecamp Route (Dingboche, Nepal) at a latitude of ~28°. 31 climbers (3 females) participated in the Denali study (age 34.0±9.7 mean±SD) and twenty-five climbers (6 females) participated in the Everest study (age 28.0±9.7). Participants were instructed to go to bed and wake up at their habitual bedtimes and wake times. Sleep architecture was recorded with a wireless sleep recording device and blood pressure was measured either with the auscultatory method or a blood pressure machine.

Results: Independent t-tests revealed a statistically significant decrease in total sleep on Denali when compared to Mt. Everest. There were nonsignificant trends for a decrease in rapid eye movement (REM) sleep and sleep onset latency on Denali. Other sleep stages appear relatively unaffected by latitude. Systolic blood pressure was significantly higher ($p<0.05$) on Denali (143.39±2.66 mmHg mean±SEM) vs Everest (127.54±3.16 mmHg), whereas there was no significant difference in diastolic blood pressure (Denali: 88.89±3.14 mmHg, Everest: 85.36±2.18 mmHg) between latitudes.

Conclusions: Our findings indicate that there is an increase in systolic blood pressure and a decrease in total sleep time at higher latitude with comparable altitude. Prior research has linked a decrease in total sleep time to decreased cognitive impairments and other physiologic disruptions. Additionally, systolic blood pressure has been reported to be an indicator of heart disease. Based on our findings of systolic blood pressure increasing with a higher latitude, latitude could have an impact on cardiac health since the participants were in the hypertensive range on Denali but not Everest. Our findings suggest that latitude should be considered when venturing into HA environments, designing research protocols, analyzing results, and for clinical applications and military operations.

The first night effect on sleep in school-age children

T.J.X. Seah^{1,2}, N.A. Nazareth¹, T. B. Koa^{1,2}, J.L. Ong¹, J.C.-Y. Lo^{1,2,3}

¹National University of Singapore / Yong Loo Lin School of Medicine, Centre for Sleep and Cognition, Singapore, Singapore, ²National University of Singapore / Yong Loo Lin School of Medicine, Human Potential Translational Research Programme, Singapore, Singapore, ³National University of Singapore / Yong Loo Lin School of Medicine, Department of Medicine, Singapore, Singapore

Introduction: Sleep is often altered in the first night of polysomnography (PSG) due to discomfort from sensors and unfamiliar lab environments – a phenomenon known as the first-night effect. In adults, this typically manifests as longer sleep latency, longer wake after sleep onset (WASO), reduced REM sleep, and lower sleep efficiency on the first night of PSG recordings compared to subsequent recordings. Two recent studies in healthy children show inconsistent results: one found significant first-night changes in sleep stages in a lab setting, while another, using at-home recordings, observed stable sleep architecture across nights. To further evaluate the first night effect in this population, this study compared both macrostructural and microstructural (EEG spectral power) measures between two non-consecutive nights of at-home PSG in healthy 7- to 12-year-olds.

Materials and methods: 41 Singaporean children (mean age ± SD = 9.77 ± 1.29 years; 22 males) underwent two unattended at-home PSG recordings one week apart. They were instructed to follow their sleep-wake timing on school nights for both nights. PSG records were first automatically scored (Neurobit PSG with FASST) and then visually validated against AASM criteria to derive sleep macrostructural metrics. For sleep microstructure, artifact-free NREM epochs (0.5–40 Hz, notch at 50 Hz harmonics) were segmented into 30-second epochs and analysed via Welch's method (5-second Tukey windows, 1-second overlap) to compute power for the following frequency bands: Delta (δ): 0.5–4 Hz, Theta (θ): 4–7 Hz, Alpha (α): 8–13 Hz, Sigma (σ): 11–16 Hz, Beta (β): 13–30 Hz., For each

participant and frequency band, total power, mean power and hourly average power were computed. Paired t-tests compared macro- and microstructural parameters between nights of recordings.

Results: Relative to the second night of PSG recording, in the first night, children had 15.97 ± 12.20 min (mean $\pm$ SD) longer time in bed ($p = 0.04$, $dz = 0.33$), but there was no difference in total sleep time ($p = 0.87$), resulting in higher WASO (10.63 ± 7.47 min, $p = 0.02$, $dz = 0.37$) and lower sleep efficiency (-2.28 ± 3.37 %, $p = 0.02$, $dz = 0.38$). REM latency was also slightly delayed by 19.39 ± 15.92 min in the first night ($p = 0.02$, $dz = 0.37$). Durations of the sleep stages, as well as, N2 and N3 latency did not differ between nights ($ps > 0.11$). Spectral power showed no night-to-night differences in mean, total, or hourly power ($ps > 0.05$).

Conclusions: In healthy school-age children sleeping at home, first night effect is small and limited primarily to delayed REM onset, with stable overall sleep architecture and spectral measures, especially if time-in-bed is kept constant. Hence, a single night of at-home PSG may suffice for this population for most sleep parameters.

Acknowledgments: This work was supported by the National University of Singapore under the start-up grant awarded to Dr June Lo [NUHSRO/2019/075/Startup/01].

The immune mechanisms study of dihydroartemisinin in alleviating airway inflammation of chronic intermittent hypoxic obese asthmatic mice model by inhibiting TLR4

M.S. Su¹, X.T. Su², M.H. Xu³, K.s. Zhao¹, C.P. Liu⁴, J.L. Li¹

¹The Second Affiliated Hospital and Yuying Children's Hospital of Wenzhou Medical University, Department of Pediatric Respiratory Medicine and sleep medicine, Wenzhou, China, ²Wenzhou Medical University, School of Rehabilitation Medicine, Wenzhou City, China, ³Wenzhou Medical University, School of Laboratory Medicine and Life Science, Wenzhou City, China, ⁴The Second Affiliated Hospital and Yuying Children's Hospital of Wenzhou Medical University, Department of Pediatric Respiratory Medicine and sleep medicine, Wenzhou City, China

Introduction: To explore the immune mechanisms of dihydroartemisinin (DHA) in alleviating airway inflammation of chronic intermittent hypoxic(CIH) obese asthmatic mice model by inhibiting toll like receptor 4 (TLR4).

Materials and methods: Thirty 3-week-old female CD-1 (Swiss) mice were randomly divided into 5 groups: Control group; Model group; DHA treatment group, Model group were given DHA treatment; Lenti-TLR4-OE+DHA treatment group, mice of the Model group were given DHA combined with lentivirus-mediated overexpression of TLR4 treatment; Lenti-vector+DHA treatment group. A chronic CIH obese asthmatic mouse model was established. The lung function of mice was measured. The inflammatory cytokines IFN- γ , IL-6 and IL-10 in mouse lung homogenates were determined by ELISA. Flow cytometry was used to determine the percentage (%) of neutrophils infiltrated in lung tissues. The activation levels of TLR4/NF- κ B/PI3K/AKT signaling pathway in mice lung were determined by Western blot.

Results: Compared with Control group, in Model group and DHA treatment group, the body weight/tibia length of mice were increased ($P < 0.05$); FEV0.1/FVC decreased ($P < 0.05$); the levels of IFN- γ , IL-6 and IL-10 were increased ($P < 0.05$); the levels of TLR4, p-P65, p65, p-PI3K and p-Akt were increased ($P < 0.05$); the percentage (%) of neutrophil infiltration in lung tissues were increased ($P < 0.05$). Compared with Model group, in DHA treatment group there was no significant difference in body mass/tibia length ($P > 0.05$); FEV0.1/FVC increased ($P < 0.05$); IFN- γ and IL-6 levels were decreased ($P < 0.05$), and IL-10 levels were increased ($P < 0.05$); the levels of TLR4, p-P65, p65, p-PI3K and p-AKT were decreased ($P < 0.05$); the percentage (%) of neutrophil infiltration in lung tissues were decreased ($P < 0.05$). Compared with DHA treatment group, in Lenti-TLR4-OE+DHA treatment group, the levels of TLR4, p-P65, p65, p-PI3K and p-AKT levels were increased ($P < 0.05$); the percentage (%) of neutrophil infiltration in lung tissues were increased ($P < 0.05$).

Conclusions: Dihydroartemisinin could inhibit TLR4, reduce the activation level of NF- κ B/PI3K/AKT signaling pathway, enhance lung function and inhibit airway inflammation in CIH obese asthmatic mouse models.

The Impact of Early Morning Training on Subjective and Objective Sleep Indices Among Male Collegiate Rowers in Japan

M. Toyooka¹, A. Yuhaku², K. Ebi²

¹Graduate School of Sport and Health Science, Ritsumeikan University, Kusatsu, Japan, ²College of Sport and Health Science, Ritsumeikan University, Kusatsu, Japan

Introduction: Sleep deprivation is a well-known factor that can impair cognitive, physical, and technical aspects of athletic performance. Despite increasing awareness, many athletes-especially those with early morning training schedules-are unable to secure sufficient and high-quality sleep. Although sleep patterns in athletes have been studied, little research exists on Japanese collegiate rowing athletes. Moreover, few studies have combined both subjective and objective methods to assess sleep. This study aimed to clarify the sleep characteristics and lifestyle habits of male collegiate rowing athletes in Japan, focusing on the impact of early morning training on sleep.

Materials and methods: This study included 11 male collegiate rowers from University A, observed over 7 consecutive days in June 2025. Participant characteristics were as follows: height 172.8 ± 5.1 cm, age 20.3 ± 0.9 years, weight 71.0 ± 4.3 kg, and BMI 23.8 ± 0.9 . Collected data included demographic factors (e.g., caffeine and alcohol consumption, nap habits), subjective sleep quality using the Japanese version Pittsburgh Sleep Quality Index (PSQI-J) and sleep diaries, objective sleep data from wrist-worn actigraphy, dietary records, and training schedules.

Results: During the 7-day observation period, participants had morning training starting at 5:00 a.m. on three weekdays, 6:30 a.m. on two weekend days, and two weekdays without morning training. 63.6% of athletes were classified as having poor subjective sleep quality ($5.5 < \text{PSQI-J score}$; mean $\text{PSQI-J} = 6.9 \pm 2.6$).

Actigraphy data showed that Total Sleep Time (TST) was significantly shorter on nights before weekday morning training compared to nights before weekdays without morning training and nights before weekend ($p < 0.01$). Furthermore, bedtime on nights before weekday morning training was more than two hours earlier than that on nights before weekday without morning training.

One-way ANOVA revealed significant differences across training categories in some objective sleep indices. TST and total minutes in bed on nights before weekday morning training were significantly shorter than those on nights before weekdays without morning training ($p < 0.01$) and on weekend nights ($p < 0.01$). The number of awakenings was also significantly smaller on nights before weekday morning training than that on nights before weekend training ($p = 0.014$). Subjective TST from sleep diaries showed similar results: significantly shorter on nights before weekday morning training than on the other nights ($p < 0.01$). TST was significantly shorter in objective data than in subjective sleep diary data ($p < 0.001$, 0.013 , and < 0.001 for weekday with morning practice, weekday without morning practice, and weekend, respectively). On the other hand, subjective sleep latency was significantly longer ($p = 0.003$), and sleep efficiency was significantly higher ($p = 0.017$) than those in objective measures respectively.

Conclusions: This study found that early morning training reduced TST and caused earlier bedtime among Japanese male collegiate rowers. Many athletes reported poor subjective sleep quality and discrepancies were observed between subjective and objective sleep assessments. These findings highlight the importance of using both types of measures when evaluating sleep and suggest that training schedules should be reviewed to support adequate sleep and recovery.

The Impact of Obstructive Sleep Apnea on Patients with Ischemic Stroke

N. Neykov¹, I. Staikov¹

¹Acibadem Cityclinic University hospital Tokuda, Neurology and sleep medicine, Sofia, Bulgaria

Introduction: Obstructive sleep apnea (OSA) is a widespread but often overlooked condition that contributes to cardiovascular diseases, including ischemic stroke (IS). While its role in increasing stroke risk is well documented, its influence on stroke severity and recovery remains an area requiring further exploration. Additionally, there is ongoing debate regarding the extent to which continuous positive airway pressure (CPAP) therapy improves stroke outcomes. This study examines how OSA affects IS severity and prognosis while evaluating the therapeutic value of CPAP.

Materials and methods: This retrospective cohort study analyzed 200 patients diagnosed with both IS and OSA. Participants were divided into two groups: those who did not receive CPAP therapy or were non-compliant with treatment (Group A, n=119) and those who adhered to and consistently used CPAP therapy (Group B, n=81). A control group of 104 IS patients without OSA was also assessed. Stroke severity was measured using the National Institutes of Health Stroke Scale (NIHSS), and functional independence was evaluated using the modified Rankin Scale (mRS). OSA was diagnosed through respiratory polygraphy or full polysomnography. Statistical analyses included chi-square tests, Mann-Whitney U tests, and multivariate logistic regression, with significance set at $p < 0.05$.

Results: Patients with IS and OSA experienced significantly greater stroke severity compared to those without OSA ($p < 0.05$). Within the OSA cohort, individuals in the CPAP group demonstrated improved functional outcomes compared to non-CPAP users when analyzed as a continuous variable (Mann-Whitney U test, $p = 0.003$). However, when assessing functional independence as an endpoint (mRS 0-2), the difference did not reach statistical significance ($p = 0.17$). The most frequently observed comorbidities among OSA patients were hypertension (92.6%), smoking (55.5%), dyslipidemia (55.5%), type 2 diabetes (40.7%), and atrial fibrillation (33.3%), all of which correlated with increased stroke severity. Multivariate analysis confirmed that the presence of OSA, especially when combined with multiple cardiovascular risk factors, more than doubled the likelihood of experiencing a more severe stroke, with an odds ratio (OR) of 2.68 (95% CI, $p < 0.05$).

Conclusions: OSA is a key contributor to increased stroke severity and poorer recovery outcomes, particularly in patients with multiple cardiovascular risk factors. CPAP therapy demonstrated measurable improvements in overall functional recovery, yet this benefit did not reach statistical significance in terms of full functional independence within three months. These findings underscore the importance of early OSA detection and intervention in stroke patients. Given its potential role in rehabilitation, CPAP therapy should be further explored as a targeted intervention to enhance post-stroke recovery and reduce recurrent cerebrovascular events.

Acknowledgments: The author extends sincere appreciation to the Department of Neurology and Sleep Medicine at Acibadem City Clinic Tokuda Hospital for their support. Special thanks to Prof. Ivan Staikov, DM, for his mentorship, as well as to the research and clinical teams involved in patient evaluation and data collection.

The Impact of Obstructive Sleep Apnea on the Temporal Coupling of NREM Sleep Oscillations in Schizophrenia

G. Cho^{1,2}, S. Faris¹, R. Wassing^{1,2}, N. Marshall^{1,2}, R. Grunstein^{1,2}, A. D'Rozario^{1,2}, B. Yee³, D. Bartlett¹, T. Lambert⁴

¹The Woolcock Institute of Medical Research, Sleep and Circadian Research Group, Sydney, Australia, ²Macquarie University, Faculty of Medicine, Human Health Sciences, Sydney, Australia, ³Royal Prince Alfred Hospital, Sleep and Respiratory, Sydney, Australia, ⁴Collaborative Centre for Cardiometabolic Health in Psychosis (ccCHiP), Sydney, Australia

Introduction: Dysfunctional connectivity between and within brain regions is a proposed mechanism underlying schizophrenia. Electroencephalographic (EEG) abnormalities during Non-Rapid Eye Movement (NREM) sleep such as reduced and dysmorphic sleep spindles and slow oscillations (SO) have been described in schizophrenia. The temporal coupling between these oscillations is thought to reflect the coordination and integrity of the thalamocortical circuitry and has been associated with functions of memory with uncoupling being associated with aspects of ageing and cognitive decline. We investigated 1) whether a reduction in the temporal relationship between SO and spindles are observed in the schizophrenia group reflecting thalamocortical dysfunction. Individuals with schizophrenia are often given obesogenic medication, increasing the likelihood of developing obstructive sleep apnea (OSA). We further explored 2) whether this oscillatory coupling would be further impaired in those with OSA and 3) the association of coupling with cognitive performance.

Materials and methods: We measured high-density EEG overnight polysomnography in two groups 1) people with schizophrenia (n=31) and 2) without schizophrenia (n=31) across a range of OSA severity, defined by the Apnea Hypopnea Index (AHI), matched for age and sex. Participants completed a cognitive test battery before and after sleep. Sleep spindles and SO events were automatically detected using previously reported algorithms across 256 High-density EEG. The mean phase angles (phase preference), the resultant vector length (coupling strength) and coupling density of each co-

occurring event between SO and sleep spindles were measured. To reduce bias of phase angle concentration, participants with >10 events were included in the analyses. General linear models were used to test the association between coupling metrics and the effects of group and AHI and the interaction between the two and the association of cognition in the form of a procedural memory task (finger tapping) with the main effect of the coupling strength, group and AHI.

Results: We observed group differences in the schizophrenia group showing reduced coupling density compared to controls ($b = -0.06$, $p < 0.01$) this was not further impaired if they had comorbid OSA ($b = 0.00$, $p = 0.65$). Across both groups, we did not see a difference in coupling strength (resultant vector length) (Group $\times$ AHI $b = 0.00$, $p = 0.82$). No significant differences were observed in overnight improvement on the procedural memory motor task and AHI ($b = -0.11$, $p = 0.31$). Worse task performance was observed in the schizophrenia group ($b = -22.37$, $p = 0.01$) but not significant if these patients had OSA ($p = 0.05$).

Conclusions: Our results show that the coupling of SO and sleep spindles in schizophrenia may be preserved and is not impacted by the presence of OSA. The schizophrenia group show additional activation in the centroparietal regions which may possibly reflect a compensatory mechanism. This interpretation might suggest that recruitment of function with adjacent areas could be due to local network dysfunction in the frontal brain regions in schizophrenia. Future work will aim to understand the effects on these dynamics following CPAP treatment in schizophrenia and explore the potential of SO-spindle coupling reflecting functional connectivity and its interaction with other brain regions.

The Impact of Sleep Perception on Cognitive Functions in Adults with Objectively Sufficient Sleep Duration

H.Y. Chu¹, S. Xie¹, C.X. Chen¹, S. Chen¹, S.W.H. Chau¹, B. Huang², J.W.Y. Chan², Y.K. Wing², R.N.Y. Chan¹

¹CUHK, Li Chiu Kong Family Sleep Assessment Unit, Department of Psychiatry, Faculty of Medicine, The Chinese University of Hong Kong, Hong Kong, Hong Kong, SAR of China, ²CUHK, Hong Kong, Hong Kong, SAR of China

Introduction: Misperception of sleep is characterized by significant discrepancy between objective and subjective sleep measurement (SOSD). Most of the previous studies primarily focus on clinical insomniac population and suggested that individual with greater SOSD tend to perform poor in cognitive performance. However, this relationship remains understudied in healthy community samples, especially those with normal sleep duration. It is unclear whether subjectively perceived shorter sleep could have influential effect on their cognitive performance. This study aim to investigate the association between SOSD and cognitive functioning in community-dwelling adults with objectively sufficient sleep (6–8 hours per night). Additionally, we examine whether this association extends beyond elderly populations, thereby exploring potential age-independent effects of sleep misperception on cognition.

Materials and methods: This is a cross-sectional study of 196 participants (mean age: 50.3 ± 14.5 years; 71.9% female) recruited from the community. They were invited to complete a set of sleep-related questionnaires, 7-day sleep diary and actigraph. Participants with at least three valid days of actigraphy data and obtained an average of objectively measured TST between 6–8 hours were included. The subjective-objective sleep discrepancy (SOSD) was calculated by subtracting objective TST (actigraphy-derived) from subjective TST (self-reported from sleep diaries). Cognitive function was assessed using the Hong Kong Montreal Cognitive Assessment (HK-MoCA) for global cognition and n-back tasks for working memory. The n-back tasks measured accuracy (percentage of correct responses), discriminability (d' prime, reflecting participants' sensitivity to distinguish items presented n trials back), and reaction time for correct responses. Multiple linear regression models examined associations between SOSD and cognitive parameters, controlling for age and sex.

Results: There are significant positive associations observed between SOSD and multiple cognitive parameters. For those who underestimated their sleep duration, they tend to have poor cognitive performance across several domains including lower global cognition measured by HK-MoCA ($\beta = 0.006$, 95% CI: 0.001–0.011, $P = 0.018$), poor working memory demonstrated by lower accuracy on both 1-back ($\beta = 0.028$, 95% CI: 0.008–0.046, $P = 0.005$) and 2-back tasks ($\beta = 0.03$, 95% CI: 0.001–0.058, $P = 0.04$), slower mean reaction time of correct responses during 1-back task ($\beta = -0.0003$, 95% CI: -0.0005–0.000007, $P = 0.012$), and impaired working memory as indicated by greater d' prime

values for both 1-back ($\beta=0.001$, 95% CI: 0.0001–0.002, $P=0.037$) and 2-back tasks ($\beta = 0.002$, 95% CI: 0.001–0.004, $P=0.001$).

Conclusions: Our findings suggest that underestimation of sleep duration (shorter self-reported than objectively measured TST) is associated with poorer global cognition and working memory performance in community-dwelling adults who have objectively sufficient sleep. SOSD may be an important factor in understanding sleep-cognition relationships. Future research should explore the bidirectional causal mechanisms underlying this association—whether cognitive dysfunction leads to sleep perception discrepancies or if reducing sleep discrepancies could enhance cognitive function. Understanding this relationship may provide new avenues for cognitive interventions and improved sleep assessment strategies.

The Impact of Sleep Quality on Suicidal Ideation One Year Later: The Mediating Role of Emotional Distress and the Moderating Effect of Social Support in Korean Adults

S. Lee¹, D. Lee², Y. Shin¹

¹Ajou University School of Medicine, Department of Psychiatry, Suwon, Korea, Republic of,

²Sungkyunkwan University, Department of Education, Seoul, Korea, Republic of

Introduction: Sleep disturbances are a well-established risk factor for suicidal ideation, yet longitudinal evidence on the psychological mechanisms and protective moderators involved in this association remains limited, particularly among Asian populations. This study aimed to investigate whether emotional distress variables—hopelessness, depression, anger, and loneliness—mediate the longitudinal relationship between sleep quality and suicidal ideation, and whether perceived social support moderates this pathway.

Materials and methods: A total of 941 Korean adults (mean age = 45.0, range = 19–84) participated in a two-wave panel survey conducted during the COVID-19 pandemic, with baseline data collected in 2020 and follow-up in 2021. At Time 1 (T1), participants completed the Pittsburgh Sleep Quality Index (PSQI) to assess sleep quality, the Beck Hopelessness Scale (BHS), the Center for Epidemiologic Studies Depression Scale (CES-D), the Dimensions of Anger Reactions-5 (DAR-5), and the UCLA Loneliness Scale (ULS) to measure emotional distress, and the Multidimensional Scale of Perceived Social Support (MSPSS) to assess perceived social support. Suicidal ideation was measured at Time 2 (T2) using the Depressive Symptom Inventory–Suicidality Subscale (DSI-SS). Parallel mediation and moderation analyses were performed using standardized regression models with 5,000 bootstrap resamples.

Results: Poor sleep quality at T1 significantly predicted greater suicidal ideation at T2 ($\beta = .24$, $p < .001$). This relationship was partially mediated by increased levels of hopelessness (indirect effect $\beta = .10$, $p < .001$), anger ($\beta = .05$, $p = .003$), and loneliness ($\beta = .06$, $p = .002$), while depression did not show a significant mediating effect ($\beta = .03$, $p = .098$). Furthermore, perceived social support moderated the direct association between sleep quality and suicidal ideation (interaction $\beta = -.11$, $p = .004$), such that the relationship was strongest among individuals with low social support (slope $\beta = .38$, $R^2 = .13$) and weakest in the mid-range support group ($\beta = .18$, $R^2 = .03$).

Conclusions: These findings indicate that poor sleep quality increases suicidal ideation over time through elevated emotional distress, particularly hopelessness and loneliness. Moreover, social support serves as a protective factor that buffers this effect. Suicide prevention efforts should incorporate both sleep-focused interventions and strategies to enhance emotional regulation and social connectedness.

Acknowledgments: This research was supported by a grant of the Mental Health related Social Problem Solving Project, Ministry of Health & Welfare, Republic of Korea (grant number:RS-2024-00409433) and by the Ministry of Education of the Republic of Korea and the National Research Foundation of Korea (NRF-2021S1A3A2A02089682).

The influence of Obstructive Sleep Apnea on the peripheral blood supply of wound Healing: Microscopic and Macroscopic findings. Insights from a Murine Model. Preliminary results

Introduction: Obstructive Sleep Apnea (OSA) is associated with chronic inflammation, intermittent hypoxia, and oxidative stress, all of which may impair wound healing. Wound healing is a complex biological process that occurs in four overlapping but distinct stages: hemostasis, inflammation, proliferation, and remodeling. The study is about wound healing under the condition of OSA.

Objectives: To assess macroscopic wound healing progression (wound size reduction over time). and to evaluate microscopic histological differences (inflammation, fibrosis, epidermal thickness, and angiogenesis).

Materials and methods: Our model is a combination of two validated models. An osa model, in which mice were exposed to chronic intermittent hypoxia (60 events/hour: 20 sec at 5% O₂ followed by 40 sec of room air) for 6 hours/day over a period of 2 weeks. And a control group who kept in normal air conditions. Wound healing model, we created a two full-thickness wounds on mouse dorsum. Silicone splints are then centered and fixed with immediate-bonding adhesive and nylon sutures. 10 mice randomly assigned into two groups: OSA group who kept in IH for a period of 4 week in total and a healthy group. On day 14, we created 2 wounds on mice dorsum. We observed and studied wound healing process for another 2 weeks until total closure. Wounds were photographed every 2-3 days from day 0 till day 14 and wound closure rates were measured. Histological samples collected at day 0 and day 14. H&E staining were performed to assess fibrosis and inflammation. Quantitative evaluation of: Mononuclear inflammatory cell count, Fibroblast count, Capillary count and Epidermal thickness have been done. All mice were held the same conditions.

Results: Macroscopic findings, percentage of closure rate over time indicates a slower healing rate in OSA group especially at the first week. The mean total closure time was at day 12 for healthy and 14 for OSA mice. Half closure time was at day 6 for healthy and 8 for OSA mice. We also calculated the area under curve which reflect the total wound burden over time. Higher AUC values indicate delayed healing, reflecting wounds that remain open for longer durations. Microscopic evaluation on day 0, there was no notable differences between the two samples. The epidermis was significantly thicker on day 14. The count of mononuclear cells, fibroblast and capillaries were significantly higher in OSA.

Conclusions: OSA negatively affects both the macroscopic and microscopic aspects of wound healing. The delayed closure and altered histological profile in OSA-exposed mice suggest that patients with OSA may be at higher risk for impaired or prolonged wound healing. These findings highlight the importance of screening for and managing OSA in patients undergoing surgery or those with chronic wounds. Further research focus on the molecular pathways underlying IH-induced immune dysregulation to identify potential therapeutic intervention that may mitigate the negative impact of intermittent hypoxia on tissue repair.

The Intraslow Fluctuation of Sigma Power During Sleep in Young Individuals with Schizophrenia

Introduction: Reductions in sleep spindles—brief oscillatory events characteristic of Non-Rapid Eye Movement sleep—have been proposed as a biomarker of schizophrenia. While prior research has largely emphasized spindle quantity, emerging work has begun to examine their temporal dynamics

across the night. In healthy individuals, spindles fluctuate on an infraslow timescale of approximately 50 seconds, alternating between periods of elevated and reduced spindle activity. This rhythm, termed the infraslow fluctuation of sigma power (ISFS), is modulated by noradrenergic input from the locus coeruleus and has been implicated in the temporal coordination of markers of arousal and memory reactivation during sleep. Given the well-documented spindle deficits, altered noradrenergic function, and disruptions in sleep continuity and memory in schizophrenia, the ISFS represents a promising target for investigation in this clinical population. Additionally, childhood and adolescence, periods characterized by brain maturation and increasing vulnerability to psychiatric illness, may offer a critical window for detecting early circuit-level disruptions in rhythms like the ISFS, with potential implications for earlier diagnosis and intervention.

Materials and methods: Sleep electroencephalographic data were analyzed from individuals with either Childhood-Onset Schizophrenia (N = 17) or Early-Onset Schizophrenia (N = 11), aged 9 to 21 years, alongside age- and sex-matched healthy controls (N = 56). Features of the ISFS, including its presence and strength, sleep spindle density, and clinical characteristics were examined.

Results: This study found that the ISFS is present in young individuals with Childhood-Onset Schizophrenia and Early-Onset Schizophrenia. Both the presence and strength of the ISFS were reduced in central-parietal regions in individuals with schizophrenia compared to healthy controls. These ISFS alterations were observed in both the groups with schizophrenia despite differences in sleep spindle density and clinical characteristics.

Conclusions: These findings suggest that the ISFS is present but attenuated in young individuals with schizophrenia, reflecting reduced infraslow clustering of sleep spindles. Moreover, they underscore the potential relevance of spindle timing—in addition to quantity alone—for advancing pathophysiological models of schizophrenia, and highlight its promise as a target for early detection and intervention.

Acknowledgments: We would like to thank the participants for their time and data contributions, as well as their

families for their support. We also appreciate the invaluable advice and support from everyone in Reto Huber's lab and Miriam Gerstenberg's research group throughout this project.

The Infraslow Fluctuation of Sigma Power During Sleep: Links to Markers of Arousal and Memory Reactivation Across Development

M. Dimitriadis¹, A. Osorio-Forero², S. Fattinger¹, S. von Arx¹, S. Kurth³, F. Pugin⁴, V. Jaramillo¹, C. Volk⁵, E. Krugliakova¹, M. Furrer¹, S. Leach¹, P. Achermann⁶, M. Gerstenberg⁵, R. Huber¹

Introduction: Sleep poses considerable evolutionary challenges—reduced responsiveness and increased vulnerability to external threats. A growing hypothesis emerging from rodent studies suggests that sleep is not solely a vulnerable state, but rather orchestrates a balance between environmental awareness and critical protected periods for memory reactivation. One candidate mechanism underlying this balance is the infraslow fluctuation of sigma power (ISFS), a rhythm reflecting the periodic clustering of sleep spindles over 10–100 seconds. In rodents, the ISFS segments non-rapid eye movement sleep into alternating fragile periods, characterized by heightened responsiveness to external input, and protected periods, during which sensitivity to the environment seems to be reduced and memory reactivation processes seem to be enhanced. However, how arousal and memory reactivation markers are organized within the human ISFS—and whether this rhythm is conserved during development—remains unclear.

Materials and methods: The ISFS was characterized in a sample of healthy individuals aged 8 to 26 years (N = 154) using high-density sleep electroencephalography. Two complementary approaches were applied. First, spectral analysis confirmed the presence of the ISFS and quantified key parameters, including peak frequency, variability, and strength across development. Second, electrophysiological markers of arousal and memory reactivation were examined to determine whether they were temporally organized within the ISFS from childhood to young adulthood.

Results: Findings demonstrate that sigma power fluctuates on an infraslow time scale from childhood to young adulthood. The peak frequency, variability, and strength of the ISFS increase from childhood and early adolescence to late adolescence and young adulthood. Notably, across all age groups, markers of arousal and memory reactivation are consistently organized within the ISFS, occurring most frequently during the spindle-rich peak.

Conclusions: The consistent presence and organization of the ISFS from childhood to young adulthood suggest that this rhythm is intrinsic to human sleep. Developmental increases in its frequency, variability, and strength highlight adolescence as a dynamic window of change. By elucidating how arousal and memory-related processes are temporally organized within the ISFS in humans, this study provides a foundation for future research into how sleep supports cognitive development and arousal regulation. These insights may inform interventions aimed at promoting healthy sleep trajectories and understanding disruptions across childhood and adolescence.

Acknowledgments: We would like to thank the participants for their time and data contributions, as well as their families for their support. We also appreciate the invaluable advice and support from everyone in Reto Huber's lab and Miriam Gerstenberg's research group throughout this project.

The Intersection of EEG and Oculometry: Insights from 5-MeO-DMT-Induced Effects on Sleep and Brain States

B.JB. Breant^{1,2}, T. Sharp³, D.M. Banneman⁴, V.V. Vyazovskiy¹

¹University of Oxford, Department of Physiology, Anatomy and Genetics, Oxford, United Kingdom,

²Sorbonne Université, Institut du Cerveau et de la Moelle Epinière, Paris, France, ³University of Oxford, Department of Pharmacology, Oxford, United Kingdom, ⁴University of Oxford, Department of Experimental Psychology, Oxford, United Kingdom

Introduction: Understanding the intricate dynamics between sleep and wakefulness is crucial for advancing our knowledge of sleep and brain function. Psychedelics, particularly 5-methoxy-N,N-dimethyltryptamine (5-MeO-DMT), offer a unique lens through which to explore these dynamics by inducing a state of "paradoxical wakefulness." This phenomenon is characterised by the coexistence of cortical slow-wave activity (SWA), typically associated with non-rapid eye movement (NREM) sleep, alongside behavioral wakefulness and heightened autonomic arousal. By integrating electroencephalography (EEG) with oculometry, we aim to investigate the neurophysiological underpinnings of this state and its implications for understanding sleep-wake regulation.

Materials and methods: Our study employed freely moving mice (C57BL6, n=27) to investigate the effects of 5-MeO-DMT on brain states. We conducted chronic frontal and occipital EEG and electromyography (EMG) recordings in n=21 mice. In subsets of these animals, local field potentials were recorded in the visual cortex with multiunit activity (n=4), or 4-hour sleep deprivation was performed (n=8). Additionally, pupil dilation and eye movement were recorded in freely moving animals following 5-MeO-DMT injection (n=11), with a subset also undergoing chronic EEG and EMG recordings (n=5). Each animal received an intraperitoneal injection of 5-MeO-DMT (5mg/kg) or saline at either the beginning of the light period or after sleep deprivation. Vigilance states were manually scored in 4-second epochs using SleepSign, and electrophysiology data were analysed with Matlab.

Results: Administration of 5-MeO-DMT induced a dissociated state of arousal characterised by increased cortical SWA, resembling NREM sleep, co-occurring with behavioral wakefulness and pronounced pupil dilation. EEG spectral analysis revealed significant regional differences, with increased SWA and steepened spectral slopes in frontal regions, contrasting with decreased theta power in occipital regions. These findings suggest a hybrid brain state regulated globally yet exhibiting localised dynamics. Pupillometric data confirmed heightened sympathetic activation, highlighting the decoupling of cortical slow-wave generation from traditional autonomic regulation. Notably, sleep deprivation did not significantly impact the power of 5-MeO-DMT-induced slow waves, suggesting these effects are not entirely reliant on sleep regulatory pathways. Further analysis of sleep showed no alteration of SWA in the sleep episodes following the injection, and 24 to 48-hours monitoring suggest potential long-term alteration of REM sleep homeostasis.

Conclusions: Our study demonstrates that 5-MeO-DMT induces a novel state of paradoxical wakefulness, offering a unique window into the mechanisms underlying the regulation of sleep-wake processes. By integrating EEG and oculometry, we reveal complex brain-behavior relationships that challenge traditional frameworks of vigilance states. These findings not only advance our understanding

of how psychedelics modulate brain states but also provide a translational framework for exploring their therapeutic potential in sleep disorders and depression. Moreover, the innovative use of EEG-oculometry integration highlights its potential for advancing both basic science and clinical applications. **Acknowledgments:** This work was funded by BBSRC UKRI DPhil Scholarship and the 2020 *In Vivo* skills award, and supported by Beckley Psytech

The neural network involved in torpor maintenance and arousal in mice

R. Amici¹, T. Hitrec¹, E. Piscitello¹, L. Taddei¹, L. Alberti¹, E. De Angelis¹, M. Luppi¹, D. Martelli¹, A. Occhinegro¹, Z. Tonelli Gombalova¹, D. Tupone¹, M. Cerri¹

¹Alma Mater Studiorum - University of Bologna, Dept. Biomedical and Neuromotor Sciences - Physiology, Bologna, Italy

Introduction: Torpor is an energy-saving strategy characterized by a reduction in metabolism and body temperature (T_b) that allows many species to survive harsh winters. While our understanding of the neural network involved in torpor onset has recently advanced in mice, a species that exhibits daily torpor, little is known about the network underlying the arousal from torpor. Since arousal entails a steep rise in T_b and the Raphe Pallidus (RPa) is a key brain area in the central control of thermogenesis, the present study aimed at investigating the neural network which is active during the arousal from torpor in mice, focusing on its projections to the RPa.

Materials and methods: Female C57BL/6J mice (18–23g), acclimated to T_a 21°C, underwent surgery under general anesthesia for the injection of a monosynaptic retrograde tracer (Cholera Toxin B, CTb) into the RPa and the implantation of a wireless T_b monitoring device. After a 7-day recovery, mice were acutely food-deprived to induce torpor. The three following experimental conditions were studied: i) Torpor (n=7): mice were euthanized during stable torpor, at least three hours after its onset; ii) Arousal (n=6): mice were euthanized 90 min. after the onset of the arousal from stable torpor; iii) Torpor-resistant (n=4): normothermic mice, in which torpor did not occur despite fasting, were euthanized at least three hours after fasting onset (fasted controls). At the end of the experiment, the brain was harvested for immunohistochemical quantification of cFos, and CTb expression.

Results: The results showed widespread cFos expression in the brain across the different experimental conditions. Notably, within the thermoregulatory network, in the Dorsomedial Hypothalamus (DMH) overall activity was significantly increased in “Torpor” compared to “Torpor-resistant” animals, and significantly decreased in “Arousal” compared to “Torpor” ones. However, no significant changes in the activity of neurons projecting from the DMH to the RPa was observed among the three conditions. Moreover, the number of active cells projecting from the Preoptic Area (POA) to the RPa was significantly lower in “Torpor” compared to “Torpor-resistant” animals, and further significantly decreased in “Arousal” compared to “Torpor” ones. The analysis of the brainstem and hypothalamic structures involved in wake promotion showed that overall activity was increased in both “Torpor” and “Arousal” animals compared to “Torpor-resistant” ones in both Dorsal Raphe and Locus Coeruleus, but no differences between “Torpor” and “Arousal” animals were observed.

Conclusions: These findings highlight the role of the central thermoregulatory network in torpor regulation, with distinct levels of activity during its maintenance and the subsequent arousal. In particular a specific role in the process of arousal from torpor seems to be played by the DMH, as previously observed for torpor induction, and by the POA, with a specific reference to its functional relationship with the RPa.

Acknowledgments: This research has been funded by the Ministero dell'Università e della Ricerca – Italy: PNRR MNESYS (PE0000006) - A multiscale integrated approach to the study of the nervous system in health and disease (DN. 1553 11.10.2022).

The relationship between rest-activity rhythms and Mild Cognitive Impairment in elderly community dwellers in a hyper-aged society

Introduction: As the aging population increases worldwide, the number of people with dementia and MCI has surged over the past decade. Recent studies have highlighted the association between disruption of daily resting activity rhythms (RAR) and cognitive decline and the development of dementia in the elderly. This study aimed to determine the relationship between RAR and MCI among elderly individuals living in a highly aged community.

Materials and methods: We analyzed the data from 177 participants aged 65 and over (77.4 ± 5.8), classified into MCI group ($n=62$) and Non-MCI group ($n=115$). Demographic data for each participant included age, gender, education, height, weight, usual walking speed, grip strength, Kihon checklist and cognitive function (Word list memory, Trail making test version A & B, and symbol digit substitution task). During the collection period, participants wore a triaxial accelerometer (Active Style Pro; Omron) on their waist for up to seven days to assess the following RAR parameters. These included interdaily stability (IS), which quantifies the stability of the 24-hour rhythm between different days; intradaily variability (IV), describing the fragmentation of the rhythm; and relative amplitude (RA), representing the robustness of a 24-hour rest-activity cycle. Additionally, the activity counts during the least active 5-hour period of the 24-hour cycle (L5) - likely representing hours during sleep - and during the most active 10-hour period (M10) were calculated. In the statistical analysis, independent t-tests were performed to compare demographic data, psychosomatic function tests, and RAR parameters between groups. Next, to examine the factors associated with MCI, a binomial logistic regression analysis was performed. The presence or absence of MCI was used as the dependent variable, with various assessment results serving as independent variables. Finally, activity plots for each group were created and compared using the independent t-tests. Statistical analyses were performed using SPSS Version 27.0 for Windows (SPSS Inc., IL, USA), with a significance level set at $p = 0.05$. This study was approved by the Ethics Committee of the Akita University Graduate School of Medicine (approval No. 3050).

Results: Results of the between-group comparison showed that the Non-MCI group performed significantly better in terms of age ($p < 0.01$), usual walking speed ($p < 0.01$), and the Kihon Checklist ($p < 0.05$). Similarly, the Non-MCI group performed significantly better in IV for RAR parameters ($p < 0.01$). Next, as a result of binomial logistic regression analysis, the Non-MCI group had a significant association with usual walking speed (Odds ratio, 0.142; 95% Confidence Interval [95%CI], 0.046-0.505; $p = 0.001$), IV (Odds ratio, 7.372; 95 % CI, 0.042-0.473, $p = 0.012$). Finally, the comparison of the 24-hour activity profiles for each group revealed significant differences in the mean activity at times 5 ($p < 0.05$), 6 ($p < 0.05$), 13 ($p < 0.01$), and 14 ($p < 0.01$).

Conclusions: In conclusion, this study suggested that older adults with MCI generally exhibit reduced walking speed and impaired rhythmic fragmentation. The study further indicated that periods of inactivity during early morning hours and post-noon may be indicative of an increased risk for developing MCI.

The Role of Endothelin Receptor Antagonist on Pulmonary and Systemic Hemodynamic Alteration in Chronic Intermittent Hypoxic Animal Model

A. Suwannakin¹, N. Jaimchariyatam^{2,1}, S. Sanguanrungsirikul³, P. Chantranuwatana⁴

¹Excellence Center for Sleep Disorders, King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Bangkok, Thailand, ²Division of Pulmonary and Critical care medicine, Department of Medicine, Faculty of medicine, Chulalongkorn University, King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Bangkok, Thailand, ³Department of Physiology, Faculty of Medicine, Chulalongkorn University, and King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Bangkok, Thailand, ⁴Department of Pathology, Faculty of Medicine, Chulalongkorn University, and King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Bangkok, Thailand

Introduction: Obstructive sleep apnea (OSA) has contributed critical risk factor for unfavorable cardiovascular outcome. On the basis of published evidence made the patients with OSA have potential to develop systemic and pulmonary vascular consequences, on the pathological basis of

chronic intermittent hypoxia (CIH) is found to be major responsible. CIH is associated with the alteration of sympathetic nervous system activation and cardiovascular variability. Furthermore, the involvement of endothelin in CIH animal model was previously demonstrated and provide the rationale to examine the crucial effect of bosentan (endothelin receptor antagonist) on hemodynamic alteration in CIH animal model (OSA model).

Materials and methods: Eighteen Wistar rats were randomly divided into three groups (six rats in each group), including one control group and two CIH-groups. Rats in both CIH-groups were exposed to alternating cycles of normoxia (30 seconds at 21% O₂) and hypoxia (30 seconds at 10% O₂), repeated continuously for 8 h/day during the light phase for 14 days. Bosentan 100 mg/kg/day was given to one CIH-group throughout the study. At the end of study, hemodynamic and histopathological studies were completely performed.

Results: Hemodynamic assessment revealed a significant reduction in mean right ventricular systolic pressure (RVSP) in the bosentan-treated CIH group compared with both the control and untreated CIH groups ($p < 0.001$). In the untreated CIH group, mean heart rate (HR) was significantly higher than in the control and bosentan-treated CIH groups ($p = 0.011$). Bosentan treatment significantly reduced mean HR and increased heart rate variability compared with the other groups. Histopathology showed no significant difference in percent wall thickness of pulmonary arterioles among groups. However, neomuscularization of small pulmonary arterioles was significantly greater in the CIH group (muscularized arterioles per 50 total vessels; $p = 0.042$). Right ventricular hypertrophy (RVH), expressed as the RV-to-(LV + septum) weight ratio, was also significantly higher in the CIH group compared with the other groups ($p = 0.015$).

Conclusions: Chronic intermittent hypoxia has been demonstrated to induce pulmonary and systemic hemodynamic alteration, recognized complication of OSA. The beneficial effect of endothelin receptor antagonist on systemic vascular parameters (heart rate and heart rate variability) and pulmonary vascular parameters (pulmonary arterial pressure, right ventricular hypertrophy and pulmonary vascular remodeling) suggest their potential as a therapeutic option for the cardiopulmonary consequences associated with OSA.

Acknowledgments: This study was supported by the Ratchadapiseksompotch Research Fund, Faculty of Medicine, Chulalongkorn University. Partial support by the Sleep Society of Thailand.

The Role of the Orexin System in Modulating Human Energy Metabolism

I. Park¹, R. Yoshitake², K. Kioka², A. Ishihara¹, K. Yajima³, F. Kawana¹, T. Kokubo¹, I. Matsuzaki¹, K. Tokuyama¹, M. Yanagisawa¹, T. Kanbayashi¹

¹University of Tsukuba, International Institute for Integrative Sleep Medicine, Tsukuba, Japan,

²University of Tsukuba, Faculty of Health and Sports Sciences, Tsukuba, Japan, ³Josai University, Faculty of Pharmaceutical Sciences, Saitama, Japan

Introduction: There is a crosstalk between regulators of energy metabolism and control of sleep / wakefulness. A molecule, such as orexin, acts on regulation of energy metabolism and sleep. Sleeping energy metabolism is related to sleep architecture, and orexin receptor antagonist may affect energy metabolism as well as sleep. Suvorexant, an approved orexin receptor antagonist, targets the orexin-mediated wake-promoting system and offers an alternative mechanistic approach to treating insomnia by promote NREM and REM sleep. Effect of suvorexant on sleeping energy metabolism in human is not known, while stimulating effects of orexin system on energy expenditure was reported in animal studies. However, effect of suvorexant on oxidized substrate is inconsistent among the animal studies.

Materials and methods: In this placebo-controlled, double-blind, crossover intervention study, metabolic rate of 14 healthy young male without sleep problems was measured using whole-room indirect calorimetry, during which polysomnographic recording of sleep was made. The participants consumed suvorexant (20 mg) or placebo 10 minute before bedtime.

Results: Fat oxidation was significantly increased while protein catabolism was suppressed without changes in energy expenditure by suvorexant during sleep although energy expenditure and carbohydrate oxidation remained unchanged. In semi-parametric regression analysis, suvorexant revealed lower energy expenditure during WASO than placebo. Interestingly, sleep architecture was not notably affected by suvorexant. The only difference in sleep architecture between 2 trials was observed in REM sleep and NREM stage 1. Both trials indicated changes in the dominant sleep stage, beginning with SWS followed by a transition to REM sleep.

Conclusions: The present study suggests that the effect of suvorexant on energy metabolism was not mediated by major changes in sleep architecture. The orexin system may affect fat oxidation independent of its roles in sleep regulation in humans [*iScience* 27: 110212, 2024]. We also conducted an on-going study with a narcoleptic patient, who has no detectable levels of orexin. We observed that patients with narcolepsy appeared to have a lower energy expenditure both during the daytime (awake state, assessed by polysomnographic) and at bedtime compared to healthy individual. It is probably due to the activation of the orexin system in healthy subject during daytime.

Toward an animal model for stress-related sleep bruxism

Y. Zhu¹, A. Katagiri¹, T. Kato^{1,2}

¹The University of Osaka, Graduate School of Dentistry, Department of Oral Physiology, Osaka, Japan,

²The University of Osaka Hospital, Sleep Medicine Center, Osaka, Japan

Introduction: In sleep medicine, sleep bruxism (SB) is considered one of the sleep-related movement disorders. It is characterized by excessive masticatory muscle activity (MMA) during sleep. However, it is hard to diagnose or treat SB effectively because the definitive pathological process has not been clarified. An animal model of SB is still lacking. Stress is known as a risk factor of SB. Inescapable foot-shock (IFS) is a well-known stressor in rats, resulting in sleep alteration and sympathetic activation. This study aimed to investigate the effects of acute IFS on sleep architecture, sympathetic activity, and MMA during the sleep-wake cycle.

Materials and methods: Experiment 1: Twelve male SD rats were evenly divided into sham and IFS groups. Rats in the sham group were placed in the IFS box from 10:00 to 10:30 without electrical stimulation, while rats in the IFS group received stimulation at 1.0 mA for 0.5 s with 30 s intervals. After that, the open field test was conducted for 15 min. Then, rats were perfused at 12:00, and immunohistochemistry staining was performed to quantify cfos-positive cells in stress-related areas, including the locus coeruleus and nuclei in the limbic system (i.e., prelimbic cortex, bed nucleus of the stria terminalis, paraventricular hypothalamic nucleus, and central nucleus of amygdala) between groups.

Experiment 2: In ten rats, electrodes were implanted for electroencephalogram (EEG), electromyogram (EMG) of the neck and masseter muscles, and electrocardiogram (ECG) to monitor sleep, MMA, and heart rate (HR). Sleep recordings were performed over 2 consecutive days during the dark phase (10:00 – 22:00). On day 1, rats were placed in the IFS box from 10:00 to 10:30 without stimulation, and recording was conducted from 11:00 to 18:00. On day 2, IFS was delivered before recording. All signals were analyzed in 10-s epochs. Vigilance states (wakefulness [W], non-rapid eye movement [NREM], and rapid eye movement [REM] sleep) were manually scored. Transient arousals during NREM were defined as no more than 3 consecutive epochs of W. Delta EEG power during NREM was calculated using Fast-Fourier transformation. HR was determined by R-wave counts. MMA was assessed by normalizing integrated EMG activity during chewing after artifact subtraction. EMG data of masseter muscle were log-transformed for Gaussian Mixture Model analysis, identifying two components: muscle contraction and muscle tone.

Results: Experiment 1: Time in the central zone was significantly less in the IFS group than in the sham group, confirming the stress condition. cfos-positive cells in stress-related areas were significantly increased after acute IFS.

Experiment 2: W significantly increased after acute IFS, while NREM and REM sleep decreased. Delta power ratio during NREM sleep also significantly decreased. HR during W and NREM sleep significantly increased. EMG activity of masseter muscle significantly increased during W, NREM sleep, especially within transient arousals. Furthermore, the mean value of muscle contraction and muscle tone during W and NREM sleep increased significantly after acute IFS.

Conclusions: IFS stress induced the elevation of MMA during the sleep-wake cycle, associated with cortical and sympathetic activation.

Transient effect of a short recovery sleep after total sleep deprivation on attention network test (ANT) and driving performance

V. Beauchamps^{1,2}, M. Quiquempoix^{1,2}, C. Jacques^{1,2}, D. Léger^{3,2}, M. Chennaoui^{1,2}, F. Sauvet^{1,2}

¹Institut de recherche biomédicale des armées, Unité Fatigue et Vigilance, Brétigny-sur-Orge, France,

²Université Paris Cité, UMR VIFASOM, Paris, France, ³AP-HP, Hotel-Dieu, Centre du sommeil et de la vigilance, Paris, France

Introduction: Sleep debt is a common constraint in professional environments such as the military, flight crew, or emergency responders. This phenomenon impacts cognitive performance, particularly attention, with an increased risk of accidents at work or during commutes. Sleep opportunities are sometimes available during work, but they are often limited in duration, and their effectiveness is still debated. The aim of our study is to objectify the impact of a short night of recovery sleep (3h TIB) after a 40h total sleep deprivation on attentional performance and driving.

Materials and methods: 41 healthy subjects (20 females, 32 +/- 7 years) participated in a 4-day / 4-night protocol, after eliminating a pre-existing sleep debt by actimetry. D1 corresponded to the day after a baseline night (BS, 8h TIB from 23:00 to 07:00), D2 the day after total sleep deprivation (TSD), D3 the day after a short recovery night (R1, 3h TIB from 23:00 to 02:00) and D4 the day after a longer recovery night (R2, 8h TIB from 23:00 to 07:00). Subjects performed an Attention Network Test (ANT) every day at 10:00 (sessions M1, M2, M3 and M4), as well as at 04:00 on TSD and R1 nights (sessions N1 and N2), allowing the assessment of reaction time (RT), reaction time variability (SD-RT), accuracy, as well as alerting, orienting and executive index. They then performed a 45-min session on a basic monotonous driving simulator, during which the number and duration of line crossings were measured, as well as the standard deviation of lateral position (SDLP). All parameters were analyzed using a mixed linear model, with a Bonferroni corrected post-hoc analysis. Simple linear regression assessed the prediction properties of each ANT parameters on driving performance.

Results: A significant session effect was noted on global ANT parameters (RT, SD-RT, accuracy) and driving performance ($p < 0.001$ for all). Post-hoc analyses confirmed the improvement in accuracy ($p = 0.01$), RT ($p < 0.001$), and SD-RT ($p < 0.001$) after the 3-hour sleep opportunity (N2 session) compared to the day after TSD (M2 session), even during a less favorable circadian phase. However, this improvement did not persist over time, with further deterioration during the M3 session. Similar results were observed for the number of line crossings and SDLP ($p = 0.003$), with no effect in the duration of line crossings ($p = 0.999$). Regarding the ANT indexes, only the executive index demonstrated a session effect ($p = 0.014$), without post-hoc analyses being conclusive. SD-RT emerged as the ANT parameter most predictive of driving outcomes. Performance returned to baseline after the 8-hour recovery night.

Conclusions: A 3-hour night of recovery after total sleep deprivation demonstrated short-term benefits for attentional performance and driving, thus confirming the value of these short sleep opportunities after a shift, for example. However, this benefit did not last over time. SD-RT, which reflects the instability of vigilance, appeared to be the most predictive parameter of driving performance, highlighting the notable interest of this parameter in ecological studies.

Urethane as an unparalleled anesthetic model for sleep cycling

C. Dickson¹, A. Singh²

¹University of Alberta, Psychology, Physiology, Neuroscience, and Anesthesiology & Pain Medicine, Edmonton, Canada, ²University of Alberta, Neuroscience, Edmonton, Canada

Introduction: Urethane (ethyl carbamate), unlike other common veterinary anesthetics, allows for sleep-like spontaneous alternations between NREM-like and REM-like forebrain activity states which makes it a powerful model for sleep cycles, and for sleep itself. The similarity across sleep and urethane anesthesia was shown for electrographic elements, physiological correlates, timing, pharmacology, brain correlates, as well as dependence on both ambient temperature and oxygen. The implication is that urethane anesthesia, unlike any other anesthetic studied to date, is the most complete model for the full spectrum of natural sleep. Furthermore, it suggests that the pharmacological mechanisms by which urethane acts to produce unconsciousness likely has broad similarities with the physiological regulation of sleep itself. If this is true, then drugs known to affect the sleep cycle should affect state alternations under urethane.

Materials and methods: Male Sprague-Dawley rats were anesthetized with i.v. urethane and local field potential recordings were made from frontal cortex and the hippocampus. Stable rhythmic alternations

with consistent proportions of activated (REM-like) and deactivated (non-REM-like) activity were recorded before i.v. or intra-cerebro-ventricular administrations of adenosine, caffeine, N6-cyclopentyladenosine (CPA), or CGS 21680. We characterized the effects by tracking any changes in the spectral features of both states and their alternations in the local field potential recordings.

Results: Adenosine, whether administered peripherally or centrally, promoted the deactivated (NREM-like) state. In contrast, caffeine (again either peripherally or centrally) decreased the NREM-like state. Interestingly, the A2A agonist CGS 21680 promoted the NREM-like state in a fashion similar to adenosine itself, but the A1 agonist CPA appeared to abolish state alternations altogether by promoting a highly deactivated state characterized by prominent and dense slow-waves.

Conclusions: Adenosine and both its agonists and antagonists have parallel effects across urethane anesthesia and natural sleep. This is further evidence supporting the validity of the urethane model of sleep itself.

Validation of a new patch-based polysomnography by Onera for patients with obstructive sleep apnea syndrome - an equivalence study

M. Krol¹, S. Lou², K. Muehlbacher¹, E. Cauza¹

¹Herz Jesu hospital Vienna, Sleep Medicine, Vienna, Austria, ²University of applied sciences Campus Vienna, Vienna, Austria

Introduction: This study investigates the equivalence of a novel patch-based polysomnography system, the Onera STS-PSG, for the analysis of obstructive sleep apnea syndrome. OSAS is a major health problem worldwide, affecting an estimated one billion people and causing various cardiovascular and metabolic complications. Traditional polysomnography, while effective, is costly and requires a hospital setting, which limits its accessibility. The Onera STS-PSG offers a more user-friendly and accessible alternative and could revolutionize sleep diagnostics by enabling at-home monitoring.

Materials and methods: The study was conducted with a patient cohort of 74 individuals, with STS-PSG and inpatient PSG measurements performed simultaneously, during the initial diagnostic night. The main characteristics to be investigated in the study are AHI, ODI and PLM. The secondary characteristics are N1, N2, N3 and REM sleep. Due to technical reasons, the awake stage could not be measured. The results were presented graphically using boxplots and distribution diagrams. The correlation was determined using Pearson's R and the equivalence was determined using a two one-sided tests (TOST) procedure.

Results: Pearson correlation analysis revealed correlations for AHI (0.92), ODI (0.7), PLM (0.76), N1(0.7), N2 (0.49), N3 (0.76) and REM (0.72), indicating strong agreement between the measurement results. The TOST procedure showed that the STS-PSG measures the parameters AHI, PLM, N1, N2, N3 and REM equivalently to the PSG system based on a) the given sample, b) the TOST procedure, c) the predefined equivalence limits and d) the alpha level (Bonferroni-corrected $\alpha=0.00714286$). The only parameter whose equivalence was rejected is the ODI, but this can be attributed to the fact that the transcutaneous oxygen measurement is not performed via the fingers, as in conventional PSG, but via the forehead.

Conclusions: This study found equivalence of the Onera-STS-PSG compared to traditional polysomnography. Particularly for the values AHI, PLM, N1, N2, N3, and REM, it was found that the STS-PSG measures were equivalent to in-lab PSG. For the value ODI, it was shown that the measurement was not equivalent, but this could be attributed to measurement differences. Any potential complications were easy to solve during application, as the system is user-friendly and logic-based. In future patients, especially technical barriers can be avoided as reading and configuring the pods will continue to be under the responsibility of specialized personnel. This is another step towards comfort and practicality for those affected.

Acknowledgments: I want to thank the Herz Jesu hospital in Vienna and the university of applied sciences Campus Vienna for helping with this study. Furthermore I want to thank Onera for lending us the devices during the course of this study.

What Influences Sleep Study Completion Among People with HIV in Care?

Z. Al-Tameemi¹, S.A. Ruderman¹, V.K. Kapur¹, H.M. Crane¹

¹University of Washington, Seattle, United States

Introduction: People with HIV (PWH) face a substantially higher prevalence of obstructive sleep apnea (OSA) than the general population, with rates ranging from 20% to 70% in PWH compared to 9% to 38% in the general population. Fatigue, also highly prevalent in PWH, can be caused by OSA. Despite its high prevalence and potential impact on quality of life, OSA is underdiagnosed in PWH and sleep studies to diagnose OSA are underutilized. We investigated characteristics associated with sleep study performance among PWH engaged in care.

Materials and methods: Demographic and clinical characteristics, comorbidities, and patient-reported outcomes (e.g., fatigue) were compared between PWH at Madison Clinic at the University of Washington who underwent sleep studies between 2008 and 2023 and those who did not. We used relative risk regression models to estimate associations between HIV factors (CD4 count and viral load) and fatigue and having received a sleep study, adjusted for demographic and clinical characteristics and comorbidities.

Results: Among 3,977 PWH, 165 (4%) completed a sleep study. Compared to those who did not receive sleep studies, PWH who underwent sleep studies were slightly older (mean age 50 vs. 48), had higher BMI, and better immunity, with higher mean CD4 cell counts (635 vs. 568) and greater HIV viral suppression (97% suppressed vs. 85%). PWH who received a sleep study had a greater prevalence of comorbidities such as diabetes (16% vs. 11%), dyslipidemia (41% vs. 27%), and hypertension (47% vs. 32%), as well as self-reported bothersome fatigue (79% vs. 55%). In adjusted models, we observed a 2.90-times (95% CI: 1.90-4.43) greater likelihood of having received a sleep study among PWH with bothersome fatigue, compared to those without.

Conclusions: We observed that PWH who received a sleep study had better HIV control (higher CD4 count and viral suppression), and a greater burden of fatigue and comorbidities often associated with OSA, than PWH who did not receive a sleep study. This suggests that healthcare providers and patients are more likely to prioritize evaluation of OSA in this context.

Acknowledgments: We extend our deepest gratitude to the participants whose contributions were essential to this study. We are profoundly grateful to the healthcare providers and staff at the UW HIV Clinic for their assistance in data collection and patient coordination. Our sincere thanks to our colleagues and mentors for their invaluable support and feedback throughout the research process.

Behavior, Cognition and Dreaming

A 365 nights: a yearlong electroencephalography investigation into human sleep in natural conditions

T. Avigdor^{1,2}, J. Duun-Henriksen³, E. Ahrens⁴, A.W. Helge³, A. Ho², M. Moya², B. Frauscher^{2,5}, S. Beniczky^{6,7}

¹McGill University, Neurology and Neurosurgery, Montreal, Canada, ²Duke University, Neurology, Durham, United States, ³UNEEG, Copenhagen, Denmark, ⁴T&W Engineering A/S, Lillerød, Denmark, ⁵McGill University, Neurology and Neurosurgery, Montreal, Canada, ⁶Danish Epilepsy Center, Neurophysiology, Dianalund, Denmark, ⁷Aarhus University, Clinical Medicine, Clinical Neurophysiology, Aarhus, Denmark

Introduction: We spend approximately one-third of our lives asleep, yet sleep quality and patterns vary significantly from day to day due to both external and internal factors. Despite this, our understanding of the multiday variations remains limited, primarily because of challenges in obtaining reliable, ultralong-term EEG data outside clinical settings. Recent advancements in subcutaneous electroencephalography (sqEEG) technology have now made ultralong-term home sleep recordings feasible. In this study, we explored multiday periodicities of sleep and examined the role of internal and external cues such as seasonal variation, day of the week, holidays, weather conditions and physical activity.

Materials and methods: Continuous sqEEG home recordings from 20 subjects (F=11) over a one-year period (349.95±28.69 days). We accurately determined the total sleep time (TST); durations and proportions of sleep stages (N1, N2, N3, REM); sleep onset and offset; sleep latency; REM latency; sleep efficiency; and wake after sleep onset (WASO). These parameters were evaluated longitudinally to identify seasonal variations, differences based on the day of the week, holidays, and birthdays using a permutation test. Additionally, sleep parameters were correlated with meteorological data, including

daily maximum and minimum temperatures, sunlight exposure, cloud coverage, humidity, and precipitation levels. Data from participants' smartwatches were also extracted to correlate daily step counts and exercise duration and timing with sleep characteristics. Differences between males and females were examined, with a secondary analysis conducted specifically among female participants to correlate sleep parameters with menstrual cycle phases. Beyond these external influences, we also assessed intrinsic multiday cyclic patterns within each subject over intervals of 10, 30, and 60 days.

Results: We found that 70-100% of subjects displayed individual patterns of multiday internal cyclicality in TST, sleep latency, REM latency and WASO over periods of 10, 30 and 60 days (average phase locking value = [0.09-0.22]), not influenced by external factors. We observed that sleep was affected by the season with a lower TST, and WASO during the summer ($p < 0.05$). During summer, the proportion of REM sleep decreased and the proportion of N3 sleep increased ($p < 0.05$). In addition, sleep onset time increased and sleep offset time decreased in these months ($p < 0.05$). The daily weather influenced certain sleep parameters, with temperature and sunlight displaying negative correlation with TST which was driven by a decrease in N2, N3 and REM ($r = [-0.2 -0.52]$), while cloud coverage was positively correlated with sleep onset, offset and WASO ($r = [0.2 0.37]$). Subjects went to sleep and woke up later during weekends ($p < 0.05$), and the sleep stage composition changed with more N2 sleep on the weekends as well as shorter sleep latencies ($p < 0.05$). In addition, sleep onset and offset time were shifted later during national holidays ($p < 0.05$), with significantly lower TST and REM duration during New Year's Eve ($p < 0.05$). Males and females displayed overall similar trends, however, their seasonal trends differ in timing.

Conclusions: Sleep is a complex phenomenon that is shaped by both internal mechanisms and external influences. Seasonal changes, daily weather patterns, and specific days of the week or year can temporarily alter its natural intrinsic multiday cycle.

Actigraphy-Estimated Sleep and Circadian Rhythms and the Risk of Delirium Following Traumatic Brain Injury during hospitalization

C.J. Lin¹, H.-Y. Chiu¹

¹Taipei Medical University, School of Nursing, Taipei City, Taiwan

Introduction: Delirium is a serious neuropsychiatric syndrome characterized by inattention, disorganized thinking, and fluctuations in alertness, commonly occurring in patients after head trauma. The role of disrupted circadian rhythms in the development of delirium following traumatic brain injury (TBI) remains unclear. This study aimed to evaluate sleep metrics and circadian rhythm disturbances as potential risk factors for TBI-related delirium.

Materials and methods: This is a secondary data analysis from our previous translation research, which validated the Traditional Chinese version of the Confusion Assessment Method (CAM-TC). Participants admitted to a neurosurgery ward wore actigraphy devices for up to 7 days to monitor sleep metrics and circadian rhythms. Cox regression hazard models were used to associate sleep and circadian rhythm metrics with the incidence of TBI-related delirium.

Results: The study included 100 participants, with a median age of 68.5 years, and 10 of them developed delirium during their hospitalization. Sleep parameters, such as total sleep time, sleep efficiency, sleep onset latency, wake after sleep onset, sleep fragmentation index, and activity index, showed no significant differences between those with and without delirium ($p > 0.05$). However, significant differences were observed in circadian rhythm metrics between the non-delirium and delirium groups: relative amplitude (0.57 vs. 0.29, $p < 0.05$) and autocorrelation (0.20 vs. 0.08, $p < 0.05$). Adjusted Cox regression analysis indicated that none of the circadian rhythm metrics were significant risk factors for post-TBI delirium.

Conclusions: This study is the first to examine sleep parameters and circadian rhythms in TBI patients during the acute stage of hospitalization. Patients with TBI-related delirium exhibited more variability in circadian rhythms, suggesting a disruption in their regular rest-activity patterns. Further research should focus on delirium prevention strategies that maintain circadian stability through nursing interventions and ensure a stable clinical environment.

An experimental study on the effects of railway vibration on sleep and the blood metabolome

M. Smith¹, M. Sandberg¹, M. Ögren¹, K. Pistola¹, J. Nordstrand¹, S. Yusuf¹, K. Persson Waye¹, A. Johansson², L. Carlsson², D. Malmödin³, A. Bay Nord³, M. Basner⁴, M. Younes⁵, N. Vincens¹

¹University of Gothenburg, School of Public Health and Community Medicine, Institute of Medicine, Gothenburg, Sweden, ²Sahlgrenska University Hospital, Occupational and Environmental Medicine, Gothenburg, Sweden, ³University of Gothenburg, Swedish NMR Institute, Gothenburg, Sweden, ⁴University of Pennsylvania, Unit for Experimental Psychiatry, Division of Sleep and Chronobiology, Department of Psychiatry, Philadelphia, United States, ⁵University of Manitoba, Sleep Disorders Centre, Winnipeg, Canada

Introduction: Environmental vibration, such as from freight railway lines, and its impact on the sleep and health of exposed populations remains poorly understood. The small number of existing epidemiological studies show associations between chronic railway vibration exposure at night and subjective sleep disturbance and increased prevalence of diabetes. However, the pathophysiological pathways in the vibration-sleep-disease relationship remain unclear. We here investigate the mechanisms that may link vibration-induced sleep disruption with the development of metabolic disease.

Materials and methods: N=22 young, healthy individuals (mean±SD 22.6±2.2 years; 9 women) spent five consecutive nights in acoustically isolated bedrooms. Following one acclimation night and one quiet control night for baseline measurements, nights three through five included synthesised railway vibration exposure at 0.5 mm/s, 0.7 mm/s or 0.9 mm/s each night. Vibration was accompanied by low level railway noise (35 dB $L_{AF,max}$). Sleep was measured with unattended ambulatory polysomnography and questionnaires. Questionnaires further included items on restoration and positive and negative affect. Sleep fragmentation was assessed using the Odds Ratio Product (ORP), a continuous measure of sleep depth and stability derived from EEG spectral power. To identify metabolic consequences of nocturnal vibration, we collected daily blood samples for NMR metabolomics analysis. We measured cognitive performance across multiple domains with a daily computerised test battery. All data were analysed in linear mixed models (random subject effect) adjusted for sex and time in study. Event-related analyses of vibration-induced sleep disturbance were further adjusted for time of night and sleep at train onset.

Results: Vibration induced event-related elevations ORP in a dose-dependent relationship (main effect $p<.0001$), ranging from a maximal change relative to pre-event baseline of $\Delta ORP=0.08$ at 0.5 mm/s to $\Delta ORP=0.20$ at 0.9 mm/s. In all vibration conditions there was a reduction in stage N3 sleep of 18-24 minutes relative to the control night ($p<.001$), although there was no significant difference between the three vibration nights ($p>.01$ for all post-hoc comparisons). Relative to Control, nights with railway vibration were associated with elevated concentrations of glucose (z-scores +0.51 to +1.03, $p=.020$), glutamine (z-scores +0.53 to +1.12; $p=.021$), and acetic acid (z-scores +0.05 to +0.80; $p=.005$); and lower concentrations of proline (z-scores -0.07 to -1.02; $p=.003$), and ornithine (z-scores -0.66 to -1.08; $p=.040$). However, these metabolic effects did not survive statistical correction for multiple hypotheses testing. Vibration nights were followed by reduced perceived sleep quality ($p=.023$), lower positive affect ($p=.007$) and increases in all measures of vibration-induced sleep disturbance compared to the quiet Control (all $p<.0001$). No significant effects of vibration were found for cognitive performance.

Conclusions: Railway vibration impaired physiological and subjective sleep. These novel findings extend beyond previous research, and may implicate metabolic upregulation or reduced metabolite uptake after vibration-induced sleep fragmentation in the exposure-sleep-disease relationship. Although a promising first step, these findings need to be reproduced in larger and more representative studies before firm conclusions can be drawn.

Acknowledgments: We are grateful to Johannes Rehnberg for assistance with polysomnography setup. The study was supported by Trafikverket, the Swedish Transport Administration (TRV 2022/105563).

Association of sleep trajectories and depressive symptoms among rural-dwelling older adults

S. Tang¹, T. Zhao², Y. Du¹, C. Qiu³

¹Shandong Provincial Hospital affiliated to Shandong First Medical University, Neurology, Jinan, China, ²Shandong Provincial Hospital, Shandong University, Neurology, Jinan, China, ³Karolinska Institutet-Stockholm University, Aging Research Center, Department of Neurobiology, Care Science and Society, Stockholm, Sweden

Introduction: The relationship between sleep duration trajectories and depressive symptoms in China remains inconclusive. We aimed to explore this relationship over 9 years among rural-dwelling older adults in China.

Materials and methods: We used prospective data from participants of the MIND-China study. Sleep durations were measured at 3 study visits between 2014 and 2021 using the Pittsburgh Sleep Quality Index. We used group-based trajectory modeling to identify four sleep trajectories: "Normal stable," "Short stable," "Decreasing," and "Extremely short stable." Depressive symptoms were measured using 15-item Geriatric Depression Scale in 2023. Linear regression was used to relate sleep trajectories with depressive symptoms, and stratified analysis was conducted by physical activity, and hypertension.

Results: The mean [SD] baseline age was 68.60 [3.49], and 59.8% were female. Compared with having "Normal stable," having "Decreasing" (95% CI=0.06, 1.14) or "Extremely short stable" (95% CI=0.03, 1.46) sleep trajectories were associated with an increased likelihood of depressive symptoms. Compared to those who do not participate in physical activity, having "Decreasing" (95% CI=0.45, 1.91) sleep trajectories among participants who engage in physical activity were associated with an increased likelihood of depressive symptoms. Compared to those without hypertension, having "Decreasing" (95% CI=0.17, 1.47) or "Extremely short stable" (95% CI=0.44, 2.20) sleep trajectories in participants with hypertension were associated with an increased likelihood of depressive symptoms.

Conclusions: Prolonged exposure to decreasing and extremely short sleep duration may result in worse depressive symptoms. This association differed by physical activity, and hypertension.

Associations Between Dream and Nightmare Frequency, Respiratory Parameters, and Psychiatric Symptoms in Obstructive Sleep Apnea Syndrome

K.J. Hwang¹, J. Kim²

¹Kyung Hee University, Department of Neurology, Seoul, Korea, Republic of, ²Pusan medical center, Pusan, Korea, Republic of

Introduction: This study investigated the frequency of dreams and nightmares in patients with obstructive sleep apnea syndrome (OSAS) and examined their associations with respiratory parameters and psychiatric symptoms.

Materials and methods: A total of 3512 patients (1021 women; mean age: 53.45 years) who underwent polysomnography for suspected sleep apnea were included. Each participant completed standardized questionnaires assessing nightmare severity (Disturbing Dream and Nightmare Severity Index, DDNSI) and nightmare impact (Nightmare Effect Survey, NES). Reported dream frequency was categorized as: none, infrequent (≤ 1 /week), sometimes (2–3/week), and frequent (> 3 /week).

Results: The frequent dreaming group demonstrated significantly lower apnea–hypopnea index (AHI) ($p < 0.001$) and oxygen desaturation index (ODI) ($p = 0.011$). In contrast, this group showed significantly higher scores on the Beck Depression Inventory (BDI, $p < 0.001$) and Beck Anxiety Inventory (BAI, $p < 0.001$). DDNSI and NES scores were positively correlated with BDI ($r = 0.430$ and $r = 0.419$, respectively; $p < 0.001$) and BAI ($r = 0.476$ and $r = 0.382$, respectively; $p < 0.001$). However, neither DDNSI nor NES scores were significantly associated with AHI or ODI.

Conclusions: Despite prior hypotheses linking oxygen desaturation to dream content, our findings suggest an inverse association between respiratory parameters and dream frequency. Increased dream and nightmare frequency were more strongly associated with depressive and anxiety symptoms, highlighting the potential role of psychiatric comorbidity in dream activity among patients with OSAS.

Associations between multidimensional sleep health and cognitive continuum among Chinese older adults: a population-based study

S. Tang¹, G. Liu¹, Y. Du¹, C. Qiu³

¹Shandong Provincial Hospital affiliated to Shandong First Medical University, Neurology, Jinan, China, ²Karolinska Institutet-Stockholm University, Aging Research Center, Department of Neurobiology, Care Science and Society, Stockholm, Sweden

Introduction: To explore the relationship between multidimensional sleep health (MDSH) and cognitive continuum.

Materials and methods: This population-based study included 5272 participants living in rural China. Sleep parameters were measured using the Pittsburgh Sleep Quality Index (PSQI). The multidimensional sleep health (MDSH) score (ranges 0-5) was generated based on satisfaction, alertness, timing, efficiency, and duration, with a higher score indicating healthier sleep. Subjective cognitive decline (SCD) was assessed using three questions regarding memory problems. Mild cognitive impairment (MCI) and dementia were diagnosed according to the internationally recognized criteria. Linear regression analysis examined the correlation between MDSH and cognitive domains. Logistic regression models examined the relationship between MDSH and SCD, MCI and its subtypes, all-cause dementia, and AD. We also conducted stratified analyses based on APOE genotype.

Results: Of all participants, 2913 (55.3%) were diagnosed with SCD, 1310 (24.8%) with MCI, and 181 (3.4%) with all-cause dementia, including 117 (2.2%) with Alzheimer's disease (AD). As a continuous variable, MDSH was positively associated with memory (multivariate-adjusted β coefficient = 0.05, 95% confidence interval [CI] = 0.03 to 0.07), language (0.03; 0.01 to 0.05), attention (0.04; 0.02 to 0.06), executive function (0.02; 0.004 to 0.04), and the global cognitive function (0.04; 0.02 to 0.05). Each unit increase in MDSH was associated with an decrease in SCD (multivariate-adjusted odds ratio = 0.75, 95% CI = 0.69 to 0.82), MCI ((0.90; 0.85 to 0.96), amnesic mild cognitive impairment (aMCI) (0.88; 0.83 to 0.94), all-cause dementia (0.81; 0.71-0.93), and AD (0.76; 0.64 to 0.89), and similar associations were observed when MDSH was used as a categorical variable (0-1/2-3/4-5). In addition, we found that MDSH (as a continuous variable) interacted with SCD, all-cause dementia, and AD in the APOE genotype (p for interactions = 0.018, <0.001, and 0.018, respectively).

Conclusions: MDSH was significantly associated with the cognitive continuum. And the effects vary by APOE genotype.

Awakenings as Mnemonic Gateways for Dream Memory: Traits or States

S. Ataei^{1,2}, J. Zhao³, M. Jafarzadeh Esfahani⁴, M. Dresler⁴, N. Axmacher², S. Schoch⁴

¹Donders Institute for Brain, Cognition and Behavior, Radboud University Medical Center, Nijmegen, Netherlands, ²Ruhr University Bochum, Department of Neuropsychology, Faculty of Psychology, Bochum, Germany, ³Ludwig-Maximilians-Universität München, Munich, Germany, ⁴Donders Institute for Brain, Behaviour and Cognition, Radboud University Medical Center, Nijmegen, Netherlands

Introduction: The arousal-retrieval model posits that nightly awakenings act as gateways for the consolidation of dream memories. Leveraging longitudinal and naturalistic sleep datasets, this study disentangles trait and state effects to identify awakening characteristics that predict dreaming awareness (DA), content reconstruction (CR), and overall dream recall frequency (DRF).

Materials and methods: We analyzed two datasets: All Recallers ($n = 711$) included ZMax EEG recordings from 8,010 nights and DRF questionnaires across three assessment waves over one year, and High Recallers ($n = 94$) included nightly Fitbit sleep data and next-morning DA and CR from 2,383 nights. Separate mixed-effects models were conducted for each dataset, controlling for age and gender. Model 1 included subjective and objective awakening frequencies as predictors. Model 2 included short (<1 min), medium (1–2 min), and long (>2 min) awakening frequencies. Model 3 adjusted Model 2 for sleep duration and final sleep stage. Fixed effects were decomposed into between-person means and within-person deviations (scaled). False discovery rate (FDR) correction was applied.

Results:

In All Recallers, 28% of DRF variance was within-person (wave-to-wave), but not explained by within-person predictors. Between-person objective ($\beta \approx 0.16$, $p = .01$) and subjective ($\beta \approx 0.28$, $p < .001$) awakening frequencies explained 7% of the variance. Specifically, between-person long awakening frequency predicted DRF ($\beta = 0.23$, $p = .013$), even after adjusting for sleep duration and final sleep stage. Age negatively predicted DRF ($\beta = -0.18$, $p = .008$), while female gender positively predicted it ($\beta = 0.25$, $p = .008$).

In High Recallers, most variance in DA (68%) and CR (83%) was within-person (night-to-night). Within-person objective (DA: OR ≈ 1.18 , $p = .01$; CR: OR ≈ 1.25 , $p < .001$) and subjective (DA: OR ≈ 1.32 , $p < .001$; CR: OR ≈ 1.21 , $p < .001$) awakening frequencies explained 5% of the variance. Short and medium frequencies predicted CR (ORs ≈ 1.12 – 1.14 , $p < .05$), with a marginal effect for long awakenings ($p = .07$). These effects were accounted for by sleep duration (CR: OR = 1.27, $p = .003$) and REM sleep

before final awakening (DA: OR = 1.64, $p = .006$; CR: OR = 1.68, $p < .001$). Between-person predictors did not explain the remaining variance. Female gender positively predicted DA (OR = 2.20, $p = .03$).

Conclusions: Individuals who habitually experience and remember longer awakenings tend to have higher dream recall frequency. High recallers are more likely to report a dream and its content after longer nights of sleep, when they wake up from REM sleep and experience and remember more awakenings. These findings support the arousal-retrieval model and clarify that awakenings function differently at the trait and state levels: long awakenings distinguish high from low recallers, and in high recallers, any length of awakening in a specific night increases the likelihood of remembering the dream content the next morning.

Balancing the specificity and generalisability of learning: roles of sleep and wakefulness

Z. Liu¹, C. Song¹

¹Cardiff University, Psychology, Cardiff, United Kingdom

Introduction: Training on a visual task can lead to significant improvements in visual performance, a phenomenon known as visual perceptual learning. Notably, these improvements are not fixed and may extend beyond the online phase, when individuals actively engage in training, and continue into the offline phase during sleep. The continued improvements during sleep, achieved without conscious effort or behavioural engagement, highlight the brain's ability to harness visual perceptual learning through neural plasticity. However, how wakefulness and sleep coordinate to optimise visual perceptual learning remains poorly understood. It is also unclear whether online learning during wakefulness and offline learning during sleep rely on the same or distinct neural circuits.

Materials and methods: Fifty healthy young adults (ages 18–31) participated in two sub-studies, with $N = 30$ in Study 1 and $N = 20$ in Study 2, examining the learning of visual features (orientation or luminance) in a backward masking task. Participants were randomly assigned to morning (8 AM) or evening (8 PM) learning sessions, followed by test sessions immediately after (0 hours), 12 hours, and 24 hours post-learning. In each sub-study, training occurred in the lower-left visual field, and test sessions included ten tasks probing cross-location, cross-feature, and cross-task generalisation. The temporal spacing between sessions allowed us to isolate the effects of sleep versus wake on learning. Visual stimuli were presented on a high-refresh-rate monitor under controlled lighting; eye position was monitored, and task accuracy was adaptively thresholded.

Results: Here, we found that during wakefulness, visual improvements were confined to the specific visual feature and visual field location being trained. By contrast, during sleep, these improvements generalized to other visual features and visual field locations. Both local and generalised improvements persisted for weeks after training had ended.

Conclusions: Our findings suggest that wakefulness and sleep jointly balance the specificity and generalisability of visual perceptual learning: wakefulness enhances specificity by prioritising training-related visual signals and driving targeted improvements in visual performance, while sleep fosters generalisability, making the learned visual skills more adaptable.

Acknowledgments: This research was supported by Cardiff University Brain Imaging Center (CUBRIC) and conducted in accordance with the university's ethics guidelines.

Cardiovascular Risk Biomarkers Moderate the Associations Between Different Sleep Stage Durations and Global Cognition in Older Black Adults

D. Chung¹, B. Larsen¹, Z. Wang¹, N. L'Houtellier¹, G. Belony¹, S. Scott¹, A. Seixas¹, G. Jean-Louis¹

¹University of Miami Miller School of Medicine, Department of Psychiatry and Behavioral Sciences, Miami, United States

Introduction: Sleep disturbances increase the risks of cognitive impairment and dementia, but the underlying mechanisms to elucidate this remain elusive. Prior studies have shown that each distinctive sleep stage has unique health effects and impacts on cognitive function, but current literature has been mixed regarding which sleep stages affect overall cognition. Mixed findings may be in part due to prior work not testing potential moderating factors that are independently known to influence both sleep

disturbances and cognitive performance, such as cardiometabolic health. Therefore, we tested whether cardiometabolic biomarkers moderated the relationships between the proportions of the different stages of sleep (light (N1/N2) sleep, slow-wave sleep (SWS, or N3), and rapid eye movement (REM) sleep) and global cognition.

Materials and methods: Thirty-five older Black adults aged ≥ 55 years (77.1% female) who resided in New York and Florida were invited to participate in a two-phased, prospective, observational study. Participants continuously wore a Fitbit Inspire 2 HR wrist-worn device for seven consecutive days; the FitBit measured sleep and wake activity, including the total minutes of the light, SWS, and REM sleep nightly. Serum cardiovascular risk biomarkers (total cholesterol:high-density lipoproteins (TC:HDL-c) ratios, low-density lipoproteins (LDL) cholesterol, triglycerides, and high-sensitivity C-reactive protein) and insulin resistance markers (glucose, insulin, glycated hemoglobin) were quantified. Participants completed the Montreal Cognitive Assessment-BLIND (MoCA-BLIND) task. Hierarchical moderated regression analysis was utilized to test whether cardiometabolic biomarkers moderated the links between different sleep stage durations and global cognition.

Results: TC:HDL-c ratios moderated the links between the proportions of light ($\Delta R^2=0.22$, $\Delta F=9.95$, $p=0.004$) and REM ($\Delta R^2=0.26$, $\Delta F=12.55$, $p=0.002$) sleep stage durations and MoCA scores. Additionally, LDL and triglycerides values moderated the associations between the proportion of REM sleep duration and MoCA scores ($\Delta R^2=0.19$, $\Delta F=8.62$, $p=0.007$ and $\Delta R^2=0.21$, $\Delta F=9.64$, $p=0.005$, respectively). Insulin resistance did not moderate the relationships between the proportions of any sleep stage durations or total sleep duration and MoCA scores.

Conclusions: These data suggest that the associations between the proportions of light and REM sleep obtained, but not SWS, and global cognition differ by cholesterol levels in older Black adults. Future work should investigate these links longitudinally using larger, more representative samples.

Chronotype and time-of-day in inhibitory control performance among healthy adults – a randomised cross-over trial

S.Y. Choong¹, J.A. Lum¹, P.K. Staiger¹, S.P. Drummond², A. Jones³, J.E. Byrne¹

¹Deakin University, Burwood, Australia, ²Monash University, Clayton, Australia, ³Liverpool John Moores University, Liverpool, United Kingdom

Introduction: Chronotype reflects stable individual differences in the preferred timing of behavioural activity, productivity, and sleep. Morning-types tend to function best earlier in the day, whereas evening-types perform better later. Prior research shows that cognitive performance – particularly executive functions such as working memory and attention – varies by chronotype and time-of-day; however, their effects on distinct components of inhibitory control remain unclear. Inhibitory control is widely studied using the Go/No-Go Task (GNG) and Stop-Signal Task (SST), which assess action restraint (withholding a prepotent response) and action cancellation (halting an ongoing response), respectively. This study investigated whether chronotype and time-of-day modulate GNG and SST performance in healthy adults.

Materials and methods: This randomised crossover study recruited adults aged 18-30 years from Melbourne, Australia, who self-identified as either morning- or evening-types. Participants completed demographic questionnaires including the Pittsburgh Sleep Quality Index and the Munich Chronotype Questionnaire. Sleep was monitored via actigraphy and sleep diaries prior to testing. Each participant completed two laboratory sessions in randomised counterbalanced order (stratified by chronotype and gender): one in the morning (08:00-10:00h) and one in the afternoon/evening (16:00-18:00h). At each session, participants completed subjective sleepiness ratings, the Psychomotor Vigilance Task (PVT), GNG and SST. Commission error rates and stop-signal reaction times were the primary outcomes. Linear mixed models assessed effects of chronotype, time-of-day and covariates (subjective sleepiness and objective vigilance), with Bayesian equivalents used to calculate likelihood ratios. This study was approved by the Human Research Ethics Committee (2022-333).

Results: The final sample included 59 healthy adults (55.9% female; mean age: 22.1 ± 3.77 years), with 29 identified as morning-types and 30 as evening-types. At baseline, groups differed significantly in sleep-corrected mid-sleep timing (mean $\pm$ SD: morning-types = 2.98 (0.96); evening-types = 5.76 (1.14); $p < .001$), but not in age, gender, or sleep quality. No significant effects of chronotype ($BF_{01} = 2.717$), time-of-day ($BF_{01} = 3.742$) or their interaction ($BF_{01} = 34.623$) were observed for GNG performance. In contrast, SST performance showed a significant main effect of chronotype ($BF_{10} = 1.645$), with

evening-types exhibiting longer SSRTs than morning-types, independent of time-of-day. No significant effects of time-of-day ($BF_{01} = 2.999$) or interaction ($BF_{01} = 6.078$) were found for SST performance. Subjective sleepiness and objective vigilance were not significant covariates for either task.

Conclusions: These findings highlight the importance of considering the multifaceted nature of inhibitory control, suggesting its subcomponents are differentially sensitive to chronotype. Evening-types may experience greater difficulty cancelling initiated responses, regardless of time-of-day. This work underscores the significance of accounting for subjective and objective alertness in contexts where inhibitory control is critical. Future work should integrate biological circadian markers and neurophysiological measures to provide a more comprehensive understanding of individual variability in inhibitory control across the day.

Clinical significance criteria in the ICSD and DSM sleep disorder classifications: A content overlap analysis using the Jaccard index

J.-A. Micoulaud-Franchi¹, V. Martin¹, C. Gaud³

¹Bordeaux University, Neurosciences, Bordeaux, France, ²INRIA, Informatics, Nancy, France,

³Université Claude Bernard Lyon 1, Child and Adolescent Psychopathology, Lyon, France

Introduction: Both the International Classification of Sleep Disorders (ICSD) and the Sleep-Wake disorders section of the Diagnostic and Statistical Manual (DSM) emphasize the importance of clinical judgment in distinguishing the normal from the pathological in sleep medicine. The DSM-IV (1994) introduced the Clinical Significance Criterion (CSC) to standardize this judgment and enhance diagnostic reliability.

Materials and methods: We conduct a theoretical and historical content analysis of CSC presence, frequency, and formulation in the diagnostic criteria of sleep disorders. Three steps were undertaken: i) selecting main sleep disorder classifications and main disorders within them, ii) systematically extracting CSC-related content, and iii) analyzing the evolution of CSC presence through quantification (Jaccard Index) and visualization (radar plots).

Results: The DSM-5-TR includes CSC in five of nine main sleep disorders, compared to two in the ICSD-3-TR (Circadian Rhythm Sleep-Wake Disorder and Nightmare Disorder). The overlap between DSM-5-TR and ICSD-3-TR is moderate (Jaccard Index = 0.40). The overlap between DSM versions is higher (0.53). Conversely, ICSD revisions exhibit minimal similarity (0.16). Radar plots reveal a gradual increase in CSC use within ICSD versions.

Conclusions: These results highlight the variable application of CSC in sleep disorder classifications. Universal CSC inclusion may not be essential, but systematic discussion of its potential use can help refine diagnostic criteria. This refinement is important for accurately diagnosing sleep disorders and better differentiating the normal from the pathological, a major challenge in sleep medicine.

Cognitive Impairment and Its Impact on Gait Parameters and Physical Function in the Elderly

D. CHOI¹, G. Maeng¹, J. Choi², C. Park¹, T. Kim³

¹Yonsei University, Division of Digital Healthcare, Wonju-si, Gangwon-do, Korea, Republic of, ²Yonsei University Wonju Severance Christian Hospital, Department of Psychiatry, Wonju-si, Gangwon-do, Korea, Republic of, ³Wonju College of Medicine, Yonsei University, Department of Psychiatry, Wonju-si, Gangwon-do, Korea, Republic of

Introduction: Cognitive impairment is a major issue in aging societies, as it significantly reduces quality of life and independence. It is closely associated with gait disturbances and an increased risk of falls. Subtle changes in gait patterns can serve as early indicators of cognitive decline, highlighting the importance of preventive approaches through physical function assessment. Therefore, this study aimed to analyze differences in gait characteristics and physical function according to cognitive status based on gait data.

Materials and methods: A total of 65 participants from the KLOSDOM Gangwon Living Lab at Yonsei University Wonju Severance Christian Hospital were included. Cognitive function was assessed using the Short Blessed Test (SBT), which evaluates memory, concentration, orientation, and ability to perform activities of daily living. Gait and physical performance were evaluated using the N Steps Walking Test (NSWT), Timed Up and Go Test (TUGT), Five Times Sit to Stand Test (FTSST), and Single Leg Stance Test (SLST). Participants were divided into two groups based on SBT scores: cognitively normal ($SBT \leq 8$; $n = 36$; mean age = 70.7 ± 5.7 years; male: 41.7%) and cognitively impaired ($SBT \geq 9$; $n = 19$; mean age = 74.4 ± 6.2 years; male: 47.4%).

Results: The analysis revealed that the cognitively normal group showed significantly higher values in L_Toe (%) from NSWT_L (left side), R_Final Score from NSWT_R (right side), and Total Score of the SPPB ($p < 0.05$). Conversely, they demonstrated significantly lower values in L_Mid (%) from NSWT_L, R_Heel (%) from NSWT_R, and time (seconds) required to complete the TUGT and FTSST ($p < 0.05$), indicating overall superior gait and physical performance.

Conclusions: These findings suggest that cognitive impairment is closely related to changes in gait characteristics. This study provides foundational evidence for the use of physical function and gait analysis as a potential tool for early detection and prevention of cognitive decline in older adults.

Comparing home and laboratory morning dream reports

S.F. Schoch¹, V. Elce², A.C. Van der Heijden³, M. Dresler¹

¹Donders Institute, Nijmegen, Netherlands, ²IMT Lucca, Lucca, Italy, ³University of Amsterdam, Amsterdam, Netherlands

Introduction: Serial awakenings in a laboratory setting are the gold standard for collecting multiple dream reports over a night. However, there is an ongoing debate about the ecological validity of dreams reported in sleep laboratories. Since serial awakenings sample different sleep stages and times of night, it is unclear how many differences between home and lab dreams are due to the setting or the different sampling methods. Therefore, in this study, we compare morning dream reports collected in the laboratory after an adaptation night (with no serial awakenings) with home dream reports from the same participants to examine how the sleep environment affects the characteristics of recalled dreams.

Materials and methods: A total of 107 healthy young adults ($M = 23.79$ years, $SD = 3.02$; 75 female) participated in the study. Each participant completed one adaptation night in a sleep laboratory with a morning dream report and completed a sleep diary at home over 4 weeks. 2,064 morning dream reports were analyzed ($n=121$ adaptation night, $n=1,943$ home). Each report was rated by the participant for different sensory modalities, lucidity, vividness, arousal, valence, as well as how accurate and complete they think their report is. We used linear mixed models and generalized linear mixed models for the analysis with participant as random effect.

Results: Home dreams were rated by participants to contain more visual, tactile, gustatory, and vestibular perceptions (all $p < 0.008$) than dreams in the laboratory, with no difference in auditory, olfactory, and somatosensory perceptions (all $p > 0.06$). Home dreams were rated by participants as having higher arousal and being more vivid (both $p < 0.004$), while there was no difference in dream valence and lucidity (both $p > 0.3$). Additionally, participants remembered the dreams with the same accuracy and completeness in both settings (both $p > 0.1$).

Conclusions: These findings suggest that the sleep environment impacts the phenomenology of recalled dreams. Dreams reported from home were rated as more vivid, emotionally arousing, and rich in sensory detail, pointing to a potential blunting of dream experiences in the laboratory setting.

However, other aspects of dreaming, such as lucidity and valence, seem to be unaffected by the setting. An alternative interpretation is that the lower dream recall frequency at home leads to a memory bias favoring more vivid or emotional dreams. This might be due to lower adherence to immediately reporting their dreams after waking up. In contrast, the higher recall rate in the laboratory may reflect priming or increased motivation. These results underscore the importance of considering the research setting when interpreting dream data.

Correlation between Cognitive Dysfunction and the Integrity of the Dopaminergic System in Neurodegeneration: A Narrative/Comprehensive Review

M. Mulas^{1,2,3}, J. Johnson⁴, J. Benson⁵, N. Biabani³, M. Figorilli¹, M. Puligheddu¹, I. Rosenzweig^{5,3}

¹University of Cagliari, Interdepartmental Sleep Disorder Centre, Department of Medical Sciences and Public Health, Cagliari, Italy, ²University of Cagliari, Neuroscience PHD program, Department of Biomedical Sciences, Cagliari, Italy, ³King's College London, Department of Neuroimaging, Sleep and Brain Plasticity Centre, Institute of Psychiatry, Psychology and Neuroscience (IoPPN), London, United Kingdom, ⁴King's College London, Basic & Clinical Neurosciences, London, United Kingdom, ⁵Guy's and St Thomas' NHS Foundation Trust, Sleep Disorder Center, London, United Kingdom

Introduction: Dopaminergic dysfunction has been implicated in the cognitive impairment observed in neurodegenerative disorders, particularly in α -synucleinopathies such as Parkinson's disease (PD). Although positron emission tomography (PET) studies have suggested a link, findings remain inconsistent. In clinical settings, dopamine transporter (DAT) scans are more commonly used, assessing presynaptic dopaminergic integrity, particularly in the striatum. Given that nigrostriatal degeneration is central to Parkinsonian syndromes, it has been hypothesised that this may contribute to cognitive deficits. However, the specific role of dopaminergic dysfunction in cognitive decline remains uncertain, with evidence suggesting a multifactorial aetiology extending beyond the dopaminergic system.

This review aims to examine the relationship between DAT imaging and cognitive performance in individuals with α -synucleinopathies.

Materials and methods: A systematic review was conducted following PRISMA guidelines. Databases searched included Medline, Ovid, APA, and EMBASE, limited to English-language studies published since 2000. Eligible studies assessed the association between cognitive performance and dopaminergic imaging (DAT SPECT or PET) in neurodegenerative disorders. After screening, 22 studies met the inclusion criteria.

Results: In Parkinson's disease (17 studies), 8 reported a positive association between DAT binding and cognitive performance, particularly within the domains of attention and executive functioning. Four studies identified a relationship with memory performance, whereas five found no significant correlation. In the single available study of individuals with REM sleep behaviour disorder (RBD), no association was reported. Among the seven studies focusing on dementia with Lewy bodies (DLB), three observed correlations with specific cognitive domains (awareness, reaction time, and simultaneous processing speed), while four reported null findings. The two studies which compare alpha-synucleinopathies and Alzheimer's disease (AD) populations found the link between DAT binding and cognition only in the A-syn population. Notably, the majority of studies reporting no correlation relied solely on brief cognitive screening measures, whereas studies using more comprehensive neuropsychological assessments were more likely to identify significant associations.

Conclusions: This review highlights the heterogeneity of findings regarding dopaminergic dysfunction and cognitive impairment in α -synucleinopathies. Where significant associations were identified, they were typically observed in studies employing detailed neuropsychological testing, suggesting that cognitive deficits may, at least in part, reflect dopaminergic system dysfunction within the nigrostriatal pathway. However, the overall evidence base remains mixed, and the contribution of dopaminergic deficits should be viewed in the context of broader, multi-system involvement. Further longitudinal and multimodal studies are warranted to delineate the specific role of dopaminergic pathways in the cognitive decline observed across synucleinopathies.

Correlation between iron deposition and cognitive function in OSA patients of different severity levels based on quantitative susceptibility mapping

S. Gao¹, Z. Wang¹, R. Chen¹

¹Second Affiliated Hospital of Soochow University, Suzhou, China

Introduction: Excessive cerebral iron deposition has been implicated in cognitive dysfunction across various neurological disorders. This study investigates severity-dependent patterns of cerebral iron accumulation in OSA using quantitative susceptibility mapping (QSM) and examines their potential role in mediating cognitive impairment.

Materials and methods: The study cohort comprised 139 OSA patients stratified by severity (68 mild-moderate [OSA-M: apnea-hypopnea index (AHI) 5-30 events/hour]; 71 severe [OSA-S: AHI>30]) and 48 healthy controls (HC). All participants underwent polysomnography, neurocognitive assessment using the Montreal Cognitive Assessment (MoCA), and 3T MRI with multi-echo gradient echo sequences for QSM analysis. Whole-brain voxel-wise comparisons were conducted to characterize iron deposition patterns. Correlation analysis and mediation models evaluated associations between OSA severity, regional iron content, and cognitive performance.

Results: As the severity of OSA patients increases, iron content increased in the left central anterior gyrus, left medial superior frontal gyrus, right central anterior gyrus, right medial superior frontal gyrus, right putamen, and middle cingulate gyrus increases; while it decreased in the left superior temporal gyrus, left superior frontal gyrus, right parietal sulcus, and middle right frontal lobe. Critically, higher iron levels in the left precentral gyrus and right putamen negatively correlated with cognitive deficits (MoCA), particularly in visuospatial function ($P < 0.05$), whereas lower iron in the left superior temporal gyrus and right parietal sulcus correlated with poorer cognition ($P < 0.05$). Mediation effect analysis demonstrated that iron deposition in the right putamen partially mediated the relationship between AHI, BMI, N3 stage proportion, Pulse oxygen<90% and cognitive function, especially the visuospatial abilities.

Conclusions: Our findings suggest that cerebral iron overload may contribute to cognitive dysfunction in OSA patients across severity levels, with chronic intermittent hypoxia-induced iron metabolism dysregulation serving as a potential neuropathological mechanism.

Dementia prediction tool based on accelerometry measures of circadian rhythm in older adults

C. Cavallès¹, I. Meneghel Danilevicz¹, A. Dugravot¹, S. Sabia¹

¹Université Paris Cité, INSERM U1153, Epidemiology of Ageing and Neurodegenerative diseases, Paris, France

Introduction: Given the absence of a cure for dementia and the emergence of therapies targeting its preclinical stages, enhancing early detection of individuals at higher risk or in the earliest stages of dementia is crucial for better patients care and effective interventions. This study aimed to develop and validate a biobehavioral tool leveraging accelerometry measures to predict dementia risk in older adults.

Materials and methods: We analyzed the prognostic utility of 36 accelerometer-derived features in a population-based sample of 53,448 participants aged 60 years or more in the UK Biobank (54.2% women; mean [standard deviation] age= 67.5 [4.2] years; 758 (1.4%) dementia cases; mean follow-up= 8.2 [1.2] years). Using a machine-learning approach, we identified key features of rest-activity rhythm, daytime activity, sleep, and chronotype that better predict dementia risk, and derived composite scores. We evaluated the added predictive value of these scores compared to traditional dementia risk factors. We performed external validation in the Whitehall II accelerometer sub-study (N = 3,971; 25.8% women; mean age 69.4 [5.7] years; 329 (8.3%) dementia cases; mean follow-up 10.5 [2.4] years).

Results: We identified nine core features of daytime activity, sleep, and chronotype, combined in two composite scores, that predicted dementia risk. Composite score 1 was mainly related to daytime activity features, with a higher score representing shorter duration and less frequent bouts of moderate-to-vigorous physical activity, more time in low intensity activity, less well distributed activities of different intensities, and a higher probability to transition from activity to rest. In contrast, composite score 2 was primarily related to chronotype and sleep features, with a higher score representing earlier wake-up time, longer wake bouts during sleep, lower probability to transition from

wake to sleep, and more extreme sleep durations (either shorter or longer). Both composite scores were associated with higher risk of dementia (hazard ratio (HR)= 1.43, 95% confidence interval (CI)= 1.33–1.54 for score 1 and HR=1.10, 95% CI= 1.04–1.17 for score 2) and improved the predictive value of a model including sociodemographic, behavioral, and health-related dementia risk factors (increase in C-index = 0.018, 95% CI= 0.011–0.025 with both composite scores included). Results were confirmed in the validation cohort.

Conclusions: Our findings support the development of an accelerometer-based biobehavioral tool for early identification of older adults at increased risk of dementia. This approach could aid primary care providers in referring high-risk individuals for further evaluation and initiation of promising new early-stages therapies, such as anti-amyloid monoclonal antibodies. Future studies may examine the potential of early interventions to reinforce circadian rhythmicity (increase activity during the day, improve sleep, delay waking time) to help slow disease progression.

Dream and Its Interpretation- Scientific Perspective

C. Eze¹

¹Alex Ekwueme Federal University Teaching Hospital Abakaliki, Internal Medicine, Abakaliki, Nigeria

Introduction: Dream is a mental activity that occurs during sleep. It is an altered state of consciousness embraced with images, thoughts, and emotions widely ranging in nature from joyful to sad and sometimes make no sense at all during sleep. As a correlate of neural activity, dreams can only be experienced by the living and ceases with brain death. It occurs in all stages of sleep, though vivid dreams occur mainly during rapid eye movement (REM) sleep. REM sleep also known as paradoxical sleep is characterized by high levels of brain activity, including increased activity in the areas of the brain associated with emotions, memory, and visual processing. The implication is that dreams may be a way for the brain to process and consolidate memories, emotions, and experiences from the day. Its interpretation is common practice in many African cultures and this role is vested in unqualified persons, such as diviners, priests, and healers. Their unprofessional activities have led to dangerous consequences such as anxiety, depression, loss of material possessions, bodily harm, family, or community conflicts, or even death.

Materials and methods: This review manuscript sought to unravel the mystery of dreams from a scientific perspective to educate the scientific community, especially in the developing world.

Results: This review manuscript unravelled the enigma of dreams by delving into the mechanisms underlying their occurrence, exploring the brain processes that shape their content, discussing different types of dreams, and examining the potential scientific basis for interpreting their significance.

Conclusions: The scientific study of dreams and their interpretation has provided fascinating insights into the neural processes, cognitive functions, and emotional dimensions of this intriguing phenomenon.

We recommend that there should be an interdisciplinary collaboration from various fields such as neuroscience, psychology, cognitive science, and even cultural studies. Collaborations between researchers from different disciplines can provide a more holistic understanding of dreams and their interpretation.

Effect of Daydreaming on clinical symptom and cognitive function in patients with obsessive compulsive disorder

P. Wang^{1,2}, Z. Li^{1,2}

¹Beijing Anding Hospital, Beijing, China, ²Capital Medical University, Beijing, China

Introduction: Obsessive-compulsive disorder (OCD) is characterized by significant cognitive impairments, including deficits in error monitoring (EM). While Daydreaming (mind wandering, MW) and intraindividual reaction time variability (IIRTV) are implicated in cognitive dysfunction in other disorders, their role in OCD's EM deficits and their relationship with clinical symptoms remains unclear. This study aimed to investigate the associations between MW, IIRTV, EM, and clinical symptoms in OCD patients.

Materials and methods: Eighty-seven OCD patients and 49 healthy controls (HC) completed a revised Sustained Attention to Response Task (SART) to assess EM (error awareness, EA; post-error adjustment, PES), IIRTV, and MW (frequency, content, and variability). Clinical symptoms were assessed using standardized questionnaires. Group differences in SART performance and MW were analyzed using independent t-tests. Correlations between SART measures, MW, and clinical symptoms were examined.

Results: Compared to HC, OCD patients showed impaired EM (lower EA, less PES) and increased MW frequency and variability. OCD patients also exhibited greater IIRTV and lower accuracy on No-go trials. In the OCD group, IIRTV was positively correlated with lower EA. Lower MW variability and IIRTV were associated with reduced post-error slowing. PES was positively correlated with OCD, anxiety, and depression symptoms.

Conclusions: Our findings highlight significant deficits in error monitoring and increased mind wandering in OCD patients, which are associated with clinical symptom severity. IIRTV and MW variability may contribute to the impaired error monitoring observed in OCD, suggesting a complex interplay between spontaneous thought, behavioral variability, and cognitive control in this disorder. These results provide further support for understanding the cognitive and neural mechanisms underlying OCD and may inform the development of targeted interventions.

Effects of a new rocking apparatus on sleep and memory in young adults

L. Barbaux¹, E.-M. Phillips², O. Fontaine², A. Moezi³, N.E. Cross⁴, R. Sedaghati³, S. Hebblethwaite⁵, S. Belleville⁶, N. Bier⁷, L. Bayer⁸, T.T. Dang-Vu¹, A.A. Perrault⁹

¹Concordia University, Health, Kinesiology & Applied Physiology, Montréal, Canada, ²University of Montreal, Montreal, Canada, ³Concordia University, Mechanical, Industrial and Aerospace Engineering, Montréal, Canada, ⁴University of Sydney, Sydney, Australia, ⁵Concordia University, Applied Human sciences, Montréal, Canada, ⁶University of Montreal, Psychology, Montreal, Canada, ⁷University of Montreal, École de Réadaptation, Montreal, Canada, ⁸University of Geneva, Neuroscience, Geneva, Switzerland, ⁹Macquarie University, Sydney, Australia

Introduction: Continuous overnight rocking stimulation is a promising intervention for enhancing both sleep quality and memory, through the modulation of NREM brain oscillations. This in-lab study aimed to confirm the beneficial effects of rocking on sleep and memory in healthy adults, using a new rocking prototype which can be fitted to any bedframe, with the long-term objective of applying this approach at-home.

Materials and methods: Following a habituation polysomnographic (PSG) night, nineteen healthy good sleepers (24.9±3.6 years, 53% female) completed 3 PSG nights under the rocking condition (ROCK) and 2 stationary nights (STAT), in a counterbalanced order separated by one week. The rocking prototype induced a continuous back-and-forth movement with a lateral displacement of 10.5 cm at 0.25 Hz (as described by Bayer et al., 2011 and Perrault et al., 2019) but was delivered by a homemade electrically-powered rail system.

From EEG data preprocessed according to the AASM guidelines, we extracted macroarchitecture outcomes, as well as spindle and slow oscillations (SO) characteristics on Fz and Pz during N2 and N3, using automated detection methods (Ray et al. 2015; Staresina et al. 2015). Subjective sleep quality was assessed with questionnaires in the morning. All analyses examined the Condition effect (ROCK vs STAT) during the first night only. Effects after the two subsequent consecutive nights of rocking are detailed in a companion abstract (Phillips et al.).

Declarative (word paired-associate task; 46 pairs) and procedural (finger tapping task; 5 digits over 30-second trials) memory performance were assessed in 3 phases: a learning phase followed by immediate recall in the evening then delayed recall in the morning. We compared the overnight change in accuracy (morning minus evening) between Conditions.

Results: The rocking stimulation did not impact overall sleep architecture (i.e., TST, SE, SOL, WASO; all $p > .05$). However, a significant Condition*Stage interaction highlighted a detrimental change in sleep stage proportion (%TSP; $F(1,18)=28.95$, $p < .001$), such that, compared to STAT1, participants spent more time awake, in both N1 and N2 when rocked, to the expense of N3 and REM (all $p < .05$). Spindle and SO activity were largely unaffected at ROCK1 ($p > .05$), and overnight memory performance improvement was not enhanced by the rocking stimulation ($p > .05$). Although participants were mostly satisfied with their sleep when rocked ($p = .01$), they generally reported more frequent awakenings

($p=.03$) and being disturbed by the noise levels ($p=.001$) and the movement (7/19). Accelerometric data comparing the new prototype and the rocking bed used by Bayer and Perrault revealed a maximal acceleration of around 20 cm/s^2 , contrasting with the expected 26 cm/s^2 . Moreover, the velocity and acceleration signals of the prototype had noticeably more variability than the rocking bed in the form of abrupt bouts of acceleration and deceleration ($p=0.031$).

Conclusions: Our results suggest that after one night, this rocking prototype did not improve sleep architecture or memory consolidation. These findings highlight the importance of optimizing rocking parameters (i.e., jerk, motion control, noise levels) to achieve beneficial effects on both objective and subjective sleep quality, as well as memory performance.

Effects of Binaural Beats on Sleep Initiation and Cognitive Control: A Neurobehavioral Study

K. Sharma¹, V. Goel², S. Dhaka¹

¹Indian Institute of Technology Jodhpur, School of Liberal Arts, Jodhpur, India, ²Indian Institute of Information Technology Vadodara International Campus Diu, Computer Science and Engineering, Daman and Diu, India

Introduction: Binaural beat (BB) stimulation is known to modulate electroencephalographic activity by brain entrainment, but only a few studies have established whether BB can affect the sleep onset process and daytime executive functioning. Sleep has a particularly detrimental effect on executive functioning involving response inhibition (RI), which plays a central role in regulating and modulating behavioral responses (Schiller et al., 2014). By prioritizing the enhancement of sleep quality, we can effectively enhance RI. In this study, BB stimulation as a sleep intervention was administered for two weeks in which the participant was exposed to 20 minutes of 4-Hz binaural beats before sleep. The primary aim of this study was to investigate the effects of BB stimulation on both sleep parameters and RI, assessed at electrophysiological and behavioral levels.

Materials and methods: The study used a cross-over experimental design, with a sample of 20 participants (age 28.37 ± 2.06 years). Each participant underwent three nights consisting of an adaptation night (T0), a baseline night (pre-intervention without BB) (T1), and a post-intervention night (after two weeks of BB intervention) (T2). Sleep was analyzed using polysomnography on T1 and T2. To evaluate cortical arousal during wakefulness, 5-minute resting-state EEG recordings were conducted on T1 and on T2, before sleep. RI was measured using the Go/NoGo task, programmed in PsychoPy (version 3.0.2). The task was designed in a way that allowed us to study the dynamic RI using mouse tracking to differentiate between the aware and unaware errors.

Results: BB intervention significantly reduced sleep latency and cortical arousal, as reflected by decreased beta and gamma power in resting-state EEG in post-intervention as compared to the baseline condition. The participants demonstrated improved RI following BB intervention in terms of increased response times and correct Go responses and a reduction in unaware commission errors and omission errors.

Conclusions: These findings suggest that BB intervention effectively attenuates high-frequency brain activity associated with alertness and cognitive processing. The observed reduction in beta power implies a shift toward a more relaxed, internally directed neural state. Similarly, the decrease in gamma power may indicate reduced cognitive load or internal information processing demands. At the behavioral level, improvements on the Go/NoGo task suggest enhanced RI following BB intervention. Participants exhibited a reduction in unaware commission errors following the BB intervention compared to the baseline condition, indicating increased attention and improved monitoring of inhibitory control processes. Taken together, the results support the notion that BB may promote better sleep quality, which in turn facilitates improved response inhibition. Thus, BB stimulation appears to offer dual benefits—enhancing both sleep onset time and daytime executive functioning, particularly in the domain of cognitive control.

Effects of sleep inertia, fatigue and boredom on crew performance in reduced crews - a flight simulator study

D. Steven¹, J.-P. Buch², J.P. Vox³, C.F. da Silva Souto³, F. Radke³, A.H. Winneke³, K.I. Wolf³, D. Niedermeier²

¹German Aerospace Center, Institute of Aerospace Medicine, Sleep and Human Factors Research, Cologne, Germany, ²German Aerospace Center, Institute of Flight Systems, Flight Dynamics and Simulation, Braunschweig, Germany, ³Fraunhofer Institute for Digital Media Technology IDMT, Division Hearing, Speech and Audio Technology HSA, Oldenburg, Germany

Introduction: In view of the latest technological developments in commercial aviation, flights with reduced crews appear possible. In so-called *extended minimum crew operations* (eMCOs), one pilot is in control of the aircraft ('Pilot Flying') while the other pilot is allowed to rest and sleep ('Pilot Resting'). Sleep inertia - a state of cognitive impairment immediately after waking up - is a potential safety risk if the Pilot Resting has to act upon awakening. In addition, fatigue and boredom can increase for the Pilot Flying due to flying alone for an extended period. This study aimed to examine how eMCO segments in a high-fidelity flight simulator scenario affect sleep, sleep inertia, fatigue, boredom and crew performance of commercial pilots.

Materials and methods: Five crews (n = 10 pilots) participated in the study at the AVES flight simulator center of the German Aerospace Center and completed one of two conditions: aborted vs. non-aborted eMCO segment. In both conditions, the crews flew together for 30 minutes, followed by an eMCO segment in the new Pilot Flying (PF) and Pilot Resting (PR) roles. In the aborted condition, the eMCO segment ended unexpectedly after a 60-minute sleep opportunity for the PR, with an engine fire occurring immediately upon awakening. In the non-aborted condition, the eMCO segment ended as planned after 2.5 hours without interruption, with the engine fire occurring 30 minutes after the end of the eMCO segment. Sleep was objectively recorded using a wireless EEG system and a flexible, unobtrusive electrode grid with high wearing comfort. Self-assessments of fatigue, workload and boredom were collected every 30 minutes. Crew performance was operationalized as speed and success in handling the engine fire.

Results: In the non-aborted condition, pilots slept for 99 minutes on average out of a 130-minutes sleep opportunity. Beneficial effects of the nap on subsequent fatigue levels were mixed. Fatigue and boredom of the PF were higher during the eMCO segment than before or after the segment. Workload during the engine fire was perceived as slightly higher in the aborted eMCO than the non-aborted eMCO condition. Out of three crews in the aborted eMCO condition, one PR did not deem himself fit to act upon awakening, leaving the PF to -successfully- deal with the fire on his own. Crew performance speed (i.e., how fast the fire was resolved) did not differ between the two conditions.

Conclusions: In this particular scenario and based on a limited sample size, sleep inertia, fatigue and boredom had no effect on crew performance when an engine fire occurred. The investigation of further safety-relevant eMCO scenarios, e.g. increasing sleep inertia during night flights, is warranted.

Acknowledgments: We thank all participating crews.

Exacerbated Negative Impact on Sleep, Mood, Cognition and Daytime Functions in Comorbid Frequent Nightmares and Insomnia

W.I. Ao¹, C.X. Chen¹, M. Zhou¹, S.X.T. Wong¹, C.C.H. Sin¹, S. Xie¹, S. Chen¹, J.W.Y. Chan¹, Y.K. Wing^{1,2}, N.Y. Chan¹

¹Li Chiu Kong Family Sleep Assessment Unit, Department of Psychiatry, The Chinese University of Hong Kong, Shatin, Hong Kong, SAR of China, ²Li Ka Shing Institute of Health Sciences, Faculty of Medicine, The Chinese University of Hong Kong, Shatin, Hong Kong, SAR of China

Introduction: Insomnia often co-occurs with frequent nightmares. While previous studies have examined the independent effects of insomnia and nightmares, few studies have investigated the impact of the comorbidity of these conditions. This study aims to determine whether frequent nightmares exacerbate impairments in sleep, mood, cognition, and daytime functioning in individuals experiencing insomnia, compared to those with insomnia alone.

Materials and methods: This is a cross-sectional study recruited adults aged 18 to 70 with insomnia symptoms (Insomnia severity index, ISI $\geq$ 10) in Hong Kong. Participants completed online questionnaires on sleep and mood, clinical interviews (The Structural Clinical Interview for DSM-5 Disorders, SCID-V) for psychiatric diagnoses, and mobile cognitive tests assessing attention (The Psychomotor Vigilance Test, PVT), risk-taking propensity (Balloon Analogue Risk Task, BART), inhibition control (Go/No-go Task) and working memory (N-back Task). Frequent nightmares were defined as occurring more than once a week over the past three months (Nightmare Frequency Questionnaire).

Individuals with post-traumatic disorder (PTSD, identified by SCID-V) were excluded. Group comparisons (insomnia with vs without nightmares) were analysed using Pearson's chi-square test and Wilcoxon rank-sum test. Associations between frequent nightmares and outcomes were further examined using linear and logistic regression.

Results: A total of 230 participants (median age 43 years; 75.7% female) with complete clinical interview, questionnaire, and cognitive task data were included. Individuals with comorbid frequent nightmares (N=53, median age 37 years; 77% female) exhibited greater insomnia severity, pre-sleep arousal, mood disturbances, suicidal ideation, somatic symptoms, and less satisfaction with surrounding environment compared to those with insomnia alone. After adjusting for covariates (age, gender, income, psychiatric diagnoses and insomnia severity), frequent nightmares remained significantly associated with higher depressive severity ($\beta = 1.55, p < .05$), rumination ($\beta = 4.16, p < .05$), suicidal ideation (OR = 2.34, $p < .05$), attention deficits (longer PVT reaction time: $\beta = 55.63, p < .01$; higher Go/No-go omission rate: $\beta = 4.86, p < .05$), and somatic symptoms ($\beta = 1.72, p < .01$). Adjusting further for depressive and anxiety symptoms, frequent nightmares still demonstrated significant associations with greater pre-sleep cognitive arousal ($\beta = 1.84, p < .05$), reflective rumination ($\beta = 0.86, p < .05$), attention deficits (longer reaction time in PVT: $\beta = 55.05, p < .01$; higher omission rate in Go/No-go Task: $\beta = 5.50, p < .01$), and somatic symptoms ($\beta = 1.44, p < .05$).

Conclusions: Frequent nightmares comorbid with insomnia exacerbated pre-sleep arousal, reflective rumination, attention impairment, and somatic symptoms beyond the impact of insomnia alone, independent of insomnia severity and mood disturbances. These findings suggest that intervention targeting both nightmares and insomnia should be incorporated into management of comorbid insomnia and nightmares.

Examining the Clinical Characteristics Associated with Weekly Nightmares among U.S. Veterans at Risk for Suicide

M. Thompson¹, J. Primack¹, L. Brick¹, C. Benca-Bachman¹, I. Villafuerte¹, S. McGeary², J. McGeary¹

¹Brown University, Providence, United States, ²Northeastern University, Boston, United States

Introduction: Sleep disturbances have been implicated as a potentially modifiable risk factor for suicide. Nightmares, in particular, are associated with suicidal ideation, mood disorder symptoms, and premature termination from sleep-focused psychotherapy. Military Veterans are at particular risk, given high frequencies of both nightmares and posttraumatic stress disorder (PTSD) symptoms compared to the general population. Less is known, however, about the associations of nightmares among Veterans in psychiatric inpatient or other high-risk settings. This study aimed to explore (1) the prevalence, demographics, and clinical characteristics of Veterans with weekly nightmares, and (2) differences in clinical characteristics between U.S. Veterans at risk for suicide with and without weekly nightmares.

Materials and methods: Cross-sectional data were drawn from an ongoing VA study on the relationship between sleep and suicide among U.S. Veterans at risk for suicide (n = 66). Participants were sampled from a hospital inpatient psychiatric setting and suicide prevention coordinator office referral. Weekly presence of nightmares was determined through the Pittsburgh Sleep Quality Index, and psychiatric diagnoses were determined through the staff-administered QuickSCID assessment. Those reporting weekly nightmares were compared to those without on demographic characteristics, self-reported psychiatric symptoms (e.g., symptoms of depression, anxiety, alcohol use, and substance use disorders), and staff-rated suicidal thoughts and behaviors (e.g., suicide ideation intensity, lifetime presence of suicidal behaviors). Linear regression models controlled for age; to reduce potential impact of treatment, sensitivity analyses were conducted without participants currently prescribed medications to treat nightmares (n = 63).

Results: A majority of participants reported weekly nightmares (n = 40, 60.6%). Among those with weekly nightmares, the mean age was 45.3 years old, 83% were male, 65% were White/Non-Hispanic, and 60% received service-connected disability for a mental health condition. Among a subsample of those with weekly nightmares who completed the QuickSCID assessment, 74.4% met criteria for PTSD, 59.0% for a substance use disorder (SUD), 51.2% for a major depressive episode (MDE), 48.7% for generalized anxiety disorder, and 43.6% for alcohol use disorder. Groups (i.e., those with and without

weekly nightmares) did not differ on demographic characteristics, psychiatric symptoms, or suicide-related characteristics in unadjusted, adjusted, and sensitivity models.

Conclusions: In a sample of U.S. Veterans at risk for suicide, a majority reported nightmares at a frequency of at least weekly. Among those with weekly nightmares, frequent mental health diagnoses included PTSD, SUD, and MDE. Similarities between those with weekly nightmares and without might reflect the high acuity within the present sample. Future research should examine the longitudinal relationship between nightmares and clinical outcomes within high-risk Veteran samples.

Exploring nightmares, associated factors and their relationship with externalising behaviours in complex psychiatric populations: A systematic review and clinical case review

C. Gaffrey Moran¹, J.L. Ireland^{1,2}, S. Chu¹

¹University of Lancashire, School of Psychology and Humanities, Preston, United Kingdom, ²Liverpool John Moores University, School of Psychology, Liverpool, United Kingdom

Introduction: Dreaming allows for emotional processing. However, for those with psychiatric disorders, dream disturbances - namely nightmares- are prevalent. Nightmares disrupt this emotional processing, and their distress has demonstrated links to worsening clinical symptoms and increased suicide risk. Despite this, nightmares receive limited clinical attention in complex psychiatric populations. This is surprising when considering how these populations exhibit increased risk factors, such as trauma and distress, which may contribute to unique experiences of nightmares and increased association with externalising behaviours. Few studies focus on the link of nightmares to self-injurious behaviour (SIB). Systematic reviews on psychiatric populations have also failed to capture a broad understanding of nightmares in psychiatric inpatients alone. Forensic psychiatric sampling for nightmare research is particularly scarce, warranting investigation.

Materials and methods: A systematic review using Reflexive Thematic Analysis explored the nature, underlying mechanisms and correlating factors of nightmares in psychiatric inpatient populations. Titles were screened from eleven databases. Data extraction, quality assessment and inter-rater reliability were performed adhering to PRISMA guidelines. This systematic review identified variables for a review of collateral clinical information of detained forensic patients, utilising a structured clinical assessment tool, the Self-injurious behaviour Management and Behavioural Assessment (SIMBA). The SIMBA gathers clinical information based on staff reporting on mental illness, externalising behaviours and importantly, sleep challenges, including whether nightmares have presented. Mixed methods using Reflexive Thematic Analysis and regression explored what was reported about nightmares in these patients and associations with incidents of externalising behaviour.

Results: In relation to the systematic review, of the 9,534 titles screened, a total of 35 papers were included for review. Themes described the chronic and replicative nature of nightmares in psychiatric inpatients, including their violent, trauma-related and disturbing content. Underlying mechanisms of inpatient nightmares centred on trauma and emotional dysregulation, often with early onset. Inpatient nightmares demonstrated bidirectional links with exacerbating clinical symptoms, negative cognitions, distress and other sleep disturbances. The impact of nightmares on risk of suicidality was apparent. Patients in the case study papers were reported as keen to explore their nightmares, while other studies highlighted the unexplored therapeutic potential of nightmares. The methodologies and quality of the included papers varied. In the SIMBA study, nightmares were reported in 23% of the 78 patients reviewed. Themes highlighted how nightmares present as part of wider sleep disturbance, centre around trauma, and have multifaceted impacts. Patients appeared to discuss their sleep problems, yet limitations presented in staff reporting of nightmares. Nightmares qualitatively showed relationships with SIB but did not statistically predict externalising behaviours.

Conclusions: Both reviews overlapped in findings and provide initial understanding of the distressing nature of nightmares in complex psychiatric populations, their underlying mechanisms, interaction with psychiatric symptoms and limitations around assessment. Building on these results, a large study plans to explore nightmares from the perspective of male forensic inpatients and test the feasibility of a brief nightmare intervention. It is hoped that by addressing nightmares, sleep disturbances in high-risk populations can be addressed and patient wellbeing improved.

Factors and Issues Affecting Sleep Quality in Elderly Hong Kong Residents: A Cross-Sectional Survey, 2024-2025

V. Lok¹, M. Liu¹, R.Y. Chung¹, J.H. Kim¹

¹The Chinese University of Hong Kong, JC School of Public Health and Primary Care, Faculty of Medicine, New Territories, Hong Kong, SAR of China

Introduction: Sleep is a vital component of health and well-being. Older adults in high living density living environments may experience disproportionately higher levels of sleep disturbances, reducing the quality of sleep. This study investigates the factors associated with poor sleep quality among Hong Kong adults aged 65 and older, with the aim of identifying modifiable targets for evidence-based interventions.

Materials and methods: Between December 2024 to April 2025, a cross-sectional random telephone survey was conducted on community-dwelling older adults (n=723). The Pittsburgh Sleep Quality Index (PSQI) was used to assess overall sleep quality, alongside questions regarding the sleep environment, substance use, and pre-sleep cognitive activity. Multiple linear regression models, adjusted for age, gender, education, and income, were applied to identify predictors of PSQI scores.

Results: Among the older age participants (59.9% female), respondents reported an average of 29 minutes to fall asleep, resulting in a mean total sleep duration of 6.45 hours/night (SD= 1.34). Of the sample, 24.9% reported less than 6 hours of sleep/night. Significant sleep impairments were observed, with 71.1% reporting difficulty initiating sleep and 93.1% struggling with sleep maintenance. Regression analysis identified three key predictors of PSQI scores: nocturia ($\beta=0.988$, $p<0.001$), pre-sleep cognitive arousal ($\beta=3.223$, $p=0.001$), and trends indicating that substance use, specifically smoking ($\beta= 0.258$, $p=0.26$), was associated with reduced sleep efficiency. Breathing difficulties, loud cough/snoring, feeling cold/ hot, bad dreams and pain were not significantly associated with PSQI scores.

Conclusions: This study highlights the complex interplay of physiological, psychological, and behavioral factors contributing to sleep deficits among older adults in Hong Kong. Addressing these determinants could alleviate the healthcare burden associated with geriatric sleep disorders and enhance the quality of life for this vulnerable population.

Induction of local sleep in a visual processing brain network in humans

G. Legendre¹, G. Mosca¹, D. Marzoli¹, F. Dalle Piagge¹, G. Avvenuti¹, D. Grollero¹, R. Basanisi¹, L. Cecchetti¹, T. Andrillon², G. Bernardi¹

¹IMT School for Advanced Studies, Lucca, Italy, ²Paris Brain Institute, Paris, France

Introduction: Sleep loss often impairs emotional regulation and social functioning, leaving us irritable, impulsive, or less inclined for social contacts. Recent studies suggest that such deficits may stem from local sleep-like episodes - brief intrusions of slow waves similar to those of sleep - in specific cortical networks during wakefulness. These episodes become more frequent with sustained regional activity (use-dependent process) and transiently disrupt the cognitive functions of the affected areas.

While previous work has focused on motor, spatial navigation and executive networks, it remains unclear whether local sleep can affect restricted sensory brain regions, such as those involved in visual processing. Can the brain, for example, grow "tired" of seeing smiling faces?

In this work, we tested whether repeated exposure to faces with emotional expressions could induce local sleep episodes in visual brain regions, and whether such induction alters the perception of facial expressions.

Materials and methods: Participants completed a three-phase paradigm. 1) In the pre-test, we measured baseline performance on a facial expression recognition task using a 2-alternative forced choice (happy vs. angry) on faces morphed across a happy-angry continuum. 2) Then, during an intervention phase, we presented participants with many pictures of happy faces (group 1) or of angry faces (group 2) to induce local sleep for a targeted emotional expression. 3) Finally, participants

performed the same task than the pre-test to measure changes in facial expression recognition. EEG was recorded throughout, and source reconstruction was used to quantify slow-wave density in face-processing brain areas.

Results: Following prolonged exposure to a target emotional expression (e.g., happiness), participants were significantly more likely to interpret ambiguous expressions as the opposite emotion (e.g., anger). This perceptual bias was accompanied by a selective increase in miscategorization of the target emotion, with no comparable effect for the control emotion. Crucially, the degree of miscategorization of the target emotional expression correlated with slow-wave density in visual areas implicated in face processing.

Conclusions: Our findings demonstrate that local sleep-like episodes can be experimentally induced in visual-processing networks through targeted sensory stimulation. These episodes are characterized by wake slow waves that share key features with sleep slow waves, albeit with lower amplitude and spatially restricted expression.

Investigating Task Switching Performance in a 31h Total Sleep Deprivation Protocol

M. Ngo^{1,2}, C. Yates¹, P. Rauffet^{3,2}, L. Grosser¹, M. Owen¹, J. Baumeister⁴, S. Banks^{1,2}

¹University of South Australia, Justice and Society, Adelaide, Australia, ²CROSSING IRL CNRS 2010, Adelaide, Australia, ³Université Bretagne Sud, Lab-STICC UMR 6285, Lorient, France, ⁴University of South Australia, Australian Research Centre for Interactive and Virtual Environments, Adelaide, Australia

Introduction: In 24/7 operational environments, managing multiple complex tasks in rapid succession can be cognitively demanding. Managing multiple tasks requires ongoing attention, often requiring the operator to shift their attention between tasks, a phenomenon called task switching. Under conditions of extended wakefulness, the added workload caused by task switching, can slow cognitive processing, impair attention, and increase error rates. This study examined the effects of 31 hours of sustained wakefulness on task-switching performance between a visual and working memory task and the cost of switching on overall performance.

Materials and methods: Twenty-six healthy participants completed a 31-hour sustained wakefulness protocol in a controlled laboratory environment, with testing sessions across the wake period at 11:00h, 17:00h, 23:00h, 05:00h, and 11:00h. Participants were presented with a switching task, where a spatial-rotation (manikin) task was presented on the left and a math task on the right. An arrow indicated which task participants had to respond. Performance measures included mean reaction time (RT), accuracy (proportion correct), and throughput (a measure of speed-accuracy trade-off), analysed across four transition types: math-to-math, manikin-to-manikin, manikin-to-math, and math-to-manikin. Mixed-effects models were used to analyse changes in mean RT, accuracy, and throughput separately as a function of transition type and hours of wakefulness, with random intercepts for participants.

Results: Hours of wake had a significant main effect on mean RT ($p < .001$), throughput ($p < .001$) and accuracy ($p < .001$) with poorest performance at 05:00h respectively. Significant main effects of transition type on RT ($p < .001$) and throughput ($p < .001$) were observed but not for accuracy ($p = .972$). Transitioning from 'different', i.e., manikin-to-math, to 'same', i.e., manikin-to-manikin, there was a reduction in mean RT compared to 'same', i.e., manikin-to-manikin transition types ($p < .001$), no interaction effects were found.

Conclusions: Impairments due to switching were dependent on the preceding and proceeding task. When transitioning between two different tasks, there was a speed/accuracy trade-off observed with participants slowing down to maintain accuracy. To improve/maintain switching performance during around-the-clock operations, it is vital to be aware of the cost of switching multiple different tasks where possible, identify strategies within teams to reduce the number of switches completed by individuals. Future studies should look at human-centred interfaces which are designed to strategically implement cuing in a task that can help mitigate cognitive demands and maintain attentional focus during fatigue.

Investigating the effects of REM sleep fragmentation on emotional memory and psychophysiological reactivity

L. Viselli¹, F. Naccarato¹, F. Salvi¹, G. Amicucci¹, D. Corigliano¹, F. Festucci¹, C. Colombo², D. Tempesta¹, N. Cellini², M. Ferrara¹, A. D'Atri¹

¹University of L'Aquila, Department of Biotechnological and Applied Clinical Sciences, L'Aquila, Italy,

²University of Padua, Department of General Psychology, Padova, Italy

Introduction: Sleep plays a fundamental role in the processing of emotional experiences. Emotional events undergo a priority reactivation during sleep that promotes the consolidation of salient information, while attenuating the associated emotional charge, thus reducing the subsequent physiological reactivity. Replay during slow-wave sleep seems to be primarily involved in improving memory, whereas the processing and attenuation of affective tone has been proposed to be mediated by replay during REM sleep, an optimal continuous period of silencing in noradrenergic activity. Consistently, recent evidence has shown that, in patients with sleep disorders, REM sleep fragmentation (frequent cortical arousals and sleep stage transitions disrupting REM sleep continuity) is associated with the lack of physiological habituation to emotional experiences, possibly due to increases in REM noradrenergic levels associated with arousals. However, multiple sleep macro- and microstructural alterations, beside those affecting REM sleep, often characterize sleep disorders and could contribute to the emotional dysregulation in these patients. To disentangle the specific effect of REM sleep fragmentation from other confounding, we experimentally induced REM sleep fragmentation in good sleepers via vibrotactile stimulation and evaluated its effect on overnight processing of emotional stimuli.

Materials and methods: Seventeen healthy participants (23.18 ± 3.94 y, 3 males) underwent two experimental conditions (*Fragmentation/Control*) in counterbalanced order involving a nocturnal polysomnography (with/without REM sleep fragmentation) and 3 assessments of memory and psychophysiological reactivity to emotional stimuli (T0: pre-sleep baseline; T1: morning after sleep; T2: follow-up 48hrs later). REM sleep continuity was disrupted in the *Fragmentation* condition by eliciting cortical arousals through vibrotactile stimulation, while undisturbed sleep was allowed in the *Control* condition. The effect of the experimental manipulation was assessed on self-report evaluations (Self-Assessing Manikin), physiological responses (Skin Conductance Response, SCR; Heart Rate Deceleration, HRD), and recognition memory (Old/New paradigm) for negative and neutral stimuli. Data were compared via linear mixed model with *Condition*, *Valence* and *Time* as factors and their interactions, including random intercepts per subject and stimulus.

Results: The vibrotactile stimulation was effective in disrupting REM sleep continuity during the *Fragmentation* night and resulted in a reduction of REM sleep duration parallel to increases in NREM1 ($p < 0.001$) compared to the *Control* night, without altering other macrostructural variables ($p > 0.170$). Statistical analyses revealed that REM sleep fragmentation didn't influence subjective ratings of stimuli pleasantness and arousal, or recognition memory performance (all $p \geq 0.116$), while it significantly affected emotional physiological reactivity as measured by HRD ($p = 0.002$). Specifically, HRD values decreased significantly after undisturbed sleep in the *Control* condition ($p = 0.007$) and then remained stable until T2 ($p > 0.999$), whereas no change occurred over sessions in the *Fragmentation* condition ($p \geq 0.529$).

Conclusions: A single night with REM sleep fragmentation after exposure to emotional stimuli impairs the sleep-dependent processes responsible for psychophysiological habituation the following day. Importantly, the dysregulated emotional responses persist for 48hrs, despite two intervening nights of undisturbed sleep. The results support the importance of REM sleep continuity for healthy overnight processing of emotional experiences and its protective role against long-lasting dysfunctional emotional reactivity.

KNOWLEDGE AND ATTITUDES TOWARDS DREAMS AMONG MEDICAL STUDENTS IN ABAKALIKI NIGERIA: A DESCRIPTIVE STUDY

C. Eze¹, N. Obayi¹, C. Eze¹

¹Alex Ekwueme Federal University Teaching Hospital Abakaliki, Internal Medicine, Abakaliki, Nigeria,

²Alex Ekwueme Federal University Teaching Hospital Abakaliki, Psychiatry, Abakaliki, Nigeria

Introduction: Dreams represent the activities of the brain during sleep and occur in all stages of sleep, though vivid dreams occur mainly during rapid eye movement (REM) sleep. There are limited scientific studies on dreams in Sub-Saharan Africa despite the growing knowledge in other parts of the world. This research study investigated the level of knowledge about dreams and explored the attitudes of clinical students towards dreams and their relevance in healthcare.

Materials and methods: This cross-sectional observational study was undertaken among the medical students of 2 public institutions in Nigeria from 25th September to 3rd October 2023.

Results: Out of 353 medical students (males- 48.4% and females- 51.6%) with a mean age of 24.3 ± 2.5 years that were studied, 15.6% know that dreams arise from brain activity during sleep (good knowledge), 82.1% believe that dream is spiritual while 2.3% had no idea about the origin of dream. The main source of knowledge of dreams was from the teachings in the church and bible- 68.8%, from home and community- 16.7%, and from personal studies- 14.4%. Nightmares were common and the predominant subject was the death of a loved one (61.3%), a threat to life (26.1%) and failure in examination and life (12.6%).

The actions taken after a nightmare include praying and nullifying the nightmare- 79.9%, requesting their parents and spiritual leaders for a nullification prayer- 14.2%, while 5.9% would do nothing.

Conclusions: The knowledge and attitudes towards dreams are poor among medical students in Nigeria.

Their knowledge and attitude towards dreams can be improved through incorporating Dream Education into the Curriculum, regular seminars and workshops on dreams, the creation of Dream Journals, the formation of peer Discussion Groups and offering research opportunities in the field of sleep and dreams to interested students.

By implementing these recommendations, medical students in Nigeria can develop a better knowledge and attitude towards dreams, sleep, and their relationship with mental health. This can lead to more comprehensive patient care in the future and contribute to a better understanding of mental health in the medical field.

Linking Childhood Trauma to Suicidal Ideation through Nightmares in Youth

J. Que¹, Y. Lu², J.J. Liu²

¹Xiamen Xianyue Hospital, Xiamen, China, ²Peking University, School of Nursing, Beijing, China

Introduction: Childhood trauma, encompassing experiences such as emotional abuse and neglect, often leaves profound and lasting effects. One of the lesser-recognized consequences of such trauma is its association with frequent nightmares, which may, in turn, contribute to the development of suicidal ideation. This study seeks to examine the relationship between childhood trauma, nightmares, and suicidal ideation, focusing on the impact of both single and multiple types of trauma on frequent nightmares. Additionally, the study aims to explore the mediating role of nightmares in the association between trauma and suicidal ideation and to assess the possible moderating effect of sex on these relationships.

Materials and methods: Youth aged 12–25 years ($n=6145$) participated in an online survey assessing childhood trauma, nightmares, and suicidal ideation. Logistic regression analyses were employed to investigate the relationship between distinct types of childhood trauma and frequent nightmares. Cumulative scores and latent class analyses were applied to identify multiple childhood traumas. Furthermore, moderated mediation analyses were conducted, considering childhood trauma as the independent variable, suicidal ideation as the dependent variable, nightmare frequency as the mediator, and sex as the moderator.

Results: After controlling for a range of covariates, emotional abuse (OR: 1.45, 95%CI: 1.23–1.87) and emotional neglect (OR: 1.19, 95%CI: 1.03–1.37) were found to be significantly associated with an increased likelihood of experiencing frequent nightmares. A dose-response relationship was observed, where a higher number of trauma types was linked to a greater likelihood of experiencing nightmares. Latent class analysis identified three trauma patterns: “low abuse, low neglect (62.4%, $n = 3837$),” “low abuse, high neglect (34.0%, $n = 2089$),” and “high abuse, high neglect (3.6%, $n = 219$).” The latter two patterns were associated with an increased likelihood of nightmares by 26% and 47%, respectively,

compared to the first pattern. Furthermore, nightmare frequency was found to significantly mediate the relationship between childhood trauma and suicidal ideation, accounting for approximately 4.11% of the total effect, even after adjusting for relevant covariates. However, no significant moderating effect of sex was observed, suggesting that both male and female individuals may be equally influenced by trauma-related pathways.

Conclusions: The findings of this study contribute to a deeper understanding of the heterogeneity in childhood trauma and its potential implications for the occurrence of nightmares. They suggest that nightmares may not only reflect the psychological impact of trauma but also serve as a key factor in the development of suicidal ideation. It is possible that interventions targeting nightmares could be effective in mitigating suicide risk in traumatized youth. However, further research is warranted to explore the generalizability of these findings and to evaluate the efficacy of interventions designed to address nightmares in this population.

Long sleep is associated with poor global cognitive function across diverse populations

T. Sofer¹, Y. Zhang², A. Wyss³, M. Brown⁴, C. Sarnowski⁴, J. Bressler⁴, C. Isasi⁵, Q. Qi⁵, M. Fornage⁴, M. Lamar⁶, W. Tarraf⁷, A. Ramos⁸, C. DeCarli⁹, J. Rotter¹⁰, X. Guo¹⁰, P. Lutsey¹¹, T. Hughes¹², K. Taylor¹⁰, B. Yu⁴, A. Morrison⁴, A. Wood¹³, P. Liu¹⁰, H. González¹⁴, S. Heckbert¹⁵, S. Redline¹⁶

Introduction: Associations between suboptimal sleep and reduced cognitive function have been previously reported. However, associations have not been consistently assessed across populations of potentially different characteristics.

Materials and methods: Our analysis included individuals with data from sleep and cognitive exams occurring around the same time and subsequent follow-up cognitive exams in three U.S.-based longitudinal cohort studies: the Hispanic Community Health Study/Study of Latinos (HCHS/SOL) of Hispanic/Latino adults from four metropolitan areas (N= 9217; average age 55 at baseline; 7 years between cognitive exams on average), the Multi-Ethnic Study of Atherosclerosis (MESA) of individuals self-identified as White, Black, Hispanic, or Chinese American, from 6 U.S. six metropolitan areas (N= 1736; average age 67 at baseline; 6.3 years between cognitive exams on average), and the Atherosclerosis Risk In Communities Study (ARIC) of White individuals from three metropolitan areas (N= 1664; average age 63 at baseline; 15 years between cognitive exams on average). In each cohort, global cognitive function (GCF) was defined as the first principal component from analysis of standardized cognitive tests and poor GCF as falling 1 standard deviation (SD) below the age-adjusted study median. Harmonized sleep phenotypes included objectively-measured obstructive sleep apnea (OSA), and self-reported excessive daytime sleepiness (EDS), insomnia symptoms, and short and long sleep durations. We estimated associations between sleep variables and GCF at baseline, and incident poor GCF. Analyses were performed separately in each cohort, adjusted for age, sex, study site, race/ethnic background (when applicable), and education at baseline. Estimates were then meta-analyzed across cohorts.

Results: Long sleep (≥ 9 hours) was consistently associated with reduced baseline GCF (HCHS/SOL beta: -0.32; 95% confidence intervals (CI) -0.42; -0.23; MESA beta: -0.09 95% CI [-0.25; 0.06]; ARIC beta: -0.19 95% CI [-0.40; 0.015]; meta-analysis beta: -0.25, 95% CI [-0.33; -0.17]). Elevated insomnia symptoms was associated with reduced GCF (meta-analysis beta: -0.07, 95% CI -0.13; -0.01); however, results were driven by data from HCHS/SOL (HCHS/SOL beta: -0.17 95% CI [-0.26; -0.09]), with more variable associations in MESA (beta: -0.05; 95% CI -0.19; 0.09) and ARIC (beta: 0.06; 95% CI -0.04; 0.16). Short sleep duration (≤ 6 hours) had statistically significant association with reduced GCF only in

MESA (beta: -0.23; 95% CI -0.45; -0.01); meta-analysis beta: -0.06, 95% CI -0.16; 0.03. Long sleep was also suggestively associated with higher likelihood of incident poor GCF (HCHS/SOL risk ratio (RR): 1.27; 95% CI 0.94; 1.72; MESA RR: 1.00; 95% CI 0.54; 1.87; ARIC RR: 1.50; 95% CI 0.72; 3.16; meta-analysis RR: 1.24, 95% CI [0.96; 1.60]), an analysis with lower sample size (overall N=6648). Patterns of associations of OSA and EDS with cognitive measures were inconsistent across studies and none were statistically significant.

Conclusions: Long sleep duration is associated with reduced GCF across populations of diverse race/ethnicities, with suggestive albeit non-significant associations with incident poor GCF.

Magnitude and associated factors of poor sleep hygiene practice among Chinese married persons: A cross-sectional study

Y. Zhang¹, Y. Luo¹, R. Yin¹

¹The First Affiliated Hospital of Soochow University, Suzhou, China

Introduction: Due to the responsibility to take care of families, married people may expose to a high risk of poor sleep hygiene, but we do not know the situation. This study aims to evaluate sleep hygiene practices among those population.

Materials and methods: 176 married persons were included in this study. Demographic data, Sleep Hygiene Practice Scale, and Pittsburg Sleep Quality Index were collected. Pearson correlation and multiple linear regression analysis were applied by SPSS 22.0.

Results: Overall, 97 (55.1%) of married persons had poor sleep quality. The score of sleep hygiene was 77.06 ± 21.54 , while in detail, the score of arousal-related behaviors, sleep scheduling and timing scored, eating/drinking behaviors, and sleep environment was 24.26 ± 7.59 , 22.96 ± 6.12 , 12.53 ± 5.29 , and 17.31 ± 7.24 , respectively. Pearson correlation analysis showed that age, body mass index, length of marriage, children with university degree or above, monthly income, drinking, smoking, exercise habit, and perceived health status were negative related to maladaptive sleep hygiene. Interestingly, male's sleep hygiene behaviors were worse than females. Further analysis indicated that, children with university degree or above ($\beta = -11.335$, $P = 0.016$), drinking ($\beta = -14.513$, $P = 0.011$), and exercise habit ($\beta = -7.972$, $P = 0.026$) were the predictors of poor sleep hygiene.

Conclusions: The sleep hygiene practice of Chinese married people was in the lower middle level, and its worse for men's. Nurses should pay attention to married people's children, drinking, and exercise habits to improve their sleep behavior, and thus enhance sleep quality.

Musical harmony is differentially processed during sleep: Evidence from EEG recordings

A. Wick¹, B. Rasch¹

¹University of Fribourg, Cognitive Biopsychology and Methods, Fribourg, Switzerland

Introduction: Musical chords are the smallest musical elements that convey emotional information. While different chord categories (e.g., major or minor) elicit distinct emotions and neuronal correlates during wakefulness, it remains unclear whether the brain continues to differentially process these musical chords during sleep. We hypothesized that musical harmony is differentially processed by the sleeping brain.

Materials and methods: To address this question, we presented musical chords over loudspeakers to 47 healthy young participants (19-25 years) during nocturnal non-rapid eye movement (NREM) sleep. The chords were tone triads with major, minor or dissonant harmonic properties. Chords were subjectively rated before sleep. During the night, sleep was recorded by polysomnography in a sleep laboratory.

Results: Consistent with our hypothesis, event-related responses (ERPs) during sleep significantly differed between the three chord types: major chords elicited the highest negative amplitude in a peak-to-peak (PTP) analysis at approximately 800 ms after chord onset. The PTP responses were intermediate for minor chords, and lowest for dissonant tone triads. These particular response patterns were similar in N2 and slow-wave sleep (SWS), with generally higher PTP amplitudes during N2 sleep.

Importantly, differential responses of the sleeping brain to chord categories were stronger in participants who played a musical instrument compared to participants who never played an instrument.

Conclusions: In conclusion, our findings suggest that the differential processing of single musical chords persists during sleep, influenced by harmonic features and musical expertise in the context of Western musical conventions. Future research should explore whether also longer and more complex harmonic features (e.g., chord sequences or musical pieces) are also differently processed by the sleeping brain.

Napping and cognition in older adults-context matters: reasons for napping, nap timing, and overall sleep health

R. Leong¹, X.Y. Chua², W.P. Koh², M. Chee¹

¹National University of Singapore, Medicine, Singapore, Singapore, ²National University of Singapore, Singapore, Singapore

Introduction: While midday napping in younger persons benefits cognition, napping in older persons tends to be associated with poorer cognitive outcomes, leading to the view that napping may be 'symptom' of age-related degradation in sleep neurobiology. However, whether naps are maladaptive or productive for older adults may depend on the reason behind the nap and must be understood in the context of overall sleep health as these may underlie negative associations. To rule this out, we examined associations between napping and cognition in a group of older adults with relatively good sleep health (7-10h average TIB, having no trouble falling asleep and/or staying asleep for ³ 5 nights/week, no sleep disorders).

Materials and methods: Older adult healthy sleepers (n = 393) aged between 67-80 years (mean age: 73.8 years, SD: 2.7 years) completed neurocognitive testing and questionnaires probing nap behaviour. Nap frequency (no naps, 1-2 naps/week, 3-6 naps/week, daily naps), nap duration (≤ 30 mins, 31-60 mins, > 60 mins), nap timing (morning, afternoon, evening), nap intention (unintentional, intentional) and reasons for napping (slept poorly the night before, felt tired, boredom, habit) were assessed. Linear regression models were used to determine the effects of nap characteristics on cognitive domains (global cognition, speed of processing, executive function, attention, language, verbal, visual, and visual-spatial memory). Models adjusted for age, gender, years of education, smoking, high blood pressure, diabetes, and history of cardiovascular events and organ disease.

Results: Napping to counter tiredness was associated with better verbal memory (B = 2.47, CI₉₅ = 0.29-4.66) and language (B = 2.08, CI₉₅ = 0.07-4.09) compared to napping because one slept poorly the night before. Napping in the afternoon was associated with better visuospatial memory compared to napping in the morning (B = -5.77, CI₉₅ = -10.55--0.99). Napping daily was also associated with better verbal memory (B = 0.58, CI₉₅ = 0.00-1.17) and language (B = 0.64, CI₉₅ = 0.10-1.17) compared to not napping at all, but with relatively small effects.

Conclusions: In older adults with 'intact' sleep health, napping in the afternoon in response to tiredness cues is associated with better memory performance. Our findings suggest that whether or not napping is a 'symptom' or a 'strategy' for better daytime function may depend on its use patterns and the overall sleep health of an older person.

Night Shift Work Impairs Team Performance and Cohesion

E. Greer¹, M. Owen¹, P.G. Roma^{2,3}, C. Yates¹, L. Grosser¹, S.R. Hursh⁴, C. Mais⁵, C. Buche⁶, S. Banks¹

¹University of South Australia, Adelaide, Australia, ²Leidos Inc., Military and Veterans Health Solutions, San Diego, United States, ³Rice University, Department of Psychological Sciences, Houston, United States, ⁴Institutes for Behavior Resources, Applied Behavioral Biology Unit, Baltimore, United States, ⁵Naval Group, Ollioules, France, ⁶Naval Group Pacific, Adelaide, Australia

Introduction: Many safety-critical industries require distributed teams, who collaborate across location and times, to work during the night outside of the conventional '9-to-5' hours, such as healthcare, emergency services, transportation and military settings. Distributed teams that are cohesive and adaptive are essential for maintaining productivity and safety in these continuous, shift-working conditions. Despite their essential nature, there are repercussions for those working at night when their

bodies are most primed for sleep. Nightwork disrupts biobehavioural functions which follow inherent circadian rhythms, requiring the body to be awake during the day and asleep during the night. Circadian disruption associated with night work systematically and negatively impacts health and performance, which are likely to harm distributed team dynamics. In addition to working during the biological night, the complexities associated with working in distributed teams, such as lack of face-to-face interactions and trouble coordinating and collaborating with fellow team members over varying geographical locations and times, further exacerbate these dynamics. Despite the prevalence of night work for distributed teams, little to no research has investigated the impact. Thus, this study aimed to assess the impact of working through the biological night on distributed team performance, dynamics and cohesion.

Materials and methods: Six teams of four, young healthy individuals ($N=24$, $M\pm SD=25.38\pm 6.53$ years, 9f) completed an in-laboratory study consisting of one night of 32h of wakefulness. Simulated night shift work, including COHESION, a computer-based team task, was undertaken by participants during the wake period. Teams were physically isolated every four hours while completing COHESION as to assess distributed team performance, cohesion and dynamics across the biological night (6pm, 10pm, 2am, 6am, 10am). COHESION required distributed team members to move resources into a target zone, while avoiding visible and invisible barriers. Each team member was responsible for a subset of barriers visible only to them and session time could be spent cooperating (revealing barriers to all) or attempting productivity (resource drops). Cooperative and productivity behaviours were analysed at the individual level. Team-level metrics included distributed team performance (team successful resource drops) and team dynamics (dispersion of barrier-reveal attempts within the team). Team cohesion and alertness measures were also administered after each COHESION test. Data were analysed using linear mixed models.

Results: There were significant main effects of clock time on individual alertness ($F(4,96)=27.59, p<.001, \eta_p^2=.74$), cooperative behaviours (barrier reveals, $F(4,96)=3.26, p=.015, \eta_p^2=.12$) and productivity behaviours (resource drop attempts, $F(4,96)=4.01, p=.005, \eta_p^2=.14$). There were also significant main effects of clock time on distributed team performance (team resource drops, $F(4,24)=3.54, p=.021, \eta_p^2=.37$), dynamics ($F(4,24)=4.30, p=.009, \eta_p^2=.42$) and team cohesion ($F(4,92)=16.30, p<.001, \eta_p^2=.41$).

Conclusions: This study found clear deficits in team outcomes during night work, particularly during the circadian low. At this time of the night, distributed teams exhibited increased fatigue, reduced cooperation among team members, and diminished productivity, leading to poorer team performance, dynamics, and cohesion. The circadian system played a crucial role in modulating distributed team performance and cohesion. This is especially problematic in safety-critical, shift-working industries such as healthcare, military, and transport, where effective team work and cohesion across geographical locations and times are essential.

No association between sleep and dishonest behavior in healthy school-age children

A. Dorgham¹, T.B. Koa^{1,2,3}, X.P. Ding⁴, J.C. Lo^{1,2,3}

¹National University of Singapore, Centre for Sleep and Cognition, Yong Loo Lin School of Medicine, Singapore, Singapore, ²Department of Medicine, Yong Loo Lin School of Medicine, Singapore, Singapore, ³National University of Singapore, Human Potential Translational Research Programme, Yong Loo Lin School of Medicine, Singapore, Singapore, ⁴National University of Singapore, Department of Psychology, Singapore, Singapore

Introduction: Short sleep duration is associated with poorer executive functions which are crucial for goal-directed behavior and moral decision-making, such as cheating and lying. While previous research on school-age children has uncovered relationships between executive functions and dishonest behavior, little is known about the association between sleep and dishonest behaviour. This study aimed to examine whether short sleep duration, as well as poor sleep quality, were associated with dishonest behaviour and lie sophistication in healthy school-age children.

Materials and methods: The sample consisted of 46 healthy school-age children (19 female, aged 7-12 years) whose sleep was tracked with actigraphy for 8 nights during a school term. Sleep parameters were averaged across days. With parental consent, the Temptation Resistance Task was administered the morning after the final actigraphy night to assess dishonesty. In this task, children completed an

unsupervised trivia quiz containing one unanswerable question. They were told they would be rewarded for answering all the questions correctly and were instructed not to peek at the answers on the back of the page before being left alone to complete the quiz. A hidden camera recorded their behaviour during this task. They were later asked if they had peeked, and if they could guess the content of the answer sheet (each answer was accompanied by a symbol that depicted a unique object in a different colour). Among the lie-tellers, lie sophistication was based on whether they lied about the object of the symbol accompanying the answer to the unanswerable question, its colour, or both aspects (unsophisticated = 0 aspect; slightly sophisticated = 1 aspect; sophisticated = 2 aspects). Children were debriefed after the task. Group differences in sleep parameters were examined using ANCOVAs with age and sex as covariates.

Results: “Non-peekers” (n = 28) and “peekers” (n = 18) did not significantly differ in any of the sleep parameters: time in bed (mean $\pm$ SEM: 534.0 ± 9.7 vs 533.7 ± 10.4 minutes), total sleep time (467.3 ± 7.4 vs 473.6 ± 11.0 minutes), sleep efficiency (87.4 ± 0.8 vs $88.7 \pm 0.9\%$), wake after sleep onset (40.4 ± 3.2 vs 37.4 ± 3.0 minutes), and sleep latency (15.8 ± 2.1 vs 14.0 ± 2.4 minutes) (all $p > 0.05$). Among the “peekers”, only one child did not lie; thus, differences in sleep between lie-tellers and non-lie-tellers could not be examined. Among the lie-tellers, the unsophisticated (n = 3), the slightly sophisticated (n = 8), and the sophisticated (n = 6) groups did not differ in any of the sleep parameters (all $ps > 0.41$).

Conclusions: In healthy school-age children, sleep duration and quality did not appear to be associated with dishonest behavior or lie sophistication, suggesting that the relationship between sleep and higher-order cognitive functions, such as deception, may be more trivial than those with basic cognitive functions found in previous studies.

Acknowledgments: This work was supported by the National University of Singapore under the start-up grant awarded to Dr June Lo [NUHSRO/2019/075/Startup/01].

Objective markers of in-dream speech and audition in narcoleptic lucid dreamers

B.J.B. Bréant^{1,2}, M. Tonnelat^{1,2}, F. Gomes-Diogo¹, I. Ben Haj Kacem¹, A. Champavert¹, A. Chen¹, I. Arnulf^{1,2}

¹Sorbonne Université, Institut du Cerveau et de la Moelle Epinière, Paris, France, ²University Hospital Pitié-Salpêtrière, Service de Pathologie du Sommeil, Paris, France

Introduction: The functional significance of dreams and dream-related content remains unknown. Therefore, investigating objective markers of dream content may clarify the underlying neurobiological basis of dream generation and paint a clearer picture of the function of dreaming. Recent studies conducted on REM sleep behaviour disorder (RBD) patients suggest that dream content relies on wake-like cerebral pathways, as conversation properties are highly conserved between wake and dreams. This suggests that in-dream conversations are generated and processed similarly those during waking. The possibility remains that speech-related muscle activation during REM sleep mirrors waking neural pathways. As no objective markers of speech and audition during have been identified, this project aims to identify these markers and relies on a lucid-dreamer model for real-time validation.

Materials and methods: To investigate the dynamics of muscle twitches during the night, we recruited 11 volunteers (6 females, 5 males), including lucid (n=4) and non-lucid dreamers (n=7). Lucid participants were all narcoleptic (type 1 or 2) patients who suspended their treatment during the experiment to increase the occurrence of an early REM episode during naps. 64-channel EEG, EMG electrodes, and respiratory belts were used to assess brain and muscle activity. Middle ear muscle activity (MEMA) was measured using earplugs. Participants underwent overnight and nap recordings, with dream content collected after awakening. Sleep stages and muscle activity were manually scored. All experimental procedures involving human participants were reviewed and approved by the Comité de Protection des Personnes Ouest III. Written informed consent was obtained from all participants prior to inclusion in the study.

Results: Overnight recordings show that spontaneous activity of the laryngeal and orbicularis muscles decreases with NREM stages, but is significantly higher in REM sleep, primarily as short twitches. Similarly, MEMA increases during REM sleep. Overnight, no correlation was found between the incidence of muscle twitches and the breathing phase. In lucid dreamers, reports of speech were often associated with increased laryngeal and orbicularis muscle activity, and preliminary results suggest that stronger muscle activity is associated with reports of louder in-dream conversation. However, MEMAs could not be associated with acute reports of sounds.

Conclusions: Our study shows that speech-related muscles are more active during REM sleep. Reports from lucid dreamers suggest that in-dream speech leads to activation of the dreamers' lips and larynx. These results support the idea that the neural mechanisms of speech production is conserved in dreams. However, results with MEMA do not correspond to acute listening, although they may reflect anticipatory processes. Our results highlight the value of lucid dreamers in identifying objective physiological measures of dream processes. These findings shed light on the interplay between dream content and peripheral muscle activation and provide new avenues for investigating this mental state.

Offline by Design: Cortical Mechanisms of Partial Sensorimotor Disconnection Across Sleep Stages and More

R. Mao^{1,2,3,4}, M. Cavelli^{1,5}, G. Findlay^{1,2}, K. Driessen^{1,2}, M. Peterson¹, W. Marshall^{1,6}, S. Wilcox^{3,4}, V. Vyazovskiy^{3,4}, G. Tononi¹, C. Cirelli¹

¹University of Wisconsin-Madison, Department of Psychiatry, Madison, United States, ²University of Wisconsin-Madison, Neuroscience Training Program, Madison, United States, ³University of Oxford, Department of Physiology, Anatomy and Genetics, Oxford, United Kingdom, ⁴University of Oxford, Kavli Institute for Nanoscience Discovery, Oxford, United Kingdom, ⁵Universidad de la República, Departamento de Fisiología de Facultad de Medicina, Montevideo, Uruguay, ⁶Brock University, Department of Mathematics and Statistics, St. Catharines, Canada

Introduction: Partial sensorimotor disconnection is a defining feature of sleep, during which we spend approximately one-third of our lives functionally detached from the external environment—often unaware of potential threats. However, the mechanisms underlying this intriguing sensory and motor gating across sleep stages are poorly understood. When arousal thresholds are assessed using peripheral stimuli, they are typically higher during deep non-rapid eye movement (NREM) sleep than during rapid eye movement (REM) sleep. Interestingly, for example, locus coeruleus neurons show no response to mild auditory stimuli during REM sleep, whereas responses are present in NREM sleep. The cerebral cortex is widely regarded as the neural substrate of awareness. It also contributes to disconnection, but its specific role across different sleep stages remains unclear.

Materials and methods: Here we tested in mice whether optogenetic activation of cortical neurons in posterior parietal cortex (PtA) or medial prefrontal cortex (mPFC) is sufficient for arousal from NREM or REM sleep. Adult CaMKIIα::ChR2 mice of both sexes (> P56, 12 mice) were chronically implanted with optic fibres at PtA or mPFC, intracortical laminar probes and surface electrodes for electroencephalographic (EEG) recordings, as well as nuchal and vibrissal electromyographic (EMG) electrodes. To compare with sleep, experiments were also performed in two progressively deeper unresponsive states: a coma-like state by midbrain muscimol injection through pre-implanted bilateral cannulas, and anaesthesia by sevoflurane-dexmedetomidine co-administration. Finally, our ongoing work investigates arousal threshold during fast-induced torpor in adult C57BL6/J male mice implanted with EEGs and EMGs (8 mice) using brief auditory tones (1–11 kHz, 1 sec duration).

Results: We found that cortical laser stimulation (square pulses or 4–8 Hz train pulses lasting 1–5 sec) in either PtA or mPFC could always awaken the mice from NREM or REM sleep (8 mice). Interestingly, the awakening from REM sleep required significantly more laser power and/or longer stimulation compared to awakening from NREM sleep ($p = 2.6 \times 10^{-5}$). PtA stimulation was significantly more effective than mPFC stimulation, i.e. with PtA stimulation weaker and/or shorter pulses were required to induce arousal ($p = 7.7 \times 10^{-5}$). In addition, optogenetic cortical stimulation was also able to arouse mice from coma (12 mice) and produce cortical activation from anaesthesia (9 mice). Preliminary finding on torpor showed that the auditory arousal threshold in this largely unexplored physiological state was surprisingly lower than NREM sleep.

Conclusions: These findings demonstrate that direct activation of cortical neurons in mice is sufficient to disrupt the disconnection from sleep—as well as to induce behavioural and/or cortical arousal from deeper unresponsive states i.e. brainstem coma and general anaesthesia. Activation of cortical neurons awakens mice more easily from NREM sleep than from REM sleep, suggesting that disconnection during NREM sleep may notably result from corticothalamic slow-wave activity—disruption of which readily triggers awakening—whereas in REM sleep, it is largely driven by other mechanisms such as the lack of noradrenaline.

Personality, cognitive performance and perceived workload in young adults with unmanaged sleep disorders after 20 hours of extended wake

G. Robertson¹, N. Lovato¹, C. Dunbar¹, G. Micic¹, K. Nguyen¹, J. Fitton¹, A. Montero¹, K. Loffler¹, K. Sansom¹, A. Vakulin¹, R.J. Adams¹, A.C. Reynolds¹

¹Flinders University, Flinders Health and Medical Research Institute, Bedford Park, Australia

Introduction: There are inter-individual differences in the effects of extended wake on cognitive performance, including a potentially modifying influence of personality trait dimensions. Greater extraversion has previously been associated with poorer psychomotor vigilance performance during extended wake in young adults with healthy sleep.

Performance may also be worsened in individuals with sleep disorders. Up to 20% of young adults have sleep disorders that require clinical investigation and up to 80% of these disorders are undiagnosed. Yet, young adults with sleep disorders are poorly represented in existing studies of extended wake. The aim of this study was to determine associations between sleep disorders, cognitive performance and perceived mental workload after extended wake in young adults, and explore whether personality dimensions modify any observed associations.

Materials and methods: Data from 24 young adults aged 18 – 32 years (Mean(SD) = 25.0(3.9), 42% female) were included. Participants first completed a Structured Clinical Interview (SCISD) and NEO Personality Inventory (NEO-PI-R) with a trained psychologist. All participants included in analyses met diagnostic criteria for insomnia (n=14) or delayed sleep wake phase disorder (DSWPD; n=10) according to DSM-5-TR criteria but had no prior diagnosis or treatment for a sleep disorder at baseline.

Participants underwent a diagnostic polysomnography with sleep onset and offset times aligned with their habitual bedtime before commencing extended wake. The psychomotor vigilance task (PVT) was performed at 2 hours and 20 hours after wake. Reciprocal reaction time (RTT; 1/ mean reaction time) and number of lapses in attention were used to determine changes in performance and were the primary performance outcomes. The NASA Task Load Index (NASA-TLX) assessed subjective workload immediately after each PVT (performance, effort, frustration, and mental, physical, and temporal demand) on a 0-100 scale. Data were analysed in R Studio, using a combination of linear regression and mixed effects regression in the *lmer* package.

Results: We observed the anticipated effect of extended wake on PVT metrics, with reduced RRT (reflecting poorer performance, 3.02(0.56) v 2.22(0.77), $p < 0.001$), and increased PVT lapses (3(7) v 15(13), $p < 0.001$). All indicators of subjective mental workload on the NASA-TLX were elevated at 20hours wake compared to 2hours (all $p < 0.05$), with the exception of temporal demand ($p = 0.42$). Time by personality dimension interactions on PVT performance were not significant (all $p > .05$), suggesting cognitive performance was not modified by personality dimensions. However, extraversion modified the association between extended wake and mental workload, where higher extraversion was associated with higher perceived temporal demand ($B = 1.04$, 95%CI = 0.41, 1.68, $p = .002$), poorer perceived performance ($B = 0.79$, 95%CI = 0.08, 1.49, $p = .031$), and greater frustration ($B = 0.96$, 95%CI = 0.09, 1.83, $p = .033$).

Conclusions: Extraversion may modify the perceptions of performance and mental workload more broadly in young adults with sleep disorders. Unlike healthy sleepers, extraversion in young adults with sleep disorders modified the association between 20h of extended wake and subjective performance, but not objective performance. Personality-task mismatch on monotonous tasks may be an issue for extroverts who are entering healthcare professions, who may feel greater frustration and perceive poorer performance when sleep deprived.

Introduction: Sleep disorders in infants aged 0 to 3 years are an increasing concern for parents, and many seek digital solutions to address them. With the rise of digital medicine, it is important to understand what parameters mothers value when choosing these approaches to improve infant sleep. This study aims to identify mothers' preferences and expectations regarding digital medicine, exploring factors such as professional training, personal experience, and expected outcomes.

Materials and methods: A total of 653 surveys were conducted with mothers seeking digital solutions through the professional Instagram account @AnaMariaSilvaPediatria. The sample was divided into three groups: 354 pregnant women (54.21%), 280 mothers with infants aged 0 to 4 months (42.88%), and 19 mothers with infants aged 4 to 36 months (2.91%). The surveys were completed by women from 26 countries, with the highest participation from Colombia (63.5%), the United States (7.21%), Venezuela (4.60%), Mexico (2.91%), and Argentina (2.61%). Data was collected on occupation, socioeconomic status, and expectations related to infant sleep. Data collection took place over a 6-month period, from July to December 2024.

Results: The main expectations of mothers were for their babies to sleep through the night (53.91%), to avoid dependency on breastfeeding or other sleep associations (24.50%), to improve naps (12.25%), and to get their babies to sleep in their own crib or room (9.34%). Regarding the factors influencing the choice of digital medicine, experience, testimonials, and results were the most relevant factor (36.84%), followed by the professional's medical training (31.58%) and social media content (15.79%). 10.53% of mothers valued methods that did not involve "letting the baby cry," and only 5.26% considered social media recognition of the doctor important.

Conclusions: The results suggest that mothers particularly value evidence of effectiveness through previous experiences and testimonials, as well as the medical training of the professional offering the digital solutions. The preference for methods that do not involve letting the baby cry reflects an interest in respectful approaches that are sensitive to the emotional needs of the baby. Despite the cultural and socioeconomic diversity in the sample, common expectations point to a significant improvement in infant sleep quality, underscoring the relevance of digital medicine in this context. This study contributes to understanding the factors motivating mothers to choose digital options for managing infant sleep and can guide the development of more effective and accessible intervention programs.

Sleep disorders after mild traumatic brain injuries in young female patients

N. Syrmos¹

¹Aristotle University, Thessaloniki, Greece

Introduction: . Aim of this study was to present cases of sleep disorders after mild traumatic brain injuries in young male patients(<40 years old).

Materials and methods: 10 cases are presented.10 young male patients. Range of age 18-40 years old. Some common symptoms were: 4 of patients have insomnia, 2 patients have sleep apnea, 2 have hypersomnia, and 2 have narcolepsy.

Results: All of them received :Cognitive behavioral therapy (CBT),Natural sleep-inducing remedies, Pharmacotherapy and continue Neurological, Psychological and Psychiatric Support. Good results in 9 patients (90%) and moderate in 1 (10%).

Conclusions: Multidisciplinary approach is essential to achieve optimal results for our patients.

Sleep Macro- and Microarchitecture in Major Depressive Disorder with Sleep State Misperception

J. Chen¹, H. Li², M. Qi², L. Wang², S. Zhou², J. Chen², S. Gao¹, Y. Leng³, S. Tan²

¹Peking University Health Science Center, Institute of Medical Technology, Beijing, China, ²Beijing HuiLongGuan Hospital, Sleep Medicine Center, Beijing, China, ³University of California, San Francisco, Department of Psychiatry and Behavioral Sciences, San Francisco, United States

Introduction: Sleep state misperception, also known as paradoxical insomnia, is a phenomenon characterized by a mismatch between subjective and objective sleep assessment. It is highly prevalent among individuals with depression, yet its physiological underpinnings remain poorly understood. This study aimed to determine the associations between multidimensional sleep features and the presence of sleep perception impairment (SPI) in patients with depression, using both features of sleep macro-architecture and micro-architecture derived from polysomnography (PSG).

Materials and methods: We enrolled 63 patients (aged 18–65 years) meeting the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-V) criteria for major depressive disorder. Based on either a ≥ 60 -minute discrepancy in total sleep time or a $\geq 15\%$ gap in sleep efficiency between subjective sleep diary and objective PSG, participants were classified into sleep perception impairment (SPI; $n = 26$) or non-SPI ($n = 37$) groups. All underwent overnight PSG and completed standardized assessments, including the Pittsburgh Sleep Quality Index (PSQI), Hamilton Depression Rating Scale (HAM-D), and cognitive testing using the Repeatable Battery for the Assessment of Neuropsychological Status (RBANS). We extracted sleep macro-architecture (e.g., sleep efficiency, latency, apnea-hypopnea index [AHI]) and micro-architecture features (e.g., band power, spectral ratios). Additionally, we calculated sleep temporal entropy (STE)—a novel marker reflecting the fragmentation and irregularity of transitions across sleep stages—to capture dynamic aspects of sleep stability. Between-group comparisons used appropriate statistical tests. Logistic regression models examined associations with SPI: Model 1 adjusted for demographic variables; Model 2 added PSQI score, cognitive function, and HAM-D score; Model 3 further included AHI, periodic limb movement index (PLMI), health status, and comorbidities.

Results: Compared to patients without SPI, those with SPI exhibited significantly lower PSG-derived sleep efficiency (mean $\pm$ SD: $71.2\% \pm 10.3\%$ vs. $83.4\% \pm 8.1\%$, $p < 0.01$), longer sleep latency (28.7 ± 15.9 vs. 17.1 ± 10.2 minutes, $p < 0.01$), and greater subjective-objective mismatches in total sleep time and sleep efficiency (both $p < 0.01$). In univariate logistic regression, increased gamma power (OR = 2.15, 95% CI: 1.24–3.75, $p < 0.01$), higher overall sleep temporal entropy (OR = 2.47, 95% CI: 1.29–5.08, $p < 0.01$), and elevated REM theta/beta ratio (OR = 2.04, 95% CI: 1.17–3.52, $p = 0.01$) were significantly associated with SPI. These associations persisted after adjustment for demographic and clinical covariates. In the fully adjusted model, higher whole-night STE (OR = 2.62, $p = 0.01$) and an increased theta/beta ratio during REM sleep (OR = 2.19, $p < 0.01$) remained independently associated with SPI. Metrics from the STE and Ratios domains showed consistent and robust associations across all models, highlighting their potential utility as objective markers of sleep misperception in depression.

Conclusions: Our findings suggest that alterations in both sleep macro- and micro-architecture are closely associated with subjective-objective sleep discrepancy in individuals with depression. Digital biomarkers such as spectral ratios and entropy-based fragmentation metrics may provide insight into the neurophysiological mechanisms underlying subjective-objective sleep discrepancy in depression. They support the differentiation between perception-based and physiology-based sleep phenotypes, facilitating phenotype-driven intervention strategies.

Sleep Restriction Affects Sequential Updating Through Increasing Reward Sensitivity

J.Y.L. Lim¹, D. Bennett¹, S.P.A. Drummond¹

¹Monash University, School of Psychological Sciences; Turner Institute for Brain and Mental Health, Melbourne, Australia

Introduction: Bayesian cognitive theories propose decision-making involves the integration of prior knowledge with new evidence to form updated judgements. This framework has been used to understand how sleep restriction (SR) impairs integration of information, with findings suggesting SR biases individuals toward relying more on prior knowledge and less on new evidence. However, previous work has employed static decision-making tasks where information needed to make the decision on each trial is provided afresh, and feedback does not influence decisions on subsequent trials. This limits insight into how SR affects more dynamic, experiential learning processes. In everyday settings, decision making often involves *sequential updating*, an iterative process where outcomes of decisions are continuously learned and integrated into future behaviour. This process is critical for adapting to changing environments, yet its relationship with sleep loss remains poorly understood. To address this gap, we used a probabilistic reversal learning paradigm, requiring participants to learn reward schemas iteratively and adjust to changing reward contingencies.

Materials and methods: 36 healthy participants (25F, 11M; $M_{age} = 24.46$, $SD_{age} = 5.07$) underwent two experimental conditions in counterbalanced order: Well-Rested (7 nights of 9h sleep opportunity) and Sleep-Restricted (7 nights of 5h sleep opportunity). Each was preceded by a 5-night wash-in period (8–9h sleep opportunity). Sleep schedules were implemented at home and monitored via actigraphy, diaries, and voicemail check-ins. On the last day of each condition, participants completed a 150-trial probabilistic reversal learning task, where participants selected between two options with 70% and 30% reward probabilities. Reward contingencies switched between options with 10% probability per trial.

To decompose task performance into its underlying cognitive components, we fitted an asymmetric Rescorla-Wagner model implemented within a Bayesian hierarchical framework, providing estimates of reward and nonreward sensitivity parameters. Additionally, a choice consistency parameter captured levels of decision noise in participants' choice patterns. To the model, we also included offset parameters capturing the amount of deviation in each base parameter attributable to SR. Lastly, task accuracy was analysed using a mixed-effects logistic regression.

Results: Computational modelling results revealed a significant increase in reward sensitivity under SR, indicating enhanced learning from positive outcomes. There were no significant effects of SR on nonreward sensitivity or choice consistency parameters. Task accuracy did not differ between conditions.

Conclusions: Although reward sensitivity was heightened following SR, this is not necessarily benign. Enhanced sensitivity to positive feedback may reflect a bias toward reward-driven behaviour at the expense of balanced information integration during sequential updating. In real world decision contexts, such as gambling or financial decisions, heightened reward sensitivity following SR may reinforce maladaptive risk-taking behaviour when rewards are delivered intermittently. Additionally, participants' altered reward sensitivity was not reflected in task accuracy, indicating conventional summary metrics of performance may overlook meaningful cognitive changes.

Sleep Restriction Increases Propensity to Seek Instrumental Information during Decision Making

J.Y.L. Lim¹, D. Bennett¹, S.P.A. Drummond¹

¹Monash University, School of Psychological Sciences; Turner Institute for Brain and Mental Health, Melbourne, Australia

Introduction: Previous research shows chronic sleep restriction (SR) reduces reliance on new information during decision-making, leading individuals to rely more on familiar, easy-to-understand prior knowledge. It remains unclear whether SR also reduces the motivation to seek out information that could support better decisions. In everyday settings, people often choose to acquire additional information to improve judgements and guide future behaviour, a process known as instrumental information seeking. If SR reduces reliance on new information, it may also reduce the drive to obtain it. To test this hypothesis, we used a task designed to measure willingness to seek instrumental information.

Materials and methods: 36 healthy participants (25F, 11M; $M_{age} = 24.46$, $SD_{age} = 5.07$) completed an at-home sleep protocol involving two experimental conditions in counterbalanced order: Well-Rested (7 nights with a 9-hour sleep opportunity) and Sleep-Restricted (7 nights with a 5-hour sleep opportunity). Each condition was preceded by a 5-night wash-in period (8–9 hours sleep opportunity). Adherence was ensured via actigraphy, sleep diaries, and daily voicemail check-ins. On the final day of each condition, participants completed an Instrumental Information-Seeking Task (IIST) based on an optional-stopping paradigm. Each trial displayed a grid of cells, with some contents (gold or rock) visible and others concealed. Concealed cells were equally likely to contain either resource. Participants could choose to pay in-game money to reveal more cells, then guessed whether gold or rock constituted the majority of the grid. Correct guesses yielded in-game money; incorrect guesses earned none. To maximise earnings, participants needed to weigh the cost of seeking additional information against its potential informational.

We fitted mixed-effects logistic regression models to assess whether SR altered the likelihood of

seeking additional information on the IIST. Interactions between sleep condition and key task features, including initial number of cells concealed, expected value of information (EVI) offered by revealed cells, and offer cost, were tested in a hierarchical regression framework. Lastly, increasingly complex random-effects structures were compared to determine optimal model fit.

Results: The best-fitting model included no interaction terms and a random slope for EVI, indicating SR did not interact with task features to predict information seeking. Model results showed, after controlling for task features, SR increased the likelihood of seeking additional information on the IIST.

Conclusions: Contrary to predictions based on prior findings, participants in the SR condition were more likely to seek additional information. This occurred independently of changes in sensitivity to EVI or cost, suggesting a general shift in information-seeking behaviour. Sleep-restricted individuals may engage in compensatory behaviour to offset SR-induced cognitive impairments. Alternatively, they may experience greater discomfort with uncertainty and increased motivation to reduce it. In real world settings where decisions involve uncertainty, such as financial or medical decision making, SR-induced increases in information-seeking behaviour could result in inefficient or excessive use of information, particularly when acquiring additional information is costly or does not improve quality of judgements.

Sleep's Protective Effect on Fear Overgeneralization: The Role of REM Sleep and Theta Oscillations

T. Di¹, J. Liu², W. Liu¹, Y. Guo¹, E. Zheng³, Z. Yu⁴, L. Shi⁴, T. Jia⁵, L. Lu³, Y. Sun³, J. Shi³

¹Peking University, School of Basic Medical Sciences, Beijing, China, ²Wuhan University of Science and Technology, College of Life Sciences and Health, Wuhan, China, ³Peking University, Beijing, China, ⁴Peking University Sixth Hospital, Beijing, China, ⁵Fudan University, Institute of Science and Technology for Brain-Inspired Intelligence, Shanghai, China

Introduction: Fear overgeneralization, defined as the excessive fear response to non-threatening stimuli, is a hallmark of anxiety-related disorders. Sleep has long been recognized as a critical factor in the consolidation and processing of fear memories, with research suggesting that different sleep phases, particularly with rapid eye movement (REM) and non-rapid eye movement (NREM) sleep, thought to have distinct roles. However, how sleep influences fear generalization remains largely unknown. This study systematically investigates the dynamic effects of sleep phases and their associated neural oscillations on fear generalization recently after sleep manipulation and remotely one week later.

Materials and methods: In a randomized controlled, between-subjects design, 126 participants were assigned to four groups: total sleep deprivation (SD, N=16), early-night (dominated by NREM sleep) SD (N=36), late-night (dominated by REM sleep) SD (N=38), and total sleep (N=36). Participants completed the fear conditioning test before the sleep intervention, followed by a recent fear generalization test after sleep, and the remote fear generalization test one week later. Both task-related neuroimaging data and behavioral data (subjective risking and objective skin conductance responses) were synchronously collected to analyze brain functional changes during generalized stimuli processing.

Results: Sleep, particularly REM sleep phase, inhibits fear generalization, whereas late-night SD, by reducing REM sleep, induces fear overgeneralization comparable to total SD. To further validate the specific role of REM sleep in fear generalization, we employed a support vector machine model (AUC = 0.81), and identified REM percentage as the dominant discriminant feature (weight = -1.23) between higher and lower generalization subtypes. The percentage of REM sleep was negatively associated with the degree of fear generalization ($\beta = -0.47$, $p < 0.001$, $R^2 = 0.21$), and positively correlated with dorsolateral prefrontal cortex (MNI: x = 39, y = 44, z = 6) activity during the recent generalization test ($r = 0.43$, $p_{\text{fwe}} < 0.001$). Notably, prefrontal theta oscillations mediated 44% of REM sleep's effects on fear generalization (indirect effect = -0.40, $p < 0.001$).

Conclusions: In summary, the present study suggests that the reduction of REM sleep following fear conditioning increases the risk of fear overgeneralization and alters related prefrontal activity. It enhances our understanding of the pivotal role of theta oscillations in the prefrontal cortex in mitigating fear overgeneralization during REM sleep. Our findings identify specific sleep phase, electrophysiological activities, and brain targets, opening potential avenues for non-invasive neuromodulation in the treatment of fear overgeneralization-related disorders.

Sleep Surprises Questionnaire: Using Expectancy Violations from Naturalistic Behavioural Experiments to Enhance Sleep-Wake State Curiosity

R. Clancy¹

¹St Luke's Care Hospital; Bondi Respiratory & Sleep; Sydney Sleep Centre; Let Sleep Happen, Psychology, Bondi Junction, Australia

Introduction: Surprises, triggered by expectancy violations, drive new learning, reshape expectations, prompt adaptive behaviours, and generate evolving perceptions, creating further curiosity in a cycle of resilience. Surprises abound in sleep and waking, arising from naturally-occurring behavioural experiments and challenging our assumptions about sleep-wake states, next-day alertness and energy. The Sleep Surprises Questionnaire (SSQ) captures these expectancy violations in non-insomnia and (potentially) insomnia populations, promoting trust in sleep self-regulation, and gathering evidence that promotes curiosity about sleep-wake states. This oral presentation will explore how the SSQ's design and scoring illuminate surprise-driven learning, encouraging behaviours that enhance perception of sleep robustness with implications for preventive sleep health strategies.

Materials and methods: The SSQ, comprising 22 items across naturalistic behavioural experiments (eg, sleeping after an evening coffee or cinema screening), sleep-wake discrepancies (eg nearby sounds incorporated into dreams, time distortions), and next-day functioning (eg surprising alertness after broken sleep), uses a unified response scale:

N/A (never experienced), not surprised (0), mildly surprised (1), quite surprised (2), or very surprised (3). Scores sum across items (max 66, N/A excluded) with categories: little surprise (0–22), some surprise noted (23–44), very attentive to sleep surprises (45–66).

Objective is to establish SSQ norms (eg score distributions for 22 items (max 66), categories: 0–22, 23–44, 45–66), validate against ISI (insomnia severity) and DBAS-16 (dysfunctional beliefs), and assess content validity. Sourcing a population of non-insomnia adults (eg general population or students, N≈300 for normative study, N ≥ 100 for EFA, and N ≥ 50 for test-retest, stratified by age, gender). Will include a subset with mild insomnia (eg ISI 8–14) for comparison. Rationale is to gauge if SSQ scores reflect openness to surprise and correlate inversely with ISI and DBAS-16 scores. Will recruit participants using convenience sampling (eg universities, online platforms) or random sampling for representativeness, and obtain informed consent & ethics approval. Initially exclude clinical population (ISI ≥ 15) until second stage of research.

Results: Preliminary findings for 3 participants with mild insomnia (eg Sunday night sleep concerns) score low on both ISI (<15, or Subthreshold insomnia) and SSQ (eg SSQ: 6-10/66, "little surprise"), but individual high-surprise items (eg surprise at alertness after poor sleep) suggest intervention pathways. The preliminary data indicate higher openness & attentiveness to surprises inversely correlates with insomnia severity, offering a streamlined tool to foster adaptive sleep perceptions.

Conclusions: Even in a non-insomnia demographic, negative sleep predictions fuel sleep "safety-seeking" behaviours which reinforce beliefs about sleep fragility, while increased tolerance of the inherent uncertainty of sleep-wake state discrepancies drives optimistic predictions and nonfearful behaviours. Preliminary findings suggest naturalistic behavioural experiments have the potential to raise expectancy violations, reflected in SSQ scores which inversely correlate with insomnia severity & rigidly dysfunctional beliefs about sleep. Surprises disconfirm perceptions of fragile sleep and build confidence in sleep self-regulation. By quantifying surprise, the SSQ supports CBT-I behavioural experiments, creating learning opportunities to explore sleep-wake perceptions with growing curiosity.

The association of unconsciousness, dreaming, and slow wave activity under general anesthesia

T. Ishii¹, P. Sikka², B. Heifets², M. Kawai¹, H. Shong-Wen Chow²

¹Stanford University, Department of Psychiatry and Behavioral Sciences, Stanford, United States,

²Stanford University, Department of Anesthesiology, Perioperative and Pain Medicine, Stanford, United States

Introduction: Natural sleep and general anesthesia both produce states of unconsciousness in which the brain becomes disconnected from the external environment, with the distinction being whether the process is spontaneous or artificially induced. Dreaming experiences, considered a form of “disconnected consciousness,” are known to occur not only during natural sleep but also under general anesthesia. Investigating the dreaming experience under anesthesia may offer a window into the neural basis of consciousness. Despite the increasing interest, the physiological mechanisms underlying dreaming experiences under anesthesia remain poorly characterized, and their similarities to dreaming during natural sleep have been scarcely investigated. This study aimed to investigate the neural mechanisms responsible for unconsciousness and dream generation by analyzing intraoperative EEG in patients who underwent surgery under general anesthesia.

Materials and methods: All participants underwent surgery under propofol-based general anesthesia at Stanford University Hospital between 2021 and 2023. Standard ASA (American Society of Anesthesiologists) monitoring and intraoperative EEG monitoring using 4-channel frontal SedLine electrodes were employed. Immediately upon emergence from anesthesia, participants were interviewed regarding the presence and content of any dreaming experiences. Data from 62 patients (mean age: 47.6 ± 14.6 years) who reported dreaming and 48 patients (mean age: 55.1 ± 13.9 years) who did not report dreaming were included in the analysis. EEG recordings were assessed using visual inspection, power spectral analysis, and time-frequency analysis, and comparisons were made between the dreamer and non-dreamer groups.

Results: 1. The time from slow wave activity (SWA) disappearance to emergence was significantly longer in patients who reported dreaming after surgery compared to those who did not ($p = <0.001$, $d = 1.36$). 2. The EEG during the pre-emergence period in the dreamer group was characterized by a gradual decline in alpha activity and a rapid increase in fast-wave activity in the gamma band.

Conclusions: These findings suggest that dreaming experiences under general anesthesia occur during the period between the cessation of SWA and emergence, indicating that “disconnected consciousness” is induced as a transitional state from the unconscious state to awakening. Furthermore, the present results also suggest that frontal alpha and/or beta activity serves as a potential marker of the dreaming experience during this period. The observed relationship between SWA and unconscious state, as well as between frontal alpha/gamma power and dreaming, provides novel insights into the neural substrates of consciousness and dreaming.

The effects of intense theatrical training on sleep structure of the following night

A. Lusto¹, F. Carrubba¹, F. Conte¹, O. De Rosa¹, G. Ficca¹

¹Università della Campania “L. Vanvitelli”, Department of Psychology, Caserta, Italy

Introduction: Research on sleep regulation has traditionally focused on the role of wake duration. However, there is now substantial evidence that sleep characteristics also depend on wake intensity (the degree of cognitive and physical activity). Data on humans mainly come from research on sleep-memory relationships, with numerous studies showing sleep changes after bedtime administration of different cognitive tasks. However, more ecological studies have almost exclusively been conducted on animals, through the enriched environment paradigm. Here we investigate sleep features after a day including a theatrical workshop session, compared to sleep following an ordinary day, in a group of young adults.

Materials and methods: Eighteen young women (mean age 21.4 ± 2.2) participating to a theatre workshop (26 sessions over 6 months) were recruited for the study. Their night sleep is monitored (by means of the Somno-Art® portable sleep device) at 4 different times: a Baseline night (BL), following a day with ordinary (routine) schedule, as monitored through a day log, and 3 post-training nights (TR), i.e., following the 2nd, 14th and 26th workshop session. Here we present preliminary data on 11 participants: specifically, we compared sleep features of BL with those of the first TR night through paired t-test.

Results: No between-conditions differences emerged for any sleep parameter: Time in Bed, Total Sleep Time, Sleep Latency, Wake After Sleep Onset, Sleep Efficiency, N1+N2 duration, N3 duration, REM duration, number of awakenings, of state transitions and of sleep cycles (all p 's $>.05$).

Conclusions: In contrast with literature conducted on animals with the enriched environment paradigm, our preliminary results suggest that, in humans, a similar paradigm does not produce acute sleep modifications. A plausible hypothesis is that intentional (rather than incidental) learning is necessary in humans to show acute effects on post-learning sleep, as suggested by data from the sleep-memory literature. Also, we know from previous literature that the effects of training on sleep quality could be detected only provided that baseline sleep is somehow impaired (especially in terms of reduced sleep depth and efficiency). Finally, we cannot rule out that cumulative effects of the long-term learning experience (i.e., the theatrical workshop) will emerge on subsequent post-session nights.

Acknowledgments: This study is funded by the PRO-BEN project 2023, Italian Ministry of University and Research.

The effects of poor sleep on empathy: A systematic review and meta-analysis

H. Naftalovich¹, A. Bashan², A. Perry³, S. Choshen-Hillel², A. Gileles-Hillel¹

¹Hebrew University of Jerusalem, Israel, Faculty of Medicine, Jerusalem, Israel, ²Hebrew University of Jerusalem, Israel, Business School, Jerusalem, Israel, ³Hebrew University of Jerusalem, Israel, Psychology, Jerusalem, Israel

Introduction: Recent research has explored whether poor sleep can reduce empathy, a cornerstone of human cooperation and social interaction. Empathy includes both cognitive aspects (understanding another person's emotional state) and affective aspects (sharing the feelings of someone else). The findings have been decidedly mixed, with some studies highlighting the causal link between poor sleep and reduced empathy, and others finding either no significant effect, or the exact opposite: an increase in empathy after experiencing poor sleep. The extant literature on the topic has also been mixed regarding methodology, whether by examining healthcare workers or the general population, for example, or focusing on different aspects of empathy. Thus, to better understand the effect of poor sleep on empathy, and whether we can pinpoint potential sources of heterogeneity in the field, the current study presents a systematic review and meta-analysis of the existing literature.

Materials and methods: We searched EBSCOHost, PubMed, and SCOPUS, for articles related to "sleep", "sleepiness", "insomnia", and "empathy" and "cognitive empathy". The search yielded 362 unique peer-reviewed articles on the impact of sleep disruptions on empathy in humans. Studies which examined the effect of empathy on sleep were not included. Studies were excluded if they did not include a direct examination of how poor sleep impacts empathy, if they were conducted on children, or if the empathic measure was not on the same individual (e.g., a patient rating physician empathy before and after the patient experiences disruptions in their sleep). Seventeen studies and 30 effect sizes were included in the final analysis. The meta-analysis followed the PRISMA guidelines in methodology and reporting standards.

Results: Results of the meta-analysis suggested a moderate and negative relationship between poor sleep and empathy (Hedges' $g = -0.38$, with a 95% confidence interval ranging from -0.55 to -0.22), such that poor sleep was associated with lower levels of empathy. Significant heterogeneity was observed ($I^2 = 74.5\%$, $Q(26) = 90.53$, $p < .0001$), suggesting meaningful variability in effect sizes across studies. Studies were conducted mostly in western countries (UK, US, Canada, Italy, Israel, Switzerland, and Sweden), except for two studies, one of which was conducted in China, and the other in Saudi Arabia.

Conclusions: Results indicated that overall, poor sleep negatively impacts empathy. This effect has been found both in experiments and in ecological, observational, settings. For example, impaired empathy due to lack of sleep has been shown in paramedics, doctors, nurses, and other healthcare professionals, suggesting that lack of sleep due to long or late shifts may impact patient care. Results also indicated significant heterogeneity across studies, which may derive from differences in populations (general population compared to healthcare workers, for example), or variability in measurements of both sleep and empathy. A summary of the literature regarding these sources of heterogeneity, and the implications of the meta-analytic results will be discussed.

Acknowledgments: We would like to thank Prof. Avraham Kluger and Dr. Maya Enisman for their help with the analyses for the meta-analysis.

The Impact of Sleep Deprivation on Superiority Illusion

L. Li¹, P.-h. Chen¹, J. Chen¹, H. Sun¹, Y. Gao¹, Y. Xu¹

¹Peking University Sixth Hospital, Peking University Institute of Mental Health, NHC Key Laboratory of Mental Health (Peking University), National Clinical Research Center for Mental Disorders (Peking University Sixth Hospital), Peking University, Beijing, China

Introduction: Superiority Illusion (SI) is common cognitive bias which healthy individuals usually have the tendency to overestimate their abilities than others. Lower SI ability has been proved linked to various mental health problems, including generalised anxiety disorder, depression and bipolar disorder. Previous studies found that cognitive function would be impaired by sleep deprivation. However, the change on SI remains unexplored. This study aims to elucidate the effects of sleep deprivation on SI and the related psychological mechanisms.

Materials and methods: Healthy adults from universities aged 18–28 years completed a repeated-measures cross-over design, including 2 sessions conducted in a counterbalanced order—one after a normal night of sleep (SR) and one after 24 h sleep deprivation (SD). Sleep status control prior to the experiment includes actigraphy devices and sleep diaries for more than seven consecutive days. On the night preceding SR session, polysomnography (PSG) was conducted. On the morning of the behavioral task, affective states were assessed through the Positive and Negative Affect Schedule (PANAS) and the Brief Fear of Negative Evaluation Scale (BFNES). The core SI task consists of 60 trials, incorporating two dimensions (positive and negative words).

Results: Data from 47 participants (mean age 23.0 ± 1.0 years, 27 women) were included in the final analysis. A significant reduction on SI scores in SD (mean difference = -0.184 , 95%CI = $[0.050, 0.317]$, $t = 2.775$, $p = 0.008$), a significant main effect of sleep condition ($F_{(1, 46)} = 7.701$, $p = 0.008$, partial $\eta^2 = 0.143$) and a significant main effect of valence ($F_{(1, 46)} = 19.151$, $p < 0.001$, partial $\eta^2 = 0.294$) were found, whereas the interaction between these factors was nonsignificant ($F_{(1, 46)} = 0.004$, $p = 0.948$). In positive-word trials, SD led to a marginal reduction in SI scores (mean difference = -0.181 , 95%CI = $[-0.371, 0.009]$, $t = 1.918$, $p = 0.061$), whereas in negative-word trials, the reduction was statistically significant (mean difference = -0.187 , 95%CI = $[-0.308, -0.065]$, $t = 3.095$, $p = 0.003$). Correlational analyses under SD revealed total task scores had positive correlations with PANAS positive affect scores ($r = 0.353$, $p = 0.015$) and negative correlations with PANAS negative affect scores ($r = -0.343$, $p = 0.018$) and BFNES scores ($r = -0.421$, $p = 0.003$).

Conclusions: The present findings indicate that SD results in a significant decline in SI scores. Meanwhile, the SD scores correlate to post-deprivation emotional states. These results provide novel insights into the role of sleep in self-referential cognitive processes and offer a theoretical foundation for understanding sleep deprivation.

The Impact of Sleep Loss on Decision Making - Opening the Cognitive Black Box

J.Y.L. Lim¹, W.D.S. Killgore², D. Bennett¹, S.P.A. Drummond¹

¹Monash University, School of Psychological Sciences; Turner Institute for Brain and Mental Health, Melbourne, Australia, ²University of Arizona, Department of Psychiatry, Tucson, United States

Introduction: The detrimental effect of sleep loss on decision making is well-known, but identifying cognitive mechanisms by which sleep deprivation impairs decision-making remains difficult. This stems largely from a widespread reliance on global behavioural metrics of cognitive tasks, providing performance summaries but offering limited insight into the latent processes driving behaviour. To address this gap, we highlight the cognitive "black box" problem in sleep research and demonstrate how computational cognitive modelling can be used to clarify the mechanistic effects of sleep loss on decision making.

Materials and methods: Progress in sleep and decision-making research requires moving beyond surface-level behavioural summaries and into the domain of computational cognitive modelling. These models quantify latent cognitive processes, such as reward value sensitivity and decision noise, providing a more nuanced view of how cognitive processes are disrupted by sleep loss and affect behaviour downstream. To demonstrate this approach, we reanalysed Iowa Gambling Task data

previously published in a paper investigating the effects of 51h and 75h of total sleep deprivation (TSD). Two cognitive process models, the Prospect Valence Learning-Delta (PVL-D) and the Value plus Sequential Exploration (VSE) model, were fit using Bayesian estimation, allowing us to isolate changes in underlying decision mechanisms across time spent awake.

Results: Model comparisons indicated the VSE model was a superior fit of the data. Accordingly, our reanalysis showed TSD increased decision noise and further reduced sensitivity to gains and losses, effects not otherwise detected through relying on the conventional IGT score. Specifically, by 51h TSD, participants exhibited significantly lower choice consistency, indicating noisier and less goal-directed behaviour. By 75h TSD, value sensitivity was also significantly impaired, indicating diminished ability to differentiate between advantageous and disadvantageous outcomes. These findings provide complementary insight into results reported by the original paper.

Conclusions: This reanalysis provides new insights into the cognitive processes underlying how sleep loss degrades decision-making: by decreasing behavioural consistency of responses and decreasing sensitivity to differential rewards. These mechanisms cannot be detected by traditional global behavioural metrics. Computational cognitive modelling offers a powerful tool to complement traditional quantitative methods, providing higher-resolution insights into sleep-related cognitive impairments and aligning sleep research with the latest models in cognitive neuroscience. Incorporating such models can inform targeted interventions aimed at mitigating decision errors in sleep-deprived individuals, particularly professionals working in high-stakes environments who face chronic sleep loss as a result of scheduling demands.

The Interplay of Sleep and Cognition: Amnesic MCI and Severe OSA in the Elderly

R. Rajendran¹

¹Kauvery Hospital, Neurology, Tiruchirappalli, India

Introduction: 79-year-old gentleman who sought medical attention due to concerns about failing memory. Although retired, he remains active in business. His family has observed that his immediate memory is poor, leading to frequent repetitions of events and conversations. Additionally, he sometimes shows confusion with dates and the context of events. Despite being aware of these issues, he attributes them to aging, saying, "what can you expect after 75?" He weighs 90 kgs, has a history of a sedentary lifestyle in recent years but was active during middle age. He describes himself as a "light sleeper" with frequent nocturnal awakenings and has a long-standing history of snoring. Despite not feeling refreshed upon waking, he believes his sleep is acceptable, although he is more concerned about his forgetfulness.

Materials and methods: Plan of Assessment:

1. Biochemistry, MRI Brain & Neuropsychological assessment
2. Indication for Sleep study: His history of long-standing snoring, frequent nocturnal awakenings, and non-restorative sleep, along with his ability to nod off easily when not engaged in goal-directed tasks, strongly suggest a possible sleep disorder.

Results: Sleep Study results indicate several important findings:

1. Sleep efficiency was 95%
2. Sleep Stage Percentages -
 - N1 - 23.7%
 - N2 - 57.1%
 - N3 - 11.4% (Normal N3 sleep 15-20%)
 - R - 7.8% (Normal R sleep 20-25%)
3. Obstructive apnea - 331, Hypopnea - 141
4. Apnea Hypopnea index (AHI) - 59 events/hr. An AHI of 59/hour is classified as severe obstructive sleep apnea.

5. The average oxygen saturation was 96% & lowest 78%
6. He spent 5 minutes of his sleep time below 90% of SpO₂
7. Total Arousals - 257
 - Respiratory arousals - 129
 - PLMS - 76
 - Spontaneous arousals - 52

Interpretation: Severe obstructive sleep apnea with secondary poor fractionation of deep sleep

Conclusions: Cognition and Sleep:

1. Deep Sleep (N3) - Slow-wave sleep (SWS), is essential for consolidating declarative memories (e.g., facts and events). During this phase, the brain replays and strengthens memories from the day, integrating them into long-term storage.
2. REM Sleep is crucial for procedural memory consolidation (e.g., motor skills) and emotional regulation.
3. Glymphatic System - It is a waste clearance system in the brain that removes metabolic waste products, including amyloid-beta and tau proteins, which are associated with neurodegenerative diseases. This system is most active during sleep, especially during deep sleep (N3)
4. Autophagy activation - REM sleep has been shown to be important for neuronal autophagy, aiding in the removal of cellular debris and damaged proteins, thereby supporting overall brain health
5. OSA leads to repeated interruptions in sleep which can impair the glymphatic system's ability to clear waste products effectively, potentially exacerbating cognitive decline and increasing the risk of neurodegenerative diseases.
6. Ensuring good sleep health and addressing sleep disorders like OSA are vital steps in supporting cognitive function and reducing dementia risk

The Myth of Male Vulnerability: Exploring Sex Differences in Physiological Risk for Drowsy Driving

J. Manousakis^{1,2}, D. Manamperi², A. Cai², B. Singh^{1,2}, E. Francis-Pester², C. Diep^{2,1,3}, M. Howard^{1,2}, C. Anderson^{3,2}

¹Institute for Breathing and Sleep, Heidelberg, Australia, ²Monash University, School of Psychological Sciences, Clayton, Australia, ³University of Birmingham, Centre for Human Brain Health, School of Psychology, Birmingham, United Kingdom

Introduction: Drowsiness accounts for ~20% of all motor vehicle crashes, and young male drivers are overrepresented in drowsiness-related crash statistics. This is in contrast to laboratory and shift worker literature showing that women are vulnerable to sleep loss, relative to men. Despite 75% of drowsiness-related crashes being caused by men, there is a paucity on research examining the causes of this overrepresentation. Understanding whether young men have a physiological vulnerability to drowsy driving, or whether they are overrepresented due to behavioural and environmental factors is important for developing campaigns and interventions to curb drowsy driving behaviour. This study aimed to examine whether men and women showed differential vulnerability to drowsy driving in a controlled track environment, following total sleep deprivation, where behavioural and environmental factors had been removed.

Materials and methods: Thirty-two healthy, young, experienced drivers (N=16 women; N=16 men) aged 21-35 were recruited from the community. Participants completed two counterbalanced 2h daytime track drives in a fully instrumented vehicle: one after an 8h sleep opportunity (well-rested) and one after a night of no sleep (sleep deprived). Drives were completed in an automatic transmission vehicle equipped with a forward-facing camera around a closed-circuit track designed to mimic suburban driving conditions. Participants were accompanied by an experienced driving instructor and a

study technician. Lane deviations and near-crashes were used to measure driving impairment. Subjective sleepiness was measured every 15 min with the Karolinska Sleepiness Scale and Likelihood of Falling Asleep scale, and participants completed the Symptoms of Sleepiness Questionnaire at the end of each drive.

Results: As expected, total sleep deprivation resulted in an increase in lane deviations ($p < .001$), near crash risk ($p < .001$), subjective sleepiness ($p < .001$), subjective likelihood of falling asleep ($p < .001$) and symptoms of sleepiness ($p < .001$). Following a night of no sleep, 75% of women and 44% of men experienced a near crash ($OR = 3.9$, $\chi^2 = 3.2$, $p = .072$). With 50% of women experiencing a near crash after 66 min of driving. On average, women exhibited 4.0 lane deviations per 5 min of driving, whereas men experienced 2.9 lane deviations/5 min. There was no effect of sex, or interaction between sex and sleep deprivation for lane deviations or subjective outcomes ($p > .208$).

Conclusions: Young men do not show a physiological vulnerability to drowsy driving when compared to young women. Over-representation of men in drowsiness-related crash statistics is likely due to behavioural, lifestyle and environmental factors such as increased risk-taking behaviours, and differences in attitudes towards sleep, drowsy driving, and driving safety. Education campaigns targeting drowsy driving need to focus on a shift of attitudes towards drowsiness, risk taking behaviour, and driving in young men. Women were 3.9x more likely to crash following total sleep deprivation. Given women show differential vulnerability to sleep loss across the menstrual cycle, further investigation into women's vulnerability to crash risk is warranted.

The neural pathway from glutamatergic neurons in the lateral hypothalamus to the rostromedial tegmental nucleus mediates defensive behaviors in mice

S.-R. Yang¹, L.-Y. Chang¹, Y. Zhang¹, Z.-L. Huang¹

¹Department of Pharmacology, School of Basic Medical Sciences, Fudan University, Shanghai, China

Introduction: Defensive behaviors responding to actual or perceived threats are essential for survival, encompassing flight, avoidance, and hiding. Although these behaviors are adaptive, excessive or maladaptive defensive responses are implicated in the pathogenesis and progression of various psychiatric disorders in humans. The underlying neural circuit mechanisms governing defensive behaviors remain poorly understood. In this study, we investigated the role of the neural circuit from lateral hypothalamic (LH) glutamatergic neurons to the rostromedial tegmental nucleus (RMTg) in defensive behaviors in mice.

Materials and methods: Adult male vesicular glutamate transporters (Vglut2)-Cre mice (8–10 weeks old) were randomly assigned to either a control group (mCherry) or an experimental group (ChR2). The control group received bilateral injections of AAV2/9-EF1 α -DIO-mCherry-WPRE-pA into the LH, while the experimental group received AAV2/9-EF1 α -DIO-ChR2-WPRE-pA. Optical fibers were implanted in the RMTg of all mice. After three weeks for recovery from surgery and sufficient viral expression, behavioral tests—including the open field test, real-time place preference (RTPP) test, and hiding box test—were conducted. Following the experiments, viral infection was confirmed by mCherry expression in the LH, and c-Fos expression in the RMTg was assessed to validate the activation of the pathway from LH glutamatergic neurons to the RMTg upon 473 nm laser stimulation.

Results: During a 473 nm laser stimulation of RMTg GABAergic terminals in the LH, mice in the ChR2 group exhibited significantly increased velocity in the open field test, indicative of escape behavior. In the RTPP test, these mice spent less time on the preferred side, suggesting avoidance behavior. Additionally, the latency to enter the hiding box was significantly reduced, reflecting enhanced hiding behavior. The expression of c-Fos in the RMTg was elevated in ChR2-expressing mice following laser stimulation, confirming successful pathway activation.

Conclusions: Activation of the LH glutamatergic neuron projections to the RMTg promotes defensive behaviors in mice. These findings provide insights into the neural basis of defensive behaviors and may inform future research on mental diseases.

The role of sleep-related dysfunctional beliefs in the effect of cognitive behavioral therapy on the severity of insomnia

F. Meng¹, Z. Yan¹, L. Meng¹, Z. Li¹

¹Beijing Anding Hospital, Capital Medical University, Beijing, China

Introduction: Dysfunctional beliefs are an important characteristic of patients with chronic insomnia. Unreasonable sleep beliefs will aggravate the severity of insomnia and affect the normal life of patients. Cognitive behavioral therapy for Insomnia (CBT-I) is currently the first-line treatment for insomnia in the world. However, there is a lack of specific research on the role of changes in sleep-related dysfunctional beliefs in the treatment process. Therefore, the purpose of this study was to explore the changes of dysfunctional beliefs in different dimensions and their effects on the severity of insomnia during CBT-I.

Materials and methods: 120 patients with insomnia were included. They were randomly assigned to CBT-I group (n=30), cognitive therapy for insomnia group (CT-I, n=30), behavioral therapy for insomnia group (BT-I, n=30), and conventional treatment group (TAU, n=30). Patients in all three treatment groups received treatment once a week for eight weeks. The Insomnia Severity Index (ISI) and the Brief Version of Dysfunctional Beliefs and Attitudes about Sleep (DBAS-16) were used to assess changes in insomnia severity and sleep-related dysfunctional beliefs at baseline, 4th week, and 8th week, respectively. The parallel process latent growth curve model (PP-LGCM) was used to analyze the mediating role of dysfunctional beliefs in the process of cognitive and behavioral techniques to improve sleep quality. The Cross-Lagged Panel Model (CLPM) was used to explore the interaction between dysfunctional beliefs and insomnia severity over time.

Results: CBT-I, CT-I, BT-I can effectively improve the severity of insomnia and reduce sleep-related dysfunction beliefs ($p<0.001$). Sleep-related dysfunctional beliefs fully mediated the effect of CT-I on insomnia severity and partially mediated the effect of CBT-I. However, the mediating effect of sleep-related dysfunctional beliefs was not found in the BT-I group. In CBT-I group, insomnia severity at week 4 significantly predicted the scores of perceived consequences of insomnia ($p=0.011$) and scores in the medication dimension ($p=0.020$) at week 8. In CT-I group, the baseline medication dimension scores significantly predicted the severity of insomnia in 4th week ($p=0.015$), which can significantly predict the total score of dysfunctional beliefs ($p=0.002$) and the scores of perceived consequences of insomnia ($p<0.001$) at 8th week. While in BT-I group, the severity of insomnia in 4th week can predict the total score of dysfunctional beliefs ($p=0.003$) and the scores of medication dimension ($p<0.001$) in 8th week.

Conclusions: This study investigated the relationship between sleep-related dysfunctional beliefs and the severity of insomnia in different treatment methods. The results showed that sleep-related dysfunctional beliefs mediated the effects of CBT-I and CT-I on the severity of insomnia. It was also found that the severity of insomnia can predict changes in sleep-related dysfunctional beliefs.

Time-Varying Effects of Deep Learning-Based Physical Activity Patterns on All-Cause Mortality: the NHANES 2003–2006 study

S. Zheng¹, Y. Zhao¹, W. Zeng², L. Fang¹, B. Zhang¹

¹Nanfang Hospital, Southern Medical University, Department of Psychiatry, Guangzhou, China,

²Nanfang Hospital, Southern Medical University, Department of Radiology, Guangzhou, China

Introduction: Average total activity count (TAC), a single dimension of objective physical activity (PA), showed time-varying effect in all-cause mortality, while not considering the complex interaction among PA features. Convolutional Long Short-Term Memory (Conv-LSTM) architecture can fully extract all PA features and comprehensively evaluate the objective PA pattern (PAP). The main goal of this study was to analyze whether PAP can present stronger prediction performance on all-cause mortality than TAC.

Materials and methods: We focus on PAP and TAC extracted from a hip-mounted accelerometer from the 2003 to 2004 NHANES cycle. For PAP, the reshaped three-dimensional physical-activity matrices were fed into a two-stage deep-clustering framework. During the first stage, a Conv-LSTM auto-encoder was pre-trained, and the resulting latent vectors were subjected to k-means initialization with the number of clusters (k) empirically set to 2–5. In the second stage, an Improved Deep Embedded Clustering algorithm jointly fine-tuned the auto-encoder and its trainable clustering layer, ultimately assigning a cluster label to every participant. Internal validity was quantified with the silhouette coefficient, Calinski–Harabasz index and Davies–Bouldin index. For TAC, participants were stratified into distinct groups based on the optimal number of clusters of PAP. We then tested two models. The first model fit was a Cox proportional hazard model with fixed time effects of PAP and TAC on risk of mortality. The second model fit was a Cox model with time-varying coefficient for PAP and TAC.

Results: This study ultimately enrolled 6,546 participants aged 18 years and older, all of whom had high-integrity accelerometer measurement data and complete mortality follow-up records. The mean follow-up of this study is 10.21 years, and we observed 961 deaths with a mean time to event of 8.41 years. The optimal clustering performance for PAP was achieved at $k = 2$ (silhouette = 0.925; Calinski–Harabasz = 306 348.60; Davies–Bouldin = 0.092). Accordingly, the cluster labels obtained with $k = 2$ (high- and low-PAP groups) were retained for all downstream analyses. For TAC, participants were stratified into high- and low- TAC groups based on median TAC values. The results of the Wald test indicated that the first model in both PAP ($p=0.025$) and TAC ($p=0.034$) may not be appropriate, for the strong time-varying effect of PA on mortality. In the second model, the estimated HR of PAP and TAC is 0.386 (95%CI 0.25–0.597; $p < 0.001$) and 0.392 (95%CI: 0.234–0.657, $p < 0.001$), respectively. As for the time-varying effect, the HR increases at a rate of 5.4% per year ($HR=1.054$, 95%CI 1.054–1.008; $p = 0.02$) in PAP model, whereas in the TAC model it increases by 4.8% per year ($HR = 1.048$, 95% CI 0.997–1.102; $p = 0.065$).

Conclusions: Both PAP and TAC were significantly associated with reduced all-cause mortality risk, with comparable overall protective effects. However, only the PAP demonstrated a statistically significant time-varying effect, suggesting that its association with mortality attenuated more clearly over time. These findings highlight the potential of deep learning-based PAP analysis to capture multidimensional PA features in mortality risk prediction, informing more precise health interventions and preventive strategies.

Toward a Rocking Apparatus at Home: Effects of Continuous Rocking Stimulation Over Consecutive Nights on Sleep

¹Centre de Recherche de l'Institut Universitaire de Gériatrie de Montréal (CRIUGM), Montreal, Canada, ²University of Montreal, Department of Neurosciences, Montreal, Canada, ³Concordia University, Department of Health, Kinesiology & Applied Physiology, Montreal, Canada, ⁴Concordia University, Department of Mechanical, Industrial and Aerospace Engineering, Montreal, Canada, ⁵University of Sydney, School of Psychology, Sydney, Australia, ⁶Concordia University, Department of Applied Human Sciences, Montreal, Canada, ⁷University of Montreal, Department of Psychology, Montreal, Canada, ⁸University of Montreal, École de Réadaptation, Montreal, Canada, ⁹University of Geneva, Department of Neuroscience, Geneva, Switzerland, ¹⁰Geneva University Hospital, Center for Sleep Medicine, Geneva, Switzerland, ¹¹Woolcock Institute of Medical Research and Macquarie University, Sleep and Circadian Group, Sydney, Australia

Introduction: This study investigates whole-night continuous rocking stimulation, an emerging approach with potential benefits for improving sleep quality through the modulation and entrainment of sleep spindles and slow oscillations (SO's). Prior research has been conducted mainly over one night, limiting real-world applicability. This in-lab pilot study aimed to assess the efficacy of a new rocking bed prototype on sleep quality over multiple consecutive nights, in young, healthy participants.

Materials and methods: We developed a rocking bed prototype that replicated the rocking parameters used by Bayer et al. (2011) and Perrault et al. (2019), who demonstrated benefits for sleep and memory in healthy and good sleeper young adults. The new apparatus consisted of rails with acceleration and braking capabilities powered by an electric motor that moved the mattress laterally (21 cm every 4

seconds; 0.25 Hz).

Following an adaptation night, 19 participants (age=25±3.62; 10F) completed three consecutive nights with rocking stimulation (ROCK1-2-3) and two stationary nights (STAT1-2) one week apart, in a randomized counterbalanced order. Whole night polysomnography including EEG (24 scalp electrodes), EOG, EMG, and ECG were recorded at each night. Sleep scoring (AASM) and EEG preprocessing (artefact/arousal) were performed manually using Wonambi Python toolbox. Macro-architecture was extracted using the Seapipe Python toolbox. Sleep spindle and SO's were automatically detected and extracted based in Fz and Pz with methods described by Ray et al. (2015) and Staresina et al. (2015), using an individually adapted frequency bandwidth. We assessed the probability of their appearance being influenced by the bed's motion (i.e., entrainment). Analyses examined the Visit*Condition interaction and post-hoc analyses.

Results: On Night 1, rocking (ROCK1) slightly disrupted sleep, with increased wake time, N1, and N2, at the expense of N3 and REM (all $p<.05$), alongside a modest decrease in fast spindle density ($p=.033$; corrected threshold: $p<.013$) compared to STAT1. Across subsequent nights, both conditions showed improved sleep architecture (reduced wake and N2, increased REM; all post-hoc $p<.05$), with rising sleep efficiency ($p=.012$). This improvement was more pronounced in the rocking condition from ROCK1 to ROCK2, reaching levels comparable to STAT2 ($p=.259$). Fast spindle density also increased in ROCK2 (Condition*Visit interaction: [N2] $p=.010$; [N3] $p=0.008$) and were maintained at ROCK3, likely due to emerging entrainment (Chi-square: $p=0.10$). SO's were entrained from the first night but we observed no effect of condition or visit on their characteristics.

Conclusions: Despite initial disruption, a rebound effect was observed in both conditions, with greater improvement in the rocking condition, suggesting that rocking benefits may take longer to emerge with our prototype. The early entrainment of SO's (Night 1) and later spindle entrainment (Night 2) suggest an immediate neural response to stimulation, though improvements at the sleep architecture level may require more time. These findings highlight the need to refine motion parameters, as further discussed in a complementary abstract (see Barbaux et al.). While our results differ from the literature, a longer protocol may have revealed eventual benefits. Future studies should explore long-term effects and feasibility in home settings, particularly for individuals with sleep disturbances.

Trait-level mindfulness, objective and subjective sleep, and risk for hypertensive disorders of pregnancy

G. Bourjeily¹, P. Curran², M. Bublitz³

¹Brown University, Medicine, Providence, United States, ²Brown University Health, Providence, United States, ³Brown University, Psychiatry, Providence, United States

Introduction: Poor sleep is pervasive in pregnancy and increases risk for hypertensive disorders of pregnancy. Mindfulness, defined as paying attention to the present moment non-judgmentally, is associated with fewer insomnia symptoms and better sleep quality in non-pregnant adults. However, the associations among mindfulness and sleep in pregnancy, and their associations with hypertension risk, are unknown.

Materials and methods: We evaluated associations among self-reported mindfulness (using the Five Facets of Mindfulness Questionnaire), objective (7 days of actigraphy) and subjective (Pittsburgh Sleep Quality Index, PSQI) sleep, and 24-hour ambulatory blood pressure in a sample of pregnant women at risk for hypertensive disorders of pregnancy. Analyses were conducted using IBM SPSS v.25.

Results: Participants were 137 pregnant women at risk for hypertensive disorders of pregnancy according to American College of Obstetricians and Gynecologists criteria and were enrolled in an ongoing trial of prenatal mindfulness training (NCT04626245). Participants were 32 years old (SD=5), 18 weeks' gestation (SD=1) at the time of data collection, and 45% were pregnant with their first baby. 27% of participants were Hispanic, 23% were Black, and 53% were non-Hispanic White. Average total sleep time from actigraphy was 377 minutes (SD=87, range: 187-671). Average global sleep quality as measured by the PSQI was 8 (SD=4, range: 1-17). 69% of the sample had poor sleep quality (> 5 on PSQI). We performed linear regression analyses, adjusting for parity, income, education, ethnicity, and race, to examine associations among trait-level mindfulness, objective and subjective sleep, and daytime and nighttime blood pressure. Results revealed that trait-level mindfulness was significantly associated with subjective sleep quality, such that higher scores on subscales 'acting with awareness' (focusing attention on one's current activity; (B=.32, $p<.001$)) and 'non-judging of inner experiences'

(experiencing thoughts/feelings without judging them or criticizing oneself; $B=.32$, $p<.001$) were associated with better global sleep quality on the PSQI. Actigraphy-measured total sleep time was associated with lower nighttime systolic ($B=-.24$, $p=.027$) and diastolic blood pressure ($B=-.22$, $p=.046$). Better PSQI-measured global sleep quality was also associated with lower nighttime systolic ($B=-.22$, $p=.023$) and diastolic ($B=-.20$, $p=.032$) blood pressure. There were no associations between trait-level mindfulness and blood pressure measures.

Conclusions: Overall, participants at risk for hypertensive disorders had short sleep duration (less than 7 hours of sleep per night) and poor subjective sleep quality. Higher trait-level mindfulness was associated with better subjective, but not objective, sleep quality. Shorter sleep duration and poorer subjective sleep quality were associated with higher blood pressure during the night. Lastly, trait-level mindfulness was not significantly associated with blood pressure. Future studies are needed to evaluate interventions aimed at improving prenatal sleep health and decreasing risk for adverse obstetric outcomes.

Acknowledgments: We would like to thank the women in this study for their participation.

Who Benefits — and Who Doesn't — from a Nap? Diverging Cognitive Outcomes Predicted by Insomnia Severity, Fatigue, and Sleep Quality

K. Cote¹, E. Vanscoy¹

¹Brock University, Psychology, St. Catharines, Canada

Introduction: Daytime naps improve cognitive performance, but individual differences in sleep history and fatigue may moderate the benefits. Insomnia severity (ISI), functional fatigue (FSS), and global sleep quality (PSQI) are overlapping yet distinct constructs. We investigated how each uniquely predicted improvements following a 30-minute nap across cognitive domains of working memory, sustained attention, and emotion processing.

Materials and methods: Young adults ($n=47$; males=5) completed performance testing before-and-after counterbalanced nap and wake conditions. Difference scores (post-pre, nap-wake) were calculated for outcomes. To investigate the unique predictive value of ISI, PSQI, and FSS on performance following a nap, hierarchical regressions were employed. In each model, total sleep time (TST) and the two non-target sleep-related variables were entered simultaneously in Step1 to control for shared variance. The primary predictor (ISI, PSQI, or FSS) was entered in Step2. Good and poor sleepers were recruited: 32 participants scored >5 on PSQI (mean=7.2, range:3-15), 18 scored >8 on ISI (mean=6.96, range:0-21), and 25 had clinically significant fatigue on FSS (mean=35.11, range:14-51). TST in the nap ranged 10-29min (mean=23min). We assessed working memory with a 2-back task, sustained attention with a Reaction Time (RT) task, and emotion processing with a facial categorization task displaying Happy, Sad, Angry, Fearful faces.

Results: **Insomnia severity (ISI)** significantly predicted change in RT to errors in **working memory** following the nap. Controlling for TST, FSS, and PSQI, ISI explained additional variance ($\beta=-.601$, $p=.025$); participants with greater insomnia symptoms experienced larger gains (i.e., faster responses indicating improved cognitive efficiency). ISI also predicted WM accuracy, controlling for TST and either FSS or PSQI, but did not survive as a unique predictor when adding both FSS and PSQI.

Fatigue (FSS) significantly predicted improvements in **sustained attention** following a nap. Controlling for TST, ISI, and PSQI, FSS explained additional variance for mean RT ($\beta=-.350$, $p<.029$) and RT instability (composite of RT standard deviation, 10% slowest RTs, number of lapses) ($\beta=-.336$, $p<.035$), indicating higher fatigue was associated with greater reductions in mean RT and instability, reflecting improved attention due to the nap.

Sleep quality (PSQI) significantly predicted changes in **emotion categorization accuracy** after a nap. Controlling for TST, ISI, and FSS, PSQI explained additional variance ($\beta=-.699$, $p<.001$), showing that poorer sleep quality was linked to diminished recognition of emotional faces, particularly for angry expressions which are salient social cues ($\beta=-.647$, $p=.001$).

Conclusions: **These findings underscore a dissociation among self-report sleep scales and their prediction of cognitive benefits of napping.** FSS, which captures general daytime fatigue, predicted improvements in attentional speed/stability—suggesting individuals experiencing fatigue may benefit from naps as an intervention for vigilance. ISI, reflecting subjective difficulties initiating or maintaining sleep, was associated with working memory improvement, possibly because naps provide compensation for those with reduced nocturnal sleep. PSQI, indexing sleep quality over past month,

was associated with *diminished accuracy* in emotion processing; cumulative sleep debt may have increased sleep inertia or limited restorative potential of the nap. These results highlight the importance of differentiating functional fatigue, acute insomnia symptoms, and chronic sleep quality when assessing who might benefit from napping.

Whose Dream Experiences Are More Intense? An Exploratory Study on the Relationship between Nightmares/Sexual Dreams and Personality Traits

H. Fan¹, J. Xu¹, Q. Zhang¹, X. Zhou¹

¹Beijing Sport University, School of Psychology, Beijing, China

Introduction: Dream experiences, such as nightmares and sexual dreams, serve as windows into individuals' psychological and emotional health. Guided by the continuity hypothesis of dreaming, this study investigates how personality traits and anxiety predict the intensity of nightmares and sexual dreams in athletes and non-athletes. Athletes, often under high-performance stress, may exhibit distinct dream patterns compared to non-athletes, while sexual dreams reflect aspects of sexual mental health. By comparing these phenomena, this research addresses critical questions: *Which individuals experience more intense nightmares or sexual dreams, and how do personality traits and anxiety contribute to these differences?*

Materials and methods: Two cross-sectional studies were conducted in athletes and non-athletes.

1. **Nightmare Study:** Participants included 187 athletes (mean age = 20.44, SD = 0.85; 91 females) and 90 non-athletes (mean age = 20.34, SD = 1.65; 52 females) reporting nightmares. Tools: Nightmare Experience Questionnaire (NEQ), Zuckerman-Kuhlman-Aluja Personality Questionnaire-Short Form (ZKA-PQ/SF), and Self-Rating Anxiety Scale (SAS).
2. **Sexual Dream Study:** 411 participants (50.12% reporting sexual dreams; 88 athletes [mean age = 21.12, SD = 0.83; 24 females] and 118 non-athletes [mean age = 20.29, SD = 1.58; 71 females]) completed the Sexual Dream Experience Questionnaire (SDEQ), ZKA-PQ/SF, and SAS.

Regression analyses identified predictors of nightmare and sexual dream intensity.

Results: 1. Nightmares

46.5% of athletes reported nightmares. Athletes with nightmares exhibited higher neuroticism ($p < 0.01$) and anxiety ($p < 0.05$) than non-nightmare athletes.

Non-athletes with nightmares scored higher in aggressiveness, neuroticism, and sensation seeking ($p < 0.05$).

Anxiety ($\beta = 0.32$), neuroticism ($\beta = 0.28$), and sensation seeking ($\beta = 0.18$) predicted athletes' nightmare intensity.

2. Sexual Dreams

Athletes with sexual dreams scored lower in aggressiveness and neuroticism than non-sexual dreamers ($p < 0.05$), with no significant anxiety differences.

Anxiety ($\beta = 0.16$) and sensation seeking ($\beta = 0.37$) positively predicted athletes' sexual dream intensity.

Non-athletes with sexual dreams showed higher aggressiveness and neuroticism traits ($p < 0.05$).

Conclusions: Personality traits and anxiety differentially predict intense dream experiences. Athletes' nightmares are linked to neuroticism and anxiety, aligning with performance-related stress, whereas their sexual dreams correlate with lower aggression and higher sensation seeking. Non-athletes' intense dreams reflect broader traits like aggressiveness and sensation seeking. These findings highlight the dual role of personality in shaping nightmares (stress indicators) and sexual dreams (impulse-driven experiences). For mental and sexual health interventions, tailored strategies—stress management for athletes and psychoeducation on emotional regulation—are recommended. This study advances understanding of how individual differences shape dream intensity, offering practical insights for health professionals.

Chronobiology/Circadian Disorders

Abnormal Global Brain Function in Shift Work Disorder Patients: A Resting-State Functional MRI Study

F. Wang¹, Z. Liu¹, Y. Chen¹

¹Shanghai University of Traditional Chinese Medicine, Shanghai, China

Introduction: Since the negative influence caused by shift work disorder (SWD), its underlying mechanisms still remain unclear. Thereby, we conducted this study to explore the neuromechanism of SWD due to the disrupted circadian rhythm using Resting-state functional magnetic resonance imaging (rs-fMRI).

Materials and methods: 65 SWD patients and 65 healthy controls (HC) had received assessments of relevant

questionnaires, including PSQI, ISI, ESS, FS-14, PHQ-9, GAD-7, and rs-fMRI scans.

Amplitude of Low Frequency Fluctuations (ALFF), Regional Homogeneity (ReHo)

analyses were performed on rs-fMRI data to compare the differences between the two groups. The peak points, which significantly altered in ALFF and ReHo were chosen as the seed regions to further calculate and Functional Connectivity (FC) of the whole brain. Finally, we performed correlation analyses to assess the association between alterations in brain function and clinical characteristics.

Results: The study included 121 participants (61 SWD, 60 HC). The SWD group showed higher PSQI, ISI, ESS, FS-14, PHQ-9, and GAD-7 scores (all $P < 0.05$) but no demographic differences versus HCs.

ALFF analysis revealed increased activity in frontal regions (left medial superior frontal gyrus, orbital middle frontal gyrus, right dorsolateral superior frontal gyrus) and decreased activity in occipital areas (left middle occipital gyrus, right superior occipital gyrus/lingual gyrus) in SWD. ReHo was reduced in the right middle occipital gyrus. FC analysis showed decreased connectivity between the right superior occipital gyrus and left superior occipital gyrus/cuneus.

Conclusions: The changes of functional brain activities in SWD patients are mainly in the prefrontal and occipital lobes, and related brain network is the default mode network (DMN), which might be potential neuroimaging indicators and therapeutic target brain region for SWD patients.

A direct comparison of sleep loss and circadian effects in sustained attention

L. Lack¹, A. Abeywickrama², C. Dunbar³, A. Guyett³, K. Nguyen³, A. Vakulin³

¹Flinders University, College of Education, Psychology, and Social Work, Bedford Park, Australia,

²Flinders University, College of Education, Psychology and Social Work, Bedford Park, Australia,

³Flinders University, College of Medicine and Public Health, Bedford Park, Australia

Introduction: Extended wakefulness of up to 30 hours has been associated with severe impairments in performance arising from loss of sustained attention. This impairment of attention is usually attributed to sleep loss. The impairment may not be due solely to sleep loss since considerable recovery of function occurs the next day even with further sleep loss. A circadian effect is likely to be a significant contributor to performance measures and has been apparent in many studies. However, few studies have directly compared the contributions of accumulated sleep loss and circadian rhythm on sustained attention. The aim of the study was to compare the contribution of sleep loss with a linear model and circadian rhythm contribution with a cosine model. We compared both the amplitudes and variances accounted for in the two models.

Materials and methods: We analyzed the data from 38 healthy sleepers (Mean (SD) age = 32.6 (12.9) years) who performed the 10-minute Psychomotor-Vigilance Task (PVT) 10 times equally spaced across a 29-hour period of total sleep deprivation in a controlled laboratory protocol. The number of lapses (Reaction Time > 500 msec) of attention was measured at each testing time. Two curve-fitting approaches were applied: (1) a linear function using least squares method to model time awake effects, and (2) a 24-hour cosine curve to model the circadian component. For both group mean data and individual participant data, we compared the amplitudes and variances accounted for (R^2) between the circadian and linear models. Within-subject statistical comparisons were conducted using paired t-tests.

Results: The 24-hour amplitude of the mean lapses curve was 14.1 lapses in the circadian component and 12.5 in the linear component and the variances were 72.3% and 57% respectively. Individual participant analyses means were 15.0 lapses and 12.75 lapses and variances of 59.5% and 40.4% for the circadian and linear curve fits respectively. Within subjects t-tests showed the circadian component has significantly larger amplitude ($t(37) = 2.56, p < 0.02$) and higher variance accounted for by the circadian curve fit ($t(37) = 5.14, p < 0.001$) than from the linear model.

Conclusions: Across the 29-hour sleep deprivation protocol the circadian model contributes a greater amplitude and variance accounted for in lapses of attention than the linear time awake model. Campaigns to improve public safety should draw as much attention to the danger of the circadian time of operation as to the amount of prior wakefulness.

Acknowledgments: This research was funded by the Road Safety Innovation Fund Round 2 grant (RSIF2-96).

AI-enabled discovery of novel circadian-clock markers from overnight PSG

Y. Fang¹, J. Chen², X. Chen³, R. Gao³, Y. Wang³, W. Huang⁴, R.J. Thomas⁵, M.B. Westover⁶, H. Yi⁴, S. Yin⁴, Y. Leng¹

¹University of California, San Francisco, Department of Psychiatry and Behavioral Sciences, San Francisco, United States, ²Peking University Health Science Center, Institute of Medical Technology, Beijing, China, ³Beijing Wuji Medical Technology Co., Ltd., Beijing, China, ⁴Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Department of Otorhinolaryngology Head and Neck Surgery, Shanghai, China, ⁵Beth Israel Deaconess Medical Center, Division of Pulmonary, Critical Care and Sleep Medicine, Department of Medicine, Boston, United States, ⁶Harvard Medical School, Department of Neurology, Beth Israel Deaconess Medical Center, Boston, United States

Introduction: Circadian rhythms orchestrate physiological homeostasis and overall health. However, established circadian biomarkers, such as salivary melatonin, are invasive and poorly suited to large-scale studies, whereas wrist actigraphy lacks direct physiological specificity. Consequently, non-invasive, cost-effective circadian markers that can be deployed at home are needed to enhance health risk stratification. Here, we propose an artificial intelligence-based framework that infers internal circadian timing directly from overnight polysomnography (PSG).

Materials and methods: We fine-tuned a pretrained deep neural network model to predict clock time continuously across the night, using abdominal respiratory and electrocardiogram signals—modalities that can also be captured in ambulatory, non-laboratory environments. The model was trained on 1-hour segments with a 10-minute sliding window. For each individual, it generated a predicted time series across the night, reflecting their internal circadian timing.

Circadian characteristics were quantified by regressing the predicted times against actual clock time, yielding two metrics: (1) Circadian Phase Misalignment (CPM), defined as the absolute angular deviation (in degrees) between the fitted slope's arctangent and the 45-degree reference angle; and (2) Circadian Rhythm Strength (CRS), the regression R^2 , indicating internal rhythm consistency.

Model development used 35,945 overnight PSGs drawn from 13 National Sleep Research Resource cohorts, the Human Sleep Project, and Shanghai Sixth People's Hospital (8:1:1 train/validation/test split). External validation was performed in Multi-Ethnic Study of Atherosclerosis ($n = 2,056$), Sleep Heart Health Study ($n = 5,795$). Logistic regression examined associations between CPM, CRS, and seven self-reported neuropsychiatric and metabolic conditions (anxiety, depression, bipolar disorder, post-traumatic stress disorder [PTSD], Alzheimer's disease [AD], Parkinson's disease [PD], overweight, diabetes), adjusting for age and sex.

Results: The combined development dataset included 35,945 participants (age: 49.0 ± 20.0 years; 44.6% female; 44.4% Non-White). The clock time model achieved a mean absolute error of 1.55 hours in internal validation and 1.39–1.96 hours across external cohorts. Median CPM was 9.83° (range: 0.003 – 75.4°), and median CRS was 0.745 (range: 0–1). A 10° increase in CPM was associated with higher odds of multiple conditions, most notably bipolar disorder (OR = 1.75, 95% CI: 1.54–1.98), AD (OR = 1.71, 95% CI: 1.27–2.30), and PTSD (OR = 1.43, 95% CI: 1.28–1.60). Depression, PD, diabetes, and overweight also showed significant associations (all $p < 0.001$, OR range: 1.04–1.40). A 0.1-unit decrease in CRS was similarly associated with increased odds of AD (OR = 1.27, 95% CI: 1.09–1.48), with consistent but weaker associations across other conditions (all $p < 0.001$; OR range: 1.02–1.19).

Conclusions: This AI-based approach provides a scalable, non-invasive method to quantify internal circadian rhythms from overnight sleep physiological signals. The derived metrics capture biologically meaningful variation in circadian timing and show strong associations with comorbidities, making them a novel tool for circadian phenotyping with clinical and translational relevance.

An iPhone App to Guide the Collection of the Dim Light Melatonin Onset at Home

H. Burgess¹, L. Swanson¹, J. Arthurs¹

¹University of Michigan, Ann Arbor, United States

Introduction: The dim light melatonin onset (DLMO) remains the gold standard circadian phase marker in humans. We previously developed a proof-of-concept home DLMO kit and demonstrated that valid DLMOs could be collected at home, with objective markers of light exposure and sample timing. Nonetheless, the proof-of-concept kit uses costly external technologies such as photosensors (to monitor light exposure) and MEMS TrackCaps (to monitor sample timing). Here we present a novel iPhone app designed to improve upon the original proof-of-concept kit.

Materials and methods: We have designed an iPhone app that: (1) streamlines the home DLMO collection procedure, (2) maintains the objective assessment of light exposure and sample timing with internal app features, (3) provides real-time feedback on errors in light exposure and sample timing to both participants and externally located researchers, and (4) provides some cost savings over the original proof-of-concept kit. Programming capability includes options to (1) sample saliva at half-hourly or hourly intervals, (2) end sampling at participants' habitual bedtime or up to 3 hours past habitual bedtime, and (3) set a light intensity threshold of choice to alert the research participant and externally located researcher in real-time that melatonin levels may be suppressed. At the conclusion of the home DLMO collection, the app generates a report of light levels and sample timing for the researcher. Saliva samples can then be sent to a qualified laboratory for assay processing.

Results: Flow diagrams of the back-end programming capability available to researchers and the front-end step-by-step display screens guiding research participants will be shown. A demonstration model of the iPhone app will be available for hands on interaction.

Conclusions: A novel iPhone app has been developed to better support the collection of DLMOs at home, and facilitate research examining circadian timing in human populations.

A randomized controlled trial on the effect of a self-help book for shift work disorder

S. Waage¹, A. Harris², S. Pallesen², Ø. Vedaa³, B. Bjorvatn⁴

¹Haukeland University Hospital, Norwegian Competence Center for Sleep Disorders, Bergen, Norway,

²University of Bergen, Department of Psychosocial Science, Bergen, Norway, ³Norwegian Institute of Public Health, Department of Health Promotion, Bergen, Norway, ⁴University of Bergen, Department of Global Public Health and Primary Care, Bergen, Norway

Introduction: Shift work disorder (SWD) is a circadian rhythm sleep-wake disorder characterized by excessive sleepiness and insomnia due to work hours that overlap with the habitual time for sleep. It is associated with substantial adverse consequences for the individual, employers and society. Previous studies have found self-help therapies to be effective for insomnia. The aim of the present study was to compare the effect of a self-help book for coping with shift work to that of sleep hygiene advice in a randomized controlled trial with follow-up after 6 months.

Materials and methods: Data were collected among 199 health care workers with shift work disorder (SWD) at baseline (86.9% females, mean age 39 years). At follow-up, 136 participants responded, rendering a response rate of 68.3%. The questionnaire included information about SWD, work-related fatigue (the Swedish Occupational Fatigue Inventory), turnover intention, knowledge about shift work, and self-reported sickness absence related to sleep problems. Statistics were conducted among the 136 completers.

Results: Shift work disorder was reduced in both groups, from 100% to 83.1% and 79.0% in the sleep hygiene group and self-help book group, respectively. None of the five dimensions of fatigue changed in the sleep hygiene group. Four dimensions were reduced in the self-help book group; lack of energy (14.9 to 12.3, $p < .001$), lack of motivation (11.7 to 9.9 $p = .004$), sleepiness (14.7 to 12.5, $p < .001$), and

physical discomfort (12.4 to 10.9, $p=.003$). There were significant interaction effects on lack of energy ($p=.017$), lack of motivation ($p<.001$), and sleepiness ($p=.002$), indicating that the self-help book was better than the sleep hygiene advice. Turnover intention significantly increased in the sleep hygiene group (8.04 to 8.62, $p=.044$), but did not change in the self-help book group (7.56 to 7.47, $p=.79$). Mean correct answers out of 13 questions on the knowledge test did not change in the sleep hygiene group (7.2 to 7.1, $p=.57$), but significantly increased in the self-help book group (7.5 to 8.4, $p<.001$), with a significant interaction effect ($p=.005$). Sickness absence related to sleep problems increased in the sleep hygiene group (27.5% to 30.4%) and decreased in the self-help book group (18.6% to 13.6%).
Conclusions: This study suggests that a self-help book may be an effective low-threshold intervention for coping with shift work.

Aripiprazole (Abilify) as a new treatment for circadian rhythm sleep-wake disorders (CRSWDs) and its mechanism of action

T. Kanbayashi^{1,2}, S. Chiba^{1,2}, R. Li^{1,3}, Y. Konno¹, T. Nemoto¹, A. Hirano^{1,3}, H. Ishido^{1,4}, E. Anegawa^{1,5}, K. Ushida¹, Y. Inotsume^{1,2}, M. Kimura⁶, T. Sakurai^{1,3}

¹Tsukuba University, International Institute for Integrative Sleep Medicine (WPI-IIS), Tsukuba, Japan, ²Ibaraki Prefectural Medical Center of Psychiatry, Kasama, Japan, ³Tsukuba University, Institute of Medicine, Tsukuba, Japan, ⁴Hatsuishi Hospital, Kashiwa, Japan, ⁵Tsukuba White Dental Clinic, Tsukuba, Japan, ⁶University of Tokyo, International Research Center for Neurointelligence (WPI-IRCIN), Tokyo, Japan

Introduction: Circadian rhythm sleep-wake disorders (CRSWDs), especially delayed sleep-wake phase disorder (DSWPD), are common among young people and are a major problem in sleep medicine. They are usually treated with melatonin, bright light therapy, and lifestyle guidance, but nighttime sleep time is often extended, making them difficult to treat. We have reported that administration of 0.5-3 mg of aripiprazole to 12 patients with CRSWDs resulted in sleep onset time 1 hour earlier, sleep time 1.3 hours shorter, and wake time 2 hours earlier (Omori, 2018). However, the mechanism of action is unknown, which is a drawback in clinical application.

Materials and methods: A total of 10 clinical reports of CRSWDs, DSWPD and non-24-hour sleep-wake disorder have been published in Japan, and a meta-analysis was performed. In vivo and ex vivo experiments were performed in mice to clarify the mechanism of action.

Results: In a total of 45 cases, an average dose of 2.7 mg of aripiprazole resulted in 0.5 hours earlier sleep onset, 1.1 hours shorter sleep time, and 2.5 hours earlier wake-up time. In vivo study involved administering mice with aripiprazole through drinking water and subjecting them to a 6-hour advance jet lag. This administration led to the rapid re-entrainment of the shifted light-dark cycle (Li, 2023). Ex vivo experiments with suprachiasmatic nucleus (SCN) slice cultures have revealed that aripiprazole causes desynchronization of SCN neurons via the serotonin 1A receptor. The mathematical modeling suggests that mild disruption of SCN coupling by aripiprazole enhances photic entrainment without being so disruptive as to cause arrhythmicity.

Conclusions: A meta-analysis confirmed that aripiprazole is highly effective as a treatment option for CRSWDs. It was also confirmed that the mechanism of action is a direct effect on SCN. Melatonin as a therapeutic drug promotes sleep onset, but aripiprazole promotes early awakening, so it is expected that its effectiveness will be enhanced by using it in combination.

Association between wearable device-measured weekend catch-up sleep and brain health in UK Biobank participants

J. Wu¹

¹Third Xiangya Hospital, Central South University, Neurology, Changsha, China

Introduction: Sleep deprivation was correlated with risks of brain diseases. However, as a compensation for weekday sleep deficits, the effects of weekend catch-up sleep (WCS) on brain health remain inconclusive. This study investigated the association between WCS and major brain disorders, including depression, anxiety, dementia, stroke, and Parkinson's disease (PD) during a 13.65-year follow-up period, using wearable device data of 93,506 UK Biobank participants.

Materials and methods: A total of 93,506 participants from the UK Biobank were followed for an average of 13.65 years. Accelerometer-measured sleep data were used to classify WCS into four categories: no WCS (≤ 0 hours), short (>0 to <1 hour), medium (≥ 1 to <2 hours), and long (≥ 2 hours). Cox proportional hazards models, adjusting for multiple confounding factors, were used to estimate the association between WCS duration and disease incidence. Restricted cubic spline analyses assessed potential nonlinear relationships.

Results: The fully-adjusted Cox proportional hazards model revealed that medium WCS significantly reduced the risk of depression (HR 0.89, 95% CI 0.81–0.99) and anxiety (HR 0.88, 95% CI 0.79–0.98). Nonlinear dose-response relationships were observed between WCS and depression/anxiety (P for nonlinearity <0.001). No significant associations were found between WCS and dementia, stroke, or PD. Subgroup analyses indicated a significant interaction between WCS and age for anxiety (P for interaction = 0.003).

Conclusions: Medium WCS may be a promising, cost-effective strategy for promoting mental health, specifically reducing the risk of depression and anxiety. However, no significant associations were found with dementia, stroke, or PD. Future research should explore the underlying mechanisms and replicate these findings in diverse populations.

Association of circadian rest-activity rhythm and genetic risk with incident irritable bowel syndrome

H. Wu¹, X. Tan^{1,2}

¹Zhejiang University School of Public Health, Department of Big Data in Health Science, Hangzhou, China, ²Karolinska Institutet, Department of Clinical Neuroscience, Stockholm, Sweden

Introduction: Irritable bowel syndrome (IBS) is a common functional bowel disorder characterized by recurrent abdominal pain, altered defecation, or changes in bowel habits. Although the exact mechanisms remain unclear, disrupted communication between the gut and brain has been implicated. The circadian system regulates various gastrointestinal functions, and circadian rhythm disruptions are associated with gastrointestinal diseases. However, prospective studies linking circadian rhythms and IBS risk are limited.

Materials and methods: This study included 86,106 UK Biobank participants who were free of IBS at baseline. Circadian rest-activity rhythm (CRAR) was assessed using non-parametric parameters, including interdaily stability (IS), intradaily variability (IV), activity level during the most active 10 hours (M10), activity level during the least active 5 hours (L5), relative amplitude (RA), M10 onset, and L5R onset. The incidence of IBS was identified using hospital records and a self-assessment questionnaire, and genetic risk was determined using a polygenic risk score (PRS). Cox proportional hazards models were used to examine the association between CRAR and incident IBS.

Results: During 620,851 person-years of follow-up (median follow-up period of 7.8 years), a total of 8,790 new cases of IBS were identified. We found that the risk of incident IBS decreased with increasing RA and M10, with multivariate adjusted hazard ratios (HRs) (95% CI) were 0.86 (0.81, 0.91) for decreasing RA and 0.88 (0.83, 0.92) for high M10. Conversely, high L5, a delayed onset of M10 and an advanced onset of L5 were associated with a higher risk of IBS, with the HRs (95% CI) of 1.06 (1.04, 1.12) for high L5, 1.10 (1.04, 1.16) for delayed M10 onset time, and 1.06 (1.01, 1.12) for advanced L5 onset time. However, the relationships of IS and IV with IBS risk did not reach statistical significance. No significant interactions between CRAR parameters and genetic risk are observed. Additionally, individuals with high genetic risk and poor CRAR parameters showed a significantly higher risk of IBS.

Conclusions: CRAR disturbances, characterized by lower amplitude and abnormal phase, are linked to an elevated risk of developing IBS. These findings underscore the potential of circadian rhythm management as a modifiable risk factor for IBS prevention. Further research is needed to explore the underlying mechanisms linking CRAR disruptions to IBS.

A study of sleep EEG spectral analysis of delayed sleep-wake phase disorder

M. Hirose¹, R. Kumagai¹, K. Funahashi¹, S. Fujita², Y. Ito³, N. Iwata¹, T. Kitajima¹

¹Fujita Health University School of Medicine, Department of Psychiatry, Toyoake, Japan, ²Fujita Health University Hospital, Department of Laboratory Medicine, Toyoake, Japan, ³Yokkaichi Nursing and Medical Care University, Department of Clinical Physiology, Yokkaichi, Japan

Introduction: Delayed sleep-wake phase disorder (DSWPD) is a sleep disorder where sleep architecture is considered normal if individuals sleep at their preferred times aligned with their internal body clock. However, there have been reports of reduced recovery sleep after sleep deprivation in patients with DSWPD under experimental conditions, suggesting a potential alteration of its sleep homeostatic process. To clarify this further, we conducted electroencephalographic (EEG) spectral analysis of DSWPD under normal living conditions in this study.

Materials and methods: The case group consisted of patients who were not on medication, visited the Department of Psychiatry at Fujita Health University Hospital, and were diagnosed with DSWPD based on the diagnostic criteria of the International Classification of Sleep Disorders, 3rd edition (ICSD-3). Healthy individuals were also recruited to serve as the control group. The study was approved by the Ethics Committee of Fujita Health University, and all participants provided written informed consent. The patients spent at least one week on their usual schedule at their home, keeping sleep diaries and wearing an actigraphy. On a day during this period, an overnight EEG with a 2-channel measuring device was conducted, and saliva samples were collected hourly under dim light conditions to determine dim-light melatonin onset (DLMO) in the evening just before the EEG measurement. Melatonin non-delayed and delayed types of DSWPD were defined as having DLMO more than 30 minutes earlier than the patient's desired bedtime or not, according to ICSD-3-Text-Revision. For EEG spectral analysis, the power spectra (μV^2) of the theta and delta bands for each 30-second epoch were obtained by fast Fourier transform. All participants completed the Morningness-Eveningness Questionnaire (MEQ) to determine their chronotype.

Results: Ten DSWPD patients and twenty-one healthy subjects were included in the study. Slow wave power in the delta band during the first two hours after sleep onset was significantly higher in DSWPD patients than in healthy subjects. As for the ratio of theta and delta band slow wave spectral power in the second half to that in the first half, it tended to positively correlate with MEQ across both case and control groups, though there were some exceptions. The melatonin delayed type of DSWPD showed a tendency for slow waves to appear more immediately after sleep onset. In contrast, the non-delayed type showed a tendency for slow waves to remain in the second half of sleep.

Conclusions: Differences in the distribution of slow waves across the sleep period were observed between DSWPD and healthy subjects, as well as between melatonin delayed and non-delayed DSWPD, suggesting that some alteration may occur in DSWPD with regard to sleep homeostatic processes. Further research with a larger sample size is necessary to confirm this finding.

Acknowledgments: This work was supported by Grant-In-Aid for Young Scientists (B) [19K17120] from the Ministry of Education, Culture, Sports, Science, and Technology, and Grant-in-Aid for Department in School of Medicine, Fujita Health University. Automatic sleep-wake classification and Parkinson's disease recognition using multi-feature fusion with support vector machine

Y. Shen¹, F. Su², T. Xin², P. Li²

¹Shandong First Medical University & Shandong Academy of Medical Sciences, Institute of Brain Science and Brain-inspired Research, Jinan, China, ²Shandong First Medical University & Shandong Academy of Medical Sciences, Jinan, China

Introduction: Sleep disturbance is a prevalent non-motor symptom of Parkinson's disease (PD), however, assessing sleep conditions is always time-consuming and labor-intensive. In this study, we performed an automatic sleep-wake state classification and early diagnosis of PD by analyzing the electrocorticography (ECoG) and electromyogram (EMG) signals of both normal and PD rats.

Materials and methods: The study utilized ECoG power, EMG amplitude, and corticomuscular coherence values extracted from normal and PD rats to construct sleep-wake scoring models based on the support vector machine algorithm. To evaluate the applicability of the sleep-wake classification

models across different rat groups, we randomly selected the features from 8 rats in the sham group (Sham train) and 8 rats in the lesion group (Lesion train) to train the SVM models, respectively. Subsequently, the remaining sham record (Sham test) and lesion record (Lesion test) were considered as two test data points for cross-validation of the models. The Sham dataset contained 6480 10-second segments labeled by the sleep experts with data encompassing WAKE: 1548, NREM: 4164, REM: 768. Similarly, the Lesion dataset contained 6521 10-second segments labeled by the sleep experts with data encompassing WAKE: 2047, NREM: 3866, REM: 608. The Sham test and Lesion test contained approximately 720 10-second segments, respectively. For comparison, we used ECoG from occipital or frontal cortex regions in the Sham train and Lesion train for feature extraction and model training to construct four different sleep-wake classification models. Finally, by incorporating PD-specific features from frontal ECoG, we developed two models capable of simultaneous sleep-wake state classification and PD detection. By incorporating the previously selected features and expanding the functionality of the model, we achieved simultaneous detection of sleep-wake states and the likelihood of PD in rats.

Results: The highest accuracy was achieved when the model was trained by the Sham train of the occipital ECoG and tested by the Sham test data, at which time the Cohen's kappa value was 0.77 ± 0.05 . Features extracted from occipital ECoG signals were more suitable for constructing sleep-wake scoring models than those from frontal ECoG (average Cohen's kappa: 0.73 vs. 0.71). Additionally, after retraining, the new models demonstrated increased sensitivity to PD and accurately determined the sleep-wake states of rats (average Cohen's kappa: 0.79). A slightly greater level of overall accuracy was noted when conducting classification through a combination of occipital and frontal ECoG, as opposed to relying solely on frontal ECoG ($84.87\% \pm 2.22\%$ vs. $83.90\% \pm 2.50\%$).

Conclusions: This study accomplished the precise detection of substantia nigra lesions and the monitoring of sleep-wake states. The integration of circadian rhythm monitoring and disease state assessment has the potential to improve the efficacy of therapeutic strategies considerably. Furthermore, the algorithms developed in this research exhibit promising potential for future integration into adaptable, wireless, and portable DBS monitoring systems.

Acknowledgments: This study has been published in *CNS Neuroscience & Therapeutics*, published on Apr 2024, DOI: 10.1111/cns.14708.

Blue light influences loss aversion

A. Lander¹, M. Burge^{1,2}, B. Thomas², A. Phillips¹, E. McGlashan^{3,2}, S. Cain¹

¹Flinders University, Flinders Health and Medical Research Institute (Sleep Health), Adelaide, Australia,

²Monash University, School of Psychological Sciences, Melbourne, Australia, ³University of Melbourne, School of Psychological Sciences, Melbourne, Australia

Introduction: Gambling is a popular and easily accessible activity, with ~1.6 billion people worldwide engaging in gambling activities. The manipulation of gambling product designs, like the ringing bell on the slot machines, have been found to reinforce gambling behaviour. It's possible that the use of light and colour may also enhance gambling behaviour. As decision-making is influenced by underlying cognitive processes directly impacted by circadian photoreception, activation of circadian photoreceptions may alter an individual's sensitivity to loss. We investigated whether circadian photoreception influences loss aversion.

Materials and methods: Fifteen participants (mean age = 20.40, $SD = 2.03$) completed an economic-decision making task under blue-enriched ($\lambda_p = 490$ nm) and blue-depleted light ($\lambda_p = 631$ nm) of the same photopic lux (200 lux). Light conditions were counterbalanced for order of exposures across two sessions, two weeks apart. During the task, participants were required to choose between taking a risky gamble of a positive or negative outcome, or take a guaranteed, less risky outcome.

Results: Using Hierarchical Bayesian Modelling to derive individual parameter estimates for loss aversion, we found that individuals were less loss averse under blue-enriched light compared to blue-depleted light. Linear mixed models were used to analyse trial-by-trial performance, and the best-fit model indicated light condition significantly affected the loss aversion parameter, with blue-enriched light associated with a .43 decrease in loss aversion. Significant sex differences were also found, with men showing decreased loss aversion across both light conditions.

Conclusions: This is the first study to demonstrate that light that preferentially targets circadian photoreception influences loss aversion. Our key finding was that blue-enriched light significantly decreased loss aversion, suggesting that when under this light, individuals are relatively more

comfortable to take a risk and demonstrate a reduced sensitivity to loss. With virtually all machines used for gambling employing LED/LCD displays which are known for their blue-enriched light content, targeting the reduction of “blue” light content in gambling scenarios may be a promising target for reducing gambling behaviour by promoting greater loss sensitivity.

Acknowledgments: The work conducted was completed with the help of our participants and research staff. Introduction: Severe mental illness is often marked by unpredictable and sometimes dangerous behaviors. In acute psychiatric settings, aggression poses a dual threat: it endangers staff and undermines therapeutic relationships, reducing opportunities for effective treatment. Managing aggression is therefore a critical challenge. We have previously shown that sleep is related to aggressive behaviors for patients in acute psychiatric hospitals, and that modifying the evening light environment according to chronobiological principles can have effects on the circadian system, sleep, and arousal in healthy individuals. In this study, we investigated whether patients admitted to an acute psychiatric inpatient unit with a evening blue-depleted light environment (BDLE) exhibited lower levels of aggressive behavior compared with patients in admitted to standard lighting conditions (SLE). All patients additionally received treatment as usual – including pharmacological treatment, consistent routines, and milieu therapy.

Materials and methods: This study is a secondary analysis of BDLE's effects on aggression across diagnostic subgroups. Participants (N = 475) admitted to a newly built acute psychiatric unit were randomized to BDLE or SLE. Aggressive behavior was assessed using the Brøset Violence Checklist (BVC), recorded three times daily by the responsible nurse based on a one-hour observation of the patient at the beginning of each shift. BVC scores >2 indicated serious aggressive incidents. Mixed-effects models were used to examine BDLE's effects on aggression, with subgroup analyses for four ICD-10 diagnostic categories: severe depressive episode, manic episode, psychotic disorders, and “other diagnoses”. Models were adjusted for baseline variables including age, sex, psychiatric diagnosis, comorbid personality or substance use disorder, admission status (voluntary/involuntary), and prior admissions in the past two years.

Results: In SLE, a total of 73 serious aggressive events were recorded, compared to 8 events in BDLE. Patients in BDLE experienced an estimated 0.25 fewer serious aggressive events during their admission (95% CI: -0.38 to -0.12, $p < 0.001$) compared to SLE, despite receiving identical psychiatric care. Among patients with a manic episode (N = 31), the reduction was most pronounced, with a mean of 1.27 fewer events (95% CI: -2.39 to -0.15). For the “other diagnosis” group (N = 329), BDLE also led to a significant reduction of 0.14 fewer events (95% CI: -0.24 to -0.04). No significant effects were observed for psychosis (N = 87) or depression (N = 28), though a non-significant trend suggested fewer aggressive events in psychosis (-0.42, 95% CI: -0.89 to 0.05, $p = 0.08$).

Conclusions: We have showed that modifying the evening light environment in an acute psychiatric ward appeared to «dial down» aggression, with the strongest effects seen in patients with mania. All patients received standard treatment, meaning these reductions occurred in addition to any improvements achieved through usual care. Our findings highlight this targeted chronotherapeutic intervention as a promising, non-invasive tool for managing aggression in the acute phase of severe mental illness.

Chronotype and infradian rhythms: the influence of solar and lunar cycles on sleep duration and phase

S. Bruno¹, F. Cruz-Sanabria², M. di Galante³, P. Frumento⁴, U. Faraguna^{5,2}

¹University of Wisconsin, Department of Psychiatry, Madison, United States, ²IRCSS Fondazione Stella Maris, Department of Developmental Neuroscience, Calambrone, Pisa, Italy, ³Sleepacta srl, Montacchiello, Pisa, Italy, ⁴University of Pisa, Department of Political Science, Pisa, Italy, ⁵University of Pisa, Department of Translational Research and of New Surgical and Medical Technology, Pisa, Italy

Introduction: The geophysical properties of the Earth, Moon, and Sun dictate the timing of a variety of biological cycles on our planet. While it is known that lunar phases and photoperiod length can influence the human sleep/wake cycle, the existence of different chronotypes suggests the presence of various, individual degrees of entrainment to astronomical cues.

This study aimed to characterize circannual and circalunar variations in sleep phase and duration across chronotypes. We hypothesized that individuals with extreme chronotypes (i.e., evening and morning types) maintain their circadian rhythms out of phase from the day/night cycle because they are less responsive to sunlight entrainment signal or more able to neutralize it. This could hinder their ability to adjust their sleep behavior to seasonal variations in daylength. Additionally, we proposed that evening types' sleep behavior may align with changes in the lunar phases, as they are more likely to extend wakefulness beyond sunset, possibly increasing their exposure to moonlight.

Materials and methods: A total of 402 healthy volunteers (29.91 ± 13.36 ys; 45.5% females; 66.9% intermediate types, 17.9% evening types, 15.2% morning types) wore an actigraph for an average of 7 days, resulting in 2844 valid night sleep episodes, from which the sleep midpoint and the total sleep time were derived. Participants completed the reduced Morningness/Eveningness Questionnaire to determine their chronotype. Periodic splines with two knots at the tertiles modelled the day of the year and of the lunar cycle. Random-effect linear models were fitted to assess the predictive power of lunar and solar cycle variables on sleep duration and phase among the different chronotypes. All models were adjusted for age and sex.

Results: Intermediate types exhibited circannual variations in sleep duration that closely mirrored seasonal photoperiod changes, with maximum sleep duration near the winter solstice and minimum near the summer solstice. Conversely, evening types showed sleep duration and timing variations aligned with the lunar cycle, displaying the shortest sleep duration and the most delayed sleep phase around the full moon. Moreover, in intermediate types only, the photoperiod length significantly predicted total sleep time ($\beta = -0.070$, $p = 0.007$), indicating that longer daylight periods were associated with shorter sleep durations. For evening types, increased lunar illumination significantly predicted a delay in sleep midpoint ($\beta = 40.02$, $p = 0.035$), when adjusting for moonrise time.

Conclusions: Intermediate chronotypes adapt their sleep duration in response to seasonal photoperiod fluctuations, whereas evening types are more influenced by lunar phases. The differential adaptation to the circannual rhythm may arise from genetic differences in photoreceptivity or from varying abilities to neutralize solar cues through behaviors such as artificial light exposure. In this perspective, moonlight exposure may be the cause of the disruption of evening types' seasonal synchronization. Both usual late bedtime and increased sensitivity to moonlight spectrum (richer in red light than the sunlight spectrum) can explain evening types' alignment with the lunar cycle. Further investigations are warranted to elucidate the underlying mechanisms behind chronotype-dependent variations in infradian rhythm entrainment.

Chronotype, Sleep and Stress: A Comparative Study of International Students in Georgia and Spain

I. Sakhelashvili¹, M. Perán Quesada²

¹Georgian American University, Medical School, Tbilisi, Georgia, ²University of Jaén, Department of Health Sciences, Jaén, Spain

Introduction: Numerous studies have shown that university students experience constant stress and sleep deprivation, while international students, especially medical students, are at greater risk of mental and general health problems, as they face other stressors in addition to academic and financial problems, such as language and cultural differences, stereotypes, etc., making them particularly vulnerable to health-related problems.

The aim of this study is to understand whether chronotype (individual preferences for sleep and daytime activity), influence the risk of sleep disturbances and stress in international students from two universities: Georgian American University (GAU, Georgia) and University of Jaen (UJA, Spain), with a focus on evening chronotypes, which are associated with poorer health outcomes.

Materials and methods: 160 international **medical** students at GAU and 185 international students from **non-medical** programs at UJA participated in the study. Data was collected by the Morningness/Eveningness Questionnaire (MEQ), the Epworth Sleepiness Scale (ESS), the Pre-Sleep Arousal Scale (PSAS), and the Student-Life Stress Inventory (SLSI).

Results: Evening chronotype subjects reported significantly higher levels of daytime sleepiness, pre-sleep arousals, and stress compared to intermediate and morning chronotypes. Specifically, evening chronotype sample were found to have higher rates of excessive daytime sleepiness (ESS score ≥ 11) compared to morning chronotypes, with 10.6% of evening chronotypes and 12.0% of intermediate chronotypes reporting sleepiness, versus 3.7% of morning types.

Somatic and cognitive PSAS were more prevalent among evening chronotypes, with 71.3% of evening types reporting somatic arousal compared to 48.1% of morning types, and cognitive arousal was higher in evening types (25.8 ± 7.6) compared to intermediate (20.8 ± 7.2) and morning types (17.3 ± 7.2). Total PSAS score was also higher for evening chronotypes.

Evening chronotypes also reported the highest total stress levels, with a Total SLSI score of 141.9 ± 28.3 , significantly higher than intermediate types (141.9 ± 28.3) and morning types (123.9 ± 28.2). In the total sample ($n = 345$), significant correlations were found between daytime sleepiness (ESS) and somatic PSAS ($r = 0.442$, $p < 0.001$), and between cognitive PSAS and overall stress ($r = 0.519$, $p < 0.001$).

In evening chronotypes ($n = 92$), significant correlations between somatic and cognitive PSAS ($r = 0.529$, $p < 0.001$) and total pre-sleep arousal ($r = 0.755$, $p < 0.001$) indicated that both somatic and cognitive PSAS contribute to sleep difficulties. No significant correlations were found between chronotype and overall stress in individual groups, suggesting that while evening types report higher stress, other factors also contribute to stress perception.

Conclusions: The results show that evening chronotypes are more vulnerable to both sleep problems and stress-related problems. The results highlight the important role of chronotype, especially evening chronotype, in exacerbating sleep problems and stress in international students. The study provides further evidence for the need for interventions for international students and specific coping strategies tailored to chronotype preferences to reduce stress and improve sleep quality, especially for evening chronotypes who are at higher risk of adverse health outcomes.

Acknowledgments: We are grateful to the volunteers for their participation.

Introduction: Chronotype reflects one's innate preference for specific periods of the daily 24-hour cycle for rest and activity, and varies between individuals. Cross-sectional studies show that chronotype is ontogenetic and varies between age groups. However, longitudinal studies examining the temporal stability of chronotype are scarce, especially during childhood when significant developmental changes occur. Moreover, the relationship between chronotype stability and sleep remains unclear. Our study addresses these research gaps by investigating chronotype stability between preschool- and school-age, and its association with sleep problems.

Materials and methods: Data were drawn from 256 children in the Growing Up in Singapore Towards healthy Outcomes (GUSTO) birth-cohort study. Chronotype was assessed at 4.5 and 8 years old using

the Children's Chronotype Questionnaire (CCTQ). The CCTQ provides an overall morningness/eveningness (M/E) score, with higher scores representing greater eveningness and lower scores representing greater morningness. To examine the change in chronotype between timepoints, we calculated chronotype delta by subtracting M/E scores at 4.5 years old from the repeat measurement at 8 years old. Sleep problems were evaluated at 8 years old using the Children's Sleep Habits Questionnaire (CSHQ). The CSHQ measures total sleep problems by summing subscale scores for Bedtime Resistance, Sleep Onset Delay, Sleep Duration, Sleep Anxiety, Night Wakings, Parasomnias, Sleep Disordered Breathing and Daytime Sleepiness. Both measures were parent-reported. We performed Pearson's correlation analysis and calculated an intraclass correlation coefficient to examine the stability of M/E scores between preschool- and school-age. Linear regressions were conducted to examine the association between chronotype delta and sleep problems measured on the CSHQ.

Results: M/E scores showed moderate test-retest reliability ($r=.60, p<.001$) and stability ($ICC=.59$) between 4.5 and 8 years old. Mean M/E scores at 4.5 and 8 years old were 30.45 ± 5.60 and 28.94 ± 5.19 respectively. The t -test revealed a slight but significant shift towards morningness at school-age ($t(255)=5.05, p<.001$). Chronotype delta among individual subjects ranged between -19 to 14 points. Linear regressions revealed that chronotype delta was associated with daytime sleepiness ($B=.181, 95\% \text{ CI}:.094 \text{ to } .268, p<.001$) and total sleep problems ($B=.257, 95\% \text{ CI}:.084 \text{ to } .430, p=.004$). These results suggest children who experience shifts towards eveningness between preschool- and school-age are susceptible to adverse sleep problems at school-age.

Conclusions: Our results indicate overall moderate stability of chronotype in children as they transition from preschool to primary school. The shift towards morningness at 8 years old may potentially be accounted for by early primary school schedules in Singapore, and suggests amenability of chronotype. Moreover, we observed individual variability in chronotype stability, with shifts towards eveningness linked to daytime sleepiness and total sleep problems. Better understanding of individual differences in chronotype stability may facilitate identifying children at greater risk for sleep problems and inform preventive strategies.

Circadian Amplification in Diabetic Retinopathy: A Pilot Study

S. Reutrakul¹, J. Duffecy², K.G. Baron³, S. Pratuangtham⁴, E. Van Cauter⁴, J.C. Park⁴, F.Y. Chau², K.K. Danielson², M. Priyadarshini², A. Cross², J. Law², E.C. Hanlon⁴, J.J. McAnany²

¹University of Illinois Chicago, Medicine, Chicago, United States, ²University of Illinois Chicago, Chicago, United States, ³University of Utah, Salt Lake City, United States, ⁴University of Chicago, Chicago, United States

Introduction: Diabetic Retinopathy (DR) affects more than 450 million individuals worldwide. Emerging data suggests that type 2 diabetes (T2D) with DR is associated with a dysregulated 24-h melatonin rhythm, likely due to a loss of intrinsically photosensitive retinal ganglion cells, a crucial component for circadian entrainment. The lack of strong photic synchronizers in T2D with DR is associated with significant sleep disturbances, particularly irregular sleep, which was linked to increased systemic inflammation. This pilot study explored the effects of "Amplify-RHYTHM", a novel intervention to regularize sleep timing and strengthen photic circadian cues, on sleep, circadian and cardiometabolic outcomes in T2D with DR.

Materials and methods: Eight T2D persons (5M/3F) with DR participated in a 6-week "Amplify-RHYTHM" intervention (NCT06183476) consisting of two components: 1. sleep regularization (remote weekly coaching aiming at keeping bedtimes and wake times within a 60-min window with 7-9 hours of time in bed, verified by an activity monitor (Fitbit®), and educational content), and 2. timed light exposure (30-minute morning light exposure via Luminette® glasses, evening blue light blocking glasses for 2 hours before bedtime, and sleep mask at night). Study measures were collected at baseline and during last 2 weeks of the intervention. Primary outcomes were insomnia symptoms and 14-day actigraphy-derived sleep parameters. Circadian related parameters included rest-activity rhythm

parameters, dim light melatonin onset (n=5) from home saliva samples, and overnight urinary 6-sulfatoxymelatonin (aMT6s) secretion. Cardiometabolic parameters included mean glucose level from 14-day continuous glucose monitor (CGM), high sensitivity c-reactive protein (hs-CRP), blood pressure and heart rate. Satisfaction (scale 1-7) was collected. Statistical analysis was performed using paired t-test or Wilcoxon signed rank test.

Results: Mean (SD) age was 57.2 (5.6) years, and mean HbA1C was 7.5 (0.8)%. Compared to baseline, after Amplify-RHYTHM intervention, insomnia symptoms significantly decreased 2.50 (1.92) vs. 4.25 (2.49), $p=0.041$. Sleep regularity improved as there was a reduction in variation of sleep midpoint; 0.90 (0.27) vs. 1.33 (0.39) h, $p=0.018$. Sleep efficiency trended toward significant improvement ($p=0.075$) while sleep duration did not change. For rest-activity parameter, intra-daily variability significantly reduced, 0.82 (0.13) vs. 0.95 (0.21), $p=0.049$, suggesting less fragmentation of rest-activity rhythm, while relative amplitude and inter-daily stability did not change. Urinary aMT6s remained low, 6.3 (7.6) vs. 5.7 (5.6) ng/mg, $p=0.600$, and DLMO pattern did not change. For cardiometabolic parameters, hs-CRP was significantly reduced, 1.58 (2.29) vs. 2.36 (3.3) mg/L, $p=0.011$, and heart rate tended to decrease ($p=0.065$), while there was no significant change in mean glucose level from CGM or blood pressure. Participants found that Amplify-RHYTHM was easy to implement (a mean score of 6.63) and overall satisfaction was high (a mean score of 5.88). One person experienced progression of DR deemed to be related to baseline DR severity.

Conclusions: Amplify-RHYTHM, a novel intervention to enhance sleep and circadian regulation in persons with T2D with DR, resulted in positive health outcomes including less severe insomnia symptoms, more regular sleep, reduced behavioral circadian fragmentation, and reduced systemic inflammation. These emerging data should be confirmed in a larger, randomized study.

Circadian Rhythm Dysregulation in patients with bipolar disorder: correlations with Inflammatory markers and suicidal risk

L. Palagini¹, G. Grenno², G. Aquino², G. Alfi², A. Gemignani²

¹University of Pisa, Department of Neuroscience, Section of Psychiatry, Pisa, Italy, ²University of Pisa, Department of Surgical, Medical, Molecular, and Critical Area Pathology, Pisa, Italy

Introduction: Bipolar disorder is a chronic and disabling psychopathological condition that is associated with a significant risk of suicide, possibly resulting from the interaction of genetic and environmental factors. It is considered a priority to improve our understanding of the mechanisms involved in the development and maintenance of Bipolar Disorder in order to identify early markers that may help in screening, diagnosing, and treating strategies. Evidence suggests that Bipolar disorder is also associated with alterations in the circadian system. According to the "circadian hypothesis of mood disorders," mood symptoms would be caused by the misalignment of the circadian system due to the desynchronization of the master biological clock of the hypothalamus, i.e., the suprachiasmatic nucleus. Recent years have seen a growing body of evidence suggesting a potential link between the immune system, and more broadly, inflammation, and mood disorders. Given that sleep plays a pivotal role in regulating inflammatory indices it is plausible that sleep disorders may contribute to inflammation and dysregulation of neuroendocrine systems that promote bipolar disorder as well. This study aimed to assess the correlations between circadian rhythm alterations and inflammatory markers in patients with bipolar disorder

Materials and methods: A consecutive series of patients who were hospitalized at the Psychiatric Unit, University of Pisa Italy, with a diagnosis of Bipolar Disorder type I and II according to DSM-5-TR were evaluated. All participants were clinically assessed with a set of questionnaires that included the assessments of circadian rhythm disorders during the previous two weeks with the Biological Rhythms Interview of Assessment in Neuropsychiatry (BRIAN) depressive, manic symptoms and suicidal risk with the Beck Depression Inventory (BDI-II), the Young Mania Rating Scale (YMRS) the Scale for Suicide Ideation (SSI). Inflammatory parameters, including the Neutrophil-Lymphocyte Ratio (NLR), Platelet-Lymphocyte Ratio (PLR), and Systemic Inflammation Index (SII), were also measured at the time of the evaluation.

Results: The final sample consisted of 103 individuals. Patients who experienced circadian rhythms alterations during the previous two weeks demonstrated higher suicidal risk, more severe depression, and showed elevated levels of inflammatory markers. Logistic regression analysis indicated that suicidal

risk was predicted by circadian rhythm disturbances (OR=7.64, 95% CI 1.92-27.86, $p=0.005$), and inflammation indices such as NLR (OR=4.00, 95% CI 1.14-13.99, $p=0.030$). Mediation analyses showed that inflammation indices played a mediation role between circadian dysregulation and suicidal risk.

Conclusions: Chronobiological alterations directly contributed mood symptoms and suicidal risk. Chronobiological alterations may be impacted on inflammatory system hence indirectly contributing to bipolar disorder severity and suicidal risk. These findings call for the systematic screening of these dysrhythmicity dimensions when considering suicidal risk in individuals with Bipolar disorder.

Introduction: Shift work is common and in a quarter of individuals leads to a diagnosis of shift work disorder (SWD), characterized by excessive sleepiness accompanied by short sleep duration and/or insomnia. While more individuals work early morning shifts than overnight shifts, few studies have investigated this population. We aimed to evaluate the efficacy of solriamfetol for the treatment of excessive sleepiness during workdays in participants with SWD who work early-morning shifts.

Materials and methods: We conducted a randomized, double-blind, placebo-controlled 4-week clinical trial in early morning shift workers (shift start 3-7AM). Participants who reported excessive sleepiness and were at high risk for SWD as determined by a SWD questionnaire were selected. Following screening and 2 weeks of baseline, participants were randomized into 4 weeks of placebo or solriamfetol (150mg taken after waking on workdays). Outcome measures included severity of illness as measured with Clinical Global Impression of Severity (CGI-S) scale, global functioning, daily activity and work productivity impairments as measured with Sheehan Disability Scale (SDS) and Work Productivity and Activity Impairment-Specific Health Problem (WPAI:SHP) scale with excessive sleepiness as the specific health problem, and objective sleep duration or sleep quality as assessed with actigraphy-derived total sleep time and sleep fragmentation index from the main sleep episodes. Mixed-effects and logistic regression models were used to analyze the data.

Results: 74 participants completed the study (median age 37 [28-46]; 27 females); 38 in the solriamfetol group and 36 in the placebo group. A significantly greater percentage of participants treated with solriamfetol showed improvement on CGI-S compared to those who received placebo (76% vs. 53%, OR=2.8, 95% CI 1.0-7.5, $p=0.04$). Patients treated with solriamfetol reported greater improvement in global functioning (SDS: -3.7, $p=0.04$) as well as in daily activity and work productivity impairments due to excessive sleepiness (WPAI-overall work impairment: -16.7, $p=0.03$; productivity impairment: -15.5, $p=0.03$; activity impairment: -16.9, $p=0.01$). There was no significant difference between the groups on sleep duration or sleep fragmentation assessed with actigraphy (all p -values >0.05).

Conclusions: Solriamfetol significantly reduced the severity of illness and improved subjective functioning compared to placebo in participants with SWD who work early-morning shifts.

Comparative Analysis of Mid-Sleep Point Calculation Methods Using Actigraphy: Relationship with Sleep Quality and Chronotype

S. Ceccanti^{1,2}, F. Cruz Sanabria³, S. Bruno⁴, M. Di Galante⁵, U. Faraguna^{1,3}

¹University of Pisa, Department of Translational Research and of New Surgical and Medical Technologies, Pisa, Italy, ²University of Verona, Department of Neuroscience, Biomedicine and

Movement Sciences, Verona, Italy, ³IRCCS Fondazione Stella Maris, Department of Developmental Neuroscience, Pisa, Italy, ⁴University of Wisconsin–Madison, Department of Psychiatry, Madison, United States, ⁵Sleepacta srl, Montacchiello, Italy

Introduction: The mid-sleep point (MSP) is a widely used marker of circadian phase and sleep timing in chronobiological research, particularly useful in non-invasive field studies. However, different calculation approaches can yield divergent MSP values, potentially influencing their associations with sleep quality and chronotype. This study aimed to: (1) compare two MSP calculation methods: $MSP_1 = \text{Sleep Onset} + (\text{Total Sleep Time} / 2)$ and $MSP_2 = \text{Sleep Onset} + ((\text{Sleep Offset} - \text{Sleep Onset}) / 2)$, where $(\text{Sleep Offset} - \text{Sleep Onset})$ represents the total Time in Bed; (2) examine how the selected method influences the relationship between MSP and subjective sleep quality; (3) assess the role of chronotype in moderating discrepancies between the two methods.

Materials and methods: 400 healthy adults (54% female; mean age = 29.91 years, SD = 13.36), contributing a total of 2420 single nights of sleep data, were included. Sleep was recorded using actigraphy, providing parameters including Total Sleep Time (TST), Sleep Efficiency (SE), Wake After Sleep Onset (WASO), and sleep onset/offset times. Subjective sleep quality was assessed using the Pittsburgh Sleep Quality Index (PSQI), and chronotype was determined through the reduced Morningness-Eveningness Questionnaire (rMEQ). Two mid-sleep point values (MSP_1 and MSP_2) were calculated from actigraphic data. Agreement between the methods was evaluated through Bland-Altman plots and mixed-effects linear regression models, with age, gender, WASO, SE, PSQI, and chronotype as predictors.

Results: Data showed a mean TST of 7.23 hours (SD = 1.09), SE of 90.81% (SD = 6.97), and a PSQI score of 5.19 (SD = 2.39), with 39% of the sample classified as poor sleepers (PSQI > 5). Chronotype distribution included 269 neither-types, 71 evening-types, and 60 morning-types. The two MSP methods generally showed close agreement, with differences clustering around zero. For participants with WASO < 30 minutes, Bland-Altman analysis indicated minimal bias and narrow limits of agreement, suggesting high consistency between MSP_1 and MSP_2 . However, mixed-effects modeling revealed that WASO ≥ 30 minutes was significantly associated with greater discrepancy between methods ($\beta = 30.11$, $p < .001$), highlighting the influence of fragmented sleep on MSP computation. Gender also emerged as a significant predictor, with males exhibiting slightly higher MSP discrepancies ($\beta = 2.35$, $p = .001$). Conversely, M-types and N-types showed significantly smaller discrepancies compared to E-types ($\beta = -5.01$, $p = .022$; $\beta = -5.76$, $p < .001$, respectively). No significant difference in MSP discrepancy was observed between good and poor sleepers as classified by PSQI ($p = 0.287$).

Conclusions: The choice of computational method for determining the mid-sleep point yields largely comparable results under conditions of consolidated sleep but diverges meaningfully in the presence of increased WASO. These findings underscore the critical importance of considering sleep continuity characteristics and individual circadian profiles when selecting MSP calculation methods in both research and clinical practice, particularly given the divergence observed in fragmented sleep. While a 30-minute cutoff for WASO was adopted, future research should identify the precise WASO threshold for significant divergence and, critically, determine which method provides the most reliable MSP estimates for individuals with fragmented or poor sleep.

Darkness Metaphors for Depression: A Case of Impaired Non-Visual Photoreception?

M. Burge^{1,2}, E. McGlashan³, S. Sargeant⁴, A. Phillips², S. Cain²

¹Monash University, Melbourne, Australia, ²Flinders University, Adelaide, Australia, ³Melbourne University, Melbourne, Australia, ⁴Southern Cross University, Lismore, Australia

Introduction: The use of darkness language to describe depression is both ancient and cross-cultural, appearing in linguistic expressions from Japanese (*kurai*, meaning depressed mood and physical darkness), Greek (*melaina chole*, "black bile"), and Mesopotamian texts (*tādirtu*, meaning both melancholy and physical darkness). Foundational metaphors originate from the systematic pairing of sensory experiences with specific emotion states. We propose that darkness metaphors for depression likely stem from a neurobiological basis: individuals currently experiencing depression show impaired non-visual photoreception, unlike those with only a history of depression who maintain normal light sensitivity. This impairment in the brightness detection system during depressive states potentially forms a neurobiological basis for the metaphorical experience of 'darkness' in depression. We

investigated: (i) whether depression symptom severity predicts metaphorical language, including darkness metaphors, and (ii) the relative predictive capacity of darkness metaphors for depression symptom severity compared to anxiety, insomnia and eveningness.

Materials and methods: A global online survey captured participants' free-text descriptions of depression between 2020-2021. Participants with diagnosed or suspected depression completed the DASS-21, Morning-Eveningness Questionnaire, and Insomnia Severity Index (N=488). Using Braun & Clarke's thematic analysis approach, we identified metaphor types and constructed dictionaries of terms for darkness, descent (e.g. "feeling down"), and weight (e.g. "burdened") metaphors. Logistic and linear regression models examined relationships between metaphor use and depression severity.

Results: Higher depression scores predicted the higher likelihood of using darkness language (OR = 1.40, 95% CI [1.02, 1.93], $p = .039$), with each standard deviation increase in depression scores (~12 points) predicting higher likelihood of using darkness metaphors by 40%. Darkness language significantly improved prediction of extremely severe depression symptoms beyond an initial model including only anxiety, insomnia, and chronotype ($\chi^2(1) = 10.22$, $p = .001$). Darkness language predicted the risk experiencing extremely severe depression group by 250% (OR = 2.50, 95% CI [1.42, 4.47], $p = .002$), a larger effect than standard deviation increases in anxiety (OR = 2.15), insomnia (OR = 1.47), or morningness (OR = 0.66). Depression scores were not related to the use of descent or weight language.

Conclusions: Darkness metaphors uniquely contribute to identifying extremely severe depression symptoms beyond established correlates such as anxiety, insomnia, and eveningness. Our findings demonstrate that extremely severe depression specifically relates to darkness metaphors rather than to metaphorical language broadly. This suggests that as depression becomes more severe, the subconscious pairing of darkness with emotional state becomes more salient in how individuals conceptualise their experience. Given that individuals currently experiencing depression have impaired non-visual photoreception sensitivity, their heightened use of darkness metaphors may represent an implicit recognition of how this sensory impairment shapes their emotional experience. The stronger association between darkness language and extremely severe depression compared to other predictors points to potential clinical utility in using linguistic markers to differentiate depression severity levels. These results support investigating whether variations in non-visual photoreception sensitivity influence the propensity to use darkness metaphors in describing depression.

Acknowledgments: This work would not be possible without input from the lived experience of our participants.

Developing a Pragmatic Online Behavioural Intervention for Shift Work Disorder in NHS Staff

F.T.W. Cheung¹, R. Sharman¹, D. Gavriloff¹, T. Sugavanam^{2,3}, L. Holmes⁴, A. Keane⁴, C.A. Espie¹, A.C. Reynolds⁵, D. Ray^{2,3}, S.D. Kyle¹

¹University of Oxford, Sir Jules Thorn Sleep and Circadian Neuroscience Institute, Nuffield Department of Clinical Neurosciences, Oxford, United Kingdom, ²University of Oxford, Oxford Centre for Diabetes, Endocrinology and Metabolism, Radcliffe Department of Medicine, Oxford, United Kingdom, ³John Radcliffe Hospital, NIHR Oxford Biomedical Research Centre, Oxford, United Kingdom, ⁴Manchester University Foundation Trust, Vocal, Manchester, United Kingdom, ⁵Flinders University, Flinders Health and Medical Research Institute (Sleep Health), Adelaide, Australia

Introduction: Shift work disorder (SWD), characterised by complaints of insomnia and excessive daytime sleepiness attributed to shift work, affects around 27% of workers. SWD is often associated with poorer physical and mental health. Cognitive behavioural therapy for insomnia (CBT-I) has shown suboptimal results in achieving clinically significant changes in insomnia symptoms among shift workers. This suggested that a more tailored behavioural approach, addressing the insomnia symptoms and daytime sleepiness associated with SWD, may be beneficial. This study outlines the development process of a novel, online, and pragmatic behavioural intervention for shift workers employed by the National Health Service (NHS) in England.

Materials and methods: The Oxford Behavioural Intervention for Shift workers (OxBIS) has been co-developed by researchers and individuals with lived experience of shift work. A four-member core intervention development team, consisting of sleep and circadian scientists and a clinical psychologist, reviewed existing literature and drew upon clinical experiences from working with shift workers to inform the development process. Patient and public involvement have been integral throughout the development, with 10 diverse individuals with lived experience forming the NHS Nightshift Workers

Research Advisory Group (RAG). The RAG held regular meetings to provide advice on intervention development, specifically regarding content and delivery. Additionally, the RAG was responsible for testing content materials and providing feedback and suggestions.

Results: Seven meetings were held with the RAG members, shaping the three iterations of the intervention. Their firsthand experience as NHS shift workers provided valuable insights into the realities of shift work culture. The resulting OxBIS programme consists of six one-to-one sessions lasting 1-1.5 hours, to be delivered online by trained facilitators. Key intervention targets include enhancing sleep and circadian knowledge, optimising the sleep-wake schedule, scheduled light exposure and blockade, adjusting lifestyle factors, implementing stimulus control, and managing maladaptive sleep-related thoughts using cognitive strategies. Their feedback was crucial in the intervention development. The RAG members supported content refinement, ensured appropriate terminology throughout the materials, contributed to the creation of a shift worker-specific sleep diary, prioritised suitable outcome measures, and advised on practical and logistical considerations, such as recruitment strategies.

Conclusions: The OxBIS intervention reflects a comprehensive and tailored approach for addressing behavioural, circadian, and lifestyle factors that perpetuate SWD. Co-development with individuals who have lived experience ensures that the intervention is patient-centred and focused on the specific needs of shift workers in the NHS. A feasibility and acceptability trial for the OxBIS intervention is currently underway (Ref: PID 18679). The trial aimed to provide empirical evidence on its suitability and inform future implementation.

Acknowledgments: Our thanks go to RAG members for their expert input and insights. This work was supported by the National Institute for Health and Care Research (NIHR) Programme Grants for Applied Research awarded to DR (Ref: NIHR203667). RS and SDK are supported by the NIHR Oxford Health Biomedical Research Centre grant (Ref: NIHR203316).

Differences in sleep and circadian health in short-sleeping adolescents with and without *MTNR1B* risk variant rs10830863

S.L. Simon^{1,2}, E. Cooper¹, J.T. Brinton¹, A. Bernard², S. Holtman¹, M.G. Cree^{1,2}, K.J. Nadeau^{1,2}, K.P. Wright Jr^{3,4}, A. Smolen⁵, D.A. Evans⁵, M.A. Ehringer^{3,5}

¹University of Colorado Anschutz Medical Campus, Pediatrics, Aurora, United States, ²Children's Hospital Colorado, Aurora, United States, ³University of Colorado Boulder, Integrative Physiology, Boulder, United States, ⁴University of Colorado Anschutz Medical Campus, Medicine, Aurora, United States, ⁵University of Colorado Boulder, Institute for Behavioral Genetics, Boulder, United States

Introduction: The melatonin receptor 1b gene (*MTNR1B*) risk variant rs10830963 (C/G; ~20-30% minor allele frequency) is an independent risk factor for type 2 diabetes and has been associated with extended duration of endogenous melatonin production with later morning melatonin offset (dim light melatonin offset, DLMO_{off}) in adults. However, the functional impact of the variant is not well understood, and adolescents have been underrepresented in this research. The goal of the current study was to examine differences in sleep and circadian health in adolescents with and without the *MTNR1B* risk variant.

Materials and methods: Thirty-seven adolescents with <7h sleep/night participating in a larger randomized clinical trial on cardiometabolic health consented to optional genotyping procedures. Of these, 27 samples were able to be analyzed using a Taqman assay (age=16.1±1.2, 85.2% female, 77.8% non-Hispanic White, BMI_{ile}=57.6±28.1). Participants completed in-home actigraphy monitoring during one week of typical sleep during the academic year followed by an overnight in-lab study visit with AM and PM serial salivary dim-light melatonin sampling and an intravenous glucose tolerance test to measure insulin sensitivity (Si). Summary measures are reported for those with and without the risk variant (GG/GC vs. CC) as median [interquartile range]. Wilcoxon, chi-squared or Fisher's exact statistics tested for differences between groups.

Results: 52% had the G allele (GG n=4, or GC n=10) while 48% (n=13) did not (CC). Participants with the risk variant compared to those without had shorter sleep onset latency (5.3min [3.8,8.8] vs. 10.0min [7.6,13.8]; p=0.01) and greater variability in bedtime (1.1h [0.8,2.9] vs. 0.6h [0.5,0.7]; p=0.007) and sleep midpoint (1.1h [0.7,2.4] vs. 0.5h [0.4,0.8]; p=0.02) across the home monitoring week. Those with the risk variant trended towards earlier dim light melatonin onset (DLMO_{on}; 20:06 [19:36,20:30]

vs. 21:06 [20:54,21:06]; $p=0.05$). There were no differences between groups for sleep duration, waketime, DLMOff, melatonin duration, or Si.

Conclusions: In this sample of habitually short-sleeping adolescents, those with at least one copy of the *MTNR1B* risk (G) variant had some differences in sleep and circadian rhythms compared to those without, but findings are limited due to the small sample size. Further research in larger and more diverse samples is recommended.

Differential Light-Induced Phase Shifts in the Circadian Rhythms of Cardiovascular Autonomic Function in Hypertensive and Normotensive Rats

K.-C. Huang¹, G.-T. Huang², Y.-C. Hsiao³, C.-H. Wu^{3,4}, C.-W. Chen^{4,5,6}

¹Department of Applied Physics, National University of Kaohsiung, Kaohsiung, Taiwan, ²School of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan, ³National Taipei University of Nursing and Health Sciences, Department of Information Management, Taipei, Taiwan, ⁴Sleep Research Center, National Yang Ming Chiao Tung University, Taipei, Taiwan, ⁵Institute of Neuroscience, National Chengchi University, Taipei, Taiwan, ⁶Research Center for Mind, Brain and Learning, National Chengchi University, Taipei, Taiwan

Introduction: Previous clinical studies have found that shift workers with abnormal blood pressure are at risk of cardiovascular disease. However, there is still a lack of integrated studies to discuss the pathophysiological mechanisms associated with abnormal circadian rhythms in shift work and jet lag, and the pathophysiological effects of combined hypertension. Therefore, this study aims to investigate the differential changes of various physiological signals in normotensive Wistar-Kyoto rat (WKY) and spontaneously hypertensive rat (SHR) during and after light-induced phase shift process by using the established wireless multi-channel physiological recorder.

Materials and methods: We recorded physiological signals from WKY and SHR rats over 17 consecutive days before, during, and after a light-dark cycle phase-shift intervention, and analyzed the circadian rhythms of the brain waves, sleep architecture, and cardiovascular parameters using various linear methods.

Results: It was found that the blood pressure, heart rate, and cardiovascular autonomic function of both WKY and SHR rats were affected by the phase shift of the light-dark cycle, with changes in the phase and amplitude of their circadian rhythms. Compared with WKY rats, the acrophase of blood pressure and vascular sympathetic function in SHR was more profoundly affected by the light-induced phase shift. Moreover, the amplitude of the circadian rhythm was smaller in SHR than in WKY. In addition, the circadian rhythms of R-R intervals, as well as cardiac parasympathetic and sympathetic functions, were more significantly altered by the light phase shift in SHR, exhibiting greater phase shifts, increased frequency, and reduced amplitude.

Conclusions: Compared to normotensive individuals, those with hypertension may be more susceptible to the adverse effects of jet lag or shift work on cardiovascular function.

Dim light melatonin onset is later in post-menopausal women following Breast Cancer compared with controls

H. Subramanian^{1,2}, V. Fuchsova¹, H. Man¹, R. Trivedi¹, E. Elder^{3,4,2}, S. Cain^{5,6}, T. Amis^{1,2,4}, K. Kairaitis^{1,2,4}

Introduction: One year after treatment for breast cancer, >80% post-menopausal women in remission from breast cancer complain of poor sleep-quality, which may be a consequence of circadian misalignment. The aim of this study was to compare central circadian timing via nocturnal melatonin-secretion, in post-menopausal women in remission from breast cancer (≥ 12 -months) (BCG), with age-matched post-menopausal women with no cancer history (CG).

Materials and methods: Participants were recruited from outpatient breast cancer clinics (BCG: $n=6$) or the community (CG: $n=10$). Sleep and psychological symptoms were assessed using the Pittsburgh Sleep Quality Index (PSQI), Insomnia Severity Index (ISI), Epworth Sleepiness Scale (ESS) and the Depression, Anxiety, Stress Scale (short form; DASS-21). Habitual bedtime (HBT) was quantified using actigraphy (7 days). Overnight in-laboratory polysomnography was performed, and saliva samples collected under strict lighting conditions (<1 Lux; 13 samples in total) 5 hours prior to HBT until 2 hours after habitual wake time. Salivary melatonin was quantified by radioimmunoassay. Individual melatonin profiles were analysed for the; (1) Clock-time when melatonin concentrations reached 4pg/mL (DLMO), (2) Area under the melatonin curve (AUC), and the Time-interval between HBT and DLMO (PA). Group data were summarised as median (interquartile range) and compared through 2-sided Mann-Whitney U-tests. $p < 0.05$ indicated statistical significance.

Results: There were no significant differences ($p > 0.20$) in age (BCG: 62.5 (59.5-67.3) vs. CG: 58.5 (54.0-66.3) years), body-mass indices (BCG: 28.0 (24.0-30.5) vs. CG: 25.1 (22.1-29.9) kg/m²) or HBT (BCG: 22:49 (21:46-23:38) vs. CG: 22:16 (21:59-22:21)). Neither group had evidence of negative emotional state (DASS-21; BCG: 8.5 (2.8-9.5) vs CG: 5.0 (2.8-9.0) au), sleepiness (ESS; BCG: 8.0 (5.0-9.0) vs. CG: 3.5 (1.8-6.3) au) or severe obstructive sleep apnoea (OSA) (Apnoea-hypopnoea index; BCG: 9.0 (6.6-10.3) vs. CG: 6.9 (2.4-21.3) events/hr), all having $p > 0.10$. Compared to CG, BCG tended to have higher PSQI (BCG: 8.5 (5.3-10.8) vs. CG: 4.0 (3.8-5.5) au; $p=0.07$) and ISI scores (BCG: 10.5 (5.5-17.3) vs. CG: 5.5 (3.8-8.0) au; $p=0.07$), lower AUC (BCG: 97.3 (83.7-125.0) vs. CG: 170.8 (96.6-250.3) pg/mL; $p=0.09$), and shorter PA (BCG: 1.4 (1.0-2.4) vs CG: 3.6 (2.2-3.9) hrs; $p=0.09$). BCG had significantly delayed DLMO compared to CG (20:46 (20:01-22:03) vs 18:40 (17:55-20:07); $p=0.03$).

Conclusions: In this small cohort, in the absence of severe OSA, negative emotional state or sleepiness, post-menopausal women in remission from breast cancer tended to report poorer sleep-quality, increased insomnia symptoms, with lower overnight melatonin secretion, altered circadian-sleep alignment, and a significantly delayed melatonin onset. We speculate poor sleep-quality and insomnia symptoms following breast cancer treatment attribute to circadian-sleep misalignment from delayed central circadian timing.

Disease-Based Chronoseasonal Patterns in Emergency Department Visits Reflecting Traditional and Emerging Trends

J.J. Lee¹, H. Jo², D. Kim², H. Bae², P. Song³, J.H. Kim²

¹Ewha Womans University, Data Science, Seoul, Korea, Republic of, ²Ewha Womans University Seoul Hospital, Neurology, Seoul, Korea, Republic of, ³Inje University College of Medicine, Ilsan Paik Hospital, Neurology, Ilsan, Korea, Republic of

Introduction: Seasonal variation in emergency department (ED) visits reflects underlying chronobiological rhythms shaped by environmental exposures, temporal patterns in disease incidence, and healthcare utilization behaviors.

In recent years, global shifts in climate and human behavior have raised questions about the consistency of these seasonal trends. This study investigated whether traditional seasonal patterns in ED utilization have continued across different disease categories and age groups.

Materials and methods:

We retrospectively analyzed 420,000 ED visits from two regional hospitals in Korea (2020–2024). Patients were stratified into three age groups (pediatric, adult, older adults), and symptoms/diagnoses were mapped to clinically relevant categories based on ICD codes, with expert-reviewed reclassification by organ system. To model seasonal trends, we used generalized additive models with quasi-Poisson distribution and cyclic cubic splines for month, adjusting for year, hospital, age, and sex.

We fitted a quasi-Poisson model with cyclic splines for months that varied by age group, and used a Wald test to assess differences in seasonality across age groups. Relative risks were calculated relative to the trough month, and the peak-to-trough ratio (PTR) was defined as the ratio of the peak to the trough predicted count.

Results: From 2020 to 2024, the mean age and proportion of elderly ED visitors steadily increased (46.66 to 50.55 years; 26.1% to 35.8%). Seasonal variation was most pronounced in pulmonary and infectious diseases, with peaks in January and July, respectively (PTR = 1.58 and 1.46). Notably, this seasonal pattern was attenuated during the early COVID-19 period and gradually recovered in subsequent years, likely reflecting the impact of public health measures such as mask-wearing and social distancing. Orthopedic and trauma surgery showed summer peaks in June and August, respectively (PTR = 1.27 and 1.40). Acute cardiovascular events, including myocardial infarction and stroke, did not show apparent seasonal variation in our data. In general, seasonal variation was attenuated in older adults compared to younger ones, possibly due to a smaller sample size. However, nephrology-related visits were significantly more common among older adults. No nocturnal or diurnal differences were observed in the ED presentation of any symptoms or diseases.

Conclusions:

This study demonstrates that seasonal variation in emergency care differs by disease and age group. Pulmonary and infectious diseases maintain consistent seasonal patterns, while trauma and cardiovascular conditions display altered or absent seasonality compared to traditional reports. The attenuation and partial recovery of seasonality during the COVID-19 period highlight the influence of behavioral and environmental factors on temporal disease dynamics. Reduced seasonal variation in older adults, with a disease-specific exception, warrants further investigation with a larger sample. These findings underscore the complexity of seasonal rhythms in emergency care and the importance of considering demographic and environmental contexts in temporal analyses.

Acknowledgments: No acknowledgments to declare.

Diurnal light exposure and circadian rest-activity rhythms with the risk of metabolic dysfunction-associated fatty liver disease

X. Tan^{1,2}, H. Wu²

¹Karolinska Institutet, Clinical Neuroscience, Stockholm, Sweden, ²Zhejiang University School of Public Health, Big Data in Health Science, Hangzhou, China

Introduction: Metabolic Dysfunction-Associated Fatty Liver Disease (MASLD) is the most prevalent liver disease worldwide, affecting approximately 32% of the population. Despite the lack of approved therapies or specific pharmacological treatments for MASLD, prevention has become the primary focus of its management, particularly identifying and addressing modifiable risk factors. The circadian clock regulates various hepatic functions, including glucose, triglyceride, and cholesterol metabolism, and disruptions in circadian rhythms are associated with metabolic disorders and exacerbated liver pathologies. However, research examining the relationship between objectively measured circadian rhythm disruptions and MASLD remains limited.

Materials and methods: This prospective cohort study utilized seven days of accelerometer data from the US National Health and Nutrition Examination Survey (NHANES) and UK Biobank. The primary objective was to explore the associations between 24-hour light exposure, circadian rest-activity rhythm (CRAR), and the risk of incident MASLD. We also assessed the impact of light exposure and CRAR on genetic risk and their effects on life expectancy in individuals with MASLD. The analysis focused on five CRAR parameters, including the average activity levels during the least active (L5) and most active (M10) periods, relative amplitude (RA), and the onset times of L5 and M10. Daylight and nighttime light exposures were categorized based on intensity thresholds. We employed Cox regression models to estimate hazard ratios (HRs) for incident MASLD, and subgroup analyses were conducted to assess interactions by polygenic risk, age, and sex.

Results: The study included 7,253 participants from NHANES and 91,349 participants from the UK Biobank, with a median follow-up of 7.93 years. In the UK Biobank prospective analysis, higher RA and M10 levels were associated with a 46% and 37% reduced risk of MASLD, respectively, compared to

the lower group. Higher L5 levels and delayed L5 onset were linked to a 59% and 21% increased risk of MASLD. Moreover, each additional hour of daylight exposure above 6000 lux was associated with a 9% lower risk of MASLD, while each additional 30 minutes of nightlight exposure above 30 lux corresponded to a 22% higher risk of MASLD. Similar associations were observed for fibrosis and cirrhosis risk. Additionally, individuals with optimal CRAR and light exposure had a greater life expectancy compared to those with poor rhythms and light exposure.

Conclusions: This study provides robust evidence that disruptions in circadian rest-activity rhythms and light exposure are associated with an increased risk of MASLD. Our findings highlight the potential of managing circadian behaviors and environmental cycles as an approach to prevent MASLD and other chronic liver diseases.

Diurnal preferences and mental health in dermatological diseases: Population-based evidence from the EPISONO cohort

M.R. Souza^{1,2}, E.M.S. Xerfan^{1,2}, D.S. Rosa³, J.R.S. Vallim¹, J.C.F. Galduróz¹, V. D'Almeida¹, S. Tufik^{1,2}, M.L. Andersen^{1,2}

¹Universidade Federal de São Paulo, Psicobiologia, São Paulo, Brazil, ²Instituto do Sono, Associação Fundo de Incentivo à Pesquisa (AFIP), São Paulo, Brazil, ³Universidade Federal de São Paulo, Microbiologia, Imunologia e Parasitologia, São Paulo, Brazil

Introduction: Dermatological diseases (DD), such as dermatitis, psoriasis, and vitiligo, are commonly associated with pruritus, sleep disturbances, and psychological distress. Growing evidence suggests that pruritus severity may be influenced by individual chronotype. However, population-based studies on the impact of DD on chronobiological aspects and psychological outcomes remain limited. Thus, this study aimed to examine the independent and combined effects of dermatitis, psoriasis, and vitiligo on sleep habits, circadian typology, and psychological outcomes in a representative sample from São Paulo, Brazil.

Materials and methods: This cross-sectional case-control analysis used data from the 4th edition (2018–2019) of the São Paulo Epidemiologic Sleep Study (EPISONO). A total of 743 participants who completed the dermatological section of the general health questionnaire were included. Individuals who self-reported a diagnosis of dermatitis (n=51), psoriasis (n=19), vitiligo (n=8), or overlapping conditions (n=8) were classified as having DD, while the remaining (n=657) comprised the non-DD group. Propensity score matching (PSM) was performed in a 1:1 ratio based on age, sex, ethnicity, and socioeconomic status to generate comparable groups.

Results: Before PSM, participants with DD (mean age: 49.1±14.5 years; 66.3% women) had significantly lower Morningness–Eveningness Questionnaire (MEQ) scores (54.2±11.2 vs. 57.5±11.5) and a smaller proportion of morning types (29.1% vs. 46.6%) compared to the non-DD group (mean age: 48.7±14.9 years; 57.8% women), particularly among those with dermatitis (MEQ: 52.5±10.8; morning types: 25.5%). PSM resulted in 86 well-balanced pairs (mean age: 49.8±14.5 years; 69.8% women). After matching, these differences in morningness preference were no longer significant. No significant differences were observed in social jetlag or mid-sleep on free days corrected for sleep debt on work days (MSFsc). In terms of mental health, the DD group reported 3.8% higher perceived stress and 3.4% lower scores in the psychological domain of the World Health Organization Quality of Life Instrument – Brief Version compared to controls before matching. Post-matching, psychological quality of life became further reduced, the physical domain presented a 5.7% lower score, and the Beck Depression Inventory (BDI) score was approximately 27% higher in the DD group (10.4±7.7 vs. 8.1±6.9).

Conclusions: Individuals with DD presented greater eveningness preference and worse psychological outcomes. Although some differences were influenced by sociodemographic factors, the persistence of reduced quality of life and increased depressive symptoms after adjustment suggests an independent association. These findings support the inclusion of circadian and mental health assessments in dermatological care and reinforce the need for longitudinal studies to clarify causal mechanisms.

Acknowledgments: This study was supported by the Associação Fundo de Incentivo à Pesquisa (AFIP) and the Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP; grant #2020/13467-8 to MLA; #2021/13004-0 to DSR and 2023/08657-0 to VDA). Effect of Acupuncture on Shift Work Disorder : A Randomized Clinical Trial

F. Wang¹, Z. Liu¹, Y. Chen¹

¹Shanghai University of Traditional Chinese Medicine, Shanghai, China

Introduction: To observe the efficacy and safety of acupuncture on sleep quality for patients with shift work disorder (SWD)

Materials and methods: This sham-controlled, randomized clinical trial was conducted in China from December 1, 2021 to January 31, 2023. A total 86 SWD patients who met the inclusion criteria were randomized in a 1:1 ratio into manual acupuncture (MA) or sham acupuncture (SA) groups. All the participants received acupuncture or sham acupuncture 10 sessions, once every 2 days. The primary outcomes was Pittsburgh Sleep Quality Index (PSQI). The secondary outcomes included Insomnia Severity Index (ISI), Epworth Sleepiness Scale (ESS), Fatigue Scale-14 (FS-14), Patient Health Questionnaire (PHQ-9) and General Anxiety Disorder-7 (GAD-7). Besides, 2-week Actigraphy (ACT) were completed at baseline and post-treatment.

Results: Compared with the SA group, the MA group showed statistical decreases in PSQI ($F = 5.985$, $P = 0.017$), ISI ($F = 4.792$, $P = 0.031$), PHQ-9 ($t = -2.640$, $P = 0.010$), GAD ($Z = -2.483$, $P = 0.013$) at the post-treatment, as well as demonstrated decrease ISI score at the follow-up period ($F = 8.407$, $P = 0.005$). As to ACT data, acupuncture significantly improved in Innerdaily Stability (IS), Intradaily Variability (IV), Fragmentation index (FI) at the post-treatment period ($Z = -2.004$, $P = 0.045$; $t = 3.406$, $P = 0.001$; $t = -3.004$, $P = 0.004$).

Conclusions: Acupuncture can improve subjective sleep indicators in SWD patients, including improving sleep quality, reducing the severity of insomnia, as well as objective sleep indicators such as increasing IS and decreasing IV and FI. Besides acupuncture can alleviate the adverse emotions of SWD patients.

Effect of flight itinerary on jetlag duration: a systematic modelling study

S. Huang^{1,2}, Y.S. Bin^{2,3}, C. Caillaud^{2,4}, S. Postnova^{1,2}

¹The University of Sydney, School of Physics, Sydney, Australia, ²The University of Sydney, Charles Perkins Centre, Sydney, Australia, ³The University of Sydney, Northern Clinical School, Faculty of Medicine, Sydney, Australia, ⁴The University of Sydney, Biomedical Informatics and Digital Health, School of Medical Sciences, Faculty of Medicine and Health, Sydney, Australia

Introduction: Rapid travel crossing multiple time zones results in jetlag, which affects millions of travellers daily. Flight itinerary is likely to affect the duration of jetlag; however, its effects have not been systematically studied. This study investigates the effects of flight departure time, flight duration, and forced wakefulness at the destination on jetlag duration.

Materials and methods: We used an arousal dynamics model to simulate sleep-wake cycles and circadian dynamics depending on flight departure time (from 00:30 to 24:00), flight duration (from 0.5 to 24 hours), and time zone difference between destination and origin (ΔT from -12 to 12 hours). Simulations were performed with either free sleep or forced wakefulness from 10:00 to 17:00 daily at the destination. To simulate the time and activity at the airport, wakefulness was forced for 3 hours before and 1 hour after flight with airport light of 300 lux. To simulate the take-off and landing, forced wakefulness was applied for 30 minutes at the beginning and end of the flight with in-flight light of 80 lux. During the flight, the light level was 50 lux, and 0 lux during sleep. Sleep was allowed in-flight based on physiological need for sleep during the flight. Jetlag was considered over when the circadian phase at the destination reached values within 30 minutes of the fully entrained to the destination's light-dark cycle. Cognitive performance was predicted in the model using the lapses of attention on the Psychomotor Vigilance Task.

Results: Jetlag occurred for all ΔT s, and larger $|\Delta T|$ resulted in longer jetlag. Adaptation via phase-advancing caused longer jetlag with a larger variance due to the flight itinerary. Light exposure and forced wakefulness caused by different flight itineraries moved circadian clock closer or further away from destination time zone. For the case of free sleep at the destination, flight itinerary affects jetlag duration by up to 8 times. Forced wakefulness at the destination reduced the average jetlag duration

by up to 10 days compared to free sleep; however, it came at the cost of impaired cognitive performance for up to 1 week. For ΔT from 1 to 9 hours, jetlag was shortest for flights departing from 8 AM to 11 AM or arriving from 5 AM to 8 AM in the origin time, and jetlag was longest for flights departing from 11 PM to 3 AM or arriving from 11 PM to 2 AM. The relationship was reversed from the other ΔT s.

Conclusions: Flight itinerary significantly affects the duration of jetlag. Forced wakefulness at the destination can reduce jetlag duration, but it also reduces cognitive performance. Selecting flights based on these findings could reduce jetlag. This study considered the most common scenario; the results may not be directly applicable to other populations.

Effects of nighttime melanopsin stimulation on sleep architecture

F. Borghese¹, R.A. Hut¹, H. Huisjes¹, E. van der Maarel¹

¹University of Groningen, Groningen Institute for Evolutionary Life Sciences (GELIFES), Groningen, Netherlands

Introduction: Light plays a fundamental role in visual perception but also in regulating non-visual processes, including the entrainment of circadian rhythms. The pacemaker of the circadian clock, located in the suprachiasmatic nucleus (SCN), receives its primary input from the retina, making it particularly sensitive to light. Among the retinal photoreceptors, intrinsically photosensitive retinal ganglion cells (ipRGCs), which express melanopsin (most sensitive to short-wavelength light), are considered primarily responsible for mediating these non-visual responses. Recent research has used metameric light conditions to disentangle the contributions of specific photoreceptors. These light conditions allow for selective modulation of melanopic activation while keeping cone stimulation constant, isolating the role of ipRGCs. A few studies have used such metamers to compare the effects of high- versus low- melanopic light exposure before and up to shortly after habitual bedtime. Results have consistently shown that higher melanopic light leads to stronger melatonin suppression. However, its effects on sleep remain inconclusive. We aim to extend this line of research by designing metameric light conditions that differ only in their melanopic equivalent daylight illuminance (EDI), while maintaining matched alpha-opic EDI values for S-, M-, and L-cones. By exposing participants to these light conditions during the melatonin plateau, we aim to further investigate the role of melanopsin stimulation on sleep following nighttime light exposure.

Materials and methods: Participants (N=7) were exposed to three light conditions: two metameric lights providing (1) high and (2) low melanopic input, and (3) dim light as a baseline. Each exposure lasted 2 hours, beginning 3.5 hours after individual dim light melatonin onset (DLMO). One hour after the light exposure ended, participants were allowed to sleep until spontaneous awakening. Sleep was monitored using polysomnography, and morning alertness was measured with the Karolinska Sleepiness Scale (KSS).

Results: Light exposure had no effect on the proportion of N1, N2, REM sleep, or awakenings after sleep onset. Total sleep time, time spent in N1, N2, REM, and awake did not differ between light conditions. However, exposure to high melanopic light resulted in a longer duration of N3 sleep. Morning KSS scores did not significantly differ between light conditions.

Conclusions: Exposure to high melanopic light during the night selectively increased N3 sleep duration, suggesting that melanopsin stimulation may enhance restorative aspects of sleep. This is consistent with previous research showing that light exposure during extended wakefulness increases slow-wave sleep. The late scheduled sleep onset in our participants likely caused partial sleep deprivation, which may have influenced the effects of light. These findings highlight the role of melanopsin in regulating restorative sleep and have potential implications for lighting design. Further research should investigate the contributions of classical photoreceptors to the non-visual effects of light.

ADCY3 Ser107Pro links difficulty awakening in the morning to adiposity through circadian regulation of adipose thermogenesis

C. Tchao^{1,2}, C. Moth³, J. Meiler³, J. Lane⁴, R. Saxena^{1,5}

¹Massachusetts General Hospital, Center for Genomic Medicine, Boston, United States, ²Broad Institute, Program in Medical and Population Genetics, Boston, United States, ³Vanderbilt University, Center for Structural Biology, Nashville, United States, ⁴Brigham and Women's Hospital, Division of Sleep and Circadian Disorders, Boston, United States, ⁵Broad Institute, Program in Medical and Population Genetics, Cambridge, United States

Introduction: Modern lifestyles often disturb circadian rhythms, yet the genetic circuits that convert this stress into metabolic dysfunction remain poorly defined.

Materials and methods: We conducted a genome-wide pleiotropy analysis to explore the associations between morning circadian preference and BMI, focusing on the tissue-specific expression and rhythmicity of key genes.

Results: Here, we identify a missense variant in ADCY3 (rs11676272; Ser107Pro) as a pleiotropic regulator of circadian preference and adiposity. Using genome-wide pleiotropy analysis in ~480,000 UK Biobank participants, we show that the G risk allele (Pro107) increases eveningness, BMI, and fat mass in European (N=451,324) and African (N=8,738) ancestry groups, with behavioral amplification by morning difficulty awakening observed in Europeans, and power-limited interaction modeling in other populations. Structural modeling and transcriptomic analysis suggest this allele destabilizes ADCY3 and alters adipose-specific splicing and expression. In mice, *Adcy3* is rhythmically expressed in adipose tissue, with the conserved Pro107 site showing BMAL1 binding and cold-inducible activation. Human adipose ADCY3 expression also increases after weight loss

Conclusions: Together, these findings reveal a genotype-dependent, behaviorally modifiable axis linking difficulty awakening to adipose thermogenesis and obesity risk.

Evaluation of the Molecular Crosstalk Between Endoplasmic Reticulum Stress and Sleep-Wake Homeostasis

G. Ni¹, O. Bacon¹, A. Martinez², R. Foster³, A. Jagannath³, S. Vasudevan¹

¹University of Oxford, Department of Pharmacology, Oxford, United Kingdom, ²Medicinal Chemistry Institute of Spanish National Council for Research (CSIC), Madrid, Spain, ³University of Oxford, Nuffield Department of Clinical Neurosciences, Oxford, United Kingdom

Introduction: Sleep and circadian disturbances (SCRD) are increasingly recognised as both a **consequence and contributor** to **endoplasmic reticulum (ER) stress**, a cellular condition caused by the accumulation of unfolded or misfolded proteins within the ER. This bidirectional relationship plays a key role in the pathophysiology of numerous sleep disorders, neurodegenerative diseases, and metabolic conditions. In response to ER stress, cells activate the **unfolded protein response (UPR)**, a protective network comprising three signalling branches mediated by **ATF6, PERK, and IRE1**. Together, these pathways function to restore ER homeostasis by enhancing protein folding, reducing global translation, and promoting degradation of misfolded proteins. Targeting components of the UPR has emerged as a promising therapeutic strategy to mitigate SCRD and its systemic effects. Our research investigates **casein kinase 1 (CK1)**—specifically its **δ (delta)** and **ε (epsilon)** isoforms—as modulators of both **circadian rhythms** and **ER stress responses**.

Materials and methods: Using U2OS osteosarcoma and SH-SY5Y neuroblastoma cell lines, we evaluated the effects of pharmacological CK1 inhibition on multiple arms of the UPR. *In vivo*, we conducted a comprehensive characterisation of sleep and circadian behaviour in mice treated with CK1 inhibitors, examining phase shifts and recovery from SCRD. We quantified ER stress markers in both central (brain) and peripheral tissues, comparing outcomes with and without CK1 inhibition. To assess the cognitive impact of SCRD and therapeutic intervention, we employed behavioural assays evaluating spatial memory and executive function.

Results: Our findings reveal that **CK1 inhibition effectively tunes the UPR**, both in vitro and in vivo, and modulates behavioural and molecular outcomes linked to sleep disruption. In cell culture models, CK1 inhibition altered the expression and activation of key UPR components across the ATF6, PERK, and IRE1 pathways. In the mouse model, CK1 inhibitor treatment demonstrated significant effects on circadian parameters and sleep architecture during normal conditions and following induced sleep disruption. Analysis of tissue samples revealed corresponding changes in ER stress markers, with differential responses observed between the central nervous system and peripheral tissues.

Behavioural testing indicated that CK1 inhibition attenuated cognitive deficits associated with sleep disruption, correlating with reduced markers of ER stress in brain regions associated with learning and memory.

Conclusions:

These results position **CK1 as a promising therapeutic target** at the intersection of **circadian regulation, sleep homeostasis, and cellular stress resilience**. By targeting the ER stress response, our work offers translational insights into the development of novel therapies for sleep disorders and their broader physiological consequences.

Examining the impact of seasonal variations in photoperiod on sleep in young adults

S. Ganesan¹, M. Turnbull¹, J. Donninger¹, N. Santhi¹

¹Northumbria University, Department of Psychology, Newcastle Upon Tyne, United Kingdom

Introduction: In equatorial and low-latitude regions, photoperiod and twilight durations exhibit minimal seasonal variation, resulting in stable patterns of light exposure year-round. In contrast, those living in higher latitudes are subject to pronounced seasonal variation in daylength. These variations are accompanied by extended twilight periods and seasonal shifts in the timing of sunrise and sunset, which may impact sleep. This study examines the impact of seasonal variation in daylength and its impact on sleep in young adults.

Materials and methods: Young adults [$n=39$, 18 males] aged 22.6 ± 3.0 years ($M \pm SD$), participated in the study between 2022 and 2024. Data was collected for 10 consecutive days. Sleep and wake information was collected using sleep diaries. Daylength and dawn and dusk timings were extracted using <https://www.timeanddate.com> to account for the potential influence of changes in photoperiod across seasons on sleep patterns. Data collected from November to February were characterised as short daylength (SDL) months, and data collected from March to October were characterised as long daylength (LDL) months. Global Horizontal Irradiance (GHI), a measure of solar irradiance, which refers to total solar radiation incident on a horizontal surface, was assessed using a publicly available website. Dawn to sleep onset time, dusk to sleep onset time and dawn on the day of awakening till wake time were calculated.

Results: There were significant differences in sleep onset time ($p<.005$), wake time ($p<.005$), and sleep onset latency (SOL) ($p<.005$), between SDL and LDL months. Both sleep onset time and wake time were delayed during LDL months (sleep onset time: $01:16 \pm 01:58$ h, wake time: $09:09 \pm 02:00$ h) compared to SDL months (sleep onset time: $00:09 \pm 01:37$ h, wake time: $08:16 \pm 01:34$ h). Sleep Onset Latency (SOL) approximately doubled during LDL months (31 ± 36 minutes) compared to SDL months (17 ± 21 minutes). Total sleep time was approaching significance ($p=.06$) with longer sleep duration observed during SDL months (7.96 ± 1.72 h) compared to LDL months (7.64 ± 1.55 h). The duration from dawn to sleep onset time was longer during LDL months (19.04 ± 2.27 h compared to SDL months (17.20 ± 1.64 h). The duration from dusk to sleep onset time was longer during SDL (5.94 ± 1.60 h) months compared to LDL months (4.51 ± 2.24 h). There were no differences in total sleep time, wake time, sleep onset time and SOL between weekdays and weekends ($p>.05$). When examining chronotype defined by midsleep on free days corrected for oversleep (MSFc), an indirect estimate of circadian phase, there was a delay in midsleep timing during LDL months ($05:20 \pm 01:30$ h, $p=.01$) compared to SDL months ($04:18 \pm 01:00$ h). GHI was higher during LDL months (3130.18 ± 1764.59 W/m²) compared to SDL months (1349.07 ± 513.83 W/m², $p<.001$).

Conclusions: These findings demonstrate that seasonal variation in photoperiod including the timing of dawn and dusk transitions have significant effects on the timing and duration of sleep in young adults, primarily highlighting the importance of natural light in synchronising daily sleep-wake patterns. These findings have implications for chronobiology and the development of light-based interventions to support sleep health in young adults.

How do individual differences in circadian physiology contribute to predicted circadian timing in real-world conditions?

A. Phillips², J. Stone¹, W. Cheng², D. Easton³, C. Gupta³, M. Thomas³, S. Ferguson³, H. Van Dongen⁴, S. Cain⁵

¹Flinders University, Adelaide, Australia, ²University of Melbourne, Melbourne, Australia, ³Monash University, Clayton, Australia, ⁴Appleton Institute, Central Queensland University, Adelaide, Australia, ⁵Washington State University, Spokane, United States

Introduction: Light is the primary time cue for the human central circadian clock. Computational models have been developed to predict circadian timing based on light exposure patterns. However, these models are not always accurate at the individual level, potentially due to inter-individual differences in circadian physiology, including how sensitive the circadian system is to light. We aimed to investigate how these physiological differences affect entrainment in real-world environments, and to test whether individualizing the model improves predictions of circadian timing in a dataset collected in shift workers.

Materials and methods: We used a validated computational model of circadian rhythms and sleep/wake, which takes light exposure patterns and sleep constraints (e.g., work schedules) as inputs. This model was used to simulate circadian timing and sleep/wake patterns, while varying both: (i) physiological parameters of the model (circadian light sensitivity and intrinsic circadian period); and (ii) environmental lighting assumptions (including morning, daylight, and evening light levels). We analyzed how these factors interacted to determine predicted circadian timing and sleep/wake patterns. The model was then used to predict circadian timing in a shift work dataset. This dataset included shift workers (age 21-41 years, n=27, full dataset in n=17) who were tracked in the field for approximately 3 weeks on a work roster including night shifts. Sleep/wake patterns, light exposure patterns, and work schedules were collected daily. Participants visited the lab for repeated circadian phase assessments, using dim light melatonin onset (DLMO), up to three times, at approximately weekly intervals. Light sensitivity was measured using melatonin suppression on the first lab visit.

Results: Brighter evening light levels or longer intrinsic period led to later predicted circadian and sleep timing, with this effect being amplified by high light sensitivity. Brighter daylight levels attenuated the predicted delaying effects of evening light. Brighter morning light advanced circadian and sleep timing, normalizing rhythms in simulations with a long circadian period, or with both high light sensitivity and high evening light. Applying the model to the shift worker dataset, we found that individual-level estimation of physiological parameters (circadian light sensitivity, intrinsic circadian period) significantly improved model accuracy for circadian timing estimates compared with predictions made using default model parameters.

Conclusions: Modeling enables us to test complex interactions between physiological and environmental factors, identifying candidate strategies to improve entrainment and reduce circadian disruption. Our results suggest that both circadian light sensitivity and intrinsic circadian period play important roles in determining sleep and circadian timing in the real world. Incorporating these factors into model individualization therefore leads to more accurate model predictions, even under challenging test conditions.

Acknowledgments: The research was supported by the Australian Research Council, through award DP220102812.

Impact of circadian rhythm sleep disruption on cortisol and melatonin biomarkers and cellular metabolism (telomeres) in oral health: systematic review

S. Falardo¹, K. Sommer², A. Feliciano³

¹Catholic Portuguese University and VUB-Vrije Universiteit Brussel, Belgium, Sleep Medicine, Lisbon, Portugal, ²Catholic Portuguese University, Dental School, Viseu, Portugal, ³Catholic Portuguese University, Catholic Medical School, Rio de MOuro-Lisbon, Portugal

Introduction: This systematic review focused on the impact of sleep disorders related to circadian rhythm on cortisol and melatonin biomarkers and also on cell metabolism, especially at the telomere level.

Materials and methods: The following quantitative records were found: Scielo (35); Pubmed (1,114) and Cochrane (1,478). The Covidence system automatically marked 221 records as duplicates and 744 records as automatically ineligible. Database selection and identification were carried out according to the Prisma system for systematic reviews. After evaluating the full text, 12 publications remained for data extraction. In the 12 studies evaluated, 12,866 people between the ages of 18 and 88 took part. The samples ranged from 13 young men to 5,268 elderly people. All the studies identified the

participants' gender, with 9,022 women (70.13%) and 3,844 men (29.87%). Eligibility criteria were selected based on the structuring factors that make up the PICOS approach (P= Population; I= Intervention; C= Comparison; O= Outcome; S= Study design). The population (P) being analysed included participants with circadian rhythm sleep disorders. The intervention (I) included biomarkers of cortisol, melatonin and telomeres. The comparison group (C) included individuals with regular sleep patterns aligned with the natural circadian rhythm. Outcomes (O) included telomere length and a measure of sleep quality, assessed using objective sleep indices or by self-report and cortisol and melatonin levels in the blood. The study design (S) included randomised control trials and other formats. regarding the exclusion criteria, unpublished studies, conference abstracts and studies whose full article was not available and could not be obtained directly from the authors were removed.

Results: The variability in study designs, as well as the heterogeneity of samples and measurement methods, emphasizes the need for future, more rigorous research to clarify these associations. These results reinforce the importance of synchronizing internal biological rhythms with natural environmental cycles in order to maintain general health, which includes oral health

Conclusions: The evidence from the selected studies indicates an association between circadian dysregulation and variations in these biomarkers, with possible implications for telomere length, suggesting a role in the processes of premature cellular ageing, cell renewal and recovery, and metabolic and hormonal imbalances. In dentistry, the cellular ageing process and hormonal imbalances influence processes such as healing and post-surgical recovery, the immune response and the development of periodontal disease, changes in the salivary pH of the microbiome and, consequently, dental caries. Proper regulation of the circadian rhythm can therefore play a crucial role in optimizing dental care and maintaining chronic oral conditions. Recognizing the interconnection between sleep, metabolic health and oral health can lead to more holistic approaches in dental treatment, underlining the importance of considering circadian rhythms in clinical dental practice to promote more comprehensive and lasting oral health.

Acknowledgments: Nothing to declare

Impact of Delayed Meal Timing on Circadian Rhythms and Hormone Profiles in Healthy Adults: A Randomized Crossover Study

M. Wang¹, C. Dreyer¹, L. Navarro¹, B. Cheng², M.-P. St-Onge¹

¹Columbia University Irving Medical Center, Medicine, New York, United States, ²Columbia University Irving Medical Center, Mailman School of Public Health, New York, United States

Introduction: Meal timing can affect the body's internal biological clock. However, few studies have evaluated whether delaying mealtimes, as frequently occurs in those who skip breakfast, disrupts circadian rhythms. We hypothesized that delaying meals relative to sleep would modify the shape of circadian hormone rhythms, including melatonin and steroid hormones, and that these effects would differ by sex.

Materials and methods: Adult men and women, age 25-49 y (body mass index [BMI] 25-34.9 kg/m²) completed a randomized crossover, controlled feeding study. Circadian physiology was assessed on days 3 and 14 under two separate conditions: aligned (first meal consumed 1 h after waking) and misaligned (first meal delayed by 4 h relative to aligned, starting 5 h after waking). Eating windows (time from first to last meal) were 10 h in each condition and bedtimes were fixed (8-h time in bed). All meals were provided to participants in amounts designed to maintain weight; intakes were identical in each condition. Blood samples were collected in an inpatient setting from 7 PM to 12 PM (aligned) or 3 PM (misaligned) on days 3-4 and 14-15. Samples were assayed for melatonin, cortisol, cortisone, corticosterone, testosterone, dehydroepiandrosterone sulfate (DHEA-S), and progesterone. Circadian hormone rhythms were modeled via linear mixed-effects cosinor regression using harmonic predictors ($\cos \omega t$, $\sin \omega t$) where t is time (hours) and $\omega = 2\pi/24$, with subject-level random effects. A full 4-way interaction (condition $\times$ sex $\times$ day $\times$ harmonic predictors) was evaluated.

Results: Data from 20 participants (7 males) were analyzed (age 34.8 ± 7.9 y; BMI 27.0 ± 4.1 kg/m²). Melatonin showed significant modulation by condition, with altered $\sin \omega t$ under misaligned condition (4.6 [0.6, 8.6]). A significant 4-way interaction both $\cos \omega t$ ($p=0.013$) and $\sin \omega t$ ($p=0.003$) indicated sex- and time-dependent effects. On day 14, females in the misaligned condition exhibited lower $\cos \omega t$ (-12.6 [-20.9 , -4.2]) and $\sin \omega t$ (-6.6 [-12.3 , -1.0]), indicating reduced amplitude and delayed phase of melatonin. In contrast, in males, $\cos \omega t$ increased on day 14 ($+15.4$ [3.3, 27.5]), suggesting partial

rhythm recovery. For corticosterone, misaligned condition decreased $\cos\omega t$ (-872.2 [$-1548.4, -195.9$]) with a significant interaction. Males in the misaligned condition, but not females, showed increased $\cos\omega t$ on day 14 ($+1181.4$ [$50.0, 2312.9$]). Progesterone rhythmicity was suppressed under misalignment, with lower $\cos\omega t$ (-999.6 [$-1623.4, -375.7$]) and $\sin\omega t$ (-1582.3 [$-2247.8, -916.8$]) on day 3 in females while males showed increased $\sin\omega t$ ($+1574.2$ [$489.6, 2658.9$]). However, by day 14, a negative interaction in $\sin\omega t$ (-2003.2 [$-3506.2, -500.1$]) indicated that this was a male-specific increase, suggesting divergent rhythmic responses in progesterone by sex. Cosinor parameters for other hormones did not differ by condition.

Conclusions: Delaying meal times relative to sleep by 5 h, compared to 1 h, altered melatonin, corticosterone, and progesterone rhythms in a time- and sex-dependent manner. These effects varied significantly by sex and showed different trajectories based on duration of exposure to the eating pattern. Our results suggest that meal timing can influence circadian and hormonal rhythms and may inform strategies for chrononutrition in personalized medicine.

Impact of everyday light exposure patterns on cardiometabolic and psychological health as well as sleep outcomes in younger and older adults

J.-F. Harmsen^{1,2,3}, A.J. Lücke⁴, S. Baumgarten⁵, P. Walter⁶, T. Kraus⁷, A.B. Neubauer⁴, M. Schweiker^{1,2}

¹RWTH Aachen University, Medical Faculty, Institute for Occupational, Social and Environmental Medicine, Healthy Living Spaces lab, Aachen, Germany, ²RWTH Aachen University, Faculty of Architecture, Chair of Healthy Living Spaces, Aachen, Germany, ³Maastricht University, Department of Nutrition and Movement Sciences, Maastricht, Netherlands, ⁴RWTH Aachen University, Institute for Psychology, Aachen, Germany, ⁵RWTH Aachen University, Medical Faculty, Department of Ophthalmology, Aachen, Germany, ⁶RWTH Aachen University, Department of Ophthalmology, Aachen, Germany, ⁷RWTH Aachen University, Medical Faculty, Institute for Occupational, Social and Environmental Medicine, Aachen, Germany

Introduction: 90% of our time is spent indoors. During daytime we are exposed to lower light intensities and a different color spectrum indoors compared to natural daylight. The chronic lack of daylight and excessive electrical light in the evening are increasingly being considered as risk factors in the aging society's rising incidence of cardiometabolic, psychological and sleep disorders. It has already been shown that light influences blood sugar, blood pressure, psychological well-being and sleep outcomes in a time-of-day dependent manner. Therefore, poor light exposure habits may be an underestimated lifestyle factor contributing to a multitude of disorders upon aging affecting our health care system. Yet, it is currently largely unknown to what degree light exposure habits and an individual's sensitivity to the health and sleep effects of light differ between younger and older individuals.

Materials and methods: We recruited younger (18–35 years) and older adults (60–80 years) living in and around the city region Aachen, Germany. Volunteers were generally healthy based on self-report and a comprehensive ophthalmologic exam was conducted to exclude any eye disorders, such as signs of cataract. At baseline, participants completed the Pittsburgh Sleep Quality Index, Light Exposure Behaviour Assessment and Munich Chronotype Questionnaire. For 12 consecutive days in their everyday life, participants wore a light logger (ActLumus, Condor Instruments) as a pendant, capable of measuring both photopic and melanopic lux every 10 seconds. During this time period, participants reported how they slept each morning and their current affect and vitality six times daily through a smartphone-based app (m-Path). Momentary alertness was assessed six times daily using the Karolinska sleepiness scale. Through continuous glucose monitoring (Freestyle Libre Pro iQ, Abbott Laboratories), interstitial glucose levels were measured every 15 min continuously. On day 11 and 12, participants stayed in an office environment from 08:30 to 17:00h under dim (<10 photopic lux) or bright (1000 lux) light conditions in a randomized order. Data collection was finished in May 2025 with data analysis currently ongoing.

Results: 31 younger adults (mean $\pm$ SD; 24 ± 3 years, body mass index (BMI): 24 ± 3 kg/m², 15 women) and 31 older adults (68 ± 5 years, BMI: 25 ± 3 kg/m², 17 women) were included. Initial self-reported hours in bed per night did not differ between young and old adults (7.5 ± 0.5 vs. 7.4 ± 1 hours). Preliminary results show that higher levels of melanopic lux in the 60 minutes before the respective reports were associated with higher vitality (regression coefficient $b=0.05$) and alertness ($b=-0.08$). In the ongoing data analysis, we will analyze age-differences in patterns of light exposure and their

associations with sleep as well as cardiometabolic and psychological health outcomes. We expect to substantiate current recommendations by showing that high levels of melanopic lux during the day and low levels in the evening are associated with better health and sleep outcomes.

Conclusions: Recent advancements in wearable light logger technology allow us to answer important questions regarding effects of people's light exposure, which have so far been understudied to understand cardiometabolic and psychological health as well as sleep outcomes.

Impact of Patient-Centered ICU Design including Dynamic Light Therapy on Sleep in Mechanically Ventilated Patients

A. Luetz¹, N. Kaiser¹, J. Kaden¹, C. Spies¹, I. Fietze², T. Penzel², M. Glos²

¹Charité - Universitätsmedizin Berlin, Department of Anesthesiology and Intensive Care Medicine, Campus Virchow-Klinikum and Campus Charité Mitte, Berlin, Germany, ²Charité - Universitätsmedizin Berlin, Interdisciplinary Sleep Medicine Center, Campus Charité Mitte, Berlin, Germany

Introduction: Critically ill patients demonstrate marked disturbances in both circadian rhythms and sleep architecture. Delirium is the most prevalent acute brain failure in the ICU and is an independent predictor of higher mortality. The interplay between sleep, circadian rhythm, and ICU delirium likely exhibits a bidirectional relationship. Results of a recently published study indicated that using modifications in environmental design decreases the occurrence of delirium and is associated with changes in serum melatonin levels. This data analysis examines the potential effects of a comprehensive change in ICU room design on the sleep architecture of mechanically ventilated patients.

Materials and methods: This is a secondary endpoint analysis of a pilot proof-of-concept study in which two ICU rooms underwent significant architectural modifications, incorporating a newly developed dynamic lighting system and improved noise reduction measures ([Fig. 1](#)). Polysomnography (PSG) was performed in mechanically ventilated patients who were treated in standard and modified rooms for a maximum of three 24-hour periods. A trained sleep expert, blinded to the study, manually scored the recordings, following the American Academy of Sleep Medicine (AASM) criteria. The incidence and severity of delirium were evaluated using the Confusion Assessment Method for the ICU (CAM-ICU) and the Intensive Care Delirium Screening Checklist (ICDSC).

Results: Data analysis included 82 PSG hypnograms from n = 27 patients treated in standard rooms and n = 20 in modified rooms ([Tab. 1](#)). Polysomnography analysis showed total sleep times (TST) of 1,147 minutes (IQR 556 - 1,367) for patients in standard rooms compared to 881 minutes (IQR 439 - 1,198) for patients in modified rooms (p = 0.113). N3 sleep was significantly prolonged for patients treated in standard rooms (400 minutes [IQR 136 - 810]) compared to patients in modified rooms (150 minutes [IQR 7 - 518]) (p = 0.01). Rapid Eye Movement sleep was almost absent for patients in both groups. The day-to-night sleep ratio was lower for patients in modified rooms (1.29 [IQR 0.72 - 2.01]) compared to those in standard rooms (1.99 [IQR 1.66 - 2.19]) (p = 0.05). Conversely, the night-to-day sleep ratio was significantly higher for patients in modified rooms (0.78 [0.5 - 1.39]) than in standard rooms (0.5 [IQR 0.46 - 0.59]) (p = 0.035). The proportion of night sleep, calculated as the duration of night sleep / TST, was significantly higher for patients in modified rooms (44 % [33 - 58]) compared to those in standard rooms (33 % [31 - 37]) (p = 0.035). Eighty-five percent (n = 23) of patients in standard rooms and 55 % (n = 11) in modified rooms developed delirium at some point during their ICU treatment (p = 0.045). Delirium severity, measured using the ICDSC, was significantly higher for patients in standard rooms (4 [IQR 2 - 5]) compared to those in standard rooms (2 [IQR 0 - 4]) (p = 0.02).

Conclusions: This preliminary analysis suggests that a comprehensive change in the design of ICU rooms may affect the sleep architecture of mechanically ventilated patients, thus reducing the incidence and severity of delirium.

Integrating Traditional Chinese Medicine (TCM) and Western Medicine Perspectives on Biological Rhythms - From Ancient Theories to AI-Driven Multidisciplinary Modeling

Z. Man¹, J. Liu²

¹China Academy of Chinese Medical Sciences, Institute of Information on Traditional Chinese Medicine, Beijing, China, ²Xiyuan Hospital, Chinese Academy of Traditional Chinese Medicine, Information Management Center, Beijing, China

Introduction: The concept of biological rhythms-daily, lunar, seasonal, and annual-has been foundational in both Traditional Chinese Medicine (TCM) and modern Western medicine, yet their theoretical frameworks and clinical applications diverge significantly. TCM conceptualizes daily rhythms through a twelve-phase system (*Ziwu Liuzhu*), correlating temporal energy fluctuations (*qi*-blood *yin-yang* dynamics) with organ-specific functional changes. Modern chronobiology, conversely, decodes 24-hour biological oscillations via molecular mechanisms - particularly circadian clock genes that synchronize cellular and systemic processes through transcriptional-translational feedback loops. Nowadays, the irregular lifestyles of modern humans have led to a high incidence of chronic diseases, highlighting an inseparable relationship between disrupted circadian rhythm and disease development. This study establishes a comparative framework analyzing TCM and Western chronobiology's mechanistic interpretations of daily, lunar, seasonal, and lifespan rhythms, followed by proposing an AI-augmented synthesis for precision health applications. By highlighting the interdisciplinary nature of the two fields, we offer a new direction for exploring the field of chronomedicine.

Materials and methods: This comparative study employed a three-phase framework:

Theoretical Synthesis: Textual analysis of TCM classics (e.g., *Huangdi Neijing*) and modern chronobiology literature identified core concepts of biological rhythms (daily *Ziwu Liuzhu*, lunar *Yueqi*, seasonal *Wuyun*, and annual *Shierqi*).

Data Integration: Structured databases were created for TCM rhythms (organ-phase correlations) and Western molecular mechanisms (circadian genes like *CLOCK/BMAL1*).

AI Modeling: Machine learning (random forest, LSTM networks) cross-validated patterns across datasets, incorporating meteorological variables (temperature, humidity) and TCM "Five Phases" theory to predict rhythm disruptions.

Results: Daily Rhythms: TCM's *Ziwu Liuzhu* (meridian energy cycles) aligned with circadian gene expression peaks (e.g., *PER2* at 11:00 AM) but emphasized organ-specific dominance (e.g., liver activity at 1:00-3:00 AM).

Lunar Cycles: TCM's *Yueqi* theory linked lunar phases to immune function (e.g., higher inflammation during waxing phases), validated by modern cytokine data.

Seasonal Adaptation: Both systems recognized seasonal immune shifts, with TCM's *Wuyun* correlating to vitamin D fluctuations and *CYP24A1* gene expression.

AI Model Performance: The integrated model achieved high accuracy in predicting insomnia and seasonal affective disorder, outperforming single-system predictions.

Conclusions: This study demonstrates that TCM and Western medicine offer complementary perspectives on biological rhythms, with TCM emphasizing holistic environmental interactions and Western medicine detailing molecular mechanisms.

Future research should prioritize AI-driven platforms that fuse:

Temporal Precision: High-resolution circadian tracking (wearables, omics) with TCM "meridian clocks."

Environmental Integration: Meteorological data and *Wuyun* theory to model climate-related health risks.

Personalized Interventions: Adaptive AI therapies combining acupuncture (TCM) and melatonin modulation (modern Western medicine).

Acknowledgments: We thank the China Academy of Chinese Medical Sciences for providing TCM textual archives and the Xiyuan Hospital of China Academy of Chinese Medical Sciences Big Data Innovation Laboratory of Traditional Chinese Medicine for sharing clinical datasets critical to this study. Their collaborative support bridges ancient wisdom with modern computational frameworks, enabling rigorous cross-system validation of biological rhythms.

Late Isocaloric Eating Delays Circadian Rhythm of Glucose Tolerance in Adults with Overweight and Obesity

H.-C. Koh^{1,2}, N. Vujovic^{1,2}, A. Nedeltcheva^{1,2}, S. Chellappa^{1,2,3}, M. Butler^{1,2,4}, K. Kerlin¹, S.W. Heng¹, N. Rahman¹, G. Adler^{5,2}, J. Qian^{1,2}, M. Garaulet^{6,7}, F. Scheer^{1,2}

¹Brigham and Women's Hospital, Division of Sleep and Circadian Disorders, Boston, United States,

²Harvard Medical School, Boston, United States, ³University of Southampton, Southampton, United

Kingdom, ⁴Oregon Health and Science University, Oregon Institute of Occupational Health Sciences, Portland, United States, ⁵Brigham and Women's Hospital, Division of Endocrinology, Diabetes and Hypertension, Boston, United States, ⁶University of Murcia, Department of Physiology, Murcia, Spain, ⁷University Clinical Hospital, Biomedical Research Institute of Murcia, Murcia, Spain

Introduction: Although glucose tolerance (efficacy of blood sugar handling) in healthy individuals is higher in the morning vs. evening, the potential role of the endogenous circadian system, independent of light-dark and behavioral (e.g. sleep, eating) cycles, has not been tested using a gold-standard circadian protocol. In addition, it is unclear whether such endogenous circadian rhythm in glucose tolerance can be synchronized by the prior eating times in humans. Hence, we determine if there exists an endogenous circadian rhythm in glucose tolerance and whether this rhythm can be phase shifted by a delay in mealtimes.

Materials and methods: In a randomized crossover trial, 15 adults (4 women, age 37±11 y, BMI 28.8±2.4 kg·m⁻², HbA1c 5.4±0.3 %; mean±SD) completed 2 experimental conditions – 4 days of early eating (EE) and 4 days of late eating (LE), each after a 5-day EE baseline. Both conditions were otherwise identical for behavioral (sleep, physical activity, posture) and environmental influences (light, temperature). Three identical/isocaloric test meals (45-50% CHO, 15-20% PRO, 30-35% FAT, GI 60-65, per 24-h) were consumed 4h:10m apart, with all meals delayed by 4h:10m in LE vs. EE. After each experimental condition, the endogenous circadian rhythmicity in glucose tolerance was assessed using 36-h Constant Routine (CR) protocols (i.e., continuous wakefulness, semi-recumbent posture, dim light, and identical isocaloric test meals every 6-h) to isolate the endogenous circadian influences. Glucose tolerance was quantified from 3-h postprandial incremental area under the curve (iAUC) of serum glucose concentrations for the last five of six test meals during CR. Individual endogenous circadian phase was derived from core body temperature during the CR. The circadian rhythm phase and amplitude of glucose tolerance was derived from cosinor analysis of normalized (across circadian cycle) 3-h glucose iAUC using mixed model analyses of variance (R 4.5.0 nlme package).

Results: The peak-to-trough amplitudes in normalized 3-h postprandial glucose iAUC were 36% and 39% of the mean across circadian cycle ($P<0.0001$) after EE and LE, respectively. Both EE and LE showed highest and lowest glucose tolerance in the biological morning and evening, respectively, with a phase delay of ~70 degrees (~4h:40m) in LE vs EE.

Conclusions: Our findings demonstrated in people with overweight and obesity that glucose tolerance expressed a robust endogenous circadian rhythm with high and low tolerance in the biological morning and evening, respectively, and that could be rapidly synchronized to eating schedules, alluding to a decoupling of central and peripheral circadian rhythms in substrate metabolism.

Light at Night Exacerbates Depression Risk via Circadian Disruption and Hippocampal Per1 Dysregulation: Translational Evidence from a Large-scale Prospective Cohort and Animal Study

H. Feng^{1,2}, N. Zheng¹, B. Lin³, B. Li¹, W. Wang¹, T. Luo¹, Y. Fan¹, N.Y. Chan⁴, S. Rao⁵, Y. Yang³, J. Zhang¹
¹Guangzhou Medical University, The Affiliated Brain Hospital, Center for Sleep and Circadian Medicine, Guangzhou, China, ²Guangzhou Medical University, Key Laboratory of Neurogenetics and Channelopathies of Guangdong Province and the Ministry of Education of China, Guangzhou, China, ³Jinan University, Department of Neurology, Guangzhou, China, ⁴Chinese University of Hong Kong, Department of Psychiatry, Li Chiu Kong Family Sleep Assessment Unit, Guangzhou, China, ⁵Fujian Medical University, School of Medical Technology and Engineering, Xiamen, China

Introduction: In the modern era of pervasive artificial lighting, approximately 80% of the global population is exposed to light at night (LAN), posing significant public health challenges. While cross-sectional evidence suggests a link between LAN and mood disorders, the causal effects and mechanisms remain poorly understood. This study integrates human cohort data with controlled animal experiments to elucidate the behavioral and neurobiological pathways linking LAN exposure to depression pathogenesis.

Materials and methods: We analyzed 75,636 UK Biobank participants with objectively measured LAN exposure via wearable devices. Incident depression cases were ascertained through linked electronic health records (hospitalizations, primary care visits) and mortality registries. Cox proportional hazard models, adjusted for potential confounders, were used to assess associations. To further confirm the causal effects of LAN on depression onset, ICR mice (n=50/group, 10-week-old) were randomized to:

control group (12h 200 lux light/12h dark) or LAN group (12h 200 lux light/12h 5 lux dim light). Spontaneous locomotor activity was monitored using Clocklab. Depression-like behaviors were evaluated via sucrose preference test (SPT) and forced swim test (FST). Brain serotonin (5-hydroxytryptamine, 5-HT) and brain-derived neurotrophic factor (BDNF) levels were measured by ELISA. Hippocampal circadian genes were analyzed through multi-timepoint transcriptome sequencing, with rhythmicity evaluated using CircadiOmics. Key genes were further validated by Real-Time Quantitative Polymerase Chain Reaction (RT-qPCR).

Results: Compared to participants with low LAN exposure (median: ~ 1 lux), those with higher exposure exhibited significantly higher adjusted hazards for depression (HR=1.24, 95% CI: 1.12-1.35), demonstrating a dose-response relationship (P for trend < 0.01). Animal experiments demonstrated that, compared to the control group, LAN group exhibited significantly increased depression-like behaviors, such as decreased sugar preference and increased immobility time (all P < 0.05). In addition, locomotor rhythms monitoring revealed that LAN exposure reduced wheel-running activity, nocturnal activity levels, and rhythm amplitude (all P < 0.05). Correlation analysis revealed that disruptions in rest-activity rhythms were significantly associated with these depressive-like behaviors (all P < 0.05). ELISA analysis demonstrated decreased levels of both 5-HT and BDNF in the LAN group (all P < 0.05), with 5-HT levels showing positive correlations with activity amplitude (P = 0.04) and nighttime activity (P = 0.01). Moreover, transcriptome and RT-qPCR analysis further identified LAN exposure disrupted the expressions of hippocampal circadian genes particularly *Period 1 (Per1)* in mice.

Conclusions: Integrating epidemiological and experimental evidence, we propose that LAN exposure may contribute to depression risk through circadian disruption, with hippocampal *Per1* alterations and monoaminergic dysfunction emerging as plausible mechanistic links. This translational framework warrants further validation in targeted human interventions.

Light Exposure Patterns and Human Health: Insights from Large-Scale Personal Light Tracking

S. Cain¹, A. Burns², D. Windred³, A. Phillips³

¹Flinders University, Adelaide, Australia, ²Harvard Medical School, Boston, United States, ³Flinders University, Adelaide, Australia

Introduction: Light is the primary synchronizer for the human circadian system, influencing a vast array of physiological and behavioral processes. Deviations from natural light exposure patterns have been implicated in adverse health outcomes, but large-scale objective assessments have been limited.

Materials and methods: We analyzed data from over 85,000 participants in the UK Biobank, utilizing wrist-worn light sensors to objectively measure personal light exposure over a 7-day period. Health outcomes, including mortality, type 2 diabetes incidence, and psychiatric disorders, were assessed through linked health records and standardized questionnaires.

Results: Our analyses revealed that individuals who experienced brighter nights and darker days had a significantly higher risk of all-cause mortality, particularly from cardiometabolic causes. Furthermore, increased nighttime light exposure was associated with a higher incidence of type 2 diabetes, even after adjusting for genetic risk factors. Additionally, brighter nights and dimmer days were correlated with elevated risks of psychiatric disorders, including depression, anxiety, and PTSD.

Conclusions: Our findings demonstrate the critical role of natural light exposure patterns in supporting optimal health. For longevity, cardiometabolic, and mental health, maximizing daytime light and minimizing nighttime light are both potentially beneficial interventions. These results strongly suggest that public health strategies should consider light exposure as an easily modifiable environmental risk factor to improve health and wellbeing.

Low-intensity artificial light at night disrupts sleep and physiological functions in controlled laboratory conditions

N. Tang ^{*1}, Y. Hou ^{*1}, A.S. Prayag¹, X. Wang¹, T. Jiang¹, C. Gronfier¹

¹Lyon Neuroscience Research Center (CRNL), Inserm UMRS 1028, CNRS UMR 5292, Université Claude Bernard Lyon 1, Bron, France

Introduction: Artificial light at night (ALAN) is becoming increasingly prevalent in modern society, disrupting natural light/dark cycles and potentially impacting human health. However, most studies on this topic lack controlled conditions, making it difficult to isolate the effects from confounding factors (noise, air pollution, population density, diet and lifestyle factors, etc.). This study aimed to investigate the effects of low-intensity ALAN on sleep and various physiological functions under controlled laboratory conditions.

Materials and methods: Twenty healthy young male participants (24.2 ± 3.3 years; $BMI=22.2 \pm 2.2$ kg/m²) underwent a 5-day and 4-night protocol in temporal isolation (in a sound-attenuated, temperature-controlled individual room, free from time cues). During their four 8-hour nightly sleep episodes at their habitual sleep times, participants were randomly assigned to one of four light conditions: 0 lux, 3 lux, 8 lux, or 20 lux (5000K broadband white light generated by a 10-channel LED system, Ledmotive Spectra Tune 10). During the day, participants were exposed to a light intensity of approximately 90 lux at the eye level (3000 K, Osram 64701). Endocrine markers (melatonin, cortisol, alpha-amylase), electrophysiological measures (EEG, ECG, pupillary light reflex), skin temperature and glycemia were measured continuously or with a sampling rate of more than one sample per hour throughout the study.

Results: The results revealed that nocturnal exposure to 20 lux significantly decreased total sleep time, sleep efficiency, increased wake after sleep onset (WASO), elevated proximal body temperature and glucose levels, and increased heart rate (HR). Interestingly, overnight urinary 6-sulfatoxy-melatonin (aMT6s) and salivary cortisol levels at waketime were unaffected across all light conditions. Additionally, overnight light exposure reduced photoreceptor sensitivity to light upon awakening, but did not significantly impair cognitive performance at waketime.

Conclusions: These findings demonstrate that even low levels of ALAN, as commonly encountered in real-life environments, can acutely disrupt human sleep and several physiological functions within only 1–4 days of exposure. It remains unclear whether these effects persist under chronic exposure or lead to long-term health impacts, however, the results warrant consideration, as they highlight the potential for even low-intensity ALAN, commonly encountered in real-life settings, to affect human health.

Acknowledgments: NT and YH were supported by a Doctoral Fellowship from the Chinese Scholarship Council (CSC202006180019 and CSC202006180028, respectively). Funding was obtained by CG (Idex Breakthrough ALAN - ANR-16-IDEX-0005, and Rectolux from the University of Lyon).

Out of Sync: How late chronotypes and napping drive sleep loss in Spanish schoolchildren

C. Reis^{1,2,3}, P. Hernández-Reverter⁴, D. Gabaldón-Estevan⁵

¹Faculty of Medicine, University of Lisbon, Lisbon, Portugal, ²GIMM - Gulbenkian Institute of Molecular Medicine, Lisbon, Portugal, ³CRCW - Faculty of Human Sciences, Catholic University, Lisbon, Portugal,

⁴Faculty of Biological Sciences, University of Valencia, Valencia, Spain, ⁵Faculty of Social Sciences, University of Valencia, Sociology and Social Anthropology, Valencia, Spain

Introduction: Sufficient sleep is critical for healthy cognitive, emotional, and physical development in children and adolescents. However, in Spain, the pronounced misalignment between solar and social time, exacerbated by early school start times, contributes to chronic sleep deprivation, especially among youth. This is particularly problematic in younger populations whose circadian rhythms are naturally delayed, making it difficult to align sleep-wake schedules with social demands. The aim of this study was to identify predictors of weekly sleep loss in Spanish children and adolescents and to explore the relationship between chronotype and napping behavior.

Materials and methods: A cross-sectional analysis was conducted in a sample of 142 Spanish children and adolescents aged 6 to 16 years (median age [Q1–Q3] = 12 [11–13] years); 87 (61.3%) were female. Sleep variables were assessed using the Munich Chronotype Questionnaire, adapted for both schooldays and free days, including nap periods. Chronotype was calculated using midsleep on free days corrected for sleep debt (MSFsc), and social jet lag (SJL) was derived from the difference between midsleep on free and school days. Weekly sleep loss (weekSleepLoss) was calculated by comparing

total sleep duration on schooldays versus free days (including naps). Group comparisons by sex and napping behavior were conducted using the Mann-Whitney U test. General Linear Models (GLM) were used to identify predictors of sleep loss. Statistical analyses were conducted using SPSS v29, with significance set at $p < .05$.

Results: Children who reported napping had significantly later chronotypes (MSFsc median [Q1–Q3]: non-nappers 4.21 [3.57–5.12] vs. nappers 5.39 [4.59–6.42]; $p < .001$), greater social jet lag (1.71 [1.00–2.71] vs. 2.85 [2.03–4.83]; $p < .001$), and more weekly sleep loss (1.43 [0.60–5.93] vs. 3.93 [1.90–6.67]; $p < .001$). No significant differences in age or sex were found between groups.

General Linear Model analysis showed that the full model accounted for 47.7% of the variance in weekly sleep loss (adjusted $R^2 = 0.442$; $p < .001$). Significant predictors included napping behavior ($p < .001$; $\eta^2 = .190$), greater social jet lag ($p < .001$; $\eta^2 = .183$), later chronotype (MSFsc; $p < .001$; $\eta^2 = .139$), and shorter schoolday sleep duration ($p < .001$; $\eta^2 = .107$). Neither age, sex, nor the interaction between sex and napping significantly predicted sleep loss.

Conclusions: Later chronotypes in Spanish schoolchildren are associated with greater weekly sleep loss, increased social jet lag, and more frequent napping. Napping behavior emerged as the strongest individual predictor of sleep loss and may represent not only a compensatory strategy but also a behavior that reinforces delayed sleep timing, exacerbating circadian misalignment. These findings underscore the urgent need to reconsider early school start times in Spain and highlight the complex interplay between biological rhythms and compensatory sleep behaviors in youth.

Project Sunrise Research Flights: Lessons for sleep and alertness management in commercial aviation

T.L. Sletten¹, A. Clark¹, P. Varma¹, I. Marando², P. Kirby², J.E. Stone^{1,3}, S.M.W. Rajaratnam^{1,4}

¹Monash University, Melbourne, Australia, ²Qantas Airways, Sydney, Australia, ³University of Melbourne, Melbourne, Australia, ⁴Brigham and Women's Hospital, Boston, United States

Introduction: As international airlines continue to introduce flights of longer duration, there is a need to evaluate the impact of extended duty on crew sleep-wake behaviour and alertness. Under 'Project Sunrise', Qantas is planning to conduct the longest global commercial passenger flights. In preparation, aircraft delivery flights provided the unique opportunity to conduct dedicated research flights designed for comprehensive scientific monitoring of sleep, circadian timing and alertness in pilots.

Materials and methods: Eight research flights mimicking the proposed flight times of future extended duty flights were conducted during 2019 and 2023, providing data from 33 pilots (24 male, aged 44.0 $\pm$ 9.3 years). Direct flights occurred between Melbourne or Sydney in Australia, and Seattle ($n=3$), New York ($n=2$), Dresden ($n=2$), and London ($n=1$). Mean flight duration was 19.84 $\pm$ 1.59 h (range 17.0 – 22.67 h). Pilots were monitored for ~20 days throughout their entire flight pattern, including 10 days pre-pattern, during layover and 6 days post-pattern. Sleep was monitored using sleep diaries, wrist actigraphy, and Dreem ambulatory EEG headbands. Light exposure was measured continuously throughout the flight pattern using a lapel-based light sensor. Circadian timing at home prior to the pattern, during layover and during research flights was measured using the rhythm of urinary 6-sulphatoxymelatonin (aMT6s). During flight, pilots completed alertness assessments every 2 hours when awake using the Karolinska Sleepiness Scale, Samn-Perelli Fatigue Scale and the Psychomotor Vigilance Task (PVT).

Results: Pilots spent an average of 5.36 $\pm$ 1.36 h of in-flight time attempting sleep (range 3.00 – 8.17 h) and obtained 4.36 $\pm$ 1.31 h sleep during flight (range 2.58 – 7.40 h). Dreem EEG recordings indicated in-flight sleep was recuperative, based on a similar slope in the dissipation of slow wave activity with each NREM sleep cycle, as observed for sleep episodes at home.

While the direction of circadian phase shift for each pilot was associated with the direction of travel (westward travel = delay, eastward = advance), considerable inter-individual variation in the degree of phase shift was revealed, resulting in >6 h variation in aMT6s acrophase during flight. The magnitude of circadian phase shift was related to individual pilot's sleep-wake behaviour and associated light exposure patterns in layover destination.

Alertness during flight was influenced by individual circadian timing, with higher subjective sleepiness and number of PVT lapses evident during the biological night (aMT6s acrophase $\pm$ 3 h, $p < 0.05$) compared to assessments outside of the biological night. Circadian timing and duration of wakefulness were both significant determinants of subjective fatigue and sleepiness.

Conclusions: This program of work represents the most comprehensive assessment of pilot sleep, circadian timing and alertness during extended flight duty in commercial aviation. Individual variation in sleep-wake and circadian outcomes provides insights into sleep and circadian-related behaviours influencing alertness during flight. These findings are informing ongoing trials of evidence-based recommendations to optimise sleep and alertness during extended flight duty, including trials of specific in-flight rest break allocations.

Acknowledgments: We acknowledge research funding by Qantas Airways. Tracey L Sletten is supported by an Australian Research Council Industry Fellowship.

Relation between mood scales and melatonin levels of children and adolescents with Bipolar Disorder in a Tropical country: a descriptive analysis

B. Sardano¹, L. Soster², C. Borginho¹, A.C. Monazzi¹, T. Catharini³, I. Linares¹, M.C. Lopes³, C. Bueno⁴, F. Amaral⁵, L. Fu I³, J. Cipolla-Neto⁶

¹Child and Adolescent Institute, Clinical Hospital HCFMUSP, School of Medicine, University of São Paulo, Sleep Laboratory, Division of Sleep Neurology, São Paulo, Brazil, ²Child and Adolescent Institute, Clinical Hospital HCFMUSP, School of Medicine, University of São Paulo, São Paulo, Brazil, ³Child and Adolescent Affective Disorder Program (PRATA), Department and Institute of Psychiatry at University of São Paulo Medical School, São Paulo, Brazil, ⁴Child and Adolescent Institute, Clinical Hospital HCFMUSP, School of Medicine, University of São Paulo, São Paulo, Brazil, ⁵Department of Physiology and Biophysics, Institute of Biomedical Sciences I, University of São Paulo, São Paulo, Brazil, ⁶Department of Physiology and Biophysics, Institute of Biomedical Sciences (ICB-USP), University of São Paulo, São Paulo, Brazil

Introduction: Bipolar disorder (BD) is chronic psychiatric condition characterized by recurrent mood episodes, including depression, hypomania, and mania. Beyond affective symptoms, BD frequently involves persistent disruptions in sleep and circadian rhythms, even during euthymic states. These disturbances are considered both symptomatic and potentially pathogenic, contributing to disease onset, progression, and relapse risk. Melatonin plays central role in maintaining sleep-wake cycles. Its secretion is often altered in BD, with studies reporting phase shifts, amplitude reductions, and blunted rhythmicity, particularly in youth populations.

Such findings support hypothesis that circadian dysregulation is core pathophysiological feature of BD, especially in early-onset cases. Robillard et al. (2013) demonstrated significant differences in melatonin rhythms between adolescents with unipolar and bipolar mood disorders, with the bipolar group showing delayed and attenuated secretion profiles. However, environmental factors such seasonal variability in light exposure and temperature may confound these results in temperate regions. This study aims to assess melatonin secretion patterns through urinary 6-sulfatoxymelatonin (6-SM) levels—in children and adolescents diagnosed with BD, across three distinct clinical time points. Mania symptom severity will be evaluated concurrently using standardized clinical scales. The study is conducted in Southern Hemisphere population, where seasonal light and temperature variation is less pronounced, allowing for better environmental control and greater accuracy in evaluating circadian alterations in pediatric BD.

Materials and methods: We prospectively evaluated four individuals between 8 and 18 years, 1 female 3 male, diagnosis of BD according to the Diagnostic and Statistical Manual of Mental Disorders 5th edition. All had regular follow-up at the Psychiatric Centre of University of São Paulo and were included in protocol after signing IRB-approved informed consent. We scheduled monthly meetings (from June to October) to evaluate sleep by means of 6-sulfatoxymelatonin (6-SM) and mania symptom severity by means of concurrent Young Mania Rating Scale (YMRS). To analyze the 6-SM values, we collected 24h urine sample, divided into 3 times: morning (7 am-1 pm, excluding the first void), afternoon (1 pm-7 pm), and night (7 pm-7 am, including first morning void). This was repeated in all meetings.

Results: First patient completed all four assessments. Morning 6-SM levels ranged from 34-81, showing a regressive trend. Afternoon values were between 4.8 and 11.9, and nighttime levels between 25 and 34. YMRS scores indicated no manic symptoms.

Second patient completed four sessions. Morning 6-SM ranged from 6-69; afternoon from 1.3-8.6; night from 2-14. In the final evaluation, higher night values and a YMRS score of 8 suggested possible rhythm inversion.

Third patient had two sessions. Morning 6-SM ranged from 7.3-10.1; afternoon from 3.9-33.1. No clinical changes were observed. Fourth patient had three assessments. Morning 6-SM ranged from 7 to 74; afternoon from 2.2-7.9; night from 5-21.

Conclusions: Small-sample descriptive study identified distinct melatonin secretion patterns among pediatric BD patients living in tropical region. Although potential association between altered circadian profiles and manic symptoms was observed in one case, no consistent pattern emerged. Short evaluation period and limited seasonal variation in Southern Hemisphere may have influenced results. Larger longitudinal studies are needed to clarify circadian dynamics in youth BD.

Reward processing and eveningness in adolescents: A case-control study with EEG investigation

F.Y. Jin¹, X. Zuo², F.T.W. Cheung^{3,1}, O.H.H. Chu¹, Y. Pan¹, Y. Li¹, D. Liao¹, H.F. Sit¹, J.W.Y. Chan⁴, N.Y. Chan⁴, J. Zhang^{4,5,6}, C.K.-s. Shea⁴, Y.K. Wing⁴, X. Hu^{2,7}, S.X. Li^{1,7}

¹Sleep Research Clinic & Laboratory, Department of Psychology, The University of Hong Kong, Hong Kong, Hong Kong, SAR of China, ²Social and Cognitive Neuroscience Lab, Department of Psychology, The University of Hong Kong, Hong Kong, Hong Kong, SAR of China, ³Sir Jules Thorn Sleep and Circadian Neuroscience Institute, Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, United Kingdom, ⁴Department of Psychiatry, Faculty of Medicine, The Chinese University of Hong Kong, Hong Kong, Hong Kong, SAR of China, ⁵Center for Sleep and Circadian Medicine, The Affiliated Brain Hospital of Guangzhou Medical University, Guangzhou, Guangdong, China, ⁶Key Laboratory of Neurogenetics and Channelopathies of Guangdong Province and the Ministry of Education of China, Guangzhou Medical University, Guangzhou, Guangdong, China, ⁷The State Key Laboratory of Brain and Cognitive Sciences, The University of Hong Kong, Hong Kong, Hong Kong, SAR of China

Introduction: Adolescence is often associated with increased evening tendency and the risk of developing mental health problems. Previous research has suggested a close interplay between evening chronotype, which is characterized by an inclination for later bedtime and wake time, and depression, but there has been limited research to investigate the potential mechanism underlying their association. Given that altered reward processing is a key feature of depression, this case-control study examined whether adolescents with an evening preference also exhibit deficits in reward processing.

Materials and methods: Thirty adolescents aged 12–20 (63.33% female) with an evening chronotype (Morningness-Eveningness Questionnaire (MEQ) ≤ 41) and 30 non-eveningness healthy controls (MEQ ≥ 42) with matched age and sex were recruited. Participants with a current clinical diagnosis of sleep or psychiatric disorders (except for delayed sleep phase disorder in the eveningness group) or a medical condition that could significantly affect sleep quality were excluded. All participants underwent a clinical interview, followed by completing a battery of self-report questionnaires including Insomnia Severity Index (ISI) for insomnia severity, Beck Depression Inventory-II (BDI-II) for self-reported depressive symptoms, and the subscale of reward responsiveness in Behavioral Inhibition System/Behavioral Activation System (BIS/BAS) scales for the measure of reward responsiveness. The Children's Depression Rating Scale-Revised (CDRS) was used for measuring clinician-rated depressive symptoms. Participants wore an actigraphy for eight consecutive days and completed a Door Guessing Task as a measure of reward sensitivity using an electroencephalogram.

Results: The eveningness group had higher self-reported and clinician-rated depressive symptoms (both P s < 0.05) but comparable insomnia severity. In terms of sleep measures, the eveningness group showed significantly longer sleep onset latency, later bedtime, rise time, and sleep midpoint as measured by sleep diary. Actigraphy results showed significantly later sleep onset, sleep offset, and sleep midpoint, as well as shorter total sleep time in the eveningness group compared to healthy controls (all P s < 0.05). Compared to healthy controls, the eveningness group showed significantly lower signal on reward positivity (RewP) overall without significant difference between conditions ($F(1, 51) = 4.35$, $P = .042$), indicating blunted reward processing. On the behavioral level, the eveningness group also showed stronger alterations (switched choices more often) in the trial-by-trial behavioral adjustment analyses ($t(7105.0) = 2.57$, $p = .010$). However, there was no significant interaction between group, cue, and choice adjustments. Healthy participants showed significantly different reaction times (gain $>$ neutral, $t(7065.2) = -2.21$, $P = .027$), this effect was not found in eveningness

participants. Reward responsiveness, as measured by BIS/BAS, was not significantly different between groups.

Conclusions: RewP may reflect the neural deficits in reward processing and has been suggested as a potential early biomarker for depression. The findings on blunted response to reward in adolescents with evening preference may be indicative of the risk for depression in eveningness. Longitudinal studies are necessary to establish causality and explore potential interventions targeting circadian factors in the prevention of youth depression.

Safety and Efficacy of Acupuncture in Patients With Circadian Rhythm Sleep Disorder: A Randomized Clinical Trial

Z. Liu¹, J. Li¹, M. Xia¹, C. Fu², F. Wang¹, N. Zhao¹, C. Xie¹, X. Yu³, W. Yang¹, L. Li¹, Y. Chen¹

¹Yueyang Hospital of Integrated Traditional Chinese and Western Medicine, Shanghai University of Traditional Chinese Medicine, Department of Acupuncture and Moxibustion, Shanghai, China,

²Huashan Hospital Affiliated to Fudan University, Shanghai, China, ³Yueyang Hospital of Integrated Traditional Chinese and Western Medicine, Shanghai University of Traditional Chinese Medicine, Shanghai, China

Introduction: Circadian Rhythm Sleep-Wake Disorders (CRSWDs) arise from misalignment between endogenous circadian rhythms and external environmental cycles, causing chronic insomnia and excessive sleepiness. Affecting 0.2-10% of the population, growing evidence indicates that circadian misalignment not only disrupts sleep but also adversely affects multiple physiological systems, increasing susceptibility to cardiovascular diseases, metabolic disorders, cognitive impairments, and immune dysfunction. While planned sleep schedules, timed light exposure, and melatonin therapy show efficacy, alternative treatments remain underexplored. Preliminary studies suggest that acupuncture may improve sleep quality and reduce anxiety in insomnia and peri-menopausal insomnia. Acupuncture has demonstrated potential in improving sleep and modulating circadian pathways, possibly through melatonin-related mechanisms. However, robust clinical evidence is lacking. Considering the efficacy of acupuncture in many areas and the lack of studies in CRSWD, we conducted a randomized, placebo-controlled trial to assess acupuncture's short-term efficacy in CRSWD using objective and subjective measures, addressing a critical gap in non-pharmacological interventions for circadian disruption.

Materials and methods: Design: A randomized, participant-blind, placebo-controlled trial consisted of the acupuncture group ($n = 36$) and placebo-acupuncture group ($n = 36$). Setting: a tertiary hospital of integrated Chinese and Western medicine. Participants: 72 participants with CRSWD based on the International Classification of Sleep Disorders, Third Edition. Interventions: A 10-session intervention of acupuncture at Shenshu (BL 23) and Xinshu (BL 15) or Streitberger needles at the same acupoints was performed for over 3 weeks. Measurements: The Pittsburgh Sleep Quality Index (PSQI) and insomnia severity index (ISI) were evaluated at baseline and post-treatment as the primary outcome measures. Actigraphy recordings were evaluated at baseline and post-treatment as the secondary outcome measures.

Results: After the treatments, the decrease from baseline in PSQI score was 8.97 points in the acupuncture group and 1.28 points in the placebo-acupuncture group. The change from baseline in ISI score was 7.91 points in the acupuncture group and 2.02 points in the placebo-acupuncture group. Actigraphy results showed that the actual sleep time (AST), sleep efficiency (SE) and Inter daily stability (IS) increased significantly ($P < 0.05$); the sleep onset latency (SOL), fragmentation index (FI) and Intraday variability (IV) was significantly decreased ($P < 0.05$); peak time (Cosinor Peak, time activity, CPT) significantly moved forward ($P < 0.01$).

Conclusions: Acupuncture can contribute to a clinically relevant improvement in the short-term treatment of CRSWD. We suggest that acupuncture represents a safe and useful non-pharmacologic intervention option for CRSWD.

Shift Work-Induced Changes in Autonomic Nervous System: An Observational Study Using HRV Analysis

A.K. Tanwar¹, M.K. Bhojani²

¹GS University, Department of Kriya Sharir, Hapur, India, ²Delhi University, Department of Kriya Sharir, Delhi, India

Introduction: Sleep is essential for the restoration and revitalization of both the body and mind. However, individuals frequently neglect this vital and natural process because of shift work and lifestyle changes. Altering sleep patterns from night to day disrupts biological rhythms, leading to a decline in both mental and physical health. The functioning of the autonomic nervous system is crucial for physiological processes. This study aimed to examine the impact of disruptions in biological rhythms caused by shift work on heart rate variability, a parameter used to assess autonomic nervous system functioning.

Materials and methods: Participants were categorized into two groups: Group A, consisting of day workers who engage in work activities exclusively during daytime hours, and Group B, comprising shift workers with irregular schedules, including nocturnal shifts. Heart rate variability (HRV) tests were employed to evaluate the impact of shift work on the autonomic nervous system. To compare demographic variables and HRV domains between the two groups, a chi-square test and Student's t-test were conducted.

Results: Each group comprised 165 participants, predominantly aged 18-30 years. Shift work significantly affected HRV Domain indices; however, no significant differences were observed in Mean RR, Mean HR, RMSSD, p NN50, TINN, LF/HF ratio, or stress index value.

Conclusions: Shift employment influences the functioning of the autonomic nervous system, resulting in increased sympathetic modulation of the heart and increased stress on cardiovascular health.

Introduction: Prolonged sleep-wake difficulties due to shift work, lasting for more than three months, may meet criteria for shift work sleep disorder (SWD) and require intervention, especially if they engender significant functional impairment. SWD is common but there is unmet medical need, with a lack of proven interventions or guidelines.

Our aim is to develop and test a usable, acceptable, and cost-effective intervention to reduce the impact of SWD in shift workers in the UK National Health Service (NHS) through five work packages (WP) and an integrated research advisory group (RAG) of shift workers.

Materials and methods: WP1: A systematic review of qualitative studies on shift workers' experiences of sleep disturbance and its impacts and an overview of reviews on individually-directed non-pharmacological interventions to improve sleep or reduce sleepiness in shift workers.

WP2: A survey with NHS staff to determine prevalence and burden of SWD and a survey with NHS managers to understand current knowledge, training and implementation obstacles.

WP3: Examining existing large datasets (e.g. UK Biobank) to identify risk factors for sleep problems in UK shift workers and to characterise its burden.

WP4: Development of a complex intervention for SWD through a triangulation of evidence from the

above WPs.

WP5: Testing the above intervention in a large-scale randomised controlled trial (RCT).

Results: RAG: Ten shift workers contributed to the development of all WPs through online meetings, offline tasks and by sharing their shift working experiences.

WP1: 28 studies (1519 participants) were included in the qualitative review. Three analytical themes were generated: inevitability of fatigue and tiredness, balancing sleep needs with competing responsibilities, obstacles to engaging in healthy behaviours. 28 systematic reviews (69 RCTs, 4,947 participants) were included in the review of reviews. High-quality reviews suggested inconclusive evidence; lower quality reviews indicated light therapy, napping, physical activity, dietary supplements, mobile health apps and mindfulness may be effective in improving sleep quality and subjective sleepiness.

WP2: Of the 443 NHS staff who completed the survey, 71% (n=315) met the probable SWD criteria. Twenty-one managers participated in the survey of managerial experience. The majority (n=15, 71%) reported lack of training/information on impact of shift work.

WP3: Of the 285,175 participants in the UK Biobank who were employed, 48,975 (17.2%) were shift workers. Shift work was associated with higher odds of sleep disorders compared to non-shift work, with greatest odds observed among those always working night shifts (OR:1.21, 95%CI:1.16-1.27). The association was significantly modified by age ($p < 0.0001$), ethnicity ($p = 0.0005$) and smoking status ($p = 0.04$).

WP4: A multi-component complex behavioural intervention for SWD has been developed (Oxford Behavioural Intervention for Shiftwork (Ox BIS)) and is being tested in a feasibility study with 30 shift workers with SWD.

WP5: The intervention and study procedures will be refined based on the feasibility study findings. A RCT with 600 participants is planned to test the cost-effectiveness of the intervention in 2026.

Conclusions: Through a systematic, interdisciplinary programme of research, we aim to address the problem of SWD in NHS shift workers.

Acknowledgments: This project is funded by the NIHR Programme Grants for Applied Research programme (NIHR203667).

Sleep regularity is related to variance in sleep stage composition

W. Cheng¹, J. Stone², Y. Yap³, J. Wiley¹, A. Phillips⁴

¹Monash University, School of Psychological Sciences, Melbourne, Australia, ²The University of Melbourne, Melbourne School of Psychological Sciences, Melbourne, Australia, ³RMIT University, School of Health and Biomedical Sciences, Melbourne, Australia, ⁴Flinders University, Flinders Health and Medical Research Institute (Sleep Health), Adelaide, Australia

Introduction: Irregular sleep-wake patterns are linked to numerous adverse health and well-being outcomes, but the underlying mechanisms remain largely unknown. One potential mechanism is changes in sleep stage composition, since irregular sleep patterns entail sleeping for variable durations, and at variable circadian phases and levels of sleep homeostatic pressure. However, this association has yet to be studied.

Materials and methods: We investigated the relationship between sleep regularity and sleep stage composition (light, deep, REM sleep) measured using Z-Machine Insight+ home EEG devices in 97 healthy young adult university students in Victoria, Australia (80.41% Female, mean±SD age 20.55±1.65 years) across a total of 1101 nights (11.35±3.46 nights per participant). Sleep regularity was measured using the Sleep Regularity Index (SRI). At the daily level, we measured sleep duration, variations in sleep onset and offset times, time awake before each sleep episode, and the hourly stage transition rates. Partial correlations were used to assess the association between sleep regularity and sleep stage composition, while controlling for mean sleep duration. Piecewise linear mixed-effects models were used to examine sleep stage composition using daily-level predictors.

Results: Lower SRI was associated with greater standard deviation in both absolute amounts (all $p < .001$, $r_{\text{partial}} = -.53$ to $-.45$) and percentages (all $p < .05$, $r_{\text{partial}} = -.53$ to $-.28$) of light, deep, and REM sleep, lower mean percentage REM sleep ($p = .042$, $r_{\text{partial}} = .24$), and more frequent wake-sleep transitions ($p = .008$, $r_{\text{partial}} = .30$). At the daily level, longer sleep duration was associated with greater absolute amounts of light, deep, and REM sleep, greater percentages of light and REM sleep, but a lower percentage of deep sleep (all $p < .05$). Shorter time awake and later sleep onset were associated with

lower amount and percentage of deep sleep (all $p < .001$). Earlier sleep offset was associated with lower percentage of light sleep, lower amount and percentage of REM sleep (all $p < .05$), and more frequent wake-sleep transitions and less frequent transitions to and from REM sleep (all $p < .001$).

Conclusions: Less regular sleep-wake patterns were associated with greater variance in sleep stage composition, which may partially explain the link between irregular sleep-wake patterns and negative health outcomes. Analysis at the daily level revealed that changes in sleep stage composition are primarily explained by changes in sleep duration, rather than changes in sleep timing. Maintaining consistent sleep duration is likely a key target for stabilizing sleep stage composition in irregular sleepers.

Acknowledgments: The authors would like to thank all participants and staff involved in the Stress and Health Study. We appreciate your time and effort to make this research possible. Cheng was supported by the Monash Graduate Scholarship and the Monash International Tuition Scholarship. Wiley and Stone were supported by NHMRC grants #1178487 and #2025333, respectively.

SleepSync: Effectiveness of a personalised, implementation-ready tool for sleep and circadian health management in shift workers

P. Varma¹, S. Postnova², S. Knock², M. Howard³, S. Rajaratnam¹, T. Sletten¹

¹Monash University, School of Psychological Sciences, Melbourne, Australia, ²The University of Sydney, School of Physics, Sydney, Australia, ³Austin Health, Institute for Breathing and Sleep, Melbourne, Australia

Introduction: Two-thirds of shift workers experience poor and inadequate sleep. This chronic disruption of sleep and circadian rhythms results in adverse consequences for health, safety and productivity. Current management strategies are mostly one-size-fits-all, not accounting for differences in human biology, work environments, individual requirements, and the need for interventions that support an ageing workforce. SleepSync is a patented smartphone application that uses biomathematical modelling (the Model of Arousal Dynamics) to deliver tailored strategies for sleep and alertness, with educational toolkits and visual feedback on recovery. It has been previously co-designed and successfully piloted in healthcare, defence and other shift work industries.

This open-label trial aimed to a) evaluate effectiveness of SleepSync in improving sleep and performance in shift working nurses, and older nurses; b) identify implementation pathways for personalised sleep and circadian health management.

Materials and methods: Thirty-two shift working hospital nurses (41.4 ± 7.1 y; 27 f; $n=14$ aged ≥ 50 y) used the SleepSync app for six weeks, including an initial two weeks of baseline where the app provided no recommendations. Sleep and mental health outcomes were assessed at baseline and post-intervention using the Insomnia Severity Index (ISI), the Sleep Hygiene Index (SHI), and the Depression, Anxiety and Stress Scale (DASS-21). Objective cognitive performance was evaluated via the 3-minute Psychomotor Vigilance Task (PVT) completed at the start and end of shift. Participant feedback on app acceptability and implementation of the app was also collected.

Results: In the overall sample, 71% of users saw remission from insomnia symptoms post app use. Mean ISI scores (Baseline = 16.4 ± 5.3 , Post app use = 10.2 ± 4.0 ; $p < .001$), SHI scores (Baseline = 27.6 ± 8.3 ; Post App Use = 20.5 ± 5.1 ; $p < .001$) and depression scores (Baseline = 5.1 ± 1.2 ; Post app use = 3.0 ± 1.8 ; $p < .01$) improved post intervention. After controlling for shift type, such as morning, evening or night, start or end of shift and age, there were significant improvements in median reaction time post app use (t -value = 4.2; $p < .01$). Preliminary analyses showed that at baseline, nurses ≥ 50 years had shorter sleep durations than those < 50 years (6.2 vs 7.4 hours, $p < .001$), but demonstrated greater reductions in ISI post-intervention (10.3 v/s 9.1 , $p = .03$).

Over 90% of users reported the app was easy to use, two-thirds of users reported the app satisfactory, 65.6% suggested they would recommend it to a friend. Integration with wearable technologies was identified as a key facilitator for long-term app use. Users noted that while they would readily use the app, it should be deployed via workforces to facilitate organisational level uptake and systemic implementation.

Conclusions: SleepSync demonstrates utility as a personalised, biomathematical model driven intervention that improves sleep, mental health and performance in shift workers, with potential to support an ageing workforce. Ongoing work is focused on a) integrating wearable technology to further personalise recommendations and reducing manual input, and b) embedding SleepSync into

organisational systems, such as healthcare and aviation as a sustainable pathway for sleep and circadian health management in shift work.

Sleep variability, eveningness and depression in adolescents: a case-control study

Y. Pan¹, F.T.W. Cheung^{1,2}, D.-D. Liao¹, F.Y. Jin¹, J.W.-Y. Chan³, N.Y. Chan³, Y.-K. Wing^{3,4}, S.X. Li¹

¹Sleep Research Clinic & Laboratory, Department of Psychology, The University of Hong Kong, Hong Kong, Hong Kong, SAR of China, ²Sir Jules Thorn Sleep & Circadian Neuroscience Institute, Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, United Kingdom, ³Li Chiu Kong Family Sleep Assessment Unit, Department of Psychiatry, Faculty of Medicine, The Chinese University of Hong Kong, Hong Kong, Hong Kong, SAR of China, ⁴Li Ka Shing Institute of Health Sciences, Faculty of Medicine, The Chinese University of Hong Kong, Hong Kong, Hong Kong, SAR of China

Introduction: Adolescence is characterized by a circadian shift towards eveningness and changes in sleep pattern. This period is also often associated with an increased incidence of psychopathology, such as depression. Greater intraindividual sleep variability has been linked to both eveningness and depression. However, limited research has explored the interplay between eveningness and depression in relation to sleep variability in youth. The present case-control study aimed to investigate sleep variability in adolescents with eveningness and/or depression, as well as to explore the correlates of sleep variability.

Materials and methods: Four groups of adolescents aged 12-20 years were recruited: eveningness and depression group (ED), eveningness only group (E), depression only group (D), and healthy controls. Eveningness was defined as a score of ≤ 41 on the Morningness-Eveningness Questionnaire. Depression groups met DSM-5 criteria for major depressive disorder or dysthymia. Participants completed a 7-day sleep diary with actigraphy monitoring and self-reported questionnaires to assess circadian preference, insomnia symptoms, depressive symptoms, and bedtime procrastination. Subjective and objective sleep variabilities were calculated using root mean squared successive differences from sleep diary and actigraphy data, respectively.

Results: A total of 95 participants (mean age: 17.82 s.d. 1.59 years, 76% female) were included in the analysis (ED: n = 23, E: n = 26, D: n = 25, C: n = 21). Both ED and D groups showed significantly more severe depressive symptoms compared to E and C groups (all ps < .001). ED group showed greater variability in time in bed (vTIB) compared to D group (sleep diary: p = .033; actigraphy: p = .040) and controls (sleep diary: p = .025; actigraphy: p = .013). ED group also showed greater variability in sleep offset (vSOFF) and rise time (vRT) as measured by sleep diary compared to D group (SOFF: p = .009; RT: p = .004) and controls (SOFF: p = .037; RT: p = .012). ED group showed greater variability in sleep offset as measured by actigraphy compared to E group (p = .034), D group (p = .005), and controls (p < .001). E group showed greater variability in time in bed as measured by actigraphy (p = .026) compared to controls. Regression analyses showed that stronger eveningness preference was independently associated with greater sleep variability in TIB, TST, and RT as measured by sleep diary, and TIB as measured by actigraphy (all ps < .05). No other associations were found between sleep variability parameters and insomnia symptoms, depressive symptoms, or bedtime procrastination.

Conclusions: The present study suggested a synergetic effect of eveningness and depression on increasing sleep variability in adolescents. Evening preference was independently associated with greater sleep variability. Future research may consider adopting a longitudinal design to further elucidate the relationships between sleep variability, chronotype preference and depression and to explore the effects of circadian-focused interventions on reducing sleep variability and depressive symptoms in youth.

The Association between Sleep Quality and Irregular Meal Timing among Malaysian Healthcare Workers in Rotating Shifts

N. Juliana¹, N.A.S. Mohd Azmi¹, N.I. Mohd Fahmi Teng², S. Azmani³

¹Universiti Sains Islam Malaysia, Faculty of Medicine and Health Sciences, Nilai, Malaysia, ²Universiti Teknologi Mara, Centre for Dietetics Studies, Faculty of Health Sciences, Puncak Alam, Malaysia, ³KPJ Healthcare University, Nilai, Malaysia

Introduction: Shift work often disrupts the natural circadian rhythm, significantly impacting both nutritional habits and sleep patterns. Among healthcare professionals, poor sleep quality may be exacerbated by irregular eating schedules, particularly in relation to chrononutrition behaviors. Despite growing global interest, studies investigating the interplay between sleep quality and chrononutrition among Malaysian shift workers remain limited. This study aimed to assess the association between chrononutrition behaviors and sleep quality among Malaysian healthcare shift workers.

Materials and methods:

A cross-sectional study was conducted involving 368 healthcare shift workers from three hospitals in Klang Valley. Participants aged 19 to 60 years working on a 3-shift rotation were selected via simple random sampling. Those with diagnosed sleep disorders, mental illness, or chronic diseases were excluded. Chrononutrition behaviors and sleep quality were assessed using the validated Chrononutrition Profile Questionnaire (CPQ) and the Pittsburgh Sleep Quality Index (PSQI).

Results: Most participants exhibited favorable behaviors in breakfast skipping, night eating, and eating window timing, while moderate behaviors were seen in evening eating, largest meal timing, and evening latency. However, 51.9% of participants demonstrated poor sleep quality. Significant predictors of sleep quality included age, marital status, and breakfast skipping behavior ($p < 0.05$). Logistic regression revealed that younger participants (AOR = 3.51; 95% CI: 1.5–8.3), those not married (OR = 1.82; 95% CI: 1.1–3.0), and those with poor breakfast skipping habits (AOR = 2.12; 95% CI: 1.3–3.5) had higher odds of poor sleep quality.

Conclusions: Findings underscore the need to prioritize sleep health in relation to eating patterns among healthcare shift workers. Targeted interventions that improve chrononutrition behaviors could be instrumental in enhancing sleep quality and overall well-being in this vulnerable population.

Acknowledgments: We acknowledge healthcare shift workers from the Ministry of Health and KPJ Healthcare Hospitals for their commitment in this study. The association between timings of food intake and the risk of obstructive sleep apnoea: findings from the 2017-2020 NHANES Study

Y.N. Yong¹, D.M. O' Driscoll^{2,3}, A.J. McCubbin¹, G.P. Texeira^{4,5}, N.B. da Cunha^{4,5}, E. Schembri^{2,3}, C.A. Crispim^{4,5}, M.P. Bonham¹

¹Monash University, Department of Nutrition, Dietetics and Food, Melbourne, Australia, ²Monash University, Eastern Health Clinical School, Melbourne, Australia, ³Eastern Health, Department of Respiratory and Sleep Medicine, Melbourne, Australia, ⁴Federal University of Uberlândia, Chrononutrition Research Group, Faculty of Medicine, Uberlândia, Brazil, ⁵Federal University of Uberlândia, Graduate Program in Health Sciences, Faculty of Medicine, Uberlândia, Brazil

Introduction: Obesity is a key risk factor contributing to obstructive sleep apnoea (OSA) and its severity. Late or mistimed eating potentiates the development of obesity and cardiometabolic disorders, with circadian misalignment as the underlying mechanism compromising metabolism. The severity of OSA and poor sleep quality may also be associated with late as compared to earlier meal timings. Given the multidirectional association between obesity, circadian misalignment and OSA risk, this cross-sectional analysis aims to investigate if mistimed eating patterns (such as extended daily eating windows and later intake timings) are associated with OSA risk in a large population cohort.

Materials and methods: Data from adult participants (not pregnant/breastfeeding) in the National Health and Nutrition Examination Survey (NHANES) 2017-2020 pre-pandemic cycle were analysed. OSA risk was computed as a composite score ranging from 0 to 7, with reference to the presence of risk factors identified in the STOP-BANG scoring system (frequent snoring, excessive daytime sleepiness, occurrence of breathing pauses during sleep, high blood pressure, body mass index (BMI) $>35\text{kg/m}^2$, age >50 years, and male gender). A score threshold of 3 was used as a predictor of OSA.

Chrononutrition variables – eating window, the first and last timing of energy intake, timing of the highest energy intake, eating midpoint and caloric midpoint, were obtained from 24-hour dietary recalls, and classified into tertiles. Weighted sample logistic regression was conducted to assess the associations between OSA risk and the aforementioned chrononutrition variables, with adjustment for demographic (race/ethnicity, education level, marital status and family income) and lifestyle (physical activity, shift work and sleep duration) variables. Sensitivity analysis with daily energy intake as a potential mediator was performed via causal mediation analysis.

Results: Among the 6,265 eligible participants, 44.7% were identified to be at risk of OSA. Compared to those in the first tertile (eating window (mean/SD): 8.13 ± 2.08 h), participants with a longer eating window (third tertile) had a higher odds of OSA risk (13.90 ± 1.59 h: OR=1.44, 95%CI(1.15, 1.80), $p=0.003$). Participants with a later last timing of intake (third tertile; $22:38 \pm 1:32$) had a higher odds of OSA risk (OR= 1.21, 95%CI(1.01, 1.45), $p=0.040$) as compared to the first tertile ($18:22 \pm 1:10$). Participants with a later caloric midpoint (time point in which 50% of energy intake was met; $18:23 \pm 1:24$) also showed an increased odds of OSA (OR=1.23, 95%CI(1.01, 1.49), $p=0.042$), relative to an earlier timing of $12:32 \pm 1:15$. However, the effect of these variables on OSA risk were attributed to daily energy intake as a mediator. There were no associations between OSA risk and other timing of intake variables observed.

Conclusions: Individuals with an extended eating window and a later last timing of intake and caloric midpoint are at an increased risk of OSA, mediated by increased energy intake throughout the wider daily window. These findings present opportunities for trialling dietary interventions such as time-restricted eating concurrent with reducing the overall energy intake, in populations with obesity and sleep disorders, such as OSA.

The Cyclical Daytime Sleeper: A Rare Case of a Sighted Teenager with Non-24-Hour Sleep-Wake Disorder

A. Valenzuela¹, A. Nguyen², D. Dominguez¹, M. Chaung²

¹Banner Health, Sleep Medicine, Mesa, United States, ²University of Arizona - College of Medicine, Phoenix, United States

Introduction: Daytime fatigue in teenagers may be hand-waved as hours of screen time before bed and it can be difficult for families to accurately describe sleep habits. These factors often obscure an underlying sleep disorder. Here we report the rare case of a sighted teenage patient who presented with sleep disturbance and erratic bedtimes and was found to have non-24-hour sleep wake disorder (N24SWD).

Materials and methods: A 16-year-old male with a past medical history of ADHD and very chronic insomnia presented to the sleep clinic for evaluation of recurrent and inappropriate sleep times with residual hypersomnolence. The pediatrician evaluated the patient for profound difficulty waking up for school as well as trouble falling asleep at night. Initially, it was suspected to be insomnia due to poor sleep hygiene secondary to significant electronic usage prior to bedtime. When symptoms did not improve, the patient was started on various hypnotics including clonidine to help with sleep. A daytime stimulant was added and titrated for wakefulness. Various pharmaceutical regimens did not help with sleep symptoms, and the patient's hypersomnolence led to cyclical absenteeism from school and risk for expulsion.

On initial presentation to the sleep clinic, patient and family had notable difficulty describing his erratic sleep routine. Two weeks of sleep diaries were provided to help characterize the patient's sleep patterns. No suspicion for sleep disordered breathing, parasomnias nor restless leg syndrome were noted.

Results: Sleep diary showed a sleep pattern delaying consistently by 1-2 hours each day. Total sleep each night was 7-9 hours, with sleep onset latency of 30 minutes and no significant awakenings. This activity is classic for non-24 sleep-wake phase disorder. This patient was treated with a combination of timed Tasimelteon and bright light therapy along with chronotherapy for resynchronization of the intrinsic circadian rhythm. His sleep pattern normalized shortly after starting treatment and patient was able to resume normal academic and social activities.

Conclusions: N24SWD is commonly seen in blind individuals affecting up to 50% of that population. It is very rare in sighted individuals, and may be harder to discern when confounded with conditions like

ADHD or poor sleep hygiene. Having patients complete a sleep diary is a cost effective and low investment intervention that may elucidate their condition and ensure timely treatment. Treatment can be straightforward with medications such as tasimelteon, and have profound impacts on a teenager's quality of life.

The Impact of Different Feeding Patterns on Neonatal Sleep Patterns: A Multicenter Cross-Sectional Survey

Q. Zhai¹, T. Bai², H. Chen², Y. Pan¹, B. Shen²

¹Shanghai Jiao Tong University, School of Nursing, Shanghai, China, ²Shanghai Children's Medical Center, Department of Nursing, Shanghai, China

Introduction: Sleep is essential for neonatal brain development, synaptic plasticity, and cognitive outcomes. Recent studies suggest that breast milk may influence infant sleep, not only through its nutritional components but also via circadian variations in its composition. However, few studies have specifically investigated the impact of feeding patterns on neonatal sleep. This study aims to investigate the effects of different feeding patterns on neonatal sleep, thereby providing preliminary evidence for the role of breast milk as a potential circadian time cue.

Materials and methods: A multicenter cross-sectional study was conducted from October 2024 to March 2025 in seven tertiary hospitals in eastern China. Trained nurses surveyed neonates and their caregivers (mostly mothers) in neonatal units using a self-designed questionnaire covering demographics, sleep status, and sleep habits. The questionnaire was adapted from the BISQ and a Chinese infant sleep scale, revised based on clinical practice, and finalized through expert consensus.

Results: A total of 533 neonates were included, with 111 in the breastfeeding group, 75 in the formula-fed group, and 347 in the mixed-feeding group. Significant differences were observed among the three groups in maternal education level ($p < 0.05$) and several sleep-related variables. These included daytime sleep duration ($F = 3.49$, $p = 0.0311$), nighttime sleep duration ($F = 3.65$, $p = 0.0268$), frequency of nighttime awakenings ($\chi^2 = 8.2165$, $p = 0.0164$), and sleep position ($\chi^2 = 13.5811$, $p = 0.0011$). Formula-fed neonates had more frequent nighttime awakenings, while breastfed and mixed-fed neonates showed slightly longer nighttime sleep durations. A subgroup analysis was conducted within the mixed-feeding group based on feeding proportion, and a significant difference was found in the frequency of nighttime awakenings ($\chi^2 = 10.2344$, $p = 0.006$), suggesting that infants receiving a higher proportion of formula may be more prone to waking at night.

Conclusions: Feeding patterns were associated with differences in neonatal sleep characteristics. Although overall sleep duration generally exceeded the recommended 18 hours, breastfed neonates had total sleep durations closer to the guideline and fewer nighttime awakenings, suggesting that breastfeeding may be more beneficial for neonatal sleep. These patterns may be related to better maternal-infant circadian rhythm alignment. Differences in sleep posture may reflect institutional guidance, which may not fully align with WHO recommendations for supine positioning. The findings highlight the potential impact of feeding practices on neonatal sleep and underscore the importance of improving caregiver awareness of infant sleep.

The Impact of Oral Contraceptive Intake Timing on Women's Sleep Patterns

A.G. Bezerra¹, M.P. Khoury^{1,2}, G.N. Pires¹, J.C.F. Galduróz¹, F.R. Araújo³, S. Tufik^{1,4}, H. Hachul^{1,4}

¹Universidade Federal de Sao Paulo, Sao Paulo, Brazil, ²Universidade Santo Amaro (UNISA), Sao Paulo, Brazil, ³Universidade Federal de Sao Paulo, Santos, Brazil, ⁴Instituto do Sono/Associação Fundo de Incentivo à Pesquisa, Sao Paulo, Brazil

Introduction: Sleep complaints are common concerns among women and can significantly impair overall well-being. Previous studies suggested a potential link between oral contraceptive use and insomnia symptoms, excessive daytime sleepiness and poor sleep quality in women of reproductive age. However, the direction of this association is unclear, with some studies suggesting that contraceptives might improve sleep, while others point out that it may worsen it. A possible explanation may rely on the real-life patterns of use, and the timing of contraceptive ingestion may play

a role in these effects. This study aimed at investigating whether the time oral contraceptives are taken influences sleep quality in women of reproductive age.

Materials and methods: Women aged 18 and older who consistently used oral contraceptives were invited to participate in an online survey. Recruitment was conducted via email and social media. Exclusion criteria included irregular contraceptive use (including changes in contraceptive use pattern in the last 3 months), users of non-oral contraceptives (such as intrauterine devices), pregnant, breastfeeding and postmenopausal women, night-shifts workers, individuals taking medications affecting sleep, and individuals with psychiatric or uncontrolled clinical conditions. The questionnaire collected demographic information and sleep-related outcomes, including chronotype (Morningness-Eveningness Questionnaire short version – MEQs), sleep quality (Pittsburgh Sleep Quality Index – PSQI), daytime sleepiness (Epworth Sleepiness Scale – ESS), and insomnia symptoms (Insomnia Severity Index – ISI). Based on self-reported contraceptive intake times, participants were divided into three groups: morning (4:00–10:00 AM), midday (11:00 AM–2:00 PM), and evening (7:00 PM–1:00 AM). Categorical variables were examined with Fisher's exact test, while continuous variables were analyzed using the General Linear Model. Analyses were performed using Jamovi software, with p-values <0.05 considered as statistically significant.

Results: Out of 705 respondents, 439 met the inclusion criteria. Of these, 71 reported taking contraceptives in the morning, 54 at midday, and 321 in the evening. The average participant age was 26.17 ± 6.68 years. Most were single, white, had completed high school, earned between four and five minimum wages, had a eutrophic BMI, and used combined oral contraceptives. Demographic variables did not significantly differ across intake timing groups. The majority of participants had an intermediate chronotype (72.2%), mild insomnia symptoms at IGI (78.5%), excessive daytime sleepiness at ESS (54.5%), and poor sleep quality at PSQI (64.8%). No statistically significant associations were found between the timing of contraceptive use and chronotype ($p=0.06$), insomnia severity ($p=0.361$), daytime sleepiness ($p=0.085$), or sleep quality ($p=0.98$).

Conclusions: The findings indicate that the timing of oral contraceptive intake does not significantly affect sleep parameters. Although being an observational study based on subjective self-report sleep outcomes, this research contributes to a relatively underexplored area of women's health. Further studies are required, including randomized controlled trials, to further investigate the effects of contraceptives on the sleep pattern of women with reproductive age.

Acknowledgments: This study was funded by Associação Fundo de Incentivo à Pesquisa (AFIP). ST and JCFG received funding from Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq). AGB and MPK received funding from the São Paulo Research Foundation (FAPESP - #2023/07603-4).

The Impact of Shift Work on Eating Patterns and Glucose Levels in Medical Interns: An Observational Study

N.I. Chee¹, S. Massar¹, R. Leong¹, A. Ng¹, M. Chee¹

¹National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore

Introduction: Shift work, particularly night shifts, is an established disruptor of circadian rhythms and is linked to adverse metabolic outcomes, including impaired glucose regulation. Medical interns represent a population at heightened risk due to long and irregular working hours. Understanding the interplay between shift schedules, eating behaviours, and glycemic control is critical for informing preventive strategies in this vulnerable group.

Materials and methods: We conducted a prospective observational study among medical interns from various departments at a large training hospital in Singapore. Participants were monitored over two weeks during regular day shifts and night shifts. Eating patterns were assessed by real-time photographic dietary logging via a mobile application. Each participant wore a continuous glucose monitoring (CGM) device for two weeks, enabling detailed analysis of interstitial glucose fluctuations. Primary endpoints included changes in meal timing, meal frequency, macronutrient distribution, and mean glucose. Statistical analysis was conducted using four time windows (evening: 17h–23h, night 23h–5h, morning: 5h–11h, afternoon: 11h–17h) and shift type (day shift, night shift) as factors in repeated measures ANOVA.

Results: A total of 61 interns (mean age 24.6 ± 1.0 years; 61% female) contributed data from 416 day shifts and 190 night shifts. Night shifts were associated with a significant shift in meal timing. While overall meal frequency was not different (2.4 ± 0.8 meals/day shift vs 2.6 ± 1.1 meals/night shift),

fewer meals were taken in the evening preceding a night shift (0.74 ± 0.5) compared to a dayshift (0.96 ± 0.4 meals, $p = 0.02$), and more meals were taken during the night (0.47 ± 0.5 meals/night shift vs. 0.05 ± 0.1 meals/day shift, $p < 0.001$) and morning period (0.69 ± 0.4 meals/night shift vs. 0.55 ± 0.4 meals/day shift, $p = 0.043$). Increased meals at night more often contained proteins, carbohydrates, and processed snacks, while meals less often contained fruit/vegetables during the evening. CGM data revealed a similar shift towards higher mean glucose levels during the nights (night shift: 88.3 ± 1.4 mg/dL vs. day shift: 82.8 ± 1.2 mg/dL, $p < 0.001$) and lower mean glucose levels in the afternoon following a night shift (night shift: 88.5 ± 1.6 mg/dL vs. day shift: 97.5 ± 1.2 mg/dL, $p < 0.001$).

Conclusions: Among medical interns, night shifts substantially alter eating behaviours, showing a redistribution of meal timing and a shift in macronutrient content toward more energy dense and processed food with lower fruit and vegetable intake. These behavioral changes were accompanied by shift in glycemic control, with higher night-time glucose levels and lower glucose during the afternoon post-night shift compared to day shifts. These findings underscore the need for targeted nutritional and organizational interventions to mitigate the adverse metabolic impact of shift work in healthcare professionals.

Acknowledgments: This study was supported by Centre Funds for the Centre for Sleep and Cognition from the Yong Loo Lin School of Medicine, and the Lee Foundation.

The impact of working nights or rotating shifts on sleep – A cross-sectional survey

T. Sugavanam^{1,2}, V. Parsons³, A. Stagg³, L. Holmes⁴, A. Keane⁴, I. Madan^{3,5}, S.D. Kyle⁶, D. Ray^{1,2}

¹University of Oxford, Oxford Centre for Diabetes, Endocrinology, and Metabolism (OCDEM), Oxford, United Kingdom, ²NIHR Oxford Biomedical Research Centre, Oxford, United Kingdom, ³Guy's and St Thomas' NHS Foundation Trust, Occupational Health, Safety and Wellbeing Service, London, United Kingdom, ⁴Manchester University NHS Foundation Trust, Vocal, Manchester, United Kingdom, ⁵King's College London, Faculty of Life Sciences & Medicine, London, United Kingdom, ⁶University of Oxford, Nuffield Department of Clinical Neurosciences, Oxford, United Kingdom

Introduction: Shift work although common in several sectors pose significant risks to the health of shift workers due to disruption of healthy sleep-wake schedules and may lead to shift work sleep disorder (SWD). Prevalence of SWD has been estimated around 27% globally, however, there are no prevalence studies in the United Kingdom. Our aim is to determine the prevalence and impact of SWD in the National Health Service (NHS) shift workers; to identify the associated health burden of SWD in this population; to describe interventions and support they have used to help with their sleep, its effectiveness, and the obstacles to their use.

Materials and methods: A cross-sectional survey (mix of validated questionnaires and bespoke questions) was developed through multiple meetings with a research advisory group comprising of ten shift workers. Survey items include: demographics, shift working pattern, SWD, physical and mental health, work productivity, interventions/support tried for sleep difficulties and its effectiveness. A participant who was employed by the NHS, worked shifts that involve working after 6pm or before 7am (i.e. non-standard hours) and worked non-standard hours for a minimum of 3 months was eligible to take part.

The study was conducted at two NHS Trusts between April and June 2025.

Results: Of the 534 who attempted the survey, 458 (86%) met eligibility criteria. 443 (97%) participants completed the survey. The mean age was 36.1 ± 10.7 years (range: 19-71). The majority of participants were female ($n=366$, 83%); registered nurses ($n=218$, 49%); and worked rotating shifts ($n=286$, 65%). Shift work duration varied from 3 months to 44 years.

Based on the SWDI, 315 (71%) met criteria for probable SWD. The proportion of probable SWD was statistically significantly higher in: females ($p=0.04$); higher NHS pay bands (5 and above) ($p=0.01$); shift work duration of more than 5 years ($p=0.01$); Registered Nurses and Midwives ($p=0.03$); the presence of a long-term health condition ($p=0.047$).

Participants with probable SWD had (i) lower EQ-5D-5L utility ($p<.001$) and VAS scores ($p<.001$) indicating poorer HRQoL, (ii) a higher proportion of likely depression ($p<.001$) and likely anxiety ($p<.001$) (iii) greater presenteeism (impairment while working) ($p<0.001$), higher overall work impairment/productivity loss ($p=0.001$) and greater activity impairment ($p<0.001$) due to their sleep problems.

The most common strategies tried by participants for their sleep problems were caffeine ($n=216$), naps

(n=206), changes in diet (n=167), change in physical activity and exercise (n=152) and over the counter sleeping aids (n=131). The majority of the participants indicated that these strategies were slightly or moderately effective. The majority (n=406, 92%) did not seek/receive support for their sleep difficulties.

Lack of awareness about available sources of support (n=155), busy schedule/time constraints (n=153) and long waiting times for appointments (n=152) were the most commonly chosen obstacles for seeking support.

Conclusions: The prevalence of SWD appears to be high in NHS shift workers. This has an adverse impact on their health and work productivity. Information collected on strategies used and their effectiveness will inform development of a new intervention for SWD.

Acknowledgments: This project is funded by the NIHR Programme Grants for Applied Research programme (NIHR203667).

The influence of chronotype on physical activity and sleep in community-dwelling older adults

J.L. Eckhardt^{1,2}, A.L. Isenberg¹, T. Monreal³, J. Stradford⁴, L. Fenton⁵, W. Mack⁶, K. Espejo¹, M. Barnecllo¹, Y. Dong¹, J. Pa¹

¹University of California, San Diego, Alzheimer's Disease Cooperative Study (ADCS), Department of Neurosciences, La Jolla, United States, ²University of California, San Diego, Neurosciences Graduate Program (NGP), La Jolla, United States, ³University of Southern California, Mark and Mary Stevens Neuroimaging and Informatics Institute, Los Angeles, United States, ⁴University of California, San Diego, SDSU/UCSD Joint Doctoral Program in Clinical Psychology, La Jolla, United States, ⁵University of Southern California, Department of Psychology, Los Angeles, United States, ⁶University of Southern California, Department of Population and Public Health Sciences, Los Angeles, United States

Introduction: Chronotype refers to an individual's natural tendency to sleep or be alert at specific times over a 24-hour period. It is widely known that different chronotypes exhibit diverse patterns of wake and sleep. However, it is less clear how having an earlier or later chronotype differentially impacts daytime activity levels, sleep, and circadian stability, particularly in older adults with objective early cognitive impairment. This study investigates how the midpoint of sleep—a reliable continuous measure of chronotype—is associated with measures of physical activity and sleep in older adults with early cognitive impairment.

Materials and methods: This analysis utilized cross-sectional data from two clinical trials with a combined sample of 196 older adults ages 50-85 with objective early cognitive impairment, defined as performance on cognitive testing measuring at least one standard deviation below age-matched normative values. Participants wore a GENEActiv accelerometer for an average of 23.5 ± 6.76 days (range: 8-37). All analyses were conducted in R (version 4.4.2), and raw accelerometry data were processed with GGIR (version 3.2-6).

Sleep midpoint was calculated as the time halfway between sleep onset and wakeup measured relative to midnight, and served as an indicator of chronotype. Daytime physical activity measures included average acceleration (milli-gravity) and accumulated time (hours) in inactivity, light physical activity, and moderate physical activity. Sleep was assessed with sleep duration (hours), which is accumulated nocturnal sleep within the sleep window. Stability of sleep-wake patterns between days was assessed with the circadian marker interdaily stability (derived with R package nparACT version 0.8).

Multivariable linear regression analyses were conducted to test for associations between sleep midpoint and activity/sleep measures. Exploratory mediation analyses were conducted *post hoc* to investigate mechanistic pathways through which sleep midpoint may impact sleep duration. Outliers beyond ± 3 standard deviations were removed from analyses. All models were adjusted for the covariates of age and sex.

Results: Sleep midpoint was significantly associated with daytime hours accumulated in inactivity ($b=0.32$, $p<0.001$) as well as daytime average acceleration ($b=-1.33$, $p=0.026$), indicating that participants with earlier sleep midpoints spent less time inactive and had higher average activity levels. Sleep midpoint was not associated with light ($p=0.57$) or moderate physical activity ($p=0.19$). Sleep midpoint was negatively associated with sleep duration ($b=-0.16$, $p=0.015$) and interdaily stability ($b=-0.02$, $p=0.003$), such that participants with earlier sleep midpoints had a longer sleep duration and more

stable sleep-wake patterns. *Post hoc* exploratory mediation analyses revealed statistically significant indirect effects of sleep midpoint on sleep duration via time accumulated in inactivity (Total Indirect Effect $b = -0.17$, $p < 0.001$).

Conclusions: In older adults with early cognitive impairment, earlier chronotypes were more active, slept for a longer duration, and had more stable sleep-wake rhythms compared to later chronotypes. The relationship between earlier chronotype and longer sleep duration was mediated by less daytime inactivity. As sleep and circadian dysfunction are an early risk factor for neurodegenerative diseases, older adults should leverage individualized lifestyle modifications to sleep midpoint and daytime activity based on their chronotype to improve sleep/circadian quality and reduce individual risk for cognitive decline.

The role of light in predicting circadian phase shifts in shift workers

Y. Ji¹, L. Shen¹, S. Postnova², S.A. Knock², Y. Zhong¹, M. E. Howard³, J. E. Stone^{4,1}, E. Facer-Childs¹, S. M.W. Rajaratnam^{1,5}, T. L. Sletten¹

Introduction: Shift workers exhibit substantial individual variability in circadian response to shift work. This variability remains poorly understood. Light exposure, a critical environmental cue for circadian phase shifts, has been shown to account for this individual variability in circadian timing following night shifts. This study aims to explore the predictive role of light exposure for circadian timing across diverse roster patterns.

Materials and methods: In an ongoing study, shift workers ($n = 40$, age 37.26 ± 9.02 years, 19 females) were monitored during a usual 6-day roster. Roster patterns included consecutive night shifts, consecutive early morning shifts, early morning-to-night rotations and night-to-early-morning rotations. Participants completed daily sleep diaries and wore a wrist activity monitor to assess sleep-wake timing, and a lapel-worn light sensor for continuous measurement of light exposure. Circadian phase was assessed on the first and last day of roster via 6-sulphatoxymelatonin (aMT6s) acrophase (peak) in urine. The phase-shifting effect of light was quantified as the mean difference in light exposure levels between the phase advance (3-7 hours after acrophase) and phase delay zones (3-7 hours before acrophase) of the circadian phase response curve to light across 6 days. Phase advance/delay zones were adjusted each day to account for individual phase shift per day.

Results: Preliminary analyses revealed substantial individual variability in the magnitude and direction of phase shifts across roster patterns (mean magnitude of phase shifts = 1.77 ± 1.60 h; range = -6.57 to $+4.92$ h). For example, following consecutive night shifts, phase shifts varied from -5.53 h to $+4.92$ h (mean = -1.11 ± 2.57 h). 10 participants exhibited a phase delay and three exhibited a phase advance. Following consecutive morning shifts, phase shifts varied from -2.38 h to $+3.22$ h (mean = $+0.80 \pm 1.31$ h). Seven participants exhibited a phase advance and two exhibited a phase delay. The degree of phase shift in either direction was significantly associated with the difference in light exposure between the advance and delay zone across the 6 days ($\beta = 0.001$, $p = .0004$, $R^2 = .29$). Including diurnal preference in the model improved explanatory power, with the multiple regression accounting for 43% of the variance in phase shifts (adjusted $R^2 = .40$). Further analyses will examine whether the predictive power of light exposure varies across different roster types.

Conclusions: Preliminary findings highlight substantial individual variability in circadian phase responses to various roster patterns. This variability was shown to be partly explained by differences in light exposure during the critical periods of the human circadian phase response curve to light. These results support the predictive role of light exposure in understanding circadian phase shifts across different roster patterns. This research is important for improving the prediction of circadian timing to inform personalised interventions for shift workers.

The role of plasma Melatonin levels in regulating systemic inflammation in patients with Obstructive Sleep Apnea Syndrome

L. Puiu¹, R.M. Nemes², C.M. Pop³, E. Tabacu⁴, S. Dumitrache Rujinski⁵, O.C. Deleanu⁶

¹Hospital of Pneumophthisiology, Pneumologie, Baia Mare, Romania, ²Respiratory pathophysiology "Marius Nasta" Institute of Pneumology, "Titu Maiorescu" University, Bucharest, Pulmonary Function Tests Department, Bucharest, Romania, ³"Iuliu Hațieganu" University of Medicine and Pharmacy, "Leon Daniello" Pneumophthisiology Clinical Hospital, Cluj Napoca, Pneumologie, Cluj-Napoca, Romania, ⁴"Marius Nasta" Institute of Pneumology, Bucharest, Pneumologie, Bucharest, Romania, ⁵"Marius Nasta" Institute of Pneumology, Bucharest, Pneumologie, Bucharest, Romania, ⁶University of Medicine and Pharmacy "Carol Davila", Pneumophthisiology II, Bucharest, Romania

Introduction: To assess the relationships between Melatonin and Obstructive Sleep Apnea Syndrome (OSAS). Melatonin, a neurohormone nocturnally produced by the pineal gland in the brain plays a crucial role in regulating the sleep-wake cycle. Melatonin has antioxidant, anti-inflammatory properties, and may be involved on glucose homeostasis related to insulin resistance and lipid metabolism.

Materials and methods: We conducted a retrospective cross-sectional study of 63 cases diagnosed with OSAS mean aged 54.74 ± 10.95 year-old, of which 40 was smokers and 23 nonsmokers. Demographic, anthropometric (Body Mass Index-BMI, neck and abdominal circumference), pack-years smoking, blood pressure, fasting lipid panels that includes: Triglycerides (TG), Total Cholesterol (TC), Low Density Lipoprotein cholesterol (LDLc), High Density Lipoprotein cholesterol (HDLc), Very Low Density Lipoprotein (VLDL) cholesterol, nonHigh-Density Lipoprotein (nonHDL) cholesterol, glycemia, leukocytes, thrombocytes, C Reactive Protein (CRP), albumin, uric acid, urea and creatinine were assessed. Melatonin and its metabolite, 6-hydroxymelatonin (a marker of plasma melatonin level) were determined through overnight urinary levels, by Liquid Chromatography Mass Spectrometry (LC-MS/MS) method and expressed in nmol/L. As a measure of insulin resistance, the Triglycerides Glucose (TyG) index was calculated as the natural logarithm (Ln) of plasma glucose and TG using the formula: $\text{Ln}(\text{TG} [\text{mg/dL}] \times \text{glucose} [\text{mg/dL}] / 2)$. Atherosclerotic cardiovascular disease (ASCVD) risk was assessed according to the American College of Cardiology/American Heart Association (ACC/AHA) guidelines. All the participants in the study completed the Epworth Sleepiness Scale (ESS) questionnaire and underwent Cardiorespiratory Polygraphy, in accordance with the established guidelines of the American Academy of Sleep Medicine. The scientific research program was conducted in accordance with the norms of ethics in effect: protection of personal data; use the biological samples for the intended purpose; and informed consent of the subjects. Statistical analysis included Spearman correlations tests, one-way ANOVA test, and two-tailed *t* test. A *p* value < 0.05 was considered statistical significant.

Results: The mean values of Melatonin was significantly higher in study group (smokers and nonsmokers) and in smokers ($p=0.0006$; $p=0.0003$). Apnea Hypopnea Index (AHI), Oxygen Desaturation Index (ODI), Pulse variance Index, TyG index, ASCVD risk were statistically significant higher in smokers versus nonsmokers ($p=0.02$; $p=0.001$; $p=0.008$; $p=0.03$; $p=0.04$). The average value of AHI in smokers and nonsmokers patients was 43.49 ± 19.76 , respectively 47.10 ± 21.60 in smokers and 35.90 ± 12.33 in nonsmokers. In study group (smokers and nonsmokers) statistically significant correlations were found between Melatonin and ODI ($r=-0.39$; $p=0.001$), AHI ($r=-0.27$; $p=0.02$), Lowest Desaturation% ($r=0.27$; $p=0.02$); Melatonin and TC ($r=0.30$; $p=0.01$), TG ($r=0.25$; $p=0.04$), LDLc ($r=0.28$; $p=0.02$), nonHDLc ($r=0.24$; $p=0.05$), while in smokers study group, between Melatonin and ODI ($r=-0.30$; $p=0.05$), TyG index ($r=0.37$; $p=0.01$), VLDL ($r=0.44$; $p=0.003$), LDLc/HDLc ratio ($r=0.34$; $p=0.02$); AHI and ASCVD risk ($r=0.34$; $p=0.03$), BMI ($r=0.34$; $p=0.03$).

Conclusions: In OSAS patients, Melatonin may have predictive value for disease severity and, should consider screening in patients with OSAS. Melatonin has a time-dependent regulation on glucose, lipid homeostasis, and body weight, and can be considered in the treatment of patients with OSAS.

Timed Blue-Light Intervention Enhances Alertness and Reduces Clinical Errors in ICU Night-Shift Nurses

C.-J. Wu^{1,2}, H.-R. Lin^{2,3}, K.-F. Zhang⁴, Y.-K. Lee^{3,4}

¹Kaohsiung Medical University, College of Nursing, Kaohsiung, Taiwan, ²Kaohsiung Armed Forces General Hospital, Nursing Department, Kaohsiung, Taiwan, ³National Sun Yat-sen University, Institute of Medical Science and Technology, Kaohsiung, Taiwan, ⁴Kaohsiung Armed Forces General Hospital, Medical Laboratory, Medical Education and Research Center, Kaohsiung, Taiwan

Introduction: Night-shift intensive care unit (ICU) nurses frequently suffer from circadian misalignment, resulting in elevated melatonin secretion, increased sleepiness, psychological stress, and reduced cognitive performance-factors associated with heightened risk of medical errors. To evaluate the efficacy of a timed blue-light intervention in mitigating circadian disruption and enhancing alertness, mood, and vigilance in ICU night-shift nurses.

Materials and methods: A quasi-experimental crossover design was implemented involving 22 ICU nurses. Participants were randomized to either wear blue-light emitting eyewear (460 nm, 1500 lux) for 20 minutes at 00:00, 02:00, and 04:00 during two consecutive night shifts, or remain under standard ambient lighting. After a one-month washout, subjects crossed over to the alternate condition. Key outcome measures included salivary melatonin levels, Karolinska Sleepiness Scale (KSS), Depression Anxiety Stress Scale (DASS-21), and 10-minute Psychomotor Vigilance Task (PVT), assessed before, during, and after each shift.

Results: Compared with the control condition, blue-light exposure suppressed melatonin levels by over 30%, decreased subjective sleepiness and stress scores by at least 20%, and improved PVT reaction time and accuracy by 15% and 10%, respectively. These effects were consistent across the crossover phases.

Conclusions: Timed blue-light exposure via eyewear is an effective, low-cost, non-pharmacological intervention to improve cognitive alertness, mood, and vigilance among ICU night-shift nurses, with potential to reduce clinical errors and enhance patient safety.

Acknowledgments: We thank the ICU nursing staff at Kaohsiung Armed Forces General Hospital for their participation and the Medical Laboratory, Medical Education and Research Center for logistical support.

Use of Apple Watch to Optimize Light Therapy and Reduce Circadian Misalignment for Night Shift Workers

M. Treger¹, A. Pockrass¹, I. Peeran¹, V. Van Rossen¹, E. Wernette¹, C. Drake¹, O. Walch², P. Cheng¹
¹Henry Ford Health, Detroit, United States, ²University of Michigan, Ann Arbor, United States

Introduction: Circadian misalignment, a primary etiology of mood, fatigue, and performance deficits in approximately 80% of shift workers, can be alleviated with targeted light interventions. However, general "light at night" interventions do not account for shift workers' variable circadian phases. Recently, our lab validated Apple Watch (AW) as a noninvasive means of predicting circadian timing (i.e. dim light melatonin onset, DLMO). Here, we extend this by examining the clinical utility of AW in informing circadian interventions. We hypothesized the AW-informed group would result in higher rates of circadian alignment following treatment vs the control (non-personalized) group. We also compared the magnitude of phase shifts between these interventions.

Materials and methods: Night shift workers (N=60) were randomly assigned to either the AW or control group, and DLMO was measured before and after treatment. AW data (accelerometer and heart rate) was collected over 2 weeks and processed through a biomathematical model of the human circadian system to produce estimated DLMOs. Light-dark schedules were then created from the corresponding phase response curves and implemented with light boxes and blue-blocker glasses (at-home or in-lab) to induce phase shifts. Participants in the control group followed a non-personalized light-dark schedule (light from 18:00 and 21:00; light avoidance from 04:00 and 10:00). Circadian alignment was operationalized as DLMO between 02:00 and 14:00, and a relative risk ratio was used to compare the rate of circadian alignment between the two groups.

Results: AW-Informed schedules resulted in a 64.7% increase in circadian-aligned subjects whereas Control resulted in a 40% decrease in circadian-aligned subjects ($p = .013$). Percent of subjects aligned post-treatment was 3.1 times higher in the AW group (62.2%) compared to the control group (20.0%). AW-Informed phase-delay schedules achieved average delays of 2.0 hours $\pm$ 4.7 SD, whereas control phase-delay schedules advanced subjects an average of 0.7 hours $\pm$ 3.7 SD ($p = .040$). The risk of

erroneously inducing circadian misalignment is 3.3 times greater using control schedules (13.3%) than AW-informed schedules (4.4%).

Conclusions: Personalized light-dark schedules made with wearables data are much more effective at correcting circadian misalignment. In fact, non-personalized "light at night" schedules may be *harmful* by further misaligning night shift workers. Consumer-based wearables are already commonplace and thus make this personalized circadian medicine solution highly scalable. In the future we aim to identify facilitators and barriers of implementing personalized circadian medicine in the real world.

Acknowledgments: Support for this study was provided from the National Institute of Health R01HL160870 and the AASM (245-SR-21) awarded to Dr. Philip Cheng.

Validation of the Bergen Shift Work Sleep Questionnaire in workers under split shift or early morning shift

A. Vallières^{1,2,3}, C.-É. Lavoie⁴, S. Waage⁵, B. Bjorvatn⁵, M. Lefrançois⁴

¹Université Laval, Ecole de psychologie, Quebec, Canada, ²Centre de recherche CERVO, Québec, Canada, ³Centre de recherche du CHU de Québec-Université Laval, Quebec, Canada, ⁴Université du Québec à Montréal, École des sciences de la gestion, Montréal, Canada, ⁵University of Bergen, Department of Global Public Health and Primary Care, Bergen, Norway

Introduction: The Bergen Shift Work Sleep Questionnaire (BSWSQ) was developed explicitly to assess sleep difficulties related to day, evening, and night shifts, as well as rest days. The BSWSQ is a unique questionnaire addressing sleep in relation to several types of shifts. Although this questionnaire possesses adequate psychometric properties, it does not capture sleep difficulties related to early morning or split shifts. These types of atypical schedules are frequent among school support staff, precarious, female-dominated jobs, and may have potential harmful effects on sleep and occupational health. To support future investigation of these impacts, this study aimed to validate an adaptation of the BSWSQ for early morning and split shifts and to examine the presence and stability of the two constructs (Insomnia/wakefulness and Sleepiness) within these shifts. The study also assesses discriminant and convergent validity.

Materials and methods: A total of 3,510 participants (94% women; 51.5% aged 45 years or older), including school daycare staff and specialized education technicians in direct student care, in the province of Quebec, Canada, were recruited and completed an online survey. The survey comprised several self-reported questionnaires: the BSWSQ – which includes 6 items targeting insomnia and sleepiness symptoms across four subscales (split, early morning, continued day shift, and rest days) – the Hospital Anxiety Depression Scale, and the Epworth Sleepiness Scale.

Results: A multilevel confirmatory factor analysis was conducted to model both stable between-person differences and within-person fluctuations in Insomnia/wakefulness and Sleepiness symptoms across work shifts, as supported by intraclass correlations (ICCs) ranging from .68 to .78. The model specified that Insomnia/wakefulness was measured by items 1 to 3 of the BSWSQ and Sleepiness by items 4 to 6 at both levels. Results demonstrated that the two-factor model (Insomnia/wakefulness and Sleepiness) held across levels, with strong fit indices and reliability metrics at both the within- and between-person levels. The metric invariant model demonstrated excellent fit to the data: robust CFI = .972, robust TLI = .952, robust RMSEA = .063, and SRMR = .038 (within) and .047 (between). Standardized loadings ranged from .609 to .768 for Insomnia/wake items and from .741 to .805 for Sleepiness items, indicating strong measurement consistency across contexts (day, morning, split) at both levels. The average Cronbach's alpha coefficient was of .851.

Conclusions: These results suggest that the two-factor structure provides an excellent approximation of the observed covariance matrices at both levels. Moreover, findings support the structural distinctiveness and reliability of both constructs (Insomnia/wakefulness; Sleepiness) at each level and indicate strong internal consistency across work shifts. Metric invariance across levels (within- vs. between persons) and scalar invariance across contexts (different work shifts), were also supported, confirming stable measurement properties. The psychometric strategy used strengthens the theoretical and applied value of the BSWSQ in occupational contexts, where sleep symptoms are intrinsically nested within individuals yet vary based on work demands. This advancement better aligns the instrument with its foundational purpose. Assessing the impact on sleep of two understudied types of atypical schedules will enrich the understanding of occupational health issues experienced by marginalized and precarious groups of workers.

Validation of the self-rating version of the Scale for Symptom Severity of Circadian Rhythm Sleep-Wake Disorders

T. Kitajima¹, R. Kumagai¹, M. Hirose¹, K. Funahashi¹, Y. Okuda², Y. Esaki¹, M. Takeuchi¹, A. Fujita¹, Y. Shinoda¹, R. Miyake¹, M. Endo¹, Y. Ito³, N. Iwata¹

¹Fujita Health University School of Medicine, Department of Psychiatry, Toyoake, Japan, ²Fujita Health University School of Medicine, Toyoake, Japan, ³Yokkaichi Nursing and Medical Care University, Department of Clinical Physiology, Yokkaichi, Japan

Introduction: There is no validated severity rating scale for intrinsic circadian rhythm sleep-wake disorders (CRSDWs), including delayed sleep-wake phase disorder (DSWPD). We developed "the Scale for Symptom Severity of Circadian Rhythm Sleep-Wake Disorders," which has relatively good reliability and validity. We adapted it into a self-rating version, and this study aimed to examine its reliability and validity.

Materials and methods: The self-rating version of the Scale for Symptom Severity of Circadian Rhythm Sleep-Wake Disorders is described in Japanese and consists of 12 items with 4 or 6 anchor points, with a total score range of 0 to 40. It includes items such as problems with sleep onset and offset at the desired times the patients defined, social adaptation, morning or daytime symptoms in physical and neuropsychiatric areas, deviations from 24-hour regularity such as free-running, irregular patterns, and variations in awakening time, over the past one week. Twenty-three patients with DSWPD, diagnosed according to the International Classification of Sleep Disorders, 3rd edition, who visited the Department of Psychiatry at Fujita Health University Hospital, were included in this study. Any ongoing treatments or comorbidities were allowed for inclusion. At any point during the patients' treatment course, patients were asked to rate their own symptoms using this questionnaire. Simultaneously, the structured interview version of the scale was administered independently by two physicians, with these scorings kept hidden from the patients. Additionally, the following assessments were conducted: the Clinical Global Impression of Illness Severity (CGI-S) by the physician in charge, and the Morningness-Eveningness Questionnaire (MEQ), Munich Chronotype Questionnaire (MCTQ), and subjective complaints regarding quality of life assessed using a Likert scale, by the patients. The study was approved by the Ethics Committee of Fujita Health University, and all participants provided written informed consent.

Results: Twenty-three patients with DSWPD were included in the analysis. The Cronbach's alpha coefficient was 0.7617. Spearman's rank correlation coefficients between the total score of the self-rating scale and each measure were as follows: 0.8395 and 0.7782 for the structured interview version of the scale (for two raters), 0.6187 for CGI-S, -0.6366 for subjective complaints by Likert scale, -0.5104 for MEQ, and 0.6359 for MSFsc (MCTQ); all these correlations were statistically significant.

Conclusions: The data in this study suggested that this self-rating version of the scale has relatively good internal consistency and criterion validity. Because the number of samples was small, it would be preferable to confirm the findings with a larger sample size, as well as to examine the response to symptom changes using longitudinal data.

Wearable-device-measured light at light exposure and Irritable bowel syndrome risk

N. Zheng^{1,2}, B. Lin^{1,3}, W. Wang^{1,2}, Y. Fan^{1,2}, Y. Yang³, J. Zhang^{1,2}, H. Feng^{1,2}

¹The Affiliated Brain Hospital of Guangzhou Medical University, Center for Sleep and Circadian Medicine, Guangzhou, China, ²Guangzhou Medical University, Key Laboratory of Neurogenetics and Channelopathies of Guangdong Province and the Ministry of Education of China, Guangzhou, China, ³The First Affiliated Hospital of Jinan University, Department of Neurology, Guangzhou, China

Introduction: Irritable bowel syndrome (IBS) affects approximately 7–21% of the global population. Circadian rhythm disruption (CRD) is increasingly recognized as a contributing factor in gastrointestinal

disorders. Light at night (LAN), a common feature of modern environments, is a primary external cue for circadian misalignment. However, the relationship between LAN exposure and IBS risk remains unclear. This study aimed to investigate whether objectively measured LAN exposure is associated with incident IBS.

Materials and methods: We analyzed data from 67,590 UK Biobank participants (mean age: 62.7 years; 59.2% female), excluding baseline shift workers. LAN exposure was measured via wrist-worn accelerometers. IBS cases were identified through linked health records. Cox proportional hazards models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for IBS risk across LAN levels, adjusting for demographic, lifestyle, metabolic, psychiatric, and sleep-related covariates. Additionally, a series of sensitivity analyses were conducted to validate the main results.

Results: Over a median follow-up of 7.0 years (466,674 person-years), 820 incident IBS cases were recorded. A non-linear association was observed: IBS risk began to rise above an average nighttime LAN level of 175 lux. Participants exposed to >175 lux had a higher risk of IBS (HR = 1.35; 95% CI: 1.05–1.73) compared to those with lower exposure. Findings remained robust in multiple sensitivity analyses: excluding early IBS cases (within 1 or 2 years), using non-imputed data, restricting the sample to participants with ≥6 days of valid accelerometer wear, adjusting for the month of accelerometer measurement, and excluding individuals with high nighttime activity levels. All results remained significant ($P < 0.05$), confirming the robustness of the association.

Conclusions: Among older adults, higher LAN exposure was associated with an elevated risk of incident IBS. LAN exposure may serve as a novel and robust predictor of IBS risk, warranting further investigation.

Wearable Ring-Based Algorithm for Chronotype Estimation from Passive Physiological Data

I. Alikhani¹, M. Karsikas¹, H. Koskimäki¹, M. de Zambotti²

¹Oura Health Oy, Science, Oulu, Finland, ²Ouraring Inc., Science, San Francisco, United States

Introduction: Chronotype, an individual's preference for sleep-wake timing, influences cognitive function, metabolic health, and overall well-being. Traditional assessments, such as the Morningness-Eveningness Questionnaire (MEQ), rely on self-reports susceptible to recall bias. Advances in wearable technology enable the passive collection of physiological and behavioral data, offering a more objective alternative. This study proposes an algorithm leveraging sleep, physical activity, and distal skin temperature data from a wearable ring to estimate chronotypes unobtrusively. The MEQ score served as the reference standard for algorithm training and testing.

Materials and methods: Eighty-three healthy participants (46 women; Age, mean $\pm$ SD: 36.5 $\pm$ 7.8 years) consented to participate in the study and provided Oura Ring data. This data was collected over an 8-month period preceding their response to the study questionnaire, resulting in a total of approximately 13000 days of data across all subjects. Each participant contributed a median of 180 days of data to the dataset. Chronotype was estimated using a final dataset comprised of 90 calendar days, derived by rolling a window with a one-month step size across each participant's available data. The participants included 7 evening types (MEQ score $\leq$ 41), 27 morning types (MEQ score $\geq$ 59), and 49 classified as intermediate chronotypes (MEQ score 42–58).

Results: Data preprocessing included filtering for sleep sessions lasting longer than three hours and recorded within one hour of the user's most frequent timezone. Participants with at least 30 valid sleep sessions within the 90-day period were included in the analysis. Periods, when the ring was not worn were excluded, and physical activity and skin temperature data were synchronized with retained sleep instances. Handcrafted features were extracted from sleep, physical activity, and skin temperature data. Sleep features included median bedtime, wake time, and the standard deviation of sleep midpoint, reflecting sleep timing and regularity. Activity patterns were characterized by identifying the 10 most active and 5 least active consecutive hours, extracting their average activity levels, times of occurrence,

relative amplitude, acrophase, and maximum activity level. Similarly, for temperature, the 5 highest and 5 lowest consecutive hours were identified, and their average temperatures, times of occurrence, relative amplitude, acrophase, maximum and minimum temperatures, and temperature range were extracted. A linear regression model was employed, with group k-fold cross-validation used to assess generalizability. The model achieved a mean absolute error of 4.79 in MEQ score estimation and explained 67% of the variance in estimating MEQ scores from the extracted features ($R^2 = .67$).

Conclusions: These preliminary findings support the feasibility of estimating chronotypes using wearable ring data, offering an unobtrusive alternative to traditional questionnaire-based assessments. The algorithm demonstrated promising accuracy in predicting MEQ scores, suggesting its potential application in personalized health and behavioral interventions. Future studies should validate the algorithm in larger and more diverse populations to enhance its generalizability and applicability.

What would you do to reduce jetlag and when? Survey of a convenience sample of undergraduate students and implications for public education

Y.S. Bin^{1,2}, J.M.Y. Cheung³, S. Ledger^{1,4}, C. Caillaud^{1,5}, S. Postnova^{1,4}, P. Cistulli^{1,2}

¹University of Sydney, Charles Perkins Centre, Sydney, Australia, ²University of Sydney, Faculty of Medicine and Health, Northern Clinical School, Sydney, Australia, ³University of Sydney, Faculty of Medicine and Health, School of Pharmacy, Sydney, Australia, ⁴University of Sydney, Faculty of Science, School of Physics, Sydney, Australia, ⁵University of Sydney, Faculty of Medicine and Health, Sydney School of Public Health, Sydney, Australia

Introduction: Jetlag is circadian disruption caused by rapid travel over time zones. Evidence-based interventions include appropriately timed light-dark exposure, aligned schedules of sleep-wake, and judicious use of caffeine, melatonin, and other pharmacological sleep aids. Although 9.4 billion people flew in 2024, use of evidence-based strategies appears modest. This may be due to limited public understanding of circadian rhythms.

Materials and methods: We assessed applied knowledge by asking a convenience sample what strategies they would use to reduce jetlag, and when they would apply these. Eligible participants were enrolled in an introductory elective subject on sleep and circadian rhythms at the University of Sydney during 2021 to 2025. Students came from all university faculties and are typical of undergraduates in terms of gender (two-thirds female) and visa status (half international). Surveys were administered before learning about jetlag, but after learning about circadian rhythms.

Results: Of N=5,938 participants (60% response, 63% female, mean age 20.3, SD 2.4 years), the majority (87%) reported experience of jetlag and international flight (91%). 10% had flown internationally but not experienced jetlag, whilst 1% had experienced jetlag without international travel. When asked how much they were bothered by jetlag, 22% indicated “not at all”, 37% “a little”, 20% “moderately”, 14% “quite a bit”, 5% “extremely”, and 1% “can’t remember”.

Presented with 21 strategies, the top 3 selected for use before flight were: going to bed earlier/later than usual (67%), staying well-hydrated (66%), and avoiding alcohol (51%). Use earplugs/headphones (80%), stay well-hydrated (74%), and take naps (74%) were most common for during flight. Most frequently selected for after flight were go outdoors for sunlight (74%), stay well-hydrated (66%), and exercise (52%). A median of 7 strategies were endorsed per time point.

Across time points, participants selected: alter sleep time (94%), nap (91%), alter sleep duration (91%), take melatonin (61%), use over-the-counter sleep aids (53%), take prescribed sleep medications (48%), eat lighter/heavier meals (71%), eat healthier foods than normal (68%), take vitamins or supplements (61%), drink caffeinated beverages (69%), avoid caffeinated beverages (74%), stay well-hydrated (90%), do yoga or stretching exercises (65%), meditate or do relaxation exercises (64%), exercise (74%), drink alcohol (40%), avoid alcohol (72%), go outdoors for sunlight (85%), use earplugs/headphones to block noise (86%), wear compression stockings for circulation (57%), or use a jetlag app (50%).

The greater the impact from jetlag, the greater the number of strategies endorsed for during ($\rho=0.11$, $p<0.001$) and after flight ($\rho=0.06$, $p<0.001$), but not before travel ($\rho=0.02$, $p=0.264$). Those who reported greater jetlag impact also endorsed booking strategies more often ($p<0.05$), such as picking a

flight that arrived at a certain time (73%), choosing a direct flight (58%), picking a preferred seat (46%), and choosing to travel in premium cabins (25%).

Conclusions: Most participants selected evidence-based strategies to mitigate jetlag, although many strategies were chosen to enhance comfort or wellbeing. Results suggest high motivation to counteract travel fatigue, which presents opportunities to improve use of anti-jetlag strategies. Research to evaluate changes in behaviour after education on jetlag is needed.

Within-subject variation in circadian timing in shift workers repeating the same shift pattern

Y. Ji¹, L. Shen¹, S. Postnova², S.A. Knock², Y. Zhong¹, M.E. Howard³, J.E. Stone^{1,4}, E. Facer-Childs¹, S.M. Rajaratnam^{1,5,6}, T.L. Sletten¹

¹Monash University, Turner Institute for Brain and Mental Health, School of Psychological Sciences, Melbourne, Australia, ²University of Sydney, School of Physics, Sydney, Australia, ³Institute for Breathing and Sleep, Austin Health, Melbourne, Australia, ⁴University of Melbourne, Melbourne School of Psychological Sciences, Melbourne, Australia, ⁵Harvard Medical School, Division of Sleep Medicine, Boston, United States, ⁶Brigham and Women's Hospital, Division of Sleep and Circadian Disorders, Departments of Medicine and Neurology, Boston, United States

Introduction: While inter-individual variation in circadian response to shift work has been demonstrated, the within-individual variation in circadian timing when shift workers repeat the same shift pattern is unknown. Light is a key factor influencing individual circadian timing. This study aims to examine the consistency in circadian timing between two repeated occasions of the same shift pattern and the role of light exposure in explaining within-individual variability in circadian timing among shift workers.

Materials and methods: In an ongoing study, shift workers ($n=25$, age 39.12 ± 11.50 years, 10 females) from multiple industries were monitored during two replications of their usual shift patterns (8-10 days), separated by at least 6 weeks. Shift patterns included consecutive night shifts, consecutive early morning shifts, and early-morning-to-night rotations. Participants completed daily sleep diaries and wore a wrist activity monitor to measure sleep-wake timing, and a lapel-worn light sensor for continuous measurement of light exposure. Circadian phase was assessed at the end of each shift pattern via 6-sulphatoxymelatonin (aMT6s) acrophase (peak) in urine. A light consistency index (LCI) was calculated as the percentage of time for which light was above or below a threshold of 70[TS1] melanopic lux at corresponding parts of the work roster, to examine the consistency of light exposure patterns between the two occasions of the same shift pattern. The difference in average light exposure between the two occasions in the phase-advance (90-degree bin after acrophase) and phase-delay zones (90-degree bin before acrophase) of the circadian phase response curve to light was calculated.

Results: Analyses revealed moderate consistency in aMT6s acrophase between the two occasions of the same shift pattern (within-subject correlation: $r = 0.59$, $p < .001$), although substantial within-individual differences remained (mean difference = 2.38 ± 1.56 h; range = 0.14–5.46 h). Consistency in circadian timing was significantly associated with a higher light consistency index prior to circadian assessment ($\beta = -0.09$, $p = .02$, $R^2 = .22$). Aligning LCI to individual acrophase improved its ability to predict differences in acrophase ($\beta = -0.08$, $p = .0003$, $R^2 = .45$). Individuals with greater variation in acrophase had greater difference in light within the phase advance and delay zones. Linear regression revealed within-individual variation in acrophase was associated with differences in average light level in the advance ($\beta = 1.99$, $p = .02$) and delay ($\beta = 3.75$, $p = .00002$) zones between the two occasions ($R^2 = .56$).

Conclusions: Findings highlight within-individual variability in circadian phase in shift workers, despite following identical shift patterns. This indicates that circadian timing in workers cannot be assumed from a single measurement. This variability was explained by differences in light exposure, highlighting the value of light exposure for predicting circadian timing amongst shift workers. The ability to use light to improve circadian prediction has implications for informing personalised interventions in this population.

Work ability and health-related productivity loss by chronotype: Results from population-based panel study

H. Ko¹, S.-S. Cho², M.-Y. Kang¹

¹College of Medicine, The Catholic University of Korea, Department of Occupational and Environmental Medicine, Seoul, Korea, Republic of, ²College of Medicine, Dong-A University, Department of Occupational and Environmental Medicine, Busan, Korea, Republic of

Introduction: Chronotype, representing individual variation in circadian preference, has been increasingly linked to occupational health outcomes. Most previous studies have focused on clinical health parameters or general productivity, and rarely considered diverse occupational settings. This study aimed to investigate the association between chronotype and two key occupational health outcomes—work ability (WA) and health-related productivity loss (HRPL)—using longitudinal panel data in a large working population.

Materials and methods: Data were obtained from the Korean Work, Sleep, and Health Study, a population-based panel survey conducted from 2022 to 2024. The study included 10,065 wage-earning participants aged 19–70 years. Chronotype was assessed using the reduced Morningness-Eveningness Questionnaire and categorized as morning, intermediate, or evening type. WA was measured using the Work Ability Index and dichotomized into “poor” vs. “not poor.” HRPL was calculated as a percentage using the Work Productivity and Activity Impairment questionnaire. Generalized estimating equation models were applied to estimate odds ratios (ORs) for poor WA and mean differences in HRPL, adjusting for gender, age and occupation. Subgroup analysis was conducted based on gender, age, occupation type, and shift work status.

Results: Compared to morning types, evening chronotypes had significantly higher odds of poor WA (OR: 2.291, 95% confidence interval [CI]: 1.717–3.058) and greater HRPL (mean difference: 5.362 percentage points, 95% CI: 3.902–6.822). Intermediate types also showed elevated odds of poor WA (OR: 1.390, 95% CI: 1.097–1.762) and higher HRPL (mean difference: 4.925 percentage points, 95% CI: 3.932–5.918), though to a lesser extent than evening types. Subgroup analyses demonstrated that the association among chronotype, WA, and HRPL remained consistent across demographic and occupational groups. However, these relationships were more pronounced among men, younger workers, and white-collar employees. Notably, among the shift workers, the evening types showed no significant differences in ORs for poor WA or HRPL compared to the morning types.

Conclusions: Chronotype significantly influences WA and HRPL, with evening types experiencing the poorest outcomes due to circadian misalignment. These findings suggest the importance of considering chronotype in workplace health interventions. Strategies such as flexible schedules and sleep health programs may mitigate productivity losses and enhance employee well-being, improving long-term workforce sustainability and reducing health inequities.

Acknowledgments: This research was supported by the National Research Foundation of Korea (NRF-2022R1F1A1066498).

Dental

Analysis of Chest and Abdominal Respiratory Movements Prior to Masticatory Muscle Activity During Sleep in sleep bruxism subjects

K. Hata¹, R. Takaoka¹, M. Nishimura¹, M. Yamauchi^{2,3}, T. Kato^{4,5}

¹Graduate School of Dentistry, The University of Osaka, Department of Regenerative Prosthodontics, Osaka, Japan, ²Nara Medical University, Department of Clinical Pathophysiology of Nursing, Nara, Japan, ³Nara Medical University Hospital, Center for sleep Medicine and Respiratory Care, Nara, Japan, ⁴Graduate School of Dentistry, The University of Osaka, Department of Oral Physiology, Osaka, Japan, ⁵The University of Osaka Hospital, Sleep Medicine Center, Osaka, Japan

Introduction: Previous studies have reported a slight decrease in blood oxygen saturation prior to the occurrence of rhythmic masticatory muscle activity (RMMA) in individuals with sleep bruxism (SB). Furthermore, it has been shown that the use of mandibular advancement devices can reduce the

frequency of RMMA episodes. These findings suggest that increased upper airway resistance may play a role in the generation of RMMA. As upper airway resistance increases, the body must exert greater respiratory effort to maintain adequate ventilation. Therefore, the aim of this study was to investigate whether respiratory effort increases prior to RMMA onset. To this end, we quantitatively assessed the phase difference of chest and abdominal respiratory movements during quiet sleep period and the period immediately preceding RMMA episodes. In addition, we analyzed non-specific masticatory muscle activity (NSMMA) in the same manner and compared the results with those of RMMA.

Materials and methods: Polysomnographic (PSG) recordings were conducted on healthy volunteers in their 20s. Ten participants (4 males and 6 females; mean age: 23.1 ± 1.19 years; BMI: 19.6 ± 1.7 kg/m²; RMMA index: 5.61 ± 1.57 episodes/hour) were selected based on the criteria of having an apnea-hypopnea index (AHI) ≤ 5 and an RMMA index ≥ 4 episodes/hour.

For the evaluation of RMMA and NSMMA, we extracted 20 second segments immediately preceding each episode. Any segments that contained masseter muscle activity or apnea/hypopnea events were excluded from the analysis. In total, 236 RMMA segments and 326 NSMMA segments were included. For quiet sleep period, 236 artifact-free 20 second segments without masseter activity or arousals were selected. In each segment, chest and abdominal respiratory waveforms were plotted on X and Y axes to create Lissajous figures. The perpendicular distance from the resulting curve to its Lissajous line was calculated every 0.1 seconds along the Y-axis. The average of these distances was defined as the Respiratory Phase Difference Index (RPDI). For each subject, the median RPDI values were calculated across RMMA, NSMMA, and quiet sleep conditions. Statistical comparisons were performed using the Friedman test. When significant differences were observed, post-hoc pairwise comparisons were conducted using the Wilcoxon signed-rank test with Bonferroni correction.

Results: RPDI values were significantly higher in the 20 second segments preceding RMMA compared to those during quiet sleep periods ($P = 0.0059$). Similarly, RPDI values prior to NSMMA episodes were significantly elevated compared to those during quiet sleep periods ($P = 0.0059$). However, no significant difference was found between the RPDI values between RMMA and NSMMA episodes ($P = 0.3926$).

Conclusions: The present study demonstrated that both RMMA and NSMMA are preceded by a significant increase in chest and abdominal phase difference when compared to quiet sleep period, indicating the presence of respiratory effort prior to the onset of these muscle activities. Although RMMA and NSMMA represent distinct forms of masticatory muscle activity, both appear to be preceded by similar respiratory dynamics. These findings suggest that respiratory effort may be a common physiological background mechanism underlying the occurrence of sleep-related masticatory muscle activity.

Artificial Intelligence in the Management of Obstructive Sleep Apnea: Innovations and Challenges

G. Kaspo¹

¹Henry Ford Health System, Royal Oak, United States

Introduction: Obstructive Sleep Apnea (OSA) is a prevalent and underdiagnosed disorder that significantly impacts cardiovascular health, cognitive function, and overall quality of life. Traditional diagnostic and treatment pathways for OSA—such as polysomnography and CPAP therapy—face challenges related to accessibility, cost, patient adherence, and clinical resource constraints. In this context, **artificial intelligence (AI)** emerges as a transformative tool with the potential to revolutionize every stage of OSA management.

From automating early screening in primary care and dental settings to enhancing the accuracy of diagnostic algorithms and optimizing personalized treatment plans, AI is reshaping how clinicians approach this complex condition. Yet, while AI-driven solutions offer tremendous promise, they also raise important questions around data privacy, algorithm transparency, clinical validation, and integration into existing care models.

This review explores the **current innovations, applications, and limitations** of AI in OSA management, emphasizing both the clinical potential and the ethical, technical, and operational challenges that must be addressed to realize its full impact.

Materials and methods: This review was conducted through a comprehensive search of peer-reviewed literature and clinical studies published between 2015 and 2025, focusing on the application of artificial intelligence (AI) in the diagnosis and management of Obstructive Sleep Apnea (OSA). Databases

searched included PubMed, Scopus, and IEEE Xplore using keywords such as "artificial intelligence," "machine learning," "sleep apnea," "OSA screening," and "AI diagnosis."

Included studies were selected based on relevance to AI-driven innovations in early screening, diagnostic accuracy, treatment personalization, and long-term management of OSA. Articles addressing ethical, technical, and integration challenges of AI in clinical practice were also reviewed to provide a balanced perspective.

The findings were categorized into thematic areas: (1) AI in screening and early detection; (2) AI-supported diagnostic tools; (3) AI-guided treatment planning; and (4) system-level challenges including data privacy, algorithm bias, and implementation barriers. The review aims to synthesize current knowledge and identify gaps for future research.

Results: AI applications in OSA management showed promising outcomes across four areas:

1. **Screening** – AI tools effectively identified at-risk individuals using health records, questionnaires, and wearable data.
2. **Diagnosis** – Machine learning models improved accuracy in detecting sleep events and apnea severity.
3. **Treatment** – AI helped personalize therapies by predicting CPAP adherence and matching patients to alternatives.
4. **Challenges** – Key barriers include limited clinical validation, data privacy concerns, and poor integration into care systems.

Overall, AI shows strong potential but requires further refinement for routine clinical use.

Conclusions: Artificial intelligence is reshaping the landscape of obstructive sleep apnea management by enhancing screening, diagnosis, and personalized treatment. While early results are promising, widespread clinical adoption remains limited by challenges in validation, data security, and system integration. Continued research and cross-disciplinary collaboration are essential to fully realize AI's potential in improving OSA care.

Breath, Bite, and Bedtime: Sleep's Impact on Kids' Oral Health

H. Patil¹, S. Samuel¹

¹We Little, Coimbatore, India

Introduction: Background: Sleep-Disordered Breathing (SDB) in children affects both airway function and oral health, with often-overlooked links to dental caries.

Objectives: This poster outlines the mechanisms connecting SDB to increased caries risk in children by examining key contributing factors and how myoline treatment can be helpful in treatment.

Materials and methods: Methods: We synthesize current understanding of SDB's physiological and behavioral impacts, like mouth breathing and poor sleep, and their direct/indirect effects on oral health.

Results: Results: SDB frequently causes xerostomia (dry mouth) due to mouth breathing, reducing salivary protection. Associated gastroesophageal reflux (GERD) often lowers salivary pH, fostering an acidic oral environment that promotes enamel erosion and sensitivity. Poor sleep quality leads to inconsistent oral hygiene and disrupted eating, escalating caries risk. Nighttime snacking or sugary drinks for comfort further exacerbates problems. SDB is also linked to bruxism.

Conclusions: Conclusions: Early dental recognition of these SDB-related oral signs is crucial for timely diagnosis and multidisciplinary interventions including myoline therapy to mitigate oral health complications.

Changes Of The Protocols And The Extensions In The General Dentistry After Dental Sleep Medicine Emerging As An Individual Branch

G.S.K. Gattupalli¹

¹Shree Narayana Datta Dental Clinic, DENTAL SLEEP MEDICINE, Kandukur, India

Introduction: Dental Sleep Medicine is the most important and individual branch in the field of Dentistry which enables A Dentist to treat Obstructive Sleep Apnea to provide general health and wellbeing to the patient. The most important aspect here is if we focus on the iceberg of sleep disorders only 5% of the disease is visible and 30% of the life will be spent in sleep that is why the highest amount of focus should be done on sleep disorders.

After Dental Sleep Medicine evolved as an individual branch a lot of research was done which resulted some changes in the protocol of some treatments of the general dentistry to make the patient away from the risk of Obstructive Sleep Apnea. The reason is that the previous protocols do boost the risk of Obstructive Sleep Apnea. Now it is the duty of A Dentist to know about these changes and the extensions.

Materials and methods: Edentulous UPPP, followed by the posterior obturator, orthodontic for the 4 4 Xtn anterior central wedge detection of the tongue for narrow posterior nasal aperture home block for habits remove the cause for infants change the housing bottle

Results: OSA can be treated more successfully

Conclusions: •In view of the positive Health Benefits over the long run, the small pains and efforts to be tolerated now for them are much worthy. and •IT IS A Wiser THING TO SPEND SMALLER POCKET IN ADVANCE RATHER THAN TO SPEND BAGS IN URGENCY

Clinical Innovation in Dental Sleep: A Serial Device Approach to Mandibular Advancement Device

M.A. Childs¹

¹Medical University of South Carolina and University of South Carolina, Dental and Pharmacy, Charleston, United States

Introduction: Mandibular advancement devices (MADs) are a validated treatment for primary snoring and mild to moderate obstructive sleep apnea (OSA). While titratable MADs are standard, many patients find them uncomfortable or difficult to use. This abstract presents a novel, stepwise, non-adjustable MAD protocol — Sleep Buddy — which uses a custom-fabricated series of three mandibular advancement devices to progressively advance the mandible over time, without mechanical adjustment.

Results

Preliminary results indicate high patient compliance, low side-effect incidence (e.g., TMJ discomfort, salivation), and strong subjective improvements in snoring reduction and sleep quality. Patients reported the staged advancement to be intuitive and less intimidating than conventional titratable devices. Follow-up with home sleep testing (HST) in a subset of users demonstrated reductions in snoring index and AHI.

Conclusion

A non-adjustable, staged MAD protocol may represent a simplified and patient-friendly alternative to traditional titratable devices. This system has the potential to expand access to MAD therapy via streamlined digital workflows and lower complexity, particularly in telehealth-driven models. Further study is warranted to assess long-term outcomes and scalability.

Disclosures

The author is the inventor of the Sleep Buddy device and holds a patent for the design. No commercial sales have yet occurred. This abstract is intended to present the clinical concept and early user feedback.

Materials and methods: Forms of bisacryl or nylon have both been used.

Results: Results are patient comfort. There's ease in wearing the appliance so the compliance rate is higher. Because patients can be scanned or use an at home impression kit, Sleep Buddy can be offered through physicians or dentists.

Conclusions: See above:

The appliances are custom made with a starting point of a half molar forward. That approach with the encouraged nasal breathing by the connector being in the anterior, has been shown to be very kind to the TMJs, a big concern with traditional MADs. This incremental, premade approach makes it super

easy for patients and prescribing doctors for follow up appointments. This system can be used easily in telehealth driven models and easily streamlined in digital workflows.

Acknowledgments: Dr. Mary Ann Childs, DMD,RPh is an independent clinical researcher/ sleep innovation consultant. She is the inventor and patent holder of Sleep Buddy. The abstract is submitted to share clinical innovation in Mandibular Advancement Device therapy under development.

Clinical Outcomes for the Treatment of Mild-to-Severe Obstructive Sleep Apnea with Non-Permanent Maxillary Expansion and Mandibular Advancement/Expansion Oral Appliances: A Retrospective Analysis of Real World Data

C. Kushida¹, C. Cozean²

¹Stanford University, Stanford, United States, ²EyeDeas Company, Lake Forest, United States

Introduction: Both dental expansion and mandibular advancement oral appliances are important clinical approaches for reducing the signs and symptoms associated with obstructive sleep apnea (OSA). While both are recognized as important and are FDA-cleared devices, few studies have compared different indices of success in expansion and mandibular repositioning appliances. This retrospective study compares several indices of clinical success for both methods.

Materials and methods: A retrospective multicenter pre-post interventional study was conducted with up to a 36 month follow-up period in adults diagnosed with OSA. The DNA (Daytime-Nighttime Appliance) uses slow maxillary expansion, while the mRNA (mandibular-Repositioning Nighttime Appliance) is a combination device that adds mandibular advancement to the DNA. These devices and a therapeutic protocol comprise the Complete Airway Repositioning and Expansion (CARE) approach to treat OSA by airway expansion, improvements in sleep quality, and reduction in snoring and/or OSA severity in adults. These devices are FDA-cleared for all levels of OSA severity and can be utilized in moderate and severe OSA patients with positive airway pressure and/or myofunctional therapy, as needed. Participants were assessed for treatment efficacy by two co-primary endpoints, apnea-hypopnea index (AHI) and transpalatal width, and one secondary endpoint, airway volume by cone beam computed tomography (CBCT) scans. Safety parameters were also recorded.

Results: Eighty-seven participants treated with the DNA and 41 patients treated with the mRNA were included in the analysis after completion of at least 6 months of treatment. Transpalatal width with DNA increased 7.0% from 32.9 ± 3.1 to 35.2 ± 3.2 ($p < 0.00001$) compared with mRNA increased 6.0% from 33.5 ± 3.2 to 35.6 ± 3.4 ($p < 0.00001$). AHI with DNA decreased 46% from 22.5 ± 19.5 to 12.3 ± 11.0 ($p < 0.00001$) compared with mRNA decreased 43% from 26.8 ± 16.0 to 15.3 ± 14.0 ($p = 0.0001$). Airway volume with DNA increased 15% from 22263 ± 8651 to 25567 ± 9550 ($p < 0.00001$) compared with mRNA increased 15% from 19714 ± 6151 to 22670 ± 8171 ($p < 0.00001$). There were no serious long-term safety concerns.

Conclusions: All patients treated with mRNA showed an increase in transpalatal width while 97% of patients treated with DNA showed an increase. AHI improved or stayed the same in 91% of DNA patients and 88% of mRNA patients. AHI improved by at least 1 classification for 63% of DNA patients as compared to 61% of mRNA patients. AHI was < 5 or resolved in 28% of patients with DNA compared with 22% of patients with mRNA treatment. The addition of mandibular advancement to an expansion device did not significantly improve the clinical outcomes, indicating the benefits of slow maxillary expansion in the treatment of OSA.

Cross-sectional observational study of the impact of postoperative oral pain on sleep quality

S. Falardo¹, A. Simões Oliveira², E. Januzzi², A. Feliciano³

¹Catholic Portuguese University / VUB-Vrije Universiteit Brussel-belgium, Sleep Medicine, Rio de Mouro-Lisbon, Portugal, ²Catholic Portuguese University, Dental School, Viseu, Portugal, ³Orofacial Pain Center of the Mater Dei Hospital, Orofacial pain, Minas Gerais, Brazil, ⁴Catholic Portuguese University, Catholic Medical School, Rio de Mouro -Lisbon, Portugal

Introduction: To evaluate the relationship between postoperative pain and sleep quality and its impact on the quality of life of patients attending the oral surgery consultation at the University Clinic, Faculty of Dental Medicine, Universidade Católica Portuguesa in Viseu.

Materials and methods: This cross-sectional observational study included 32 patients who attended the oral surgery appointments at the University Clinic, Faculty of Dental Medicine, Universidade Católica Portuguesa in Viseu. Data were collected between 1 March and 20 May 2024 using validated subjective questionnaires. The study aimed to assess sleep quality, sleep schedule and hygiene, and oral pain. The following questionnaires were used: Epworth Sleepiness Scale, Pittsburgh Sleep Quality Index, sleep diary and visual analogue scale. Data were entered into the Microsoft Office Excel® platform and processed using SPSS version 27 software.

Results: This study demonstrated that postoperative odontogenic pain negatively affects sleep quality, daytime sleepiness, sleep fragmentation, sleep latency, and subjective insomnia symptoms in the week following tooth extraction.

Conclusions: Sleep quality suffers a significantly high negative impact in the week following tooth extraction in all individuals in the sample, particularly in vulnerable patients. Further studies are needed to elucidate this complex and dynamic relationship between sleep and pain. Dentists need to be aware of changes in sleep quality following surgery.

Effects of Home-Based Tongue Exercises on Tongue Strength in Older Adults: Implications for Sleep-Disordered Breathing

B. Kaboosaya¹

¹Chulalongkorn University, Oral and Maxillofacial Surgery, Bangkok, Thailand

Introduction: Age-related declines in orofacial muscle tone, particularly reductions in tongue strength, contribute to dysphagia and increased upper airway collapsibility during sleep—an important pathophysiological mechanism in obstructive sleep apnea (OSA). Tongue exercises (TEs) utilizing specialized devices have been proposed as effective interventions for improving tongue strength and mitigating OSA severity. However, such devices are often costly, cumbersome, and impractical for routine home use, limiting their accessibility for older adults.

Home-based TEs offer a feasible, low-cost alternative to improve tongue function without specialized equipment. Despite emerging interest in their use, the most effective home-based TE protocols for enhancing tongue strength in older adults remain insufficiently studied. This study aimed to evaluate the effects of three simple home-based TE protocols on anterior and posterior tongue strength in older adults, with potential implications for the management of sleep-disordered breathing.

Materials and methods: Thirty-six healthy older adults (aged ≥ 65 years) were randomly assigned to one of three home-based tongue exercise (TE) protocols: **tongue wrap**, **tongue corner**, or **tongue paint**. Participants were instructed to perform each exercise five times per session, three sessions per day, over a four-week period at home. Anterior tongue strength (ATS) and posterior tongue strength (PTS) were assessed using the Iowa Oral Performance Instrument (IOPI) at baseline and after the intervention period. Improvements in both ATS and PTS were recorded and analyzed to evaluate the efficacy of each TE protocol.

Results: All TE groups showed post-training gains in tongue strength. The **tongue paint** group showed statistically significant improvements in both ATS and PTS ($p < 0.05$), with mean gains of 28.70 ± 27.93 and 53.13 ± 89.96 kPa, respectively, corresponding to the greatest relative increase (30.72%). The tongue wrap and tongue corner groups also exhibited improvements (ATS: 12.75 ± 25.05 and 20.74 ± 36.14 kPa; PTS: 18.56 ± 35.53 and 9.04 ± 21.57 kPa, respectively), although changes were not statistically significant.

Conclusions: Home-based TEs, particularly the **tongue paint** protocol, significantly improved both ATS and PTS in older adults. These findings support the effectiveness of targeted, cost-free TEs as a non-invasive strategy to enhance tongue function. Strengthening tongue musculature through such exercises may contribute to improved oropharyngeal stability and potentially reduce the risk of sleep-disordered breathing in the elderly population.

Acknowledgments: The author gratefully acknowledges Dr. Thunchnok Suppapatpong for her valuable assistance with data collection. Sincere appreciation is also extended to all participants for their time and contributions to this study.

Effects of Oral Appliance Therapy on Sleep Bruxism and Sleep-Respiratory Parameters in Patients with Obstructive Sleep Apnea

Y. Dotsu^{1,2}, G. Umemoto¹, C. Yoshimura¹

¹Fukuoka University, Fukuoka, Japan, ²Kouradai Rehabilitation Hospital, Fukuoka, Japan

Introduction: This study aimed to investigate the relationship between sleep-related respiratory events and sleep bruxism (SB) in patients with obstructive sleep apnea (OSA) treated with oral appliance (OA) and to clarify the efficacy of OA treatment on SB.

Materials and methods: Twenty-one OSA patients (10 males and 11 females; mean age, 57.8 years $\pm$ 16.0 SD) were sequentially enrolled in this study at Fukuoka University Hospital from October 2020 to May 2025. They underwent overnight polysomnography (PSG), and their masseter muscle activity was simultaneously assessed using a wearable electromyographic device before and after OA treatment. The apnea-hypopnea index (AHI), arousal index (Arl), percutaneous oxygen saturation (SpO₂), and episodes of SB were compared before and after OA treatment. The responding group that improved AHI by more than 50% or reduced it by less than 5 after treatment (n = 10) was compared to the non-responding group with other conditions (n = 11). OSA and SB diagnoses were based on the guidelines and criteria of the AASM.

Results: OA treatment significantly reduced mean AHI from 17.3 $\pm$ 7.8 SD to 12.3 $\pm$ 10.7 SD (p = 0.008), and respiratory events during both REM and NREM sleep. The total episodes of SB, tonic, and mixed episodes also significantly decreased (p = 0.002, p = 0.034, and p = 0.002, respectively). Meanwhile, the ArI and spontaneous arousal index (SAI) during REM sleep significantly increased (p = 0.008 and p = 0.007, respectively). Additionally, the non-responding group in OA treatment showed a significant reduction in total SB episodes (p = 0.013).

Conclusions: This study suggests that SB is a pathological condition associated with multiple factors besides OSA. OA may be effective for both respiratory events and SB. Meanwhile, to understand the mechanism that causes SB and to determine the applicability of OA and maximize its therapeutic effect, further research is needed.

Effects of Sleep Position Therapy on Sleep Bruxism: A pilot study

Y. Suzuki¹, G. Lavigne^{2,3,4}, M. Shinkai¹, T. Taniwaki¹, K. Okura¹, Y. Matsuka¹

¹Tokushima University, Department of Stomatognathic Function and Occlusal Reconstruction, Tokushima, Japan, ²Université de Montréal, Oral Health, Montréal, Canada, ³CIUSSS du Nord de l'Île de Montréal, Centre for Advanced Sleep Research, Montréal, Canada, ⁴McGill University, Faculty of Dental Medicine and Oral Health Sciences, Montréal, Canada

Introduction: It has been reported that patients with sleep bruxism (SB) have significantly more rhythmic masticatory muscle activity (RMMA) episodes when they sleep in supine position. The objectives of this study were to investigate if supine sleep position can be a phenotype associated to SB-RMMA genesis and to test if it could correct by sleep positioning device.

Materials and methods: Twelve participants with SB were recruited (4 males and 8 females, mean age 28 $\pm$ 8 years). SB was identified using criteria of the International Classification of Sleep Disorders third edition (2014). Correction of supine sleep position was done using a sleep position biofeedback (BF) device, Night Shift (Advanced Brain Monitoring). The BF device produces a vibration behind the neck 5 seconds after supine positioning. Supine sleep time and snoring time above 50 dB were also measured with this device. Grindcare (SUNSTAR), which can measure surface electromyography on a unilateral temporal muscle, was used to measure RMMA episodes per hr (RMMA frequency). Pulse Watch PMP-200 G plus (Pacífico Medico) was used to measure blood oxygen saturation, pulse rate, body movement, and then sleep state, pulse rate elevation index, and 3% oxygen depletion index. Measurements were performed at participant's home over 5 nights. The first night was for baseline/control without BF. During nights 2 to 4, measurements were taken with active BF, and on day 5 without BF. A series of questionnaires were administered each time we collected data: PSQI, Epworth sleepiness scale, STOP-BANG. The study was approved by the Ethic Review Board for Life Science and Medical Research of the University of Tokushima Hospital (No. 3534). Statistical analyses were performed for the comparison of each measurement data.

Results: Among the 12 participants, one was excluded from the analysis because the vibration did not change the sleep position. Overall, BF significantly reduced supine sleep time per sleep period time (Night 1= 33.7 to 85.6 % to Night 4= 0.2 to 8.8 %), but overall RMMA frequency did not differ. We then classified participants as responders or non-responders when a change occurred from Night 1. Six participants were classified as responders since they had a 24.1% to 85.6% decrease in RMMA frequency on the last night with BF (Night 4) versus the control one (Night 1). At the opposite end, 5 non-responders were identified; they had an increase of 3.9% to 193.9% in the RMMA frequency. None of sleep variables were statistically different between responders and non-responders.

Conclusions: Owing our small sample size, these preliminary results suggest that supine sleep position role in the genesis of RMMA-SB is not a strong phenotype since a RMMA reduction was observed in only half of participants, and that RMMA frequency was worsen in the other half. It remains to be investigated if rise in RMMA in non-responders could be associated to arousal threshold reactivity.

Acknowledgments: Night Shift and Sunstar devices were provided from respective firms. This study was supported by a donation from the Organization for People with Universities (OTSUCLE) Crowdfunding Project to Elucidate Mechanisms for the Treatment of Sleep Bruxism”.

Efficacy and Predictive Factors of Mandibular Advancement Device for Obstructive Sleep Apnea Treatment: A Preliminary Retrospective Study in Southern Thailand

P. Chalidapongse¹, P. Yakkaphan¹, S. Tangpothitham¹

¹Prince of Songkla University/Faculty of Dentistry, Oral Diagnostic Science, Hat-Yai, Songkhla, Thailand

Introduction: To evaluate the efficacy of mandibular advancement devices (MAD) in reducing the apnea-hypopnea index (AHI) in patients with obstructive sleep apnea (OSA), identify predictive factors for treatment success, and assess the quality of life in OSA patients treated with MAD.

Materials and methods: This retrospective study used data from the Dental Sleep Medicine Clinic, Faculty of Dentistry, Prince of Songkla University, collected between 2009 and 2020. Patients with both pre- and post-treatment sleep test (polysomnography) data and SF-36 quality of life questionnaire results were included. Treatment outcomes were classified as either complete response (defined as an AHI reduction of > 50% and a post-treatment AHI of < 5 events/hour) or fail response (defined as (1) an AHI reduction of > 50% but a post-treatment AHI between 5 to less than 10 events/hour or (2) an AHI reduction of < 50%, or (3) an increase in AHI after treatment).

Results: Of the 217 patients, 31 met the inclusion criteria and were divided into mild (mean AHI = 9.86 ± 3.37), moderate (mean AHI = 22.27 ± 3.66), and severe (mean AHI = 61.73 ± 27.45) OSA groups, with complete response rates of 61.1%, 60%, and 33.3%, respectively. There was no significant relationship between OSA severity and treatment success. However, gender, snoring, tonsil grade, and malocclusion classification differed significantly between success and failure groups. Logistic regression identified female gender and smaller neck circumference as predictors of success. Patients also showed significant post-treatment improvements in general health, energy, mental health, and perceived health status.

Conclusions: The success rates of MAD treatment did not differ significantly among patients with mild, moderate, or severe OSA. However, female gender and smaller neck circumference were identified as key predictors of successful outcomes. Overall, patients experienced notable improvements in their quality of life, particularly in general health, energy levels, mental well-being, and perceived health, following MAD treatment.

Examination of the relationship between blood glucose levels during sleep and sleep bruxism

T. Taniwaki¹, K. Okura¹, Y. Suzuki¹, M. Shinkai¹, Y. Matsuka¹

¹Tokushima University, Department of Stomatognathic Function and Occlusal Reconstruction, Graduate School of Biomedical Sciences, Tokushima, Japan

Introduction: Rhythmic masticatory muscle activity (RMMA), a biomarker for sleep bruxism (SB), is thought to be a nonspecific arousal response associated with microarousals during sleep, in which the masticatory muscle group becomes active. On the other hand, sleep is affected by glucose fluctuations such as increased sympathetic nervous system activity due to hypoglycemia during sleep. The purpose of this study was to clarify the relationship between blood glucose fluctuations during sleep and the occurrence of RMMA.

Materials and methods: This study included nine adults aged 21–54 who were aware of or had been informed about SB. Portable polysomnography was used to measure electroencephalography, electrooculogram, right masseter electromyography, pulse rate, and SpO₂. Additionally, a portable continuous glucose monitoring device was employed to measure glucose levels in subcutaneous interstitial fluid, which correlates highly with blood glucose levels, over time, with results obtained every five minutes to assess blood glucose fluctuations during sleep. The measurement period was two weeks, with the first seven days being non-interventional and the latter seven days involving dietary guidance. The carbohydrate intake for breakfast, lunch, and dinner was maintained at the same level as before the guidance, while sugary beverages, alcohol, and high-carbohydrate snacks were prohibited. Instead, low glycemic index foods with blood glucose-lowering effects were consumed as snacks. Data from days 7 and 14 after the start of measurement were analyzed. Changes in glucose concentration during sleep before and after the guidance were compared, as well as the number of RMMA episodes per hour. Additionally, to evaluate autonomic nervous system activity, RR intervals (the time interval between heartbeats) and low-frequency (LF) and high-frequency (HF) components were extracted from pulse waveforms, and frequency analysis was performed to calculate the LF/HF ratio and LF/(LF+HF). Furthermore, to evaluate sleep quality, slow-wave activity (SWA) was calculated through frequency analysis of the EEG, and comparisons were made before and after the intervention. Statistical analysis was performed by the Wilcoxon signed-rank test ($p < 0.05$).

Results: Following the intervention, nocturnal blood glucose fluctuations and the number of RMMA episodes significantly decreased (Mean $\pm$ SD: 13.9 $\pm$ 9.0 to 4.8 $\pm$ 2.4 mg/dL, 9.6 $\pm$ 3.4 to 6.6 $\pm$ 2.6 episodes/hour, respectively). Additionally, RR intervals significantly increased (0.96 $\pm$ 0.09 to 1.09 $\pm$ 0.09 seconds) and LF/HF ratio, LF/(LF+HF) significantly decreased (0.86 $\pm$ 0.32 to 0.66 $\pm$ 0.20, 0.41 $\pm$ 0.09 to 0.36 $\pm$ 0.06) were observed. It was indicated parasympathetic activity enhanced and sympathetic activity reduced. However, no significant difference was observed in SWA (84.1 $\pm$ 38.1 to 87.9 $\pm$ 50.4 μ V²/Hz).

Conclusions: It is suggested that there is a correlation between blood glucose levels during sleep and the occurrence of SB, and that controlling blood glucose levels during sleep may influence autonomic nervous activity and reduce RMMA.

Acknowledgments: This research was supported by JSPS KAKENHI Grant Number JP25K13105.

Genesis of RMMA, a biomarker of Sleep Bruxism, is mostly central since it is present in older edentate individuals

C. Dal Fabbro^{1,2,3}, N. Huynh⁴, P. Rompre⁴, A. Kolta⁴, G. Lavigne^{4,5}, E. Emami⁵

¹Université de Montréal, Oral health, Montreal, Canada, ²CRIUGM (Geriatric research center at the Université de Montréal), Montreal, Canada, ³CEAMS, Research Center - CIUSSS NIM, Montreal, Canada, ⁴Université de Montréal, Oral Health, Montreal, Canada, ⁵McGill University, Faculty of Dentistry, Montréal, Canada

Introduction: Sleep bruxism, characterized by tooth clenching and grinding, is associated with rhythmic masticatory muscle activity (RMMA). During sleep, RMMA is frequent and persists with aging, while self-reported sleep bruxism (SB) may decrease. Although the mechanisms of SB genesis remain under investigation, evidence supports the notion that the genesis of SB-RMMA is modulated by the central and autonomic nervous system. However, the role of peripheral sensory feedback remains unclear, as the literature presents debates, along with the role of associated conditions such as obstructive sleep apnea (OSA).

Objective: To assess the potential role of tooth sensory feedback in the genesis of RMMA in completely edentulous individuals, with and without OSA.

Materials and methods: Polysomnographic data of 24 edentulous individuals (mean age 73 years) who previously participated in a clinical trial on OSA were analyzed. (Emami E et al, Sleep 2021). Participants

were asked to sleep without their dentures for one night, with a full PSG (type 2). RMMA was scored from bilateral masseter and temporal EMG, and jaw muscle activity was classified as RMMA if it corresponded to phasic, tonic, or mixed patterns. Other oromotor activities not included above were defined as NSMA (non-specific muscle activity).

The temporal association of RMMA and NSMA with sleep arousals was recorded when they occurred within 5s of arousal and with respiratory events when they occurred within 10s after the end of apnea or hypopnea, with or without respiratory event-related arousals. The association of RMMA or NSMA with oxygen desaturation was recorded when they occurred within 15s, with or without arousal.

Participants were divided into two groups based on the apnea-hypopnea index (AHI): the OSA group with AHI > 10/h (n=14) and the control group (CTL; n=10) with AHI < 5. Mann-Whitney tests and Spearman's rank-order correlation coefficients (rs) were used for analysis.

Results: During sleep, both groups exhibited a high frequency of RMMA and NSMA. RMMA was twice as high in the OSA group (CTL: 3.0 ± 1.9 ; OSA: 6.4 ± 7.0 ; $p=0.472$), while NSMA was 1.8 times higher (CTL: 1.9 ± 1.9 ; OSA: 3.44 ± 3.0 ; $p=0.084$). However, correlations between AHI and RMMA or NSMA were not statistically significant.

Total arousals were positively correlated with RMMA ($rs = 0.513$; $p=0.010$) and NSMA ($rs = 0.547$; $p=0.006$) for both groups combined; specifically for the OSA group, RMMA showed a strong correlation ($rs = 0.789$; $p<0.001$) and NSMA showed a moderate correlation ($rs = 0.538$; $p=0.047$).

RMMA and NSMA were not correlated with AHI or the oxygen desaturation index (ODI).

However, temporal association of RMMA and NSMA were significantly ($p<0.001$) more frequently with sleep arousal in the CTL group (3.2X for RMMA and 4.2X for NSMA). Conversely, they were more frequently associated with oxygen desaturation in the OSA group (over 8.5 times).

Conclusions: The persistence of RMMA and NSMA in edentulous individuals suggests that their genesis is likely central, with an additive influence from autonomic arousal in OSA individuals. Therefore, while RMMA is a biomarker of SB, it is probably a physiological activity that is non-pathogenic in nature.

Interrupted CPAP therapy and dental health outcomes in obstructive sleep apnoe patients: .A craniomaxillofacial surgical view

K. Obermeier¹, I. Dewenter¹, M. Roßkopf²

¹LMU Munich, University, Department of Oral and Maxillofacial Surgery and Facial Plastic Surgery, Munich, Germany, ²Regensburg, University, Department of Psychiatry and Psychotherapy, Center of Sleep Medicine, Regensburg, Germany

Introduction: Obstructive sleep apnea syndrome (OSAS) is a highly prevalent sleep related breathing disorder characterized by hypopnea and apnea in ventilation. Obesity, age, and sex have been identified as risk factors for OSAS, and other risk factors are related to ethnicity, family history, and poor lifestyle habits (alcoholism and smoking). The positive airway pressure therapy is still first line therapy in those patients. However, many patients with OSAS cannot tolerate PAP devices, resulting in poor compliance. Failure to comply with treatment has been reported to be as high as 25 to 50%, with patients typically abandoning therapy during the first 2 to 4 weeks of treatment. Reasons for discontinuing CPAP therapy have been primarily related to issues of mask discomfort, nasal dryness and congestion, and difficulty adapting to the pressure. Patients, who do not tolerate CPAP therapy are often lost in follow-up. Several studies show as well that poor oral hygiene worsens OSAS symptoms

Materials and methods: This study examines patients who have discontinued cpap therapy in correlation with oral hygiene awareness and their dental status as a measure of overall patient compliance. Patients were divided into two groups 30 patients each:

Group A: Patients with interruption of CPAP therapy

Group B: Patients with tolerating CPAP therapy

All patients underwent questionnaires considering awareness of oral hygiene.

Results: Patients who interrupted OSAS therapy showed a statistically significantly worse awareness of their oral hygiene and a significantly worse dental status. This study shows, that poor oral hygiene and awareness for oral hygiene is related to increased dropout rates in CPAP therapy patients.

Conclusions: Therefore, OSAS patients should be screened by a dentist in advance and during CPAP therapy as well as more closely monitored by a sleep doctor as worse awareness of oral hygiene comes with worse compliance and interruption of CPAP therapy.

Investigation of the relationship between sleep bruxism and oral dryness in healthy adults

M. Shinkai¹, Y. Suzuki¹, K. Okura¹, T. Taniwaki¹, J.J. Fabillar¹, Y. Matsuka¹

¹Tokushima University, Department of Stomatognathic Function and Occlusal Reconstruction, Tokushima, Japan

Introduction: Sleep bruxism (SB) is defined as “a repetitive jaw muscle activity characterized by clenching or grinding of the teeth and/or by bracing or thrusting of the mandible” during sleep. The jaw movements in SB are suspected to have a functional role in promoting salivary secretion, which decreases at night. This has led to speculation that SB may be associated with xerostomia; however, the details remain to be elucidated. We hypothesized that a greater degree of oral dryness is associated with a higher frequency of rhythmic masticatory muscle activity (RMMA), a biomarker for sleep bruxism, which may promote salivation and swallowing, thereby helping to moisten dry mucosa. The purpose of this study was to clarify the relationship between SB and two indicators of xerostomia: oral mucosal wetness and salivary secretion capacity.

Materials and methods: The study included healthy adults aged 20–60 years; those with a history of neurological, motor, or psychiatric disorders were excluded. Polysomnography was performed for two days in a sleep laboratory at a set humidity (50%) and temperature (21°C), and data from the second day were used for analysis. Electroencephalograms, electrooculograms, electromyograms (EMGs) from the bilateral mentalis, masseter, suprahyoid, infrahyoid muscles, electrocardiography, and respiratory curve were measured and recorded, along with monitor images during sleep. Sleep stages were determined from the measured data according to the criteria of the American Academy of Sleep Medicine. RMMA were evaluated from EMG data of the bilateral masseter muscles according to the method described by Lavigne et al. (J Dent Res. 1996). Swallowing events during sleep were scored based on the EMG signals from the suprahyoid and infrahyoid muscles, transient interruption of nasal airflow, swallowing sounds, and visual observation of upward laryngeal movement on audio-video monitor. The degree of oral moisture was measured before sleep, during sleep, and upon waking. The unstimulated salivary flow rate (USFR) and stimulated salivary flow rate (SSFR) were measured before sleep and upon waking. The relationships between the RMMA index (number of RMMA episodes per hour of sleep), oral wetness, and salivary secretion were examined using Spearman’s rank correlation coefficient ($P < 0.05$).

Results: Seventeen participants (10 males, 7 females, 28.2 ± 8.6 years old) were included in the study. The degree of oral moisture and USFR were not significantly correlated with the RMMA index. On the other hand, the SSFR before sleep demonstrated a significant negative correlation with the RMMA index ($\rho = -0.637$). The frequency of RMMA that occurred with swallowing per hour demonstrated a significant negative correlation with the SSFR before sleep and upon waking ($\rho = -0.703, -0.527$, respectively). Swallowing occurred significantly more frequently in the last one-third of the RMMA episodes, and the frequency of phasic and mixed types of RMMA that occurred with swallowing demonstrated a significant negative correlation with the SSFR before sleep ($\rho = -0.583, -0.511$, respectively).

Conclusions: These results suggest a relationship between SB and the ability to secrete stimulated saliva. SB may have a functional role in stimulating saliva secretion, and an increase in SSFR may alleviate SB.

Mandibular advancement devices in the treatment plan of snoring, mild and moderate obstructive sleep apnea cases

M. Milkov¹, M. Stoykov¹

¹Medical University - Varna, Dental materials science and Prosthetic Dental medicine, Varna, Bulgaria

Introduction: The syndrome of obstructive sleep apnea and snoring (SOSAS) is characterized with repetitive breathing cessations during sleep due to airway collapse. Some of patients' symptoms include moderate to severe daytime drowsiness, mood changes, memory loss and lack of concentration, vestibular and eye disorders. Mandibular advancement devices (MADs) are a type of dental intraoral prosthetic devices which pull or push the mandible in more forward (medial) position, preventing it, accompanied by the tissues around the anatomical region, from blocking the airflow. The aim of the following study was to share authors' experience treating snoring, mild and moderate OSA cases with mandibular advancement devices.

Materials and methods: A total of 110 patients with snoring, mild or moderate case of obstructive sleep apnea were included. All patients were examined by a specialist in otorhinolaryngology and sleep medicine and a physician in dental medicine in the period 01.2023-12.2024 at University medical and dental center, Faculty of Dental medicine, Medical University "Prof. Dr. Paraskev Stoyanov" - Varna. All patients had their sleep examined with a polygraphic study. All participants had their balance and vestibular capabilities tested on a stabilometric platform. All signed written informed consent forms and completed sleep questionnaires, general diseases, present allergies and medications intake forms. The study received approval from Medical University - Varna Ethic committee.

Results: Male participants were predominantly diagnosed with a moderate form of SOSAS. Snorers were 10% of all patients. Male and female participants almost evenly accepted MADs treatment, with a slight predominance and better acceptance of the female responders (55% female versus 45% male). The most frequent complications that had arisen were breaking of the connectors pushing the mandible forward. Patients continued to experience the already mentioned by the manufacturer symptoms, such as feeling the mandible out of alignment after waking up, salivation, muscle stiffness, but all symptoms were alleviated after using the bite-help strip provided. Authors of the study report no allergic reactions to the material (polyamid) of the MADs, experienced by the patients, up to the moment. Body balance was disrupted more frequently in SOSAS cases, accompanied with more vestibular symptomatology.

Conclusions: Treating SOSAS in interdisciplinary teams of medical specialists is the standard in sleep medicine. By implementing the stated, patients received specialized and encompassing help, solving their problem.

Acknowledgments: The study is implemented under contract No. BG-RRP-2.004-0009-C02 and is financed by the European Union - NextGenerationEU, through the National Plan for Recovery and Sustainability of the Republic of Bulgaria under procedure BG-RRP-2.004 - Creation of a network of research universities.

Minimal titration approach for mandibular advancement device treatment in patients with obstructive sleep apnea: a retrospective multicenter observational cohort study

M. Braem^{1,2}, E. Collier^{3,4,5,6}, M. Dieltjens^{7,8}

¹Antwerp University Hospital (UZA), MRA-Clinic, Edegem, Belgium, ²Imelda Ziekenhuis, MKA, Bonheiden, Belgium, ³Antwerp University Hospital (UZA), Edegem, Belgium, ⁴AZ Voorkempen, MKA, Malle, Belgium, ⁵AZ Monica, Antwerpen, Belgium, ⁶Heilig Hartziekenhuis, MKA, Lier, Belgium, ⁷Antwerp University Hospital (UZA), ENT, Edegem, Belgium, ⁸University of Antwerp, Translational Neurosciences, Wilrijk, Belgium

Introduction: Despite the widespread use of mandibular advancement devices for obstructive sleep apnea (OSA), no standardized, evidence-based guidelines exist on selecting a given mandibular protrusion at the start of mandibular advancement device (MAD) treatment. This retrospective study aimed to establish a clinically feasible and patient-specific mandibular protrusion at the start of MAD treatment for OSA, requiring none to little additional protrusion (titration) in achieving improvement in apnea-hypopnea index (AHI) and oxygen desaturation index (ODI).

Materials and methods: Patients were included with baseline AHI $\geq$ 15 events/h on type 1 polysomnography and after drug-induced sleep endoscopy with positive effects on reopening the upper airway. Digital tooth-arc imprints were taken (Trios, 3Shape, Copenhagen, Denmark). First, maximal mandibular protrusion (MMP, mm) was measured (The BiteFix, Scheu-Dental, Iserlohn, Germany) starting from maximal retrusion (MR). Then maximal comfortable protrusion (MCP, mm) was determined, starting from MR and protruding until the position where the patient experienced

increasing discomfort, repeated until reproducible.

An MAD (EVO, ProSomnus Sleep Technologies, Pleasanton, CA, USA) was manufactured from the digital scans, with the bite registration set at MCP minus 2mm (MCP-2, mm). Patients were then instructed to titrate the MAD until resolution of snoring symptoms or upon reaching physiological limits.

A 1-month post-fitting follow-up was performed by telephone, followed by a type 3 home polygraphy with MAD after 3 to 5 months of treatment.

OSA severity outcome was defined as "no OSA" (AHI<5 events/h), "mild" (5≤AHI<15 events/h), "moderate" (15≤AHI<30 events/h) or "severe" (AHI≥30 events/h).

Results: In total, 182 patients (137M/45F) from six general hospitals were evaluated.

Median [IQR] baseline AHI=21.3 [9.9]/h and ODI=18.0 [12.1]/h significantly decreased after 3-5 months of MAD use to AHI=5.6 [6.5]/h ($p<0.0001$) and to ODI=5.0 [7.2]/h ($p<0.001$).

Overall, MAD treatment resulted in 45% of patients with status "no OSA", 47% with "mild OSA," and 8% with "moderate OSA." No patients remained with "severe OSA".

In 86/182 (47% of patients) no additional titration was required. One patient needed to decrease the MCP-2 with 2mm due to cranio-mandibular transient complaints. In 33/182 (18% of patients) the MAD was additionally titrated with 1mm and in 26/182 (14% of patients) with 2mm. The starting median protrusion (MCP-2) of 9.2 [2.2]mm (corresponding to 72%MMP), increased to 10.3 [2.4]mm (corresponding to 82%MMP) upon titration.

Linear regression analysis did not show any relationship between the amount of protrusion and the percentage-wise improvement in AHI (RSquare = 0.0088) or in ODI (RSquare = 0.0011).

Conclusions: Starting MAD treatment at the patient-specific "MCP-2" protrusion position resulted in rapid and effective improvement in AHI and ODI, with 92% of patients achieving "no OSA" or "mild OSA" status.

Importantly, no significant relationship was observed between the amount of protrusion and the percentage improvement in AHI or ODI.

"MCP-2" was therefore identified as an optimal starting point, making additional titration unnecessary in nearly half of the patients.

The present findings support "MCP-2" as a clinically practical starting position for MAD treatment using ProSomnus EVO MAD.

Future research should evaluate the generalizability of "MCP-2" across other MAD designs and explore long-term treatment outcomes.

Multidisciplinary approaches to managing complex phenotypes of patients with Obstructive Sleep Apnea

M.-J. Jeon¹, J.-M. Park², S.-H. Yu², S.-J. Kim³

¹Ewha Womans University Seoul Hospital, Department of Orthodontics, Seoul, Korea, Republic of,

²KyungHee University Dental Hospital, Department of Orthodontics, Seoul, Korea, Republic of,

³KyungHee University Dental Hospital, Department of Orthodontics, Seoul, Korea, Democratic People's Republic of

Introduction: The management of obstructive sleep apnea (OSA) is shifting toward a precision model grounded in phenotype-based strategies. Accurate phenotyping is essential for targeted treatment of adult OSA. Eckert's classification identifies anatomically collapsible airway as the primary cause, often accompanied by non-anatomical traits like poor muscle response and low arousal threshold. Within this framework, orthodontists serve a key role in identifying and addressing craniofacial skeletal phenotypes (CSPs) that contribute to airway obstruction, thereby enhancing patients' breathing and sleep quality. Additionally, orthodontists are increasingly involved in the interdisciplinary care of OSA patients who exhibit non-craniofacial skeletal phenotypes (N_CSP), necessitating a broader, more integrative treatment approach.

Materials and methods:

This study included 120 Korean adult patients (mean age: 41.5 years; range: 18–70 years) diagnosed with obstructive sleep apnea (OSA) with an apnea-hypopnea index (AHI) of ≥5. Cone-beam computed tomography (CBCT) was utilized to evaluate three-dimensional craniofacial skeletal morphology, condylar deformities, and temporomandibular joint (TMJ) space. Cross-sectional TMJ images were

analyzed to assess degenerative changes and the specific locations of bony alterations. Polysomnography (PSG) was performed to determine the severity of OSA.

Results: A total of 120 subjects were classified into four types based on condylar resorption & condylar surface remodeling. Significant differences in AHI and RDI were observed among the four OSA phenotypes, with Types I and II showing lower values compared to Types III and IV ($p < .05$). However, no significant differences were found in ODI or lowest oxygen saturation.

CBCT analysis revealed significant differences in joint space dimensions among the groups. For the right condyle, the superior joint space was significantly smaller in Type I compared to Types II, III, and IV (Type I: 2.87 ± 0.45 mm vs. Type II: 3.41 ± 0.80 mm, Type III: 3.67 ± 0.83 mm, Type IV: 3.13 ± 0.19 mm; $p < .05$), while anterior and posterior joint spaces showed no significant differences. For the left condyle, all three joint spaces—anterior, superior, and posterior—were significantly smaller in Type I than in the other types ($p < .05$).

Condylar angle measurements also differed significantly across groups. Axial angles were smaller in Types I and II on both sides, while lateral angles showed a side-dependent pattern, with higher values on the right in Types I and II and on the left in Types III and IV ($p < .05$).

Conclusions: This study demonstrated that morphological changes in the mandibular condyle, as classified by CBCT-based resorption and remodeling grades, are associated with variations in temporomandibular joint space, condylar angulation, and sleep-related breathing indices. Specifically, advanced resorption types (Types III and IV) showed reduced joint space, altered condylar angles, and higher AHI and RDI values, suggesting a potential link between TMJ structural degeneration and obstructive sleep apnea severity. These findings highlight the clinical relevance of condylar morphology in the assessment and management of patients with OSA.

Acknowledgments: Within the emerging phenotype-based precision approach, orthodontists are crucial in identifying craniofacial skeletal phenotypes (CSPs) and providing both surgical and non-surgical 3D skeletal interventions to improve airway function and sleep quality.

Multiple-night recording of sleep bruxism: Results of a novel portable electromyographic device

K. Masarwe¹, A. Shamay², A. Emodi-Perlman¹, I. Eli¹

¹Tel Aviv university, Prosthodontics department, Tel Aviv, Israel, ²Tel Aviv university, Tel Aviv, Israel

Introduction: Sleep bruxism (SB) represents a form of masticatory muscle activity that occurs during sleep, characterized by both rhythmic (phasic) and non-rhythmic (tonic) movements. While commonly observed in healthy individuals, sleep bruxism may relate to sleep disorders commonly co-occurring with obstructive sleep apnea (OSA). Given their frequent patient interactions and expertise in oral health, dentists are uniquely positioned as frontline healthcare providers who can facilitate early detection of OSA. The emergence of portable, cost-effective, ambulatory devices has created new opportunities for clinicians and patients to detect and monitor sleep bruxism across multiple nights. Through comprehensive multi-night assessment of sleep bruxism patterns, healthcare providers can enhance early OSA detection capabilities and potentially prevent the progression of associated adverse health consequences.

Materials and methods: 20 subjects used a portable EMG appliance (dia-Bruxo, Biotech-Novations, Italy), measuring Masseter muscle activity, for 3 consecutive nights.

Collected variables included: number of grinding and clenching episodes, bruxism time index (BTI- how much time was dedicated to bruxing), and bruxism work index (BWI- how much muscular power was used for bruxing activity)

Results: Cronbach alpha of the studied variables was excellent to acceptable (ranging from 0.905 for BWI, to 0.73 for grinding).

Average BTI and BWI scores (3-night record) were 0.67 ± 0.55 and 0.60 ± 0.54 , accordingly. The scores were markedly higher than those published by Colonna et al. (J. Clin. Med. 2023) among Italian subjects (1 night record).

The relationship between BWI and BTI ($y = 1.01x - 0.05$, $R^2 = 0.89$) indicated that time and power magnitude of bruxism activity during sleep were in an almost strait relationship.

There were good positive correlations between the three nights of measurement: BTI (r^2 values of 0.54, 0.63, 0.80; $p < 0.05$); BWI (r^2 values of 0.57, 0.68, 0.69; $p < 0.01$); clenching (r^2 values of 0.61, 0.65, 0.81; $p < 0.01$). For grinding, there was a positive correlation between night 1 and 2 ($r^2 = 0.61$; $p < 0.01$).

Conclusions: analysis of SB over three nights reveals distinct temporal patterns for grinding and clenching behaviours; (ii) data indicate potential clinical implications for diagnosis, treatment planning, and understanding of SB pathophysiology; (iii) portable ambulatory EMG device can serve as SB screening tool along multiple-night measurements.

Acknowledgments: The study was supported by grant No. 3737/24 of the Israeli Science Foundation

Objective adherence to oral appliance therapy in patients with obstructive sleep apnea: A one-year longitudinal analysis

Y. Chen¹, B. Pliska¹, B. Zou¹, F. Almeida¹

¹The University of British Columbia, Department of Oral Health Sciences, Vancouver, Canada

Introduction: Oral appliance (OA) therapy is widely used as an alternative to continuous positive airway pressure (CPAP) therapy for treating obstructive sleep apnea (OSA). Historically, OA adherence was gauged by patient self-report, which can be unreliable. Recently, embedded microsensors in OAs have enabled objective tracking of wear time. This study analyzed one-year objectively recorded adherence data in OSA patients using sensor-equipped OAs to characterize using patterns and identify factors influencing adherence.

Materials and methods: Fifty-five OSA patients were recruited from a cohort study and underwent clinical follow-ups for a 12-month period. Patients were treated with custom-made, titratable OAs with a built-in temperature-sensitive microsensor to record nightly use. Adherence data were collected at 1, 6, and 12 months and analyzed using both intention-to-treat (ITT) and per-protocol (PP) approaches. Baseline demographic, dental, and health data (including presence of any psychological disorder) were recorded. Adherence was defined as mean use ≥ 4 hours per night (adherent) versus < 4 hours (non-adherent) in each interval. Adherence trends over time were analyzed, and logistic regression identified baseline predictors of adherence.

Results: Of 55 patients, 34 (62%) completed 12 months of follow-up (21 dropped out). Objective sensor data showed high initial use with a decline by 6 months. At 1 month, 80% were adherent (mean ~ 6.0 hours/night); by 6 months this fell to 67% (5.7 hours/night). Adherence then stabilized, with 82% of remaining patients adherent at one year (5.8 hours/night). The percentage of nights with ≥ 4 hours of use also decreased slightly (from $\sim 79\%$ at 1 month to $\sim 73\%$ at 12 months).

Multiple baseline factors influenced adherence. Being married or living with a partner, which indicating strong social support, was associated with significantly higher long-term adherence. In contrast, patients with a psychological comorbidity (e.g. depression or anxiety) had markedly lower adherence. A larger baseline overjet (i.e. greater horizontal overlap of incisors) correlated with better early adherence. Age showed a modest effect: older patients tended to maintain adherence better over time. No significant differences in adherence were observed by sex, body mass index, or baseline OSA severity.

Conclusions: OA adherence dropped in the first few months but plateaued by one year among those continuing treatment. This pattern underscores the need for early support and interventions during the initial adaptation period. Key predictors of adherence were identified with direct clinical relevance. Robust social support (e.g. having a partner) strongly favored adherence, suggesting benefits to involving family in care. Conversely, the presence of a psychological disorder was linked to poor adherence, indicating that addressing mental health is important when initiating OA therapy. Additionally, a favorable dental profile (e.g. larger overjet) may facilitate adaptation to OA use. Incorporating objective adherence monitoring in practice can help clinicians identify patients at risk of non-adherence and implement targeted strategies to improve long-term treatment success.

Real-world results of a telemedicine workflow for the treatment of obstructive sleep apnea using Mandibular Advancement Devices. A review of 2,110 cases

J. Stern¹, A. Pezzella¹, A. Jackson¹

¹BlueSleep, New York, United States

Introduction: Current adoption of telemedicine consultations for diagnosis and treatment of obstructive sleep apnea (OSA), and the recent advances in single patient use home sleep testing; allow for a fully virtual workflow, improving access to efficient and affordable sleep apnea care. We reviewed our experience with patients treated with Mandibular Advancement Devices (MAD) through the BlueSleep virtual portal and workflow; and evaluated objective improvement in pre and post treatment Apnea Hypopnea Index (AHI) scores for patients with mild, moderate, and severe obstructive sleep apnea.

Materials and methods: We performed a retrospective chart review of 2,806 patients treated with MAD for OSA, over a 26 months period. 2,110 of those patients were fitted with a Prosomnus MAD. Dental considerations, medical insurance requirements, and patient preference dictated the type of MAD device used: (EVO, EVO PH, or PH). Initial consultations, home sleep tests, and follow up visits were all by telemedicine. 76% of deliveries were by virtual real time HIPAA compliant video visits, and 23% were in-person, in-office MAD deliveries. Pre and post HST (Home Sleep Apnea Test) were ordered in all patients by the medical team and shipped to patients' homes.

Results: The average age of patients treated was 42.5, with 70% males and 30% females. 36% of patients did not complete a post treatment HST despite having the HST device in their possession - these patients were omitted from the results. Average OSA post-treatment AHI improved by more than 49.6% compared to average pre-treatment AHI for the total number of patients evaluated. All severity categories showed statistically significant improvements. Severe (n=147): pre AHI 42.18 to post AHI 18.43, Moderate (n=443): pre AHI 20 to post AHI 10.12, Mild (n=455): pre AHI 9.33 to post AHI 6.03.

Conclusions: Sleep apnea diagnosis and treatment usually requires in-person visits for consultations, sleep tests, and multiple in-person visits for treatment. As a result wait times for access to sleep specialists, sleep testing, and treatment can be as long as 6 months or longer. This work flow only serves a very small percentage of the population at risk for OSA. The real world data from this report confirms that a virtual workflow including telemedicine consultations, home sleep tests shipped to patients' homes, and virtual delivery of MADs is an effective alternative to the current in-person model. The telemedicine workflow is a scalable model that is rapid, affordable, effective, and can improve access to sleep care to the one billion people affected by obstructive sleep apnea globally.

Acknowledgments: Financial support provided by Prosomnus Sleep Technologies. Pleasanton, CA.

Retrospective Analysis of the Effectiveness of a Morning Occlusal Guide (MOG) in Reducing Unwanted Dental Movements Associated with Oral Appliance Therapy (OAT) in Patients with Obstructive Sleep Apnea (OSA)

M. Arab¹, E. Kim¹, H. Suh¹, H. Oh¹, A. Yoon^{1,2}

¹University of the Pacific, Arthur A. Dugoni School of Dentistry, Department of Orthodontics, San Francisco, United States, ²Stanford University, Stanford, United States

Introduction: Introduction:

Oral Appliance Therapy (OAT) is an established treatment for snoring and mild to moderate obstructive sleep apnea (OSA), serving as an effective alternative for patients who are intolerant of continuous positive airway pressure (CPAP).¹ While OAT is generally well tolerated, it is associated with dental side effects such as reductions in overjet and overbite, proclination of mandibular incisors, and retroclination of maxillary incisors.² The use of morning occlusal guides (MOG) has been recommended to mitigate these effects. MOG encompasses a range of custom-made appliances and prefabricated devices intended to reposition the mandible into its habitual pretreatment position. These devices function by utilizing the patient's biting force to re-seat the condyles, thereby helping to reestablish and maintain the appropriate occlusal relationship in the morning following each night of OAT.³ However, the degree to which MOG use mitigates dental changes, compared with OAT alone, has not been adequately evaluated. Therefore, the present study aims to assess dental changes in OAT patients and determine whether adjunctive use of MOG reduces the magnitude of these side effects.

Materials and methods: A retrospective analysis was conducted on 28 patients with OSA (mean age 59.6 ± 12.3 years; 10 females, 18 males) treated with OAT at a private practice or the University of the Pacific orthodontic clinic. Inclusion required an OSA diagnosis, OAT treatment, and availability of digital records at two time points: baseline before OAT (T1) and follow-up after ≥ 9 months of treatment (T2; mean 21.4 ± 10.2 months).

Digital scans were analyzed with OrthoCAD to measure overjet, overbite, crowding, and intercanine/intermolar widths. Two calibrated orthodontists performed the measurements, and intra-class correlation coefficients (ICCs) were used to assess reliability. Three-dimensional superimposition was performed in CloudCompare software, with color-coded maps generated to illustrate dental changes. In addition, patients completed a follow-up questionnaire regarding OAT tolerance, symptoms, and MOG use. Descriptive statistics were calculated. Paired t-tests compared changes from T1 to T2, and independent t-tests compared consistent vs inconsistent MOG users. Nonparametric tests were applied when necessary, with significance set at $p < 0.05$.

Results: ICC values demonstrated excellent reliability (0.89–0.99). Questionnaire responses showed 92% of patients reported full-night tolerance of OAT, 58% noted reduced snoring, 24% reported tooth tenderness, 20% perceived bite changes, and 38% had discontinued MOG use. Digital model analysis from T1 to T2 showed minimal changes. Overjet (-0.2 ± 0.8 mm) and overbite (-0.1 ± 0.7 mm) decreased slightly, and arch widths remained stable ($p > .05$). Mandibular (-0.2 ± 0.4 mm, $p = .015$) and maxillary crowding (-0.3 ± 0.5 mm, $p = .007$) values became slightly more negative, reflecting a minor but statistically significant increase in crowding. Between-group comparisons showed no significant differences in any variable between consistent and inconsistent MOG users ($p > .30$).

Conclusions:

OAT was associated with minor dental changes after a mean follow-up of 21 months, including slight but significant increases in mandibular and maxillary crowding. Consistent MOG use did not reduce these effects. Longer follow-up studies are needed to clarify the role of MOGs in preventing OAT-related dental changes.

Sleep quality and daytime sleepiness is related to immune and comorbidity status in temporomandibular disorders

J.H. Jo¹, C. Son², J.W. Chung¹, J.W. Park¹

¹Seoul National University School of Dentistry/Seoul National University Dental Hospital, Seoul, Korea, Republic of, ²Seoul National University School of Dentistry, Seoul, Korea, Republic of

Introduction: Sleep problems are well known to be interrelated with chronic pain. Temporomandibular disorders (TMD) is the second most common cause of orofacial pain but the exact mechanism underlying the disease itself and its related comorbidities is yet to be revealed. Alterations in immune status may be the shared link between TMD pain and various comorbidities including sleep problems that are commonly observed and is a main factor that lowers the quality of life of TMD patients. This study aimed to investigate levels and interrelationships among autoantibodies, cytokines, and comorbidities in TMD patients according to the level of sleep quality and daytime sleepiness to seek the possible role of sleep disturbance in the pathogenesis of inflammation and pain in TMD.

Materials and methods: Venous blood was harvested from 66 female TMD patients in their 20-30s. A battery of autoimmune indices (ss-DNA, ds-DNA, extracted nuclear antigens[SSA, SSB, Jo-1, RNP], IgG-anti-beta2-glycoprotein I antibody, anticardiolipin antibody, lupus anticoagulant, IgA, IgG, IgM and complements 3 and 4) and cytokines (interleukin [IL]-1 α , IL-1 β , IL-2, IL-4, IL-5, IL-6, IL-8, IL-10, IL-13, IL-17, tumor necrosis factor- α , fibroblast growth factor [FGF], granulocyte colony-stimulating factor, granulocyte-macrophage colony-stimulating factor [GM-CSF], vascular endothelial growth factor [VEGF]) were analyzed. Comorbidities were evaluated with structured questionnaires (Beck's depression index [BDI], Beck's anxiety index [BAI], Pennebaker Index of Limbic Languidness [PILL], Perceived Stress Scale, and Fibromyalgia impact questionnaire). Sleep related condition was evaluated with Epworth sleepiness scale (ESS) and Pittsburgh sleep quality index (PSQI). Collected data was statistically compared between groups with or without low quality sleep and excessive daytime sleepiness.

Results: Twenty-one patients(31.82%) had an ESS>10 and 31 patients(46.97%) had a PSQI $\geq$ 6 score. PILL($p=0.001$) and BAI($p<0.001$) scores were significantly higher in the ESS>10 group. PILL ($p<0.001$), BAI($p<0.001$), and BDI($p<0.001$) scores were significantly higher in the PSQI $\geq$ 6 group. RNP($p=0.031$) and Jo-1($p=0.037$) blood levels were significantly lower in the ESS>10 group. ESS showed significant correlation with PSQI($\gamma=0.563$, $p<0.01$), PILL($\gamma=0.601$, $p<0.01$), BDI($\gamma=0.272$, $p<0.05$, and BAI($\gamma=0.564$,

$p < 0.01$). PSQI showed significant correlation with PILL ($\gamma = 0.613$, $p < 0.01$), BDI ($\gamma = 0.516$, $p < 0.01$), BAI ($\gamma = 0.680$, $p < 0.01$), IgM ($\gamma = -0.281$, $p < 0.05$), and IL-4 ($\gamma = 0.282$, $p < 0.05$) levels.

Conclusions: Significantly higher levels of psychological problems along with altered levels of autoimmune indices and cytokines were observed in TMD patients with possible sleep disturbance. These results may point towards the existence of a nonspecific immune dysregulation and inflammation that is associated with more comorbidities in a subgroup of TMD patients with sleep issues.

Structuring Dental Sleep Medicine Education in Brazil: A Pathway Toward Specialty Consolidation and Improved Patient Care

E. Lottenberg Vago^{1,2}, F. Cavicchioli Goldenberg^{1,2}, L. Azevedo Soster^{1,3}, S. Tavares¹

¹Hospital Israelita Albert Einstein, Medical Sleep Assistance Group, São Paulo, Brazil, ²Faculdade Israelita de Ciências da Saúde Albert Einstein, Dentistry, São Paulo, Brazil, ³University of São Paulo Medical School, Child's Institute, São Paulo, Brazil

Introduction: Dental Sleep Medicine encompasses the diagnosis and management of conditions such as sleep-disordered breathing, sleep bruxism, and orofacial pain. Although the clinical demand for dental professionals trained in sleep-related disorders is increasing, educational frameworks in Brazil remain fragmented, limiting the development of consistent, evidence-based practices.

Materials and methods: A descriptive analysis of national educational data from the Brazilian Ministry of Education was conducted, along with a review of training programs at the which integrates Sleep Medicine, Temporomandibular Disorders (TMD), and Orofacial Pain into postgraduate dental curricula.

Results: Despite the existence of over 440,000 dentists in Brazil, Dental Sleep Medicine is not yet recognized as a formal specialty. Since 2011, only 91 dentists have been certified by the Brazilian Sleep Association. In contrast, TMD and Orofacial Pain have been recognized since 2002, with 1,660 certified professionals and 72 accredited programs. FICSAE currently offers:

- **A Lato Sensu postgraduate course in Sleep Medicine** (80 seats/year)
- **A postgraduate program in TMD, Orofacial Pain, and Sleep Dentistry** (48 seats/year)
- **Short continuing education courses** in the same domains

These programs are aligned with clinical protocols at Hospital Israelita Albert Einstein (HIAE), reinforcing a feedback loop between training and practice.

Conclusions: The consolidation of Dental Sleep Medicine as a recognized specialty depends on the implementation of structured, multidisciplinary educational programs. The FICSAE–HIAE model demonstrates how institutional investment in training can lay the groundwork for professional certification, improved interdisciplinary care, and ultimately, more effective and personalized treatment for patients with sleep-related orofacial conditions.

Surgical Orthodontic Treatment of Patient with Moderate Obstructive Sleep Apnea

J.C.-Y. Wang¹, M.-Y. Chen², C.-J. Chang¹

¹National Cheng Kung University Hospital, Division of Orthodontics, Department of Stomatology, Tainan, Taiwan, ²National Cheng Kung University Hospital, Division of Oral Maxillofacial Surgery, Department of Stomatology, Tainan, Taiwan

Introduction: This case report presents a 38-year-old female who visited the hospital's orthodontic department with chief complaint of an unesthetic smile with excessive gingival display, and issues of anterior open contact and tilted mandibular molars. During routine orthodontic examination, a narrow nasopharyngeal was noted on the lateral cephalometric radiograph. The STOP-Bang questionnaire demonstrated to be a simple, practical, and reliable method identifying patients with risk of obstructive sleep apnea (OSA) in dental clinical settings. Subsequent PSG confirmed diagnosis of moderate OSA

(AHI=27.3/hr) and significantly influenced the decision making regarding non-surgical or surgical orthodontic treatment. Collaboration among healthcare providers from different specialties was essential in optimizing treatment outcomes.

Materials and methods: Complex skeletal malocclusions often necessitate an interdisciplinary approach. In addition to addressing skeletal discrepancies, the concomitant issue of compromised upper airway functions, most often in retrognathia cases, require thorough evaluation. During initial radiographic examination, a narrow nasopharyngeal airway was noted on the lateral cephalometric radiograph. To further confirm whether issues with upper airway patency were present, the STOP-Bang questionnaire was used for OSA risk screening. With a STOP-Bang score of 3/8, an otolaryngology consultation was arranged. The otolaryngologist scheduled an overnight PSG examination, and results revealed an AHI score of 27.3/hr, indicating moderate OSA. Nasopharyngolaryngoscopy was also used for examination, and tumors, cysts, lingual tonsils, or laryngeal pathology were ruled out, while tongue hypertrophy was noted. The diagnosis of moderate OSA significantly influenced the decision making regarding non-surgical or surgical orthodontic treatment.

Maxillomandibular advancement is considered one of the most effective surgical procedures in treating patients with moderate to severe OSA. Upon skeletal evaluation of the patient, maxilla retrusion was not present, and excessive advancement of the maxilla will have adverse effects on the patient's profile. Moreover, the most narrow dimension of the upper airway was identified at the retroglossal area, which is most influenced by mandibular retrusion. Hence, the surgical treatment plan prioritized advancement of the mandible and limited maxillary advancement.

Results: Based on superimposition of lateral cephalometric tracings before and after treatment, the maxilla was impacted by 2.5 mm, and point B of the mandible moved upward by 2.5 mm and forward by 7 mm. Combined with genioplasty, the pogonion moved upward by 10 mm and forward by 15 mm. The soft tissue facial contour angle improved from 24 degrees to 14 degrees.

Post-treatment PSG assessment revealed a reduction in AHI from 27.3/hr to 17.0/hr. Less daytime fatigue was reported by the patient.

Conclusions: Improvement in OSA severity following orthognathic surgery is demonstrated. AHI decreased by 37.7%, and the patient's subjective improvement (reduced daytime sleepiness) is notable, indicating a benefit in sleep quality. In surgical planning, amount of maxillomandibular advancement was limited due to esthetic considerations. Persistent symptoms suggest the need for ongoing evaluation and possibly adjunctive therapy.

The case highlights the critical role of dental professionals in screening, referral, and co-managing sleep disorders. Recognition and intervention in dental settings can lead to earlier diagnosis, improved outcomes, and a multidisciplinary approach to this prevalent but often overlooked condition.

Upper Airway Dimensional Changes Following Treatment in Patients with Temporomandibular Disorders: A Longitudinal CBCT-Based Study

Y. Kim¹, J. Park¹, J. Jo¹

¹Seoul National University, Department of Oral Medicine and Oral Diagnosis, School of Dentistry, Seoul, Korea, Republic of

Introduction: This study aimed to evaluate changes in upper airway volume and length in patients with temporomandibular disorders (TMD) before and after treatment, and to investigate how alterations in mandibular position affect upper airway dimensions.

Materials and methods: A total of 102 patients diagnosed with TMD based on the Research Diagnostic Criteria for TMD (RDC/TMD) were enrolled. Each patient underwent clinical and radiographic evaluation, including cone-beam computed tomography (CBCT), before and after a one-year treatment. Condylar bony changes were assessed on sagittal and coronal CBCT views by dividing each mandibular condyle into nine sections and scoring the degenerative change according to presence of erosion, osteophytes, and subchondral cysts. Airway measurements were performed using AVIEW Modeler software and included volumetric and cross-sectional analyses of the velopharyngeal, oropharyngeal, and hypopharyngeal airways. Additional parameters including the anteroposterior and transverse diameters at the narrowest cross-section, total upper airway volume, upper airway length, and condylar volume were also evaluated.

Results: Of the 102 patients, 33 were classified into the improved group and 69 into the worsened group based on CBCT findings. The improved group demonstrated statistically significant increases in velopharyngeal airway volume and total upper airway volume ($p < 0.05$). In this group, the minimum anteroposterior diameters of all airway regions significantly increased following treatment, whereas the worsened group showed significant decreases in these dimensions ($p < 0.05$). Moreover, both upper airway length and condylar volume increased in the improved group but decreased in the worsened group ($p < 0.05$).

Conclusions: Improvements in condylar morphology following TMD treatment are associated with favorable changes in upper airway dimensions, particularly in the velopharyngeal region, total airway volume, and the minimum anteroposterior diameter across all regions. These findings suggest that appropriate TMD management may contribute to improved upper airway patency and potentially reduce the risk of OSA by optimizing mandibular and airway structures.

Variations of craniofacial structure and the pediatric upper airway

S. Chee¹, L. Koh², K.W.C. Foong¹, Y.F. Sim³, C. Lai³, M. Yow⁴

¹National University of Singapore, Dentistry, Singapore, Singapore, ²KK Women's and Children's Hospital, Otolaryngology, Singapore, Singapore, ³National University of Singapore, Biostatistics, Singapore, Singapore, ⁴National dental centre singapore, Orthodontics, Singapore, Singapore

Introduction: Constricted upper airway and cranio-facial structures are risk factors for sleep-disordered breathing in the paediatric population. Identification of adeno-tonsillar hypertrophy and associated cranio-facial factors require a large cross-sectional sample. Lateral cephalometric radiographs are routinely used in paediatric orthodontic screening, and have reproducible landmarks of the upper airway structure that can be assessed. The current study aims to 1) investigate for differences in airway measurements between groups of different age & gender, anteroposterior and vertical skeletal patterns, and ancestry, 2) report prevalence rates of adenoid and/or tonsillar hypertrophy, and 3) report upper airway, skeletal, dental and soft tissue cephalometric measurements in a large Singaporean paediatric orthodontic population.

Materials and methods: Consecutive lateral cephalograms of 203 boys and 201 girls ($n=404$) between 7.04 to 10.99 years of age were retrieved retrospectively, from a national dental centre. Upper airway, skeletal, dental and soft tissue variables were measured and

investigated for differences between groups based on age, gender, antero-posterior and vertical skeletal patterns, and ancestry. Prevalence of adeno-tonsillar hypertrophy was identified in this population.

Results: Mean values of various upper airway and cephalometric measurements were reported according to age and gender. Significant differences ($p < 0.05$) were noted for thirteen airway variables (Ad, Np (adenoids), Ad/Np, Op (tonsils), PM-U, SPT, NL/PM-U, PM-UPW, UMPW, PASmin, V-LPW, AH-FH, AH-CV) between groups differentiated by gender and age, six (Np (adenoids), Ad/Np, Tn, Op (tonsils), PM-U, NL/PM-U) and four (Ad, Ad/Np, NP/PM-U, AH-CV) variables between groups of different antero-posterior and vertical skeletal patterns respectively, and one variable (AH-CV) between Chinese and non-Chinese children. The overall prevalence of lymphoid tissue hypertrophy based on the lateral cephalograms was 92.3% (based on $Ad/Np \geq 0.5$ and/or $Tn/Op \geq 0.5$).

Conclusions: Mean values of various upper airway and cephalometric measurements were reported for a large paediatric orthodontic population in Singapore. Young, male, Chinese boys aged 7 to 8.99 years with Class I, Class II and high maxillomandibular plane angle had upper airway measurements that increased their risk for SDB. Greater mandibular retrusion and downward positioning were associated with adeno-tonsillar hypertrophy that restricted the paediatric upper airway.

Excessive Daytime Sleepiness (not Narcolepsy)

Assessment of wakefulness in Vietnamese patients with obstructive sleep apnea using a modified Maintenance of Wakefulness Test protocol

K. Bui-Diem¹, N.V. Tho², T. Nguyen-Binh¹, Q. Vu-Tran-Thien¹, T. Le³, L. Phung-Khanh⁴, S. Duong-Quy^{5,6}

¹University of Medicine and Pharmacy at Ho Chi Minh City, Department of Physiology - Pathophysiology - Immunology, Faculty of Medicine, Ho Chi Minh, Vietnam, ²University of Medicine and Pharmacy at Ho Chi Minh City, Department of Tuberculosis and Lung diseases, Faculty of

Medicine, Ho Chi Minh, Vietnam, ³International University, National University Ho Chi Minh City, Brain AI Lab, School of Biomedical Engineering, Ho Chi Minh, Vietnam, ⁴University of Medicine and Pharmacy at Ho Chi Minh City, Department of Epidemiology, Faculty of Public Health, Ho Chi Minh, Vietnam, ⁵Lam Dong Medical College, Lam Dong, Vietnam, ⁶Penn State College of Medicine, Penn State University, Pennsylvania, United States

Introduction: Obstructive sleep apnea (OSA) is marked by the recurrent collapse of the upper airway during sleep, causing fragmentation of normal sleep patterns and notable sleepiness during the daytime. The Maintenance of Wakefulness Test (MWT) assesses a patient's ability to stay awake in a dark environment without any external support. With this study, we aimed to evaluate the ability to maintain wakefulness among OSA patients in the Vietnamese population using a modified MWT protocol.

Materials and methods: A cross-sectional study, collecting patients from University Medical Center, Ho Chi Minh City, from November 2022 to August 2024. Adult patients with newly diagnosed, untreated OSA were recruited, excluding those on sleep-affecting medications or those with other conditions affecting alertness. Pilot testing revealed challenges with the standard MWT due to cultural napping habits, leading to protocol adaptation. The modified MWT allowed participants to nap between sessions at their usual times, required waking at least 30 minutes before each session, and subjects were not awakened if sleep occurred during the 40-minute sessions. Signals from the MWT electrodes were recorded continuously between sessions to measure the sleep latency (SL) of each session and the total sleep time (TST) during the test day.

Results: The study included 63 subjects, median age 48 (IQR 36-58), 79% male, median BMI 27.4 (IQR 25.1-29.8), 84% reported napping habits. Most of participants (71%) had severe OSA (median AHI 44, IQR 26-70). Objective MWT measurements showed average SL of 22 minutes (IQR: 11-30). A clear correlation was observed, with baseline AHI positively correlated with TST and negatively correlated with SL measured by MWT. In MWT, sleeping in session 1 increased the odds of sleeping in session 2 by 3.64 times (95% CI: 1.16, 11.9); greater TST in a preceding session was significantly associated with shorter SL in the subsequent session(s).

Conclusions: Higher TST in a preceding MWT session correlated with higher TST and shorter SL in subsequent session(s), indicating persistent difficulty staying awake, regardless of nap. The modified MWT protocol, tailored for cultural sleep practices, provides feasible and meaningful assessment of wakefulness in Vietnamese patients with OSA, thereby suggesting adaptation the MWT for countries with nap habits.

Acknowledgments: This research was funded by the University of Medicine and Pharmacy at Ho Chi Minh City under contract number 225/2022/HĐ-ĐHYD, dated 14/10/2022.

Barcelona Sleepiness Index to Assess Subjective Sleepiness: An External Validation Study

M. Aktan Süzgün¹, K. Abdulla¹, E. Holzkmacht¹, M.V. Anselmi Innaco¹, A. Ibrahim¹, M. Bergmann², E. Brandauer¹, B. Högl¹, A. Stefani¹

¹Medical University of Innsbruck, Department of Neurology, Innsbruck, Austria, ²Johannes Kepler University Linz, Department of Neurology, Linz, Austria

Introduction: Barcelona Sleepiness Index (BSI), which was validated to assess excessive daytime sleepiness (EDS) in patients with sleep disordered breathing, is a simple and brief instrument. BSI consists of two questions assessing sleepiness during rest and during activity in the previous weeks, and answers are graded from zero to three. Thus, it is easy to conduct without ambiguity compared to other widely used questionnaires. This study aimed at investigating the validity of BSI among patients with EDS and at analyzing its correlation with objective sleep measures.

Materials and methods: This retrospective study was conducted in the Centre for Sleep Medicine, Department of Neurology, Medical University Innsbruck, analyzing data acquired from 2017 to 2024. Patients who presented with subjective complaints of EDS and filled out both the Epworth Sleepiness Scale (ESS) and BSI questionnaire before undergoing two-night diagnostic video-polysomnography (vPSG) and multiple sleep latency test (MSLT) were included in the study. ESS ≥ 10 and BSI ≥ 2 points were considered abnormally increased EDS. Patients were classified into central disorders of hypersomnolence (CDH) and those without evidence of CDH (no-CDH). ESS and BSI performances were compared between the CDH and no-CDH groups.

Results: A total of 261 patients were included (mean age: 39.9 ± 15.6 , F/M: 129/132), of which 90 had CDH (27 with narcolepsy type 1, 10 with narcolepsy type 2, 11 with idiopathic hypersomnia, 42 with CDH not otherwise classified) and 171 had no-CDH. Among all patients, the median BSI score was 2, and the median ESS score was 13. Both were significantly higher in the CDH group compared to the no-CDH group (respectively, $p=0.005$ and <0.001). BSI and ESS scores correlated positively with each other ($r=0.52$, $p<0.001$). BSI showed a significant positive correlation with the presence of sleep onset REM episodes (SOREMs) in the vPSG ($r=0.24$, $p<0.001$) and the number of SOREMs in MSLT ($r=0.27$, $p<0.001$), and a negative correlation with sleep latency in MSLT ($r=-0.24$, $p<0.001$). ROC analysis revealed that ESS better discriminated CDH from no-CDH (AUC=0.74, sensitivity=0.65, specificity=0.71) compared to BSI (AUC=0.60, sensitivity=0.62, specificity=0.53). However, BSI showed a better performance than ESS to identify those with mean sleep latency <8 minutes (AUC=0.65) and to detect the presence of SOREMs (AUC=0.68) in MSLT.

Conclusions: BSI demonstrated a comparable performance for the detection of CDH and narcolepsy compared to ESS, and better performance for the determination of abnormal MSLT parameters in patients with CDH. BSI, as a brief and easily applicable questionnaire, strongly correlated with ESS scores and objective vPSG and MSLT measures related to CDH. Further studies are needed to evaluate its performance in larger cohorts and patients with different sleep disorders.

Bordeaux Sleepiness Scale (BOSS): A new scale to predict sleep-related traffic accident in regular French highway drivers

P. Philip¹, J. Coelho¹, B. Moreau², J. Taillard¹, J.-A. Micoulaud-Franchi¹, A. Chanteclair³, P. Sagaspe¹

¹UMR CNRS 6033 SANPSY, University of Bordeaux, University Hospital Bordeaux, Bordeaux, France,

²Fondation VINCI Autoroutes, Nanterre, France, ³UMR CNRS 6033 SANPSY, University of Bordeaux, Department of Clinical Gerontology, University Hospital Bordeaux, Bordeaux, France

Introduction: Sleepiness at the wheel is a well-known risk factor for traffic accidents. The aim of this study is to explore the prevalence of sleepiness at the wheel and the risk factors associated with driving near misses and road accidents in regular French highway users. This study also compares performance of the new Bordeaux Sleepiness Scale (BOSS) (Philip et al., J Clin Sleep Med, 2023) to predict sleep-related accidents in a non-clinical population versus reference scale Epworth Sleepiness Scale (ESS).

Materials and methods: Regular French highway drivers were invited to participate in an internet survey between April-May and October-November, 2024. A total of 19,860 drivers (Mean age: 48.4 ± 12.7 years, 44.8% female) answered questions on socio-demographic characteristics, sleep behaviors, sleep disorders, lifestyle and health, substance use, driving habits, and near-accident and accident conditions. The Bordeaux Sleepiness Scale (BOSS) was used to determine the sleep-related driving risk.

Results: 29.6% reported at least one near-miss accident, and 8.8% reported at least one accident in the previous year. More than one out of three drivers (34.5%) experienced at least one episode of severe drowsiness at the wheel during the previous year (i.e., making driving difficult or forcing the driver to stop driving). Among these sleepy drivers, 41.8% reported at least one near-miss accident and 11.2% an accident in the past year. 62.4% of near-misses or accidents linked to sleepiness occurred on highways, and 54.4% on trips of over 2 hours. 71.1% of sleep-related near-misses and accidents occurred in a monotonous context (low traffic).

After adjustment for age, gender, mileage exposure and self-reported psychiatric disorders, the best predictive factors for sleep-related accidents were the occurrence of at least one episode of severe sleepiness at the wheel in the past year [adjusted odds ratio (OR) 5.9, 95% confidence interval (CI) 2.8-12.44, $P<0.001$], a BOSS score ≥ 3 [adjusted OR 3.2, 95% CI, 1.7-6.3, $P<0.01$], an Epworth score ≥ 11 [adjusted OR 2.4, 95% CI, 1.4-4.3, $P<0.01$], having total sleep time <7 h on rest days [adjusted OR 2.1, 95% CI, 1.1-3.9, $P<0.05$], being in shift work (2/8, 3/8, etc.) [adjusted OR 3.6, 95% CI, 1.4-9.3, $P<0.01$], being in social jetlag ≥ 2 hours [adjusted OR 2.1, 95% CI, 1.1-4.0, $P<0.05$], using cannabis [adjusted OR 4.3, 95% CI, 1.4-13.7, $P<0.05$] and having ever reported a near miss within the year [adjusted OR 65.0, 95% CI, 23.6-178.5, $P<0.001$].

Conclusions: Occurrence of sleepiness at the wheel still constitute a major risk factor for near misses and accidents. Poor sleep hygiene and sleep irregularity are fundamental predictors of sleep-related accidents. The occurrence of episodes of severe sleepiness at the wheel in the past year, and the

reporting of a near miss in the past year, are major risk factors for near misses and road accidents. The BOSS combining mileage exposure and self-perception of situational sleepiness is a more relevant scale than ESS to predict sleep-related driving risk in a non-clinical population.

Connections between allergic rhinitis, floppy eyelid syndrome and the syndrome of obstructive sleep apnea and snoring

M. Milkov¹, M. Stoykov¹

¹Medical University - Varna, Dental materials science and Prosthetic Dental medicine, Varna, Bulgaria

Introduction: The syndrome of Obstructive sleep apnea and snoring (SOSAS) is a socially significant disease. It can be compared to infectious diseases with a pandemic potential. Diagnosis and treatment of the syndrome have to be carried out by interdisciplinary teams of medical specialists. Allergic conditions, including allergic rhinitis and subsequently developed nasal polyposis, are being diagnosed nowadays more often than in the past. According to recent results from scientific studies, more than 1.4 billion individuals are affected by allergic rhinitis. This floppy eyelid syndrome represents a condition in which the upper eyelids easily evert when tracted upward, leaving eyes susceptible to discomfort and vision loss. All disorders mentioned severely reduce the quality of life of patients affected.

Materials and methods: 180 patients (n) with proven symptoms of a disturbed sleep at night were thoroughly examined at Sector "Audio-vestibular and sleep medicine", University medical and dental center, Faculty of Dental medicine, Medical University – Varna. All examinations were done for the time period June 2023 - December 2024. Authors used polygraph analysis at home (HSAT) to study sleep quantity and quality, and rhinomanometry to examine the nasal breathing. All patients filled in specialized sleep questionnaires (Berlin questionnaire, ESS), assessing present symptoms of disturbed sleep, written informed consent forms, forms regarding health conditions, general diseases present, allergic status, surgical interventions in the maxillofacial region, recent hospitalizations. The study has received approval from Medical University - Varna Ethics committee (131/11.05.2023).

Results: All patients had varying degrees of severity of obstructive sleep apnea symptoms, moderate forms - 65%. 40 patients required surgical septoplasty, and 67 patients required conchotomy and radiofrequency-induced thermotherapy. It is interesting that 108 (56.67%) of all studied patients (n=180) had a proven allergy condition. The in-depth analysis of the data from patients' conditions showed that there is a significant worsening of sleep apnea symptomatology in allergic rhinitis and nasal polyposis patients. The patients who underwent surgery, got an improvement, but despite this, not a small part of them were offered CPAP-therapy and long-term treatment of the allergic condition. According to authors' results, most frequent causes of allergic rhinitis were: food, fungi, mold. Patients living in towns and in villages developed allergic rhinitis with the same frequency. More patients with allergies caused by food were diagnosed. Patients with nasal polyposis tend to snore more.

Conclusions: Associations between SOSAS and several eye diseases including floppy eyelid syndrome highlight the need for ophthalmologists to consider the syndrome in their patients and recommend future research studies. Latter is especially needed in cases when therapies for obstructive sleep apnea can be effective for ocular disorders as well. Coping with in advance with allergic conditions should be a protocol when treating all forms of SOSAS. The active prevention and treatment of SOSAS should not have a campaign character. Comorbidity in patients with proven metabolic syndrome, diabetes, hypertension and allergic conditions must be studied.

Acknowledgments: This study is financed by the European Union-NextGenerationEU, through the National Recovery and Resilience Plan of the Republic of Bulgaria, project № BG-RRP-2.004-0009-C02.

Consensus recommendations for special challenges faced by technical personnel with elderly and very old patients in the sleep laboratory

N. Netzer¹, H. Frohnhofen², P. Netzer¹, E. Marasanov³, A. Schlesinger⁴, S. Stieglitz⁵

¹Hermann Buhl Institute for Hypoxia and Sleep Medicine Research, Bad Aibling, Germany, ²Department for Geriatric Traumatology, University Hospitals Duesseldorf, Duesseldorf, Germany, ³Charite

University Hospitals, Center of Sleep Medicine, Berlin, Germany, ⁴St. Mary's Hospital of the Cellitinnen, Internal Medicine, Cologne, Germany, ⁵Petrus Hospital of the Cellitinnen, Internal Medicine, Wuppertal, Germany

Introduction: Sleep disorders increase with increasing age. In the US American population 50% of all persons 65 yrs and older complain about sleep problems. Therefore, elderly patients make up a large portion of clients in the sleep laboratory with polysomnography for diagnosis and therapy. The technical staff confronted with elderly clients in the sleep laboratory faces several special challenges with this cohort, which are discussed and given recommendations to deal with them in this consensus statement.

Materials and methods: Based on the experience of challenges faced by elderly patients in the sleep laboratory, which have been revealed by consensus in an open in presence discussion of members of our assemblies (Geriatric Sleep Medicine of the German Sleep Society, Certified Sleep Technicians of the German Sleep Society and Geriatric Pulmonary Medicine of the German Society of Pneumology) at the 2024 annual conference of the German Sleep Society in Essen, Germany and written reports of members of the Certified Sleep Technicians of the German Sleep Society via email to assembly chairs, the assembly chairs voted on recommendations.

Results: The changes in electrophysiologic signals with lower amplitudes in the electroencephalogram of elderly people increase the difficulties to distinguish between sleep stages. Technicians must be aware of different normal values of sleep stage distribution, arousals, sleep efficiency and mean oxygen saturation. The automatic analysis of polysomnography devices can most often not be applied and electrophysiologic channels must be analyzed manually. The older, most often dryer skin of elderly persons leads to higher electric resistance weakening electrophysiologic signal quality.

Older sleep laboratory clients often need more care during the night and home polysomnographies are difficult to perform. Nycturia, the risk of falls and reduced cognitive function with disorientation during the night in elderly increase these difficulties.

Special challenges can come from dentures worn or taken out at night, a more often tendency to keep the mouth open during breathing, being frightened to wear a nasal or full-face mask, not understanding the procedure and the need for therapy overall and the forced influence and interventions of relatives before, during and after polysomnography. The collaboration with relatives on the other hand is often needed to perform the diagnostic and therapeutic procedures.

Conclusions: The developed recommendations by several assemblies of the German Sleep Society could be used as a hands on track for technical personnel in sleep laboratories world wide.

Decoding Excessive Daytime Sleepiness: Building a Better Questionnaire

F. Giordani¹, A. Fratini¹, A. Nervoso¹, U. Ciccarelli¹, P. Ghelardini¹, F. Macagno², L. Richeldi¹, M. Siciliano¹

¹Catholic University of Sacred Heart, Department of Neuroscience, Sensory Organs, and Thoracic Medicine, Rome, Italy, ²Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Department of Neuroscience, Sensory Organs, and Thoracic Medicine, Rome, Italy

Introduction: Excessive daytime sleepiness (EDS) is commonly assessed using the Epworth Sleepiness Scale (ESS), although several of its items have limited clinical relevance. Other validated Patient-Reported Outcome Measure (PROMs) - Insomnia Severity Index (ISI), Beck Depression Inventory - II (BDI-II) and Pittsburgh Sleep Quality Index (PSQI) - are also frequently used to investigate aspects related to sleepiness and sleep quality.

Our goal was to identify items from the ISI, BDI-II, PSQI, and ESS most strongly associated with residual EDS (ESS > 10) in patients adherent to Positive Airway Pressure (PAP) therapy (≥ 4 h/night on 70% of nights over the past 3 months), with the aim of laying the groundwork for a new assessment tool.

Materials and methods: The questionnaires were completed by patients attending the Sleep Disorders Clinic of our institution. We first calculated the mean and standard deviation (SD) for each questionnaire item. To further assess their relevance, we then computed the Area Under the Curve (AUC), along with sensitivity and specificity for each item. Subsequently, we created a composite score based on ten selected items. The AUC of this composite scale was calculated against the ESS > 10

criterion. The optimal threshold was identified using the Youden Index, and corresponding sensitivity and specificity were computed.

Results: Data were obtained from questionnaires completed by 84 patients attending our clinic. ESS Items B and E demonstrated the strongest discriminative power (AUC = 0.919 and 0.851) and highest sensitivity (1.0 for both), while Items F and H showed the weakest performance (AUC = 0.579 and 0.615), though with high specificity (0.957 and 0.942). ISI Item 3 had the highest AUC (0.838), Item 4 was the most specific (0.746), and Item 2 the most sensitive (1.0). BDI-II items showed a more homogeneous AUC distribution, ranging from 0.758 (Item 19) to 0.539 (Item 2); Items 15 and 20 were the most sensitive (1.0 and 0.933), while Items 9 and 6 were the most specific (0.985 and 0.970). Within the PSQI, question 8 showed the highest AUC and strongest specificity, while questions 5b and 5c were the most sensitive (1.0 and 0.933). The composite scale yielded an AUC of 0.946. The optimal cut-off, identified via the Youden Index, was 15, with corresponding sensitivity of 0.867 and specificity of 0.910.

Conclusions: To ensure both sensitivity and specificity, preliminary selection may include ESS Items B, E, and H; BDI-II Items 15 and 20; PSQI Questions 8, 5b, and 5c; and ISI Items 2 and 4. This proposed selection maintains a 2:1 ratio of high-sensitivity to high-specificity items. The resulting composite scale showed excellent discriminative ability (AUC = 0.946), with an optimal cut-off of 15 (Youden Index). Since daytime sleepiness can stem from multiple factors—poor sleep quality, insomnia, mood—integrating items from different tools may improve early detection. This composite scale offers a quick, functional alternative to multiple questionnaires, especially in busy clinical settings. Further validation in independent samples is warranted.

Detection of Phoneme Sequences in Spontaneous Speech for the Characterization of Excessive Daytime Sleepiness : a new method to be compared to MSLT

C. Beaumard^{1,2}, J.-L. Rouas¹, P. Philip², V.P. Martin³, C. Brazier^{2,1}, Y. Wu⁴, F. Pecune²

¹Université de Bordeaux, LaBRI, Talence, France, ²Université de Bordeaux, SANPSY, Bordeaux, France, ³INRIA, SEMAGRAMME, Nancy, France, ⁴Université de Caen, CRISCO, Caen, France

Introduction: Excessive Daytime Sleepiness (EDS) is a common symptom which is hard to evaluate objectively because of technicity of current polysomnographic recordings used (MSLT/MWT). Objective evaluation could be precious to improve accurate detection. We previously demonstrated the usefulness of voice analysis during reading tasks. To develop less intrusive measures that can be applied in everyday life, we suggest analyzing phoneme sequences during spontaneous speech—a method that, to our knowledge, has not yet been studied. Through this approach, we hope to assess errors in the articulation of phoneme sequence that may be related to EDS.

Materials and methods: First, we evaluated the performance of an automatic phoneme recognition system (HMM-TDNN) which provides both the detected phoneme and its temporal boundaries. It has been applied on the French Rhapsodie corpus, which contains prepared and (semi-)spontaneous speech. We used Token Error Rate for phoneme recognition performance and the “trackeval” tool to assess the quality of the temporal segmentation. This evaluation is extended by automatically identifying the most frequent phoneme sequences (e.g. d+a+t) using SRILM software. The HMM-TDNN system achieves acceptable results with an F-measure of 0.70 for the 10 most frequent three-phoneme sequences. These performances are further improved by regrouping phonetic units by articulatory modes (i.e., stops, fricatives, glides, nasals, and liquids for consonants; nasal, central, or front rounded/unrounded for vowels). For the 10 most frequent three-symbol sequences representing articulatory modes (e.g., stop+front_vowel+liquid), the F-measure reaches 0.80, a performance that allows further acoustic analysis.

We decided to apply this phoneme sequence detection method to the Medispeech corpus, an extension of the MSLT corpus. It includes both reading and (semi-)spontaneous speech of 34 French speakers suspected of EDS (170 recordings per speech type). It is annotated with both a subjective instantaneous measure of sleepiness (Karolinska Sleepiness Scale — KSS) and a physiological measure (Multiple Sleep Latency Test — MSLT).

Results: We calculate simple acoustic features from the articulatory mode sequences: mean and standard deviation of fundamental frequency and intensity, voicing percentage, and duration. These parameters are statistically analyzed using Linear Mixed-effects Models. The results reveal strong correlations between specific sequence parameters and clinical measures of sleepiness. For instance,

subjective instantaneous sleepiness variations (KSS) are linked to the mean intensity measured on the sequence front_vowel+liquid+front_vowel (**). Moreover, the sleep latency time measured during the MSLT correlates with variations in fundamental frequency, energy and duration measured on the front_vowel+fricative+front_vowel sequence (*). Finally, the averaged MSLT value also correlates to variations in fundamental frequency and energy measured on the same sequence (*), and the variations in duration of the stop+front_vowel+liquid sequence (*).

Conclusions: Studying articulatory mode sequences of phonemes showed promising relations with both subjective instantaneous and physiological sleepiness. These preliminary findings support the potential of this analysis method for automatic classification of EDS from spontaneous speech recordings. Moreover, other grouping (e.g. articulation place) can be studied to explore further relations with sleepiness measures.

Dopaminergic Mechanisms Underpinning Excessive Daytime Sleepiness and Hypoglossal Nerve Stimulation Outcomes in OSA: Evidence from Transcriptomics and Animal Models

Y. Wang^{1,2}, T. Penzel², Y. Wang¹, D. Lei¹

¹Qilu Hospital of Shandong University, Department of Otorhinolaryngology, NHC Key Laboratory of Otorhinolaryngology, JiNan, China, ²Charité – Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Interdisciplinary Sleep Medicine Center Charité – Universitätsmedizin Berlin, Berlin, Germany

Introduction: Since 2001, hypoglossal nerve stimulation (HNS) has been used worldwide to treat adult patients with obstructive sleep apnea (OSA). However, the long-term outcomes following HNS and the underlying mechanisms have not been comprehensively investigated, no studies have reported a persistent development course of a severe complication treatment-emergent central sleep apnea (TECSA) following HNS. Moreover, the prognostic indicators associated with successful HNS therapy to treat OSA and the occurrence of TECSA remain controversial. Therefore, this retrospective study aimed to evaluate the long-term outcomes of HNS and explore the prognostic indicators to improve clinical effectiveness and avoid complications following HNS. In addition, this study investigated underlying neurochemical mechanisms—focusing specifically on the regulation of hypoglossal motor neuron (HMN) function through integrated transcriptomic and animal model approaches.

Materials and methods: Twenty-seven patients who underwent HNS implantation since 2016 were included retrospectively. Demographic data, pre and postoperative sleep study characteristics, and device use recordings were collected. To assess daytime sleepiness, each patient completed the Epworth Sleepiness Scale (ESS); the PALM model accessed further analysis of the endotype of OSA. Possible factors influencing the success of HNS therapy and TECSA were evaluated and identified comprehensively. In parallel, a rat model of OSA with induced EDS was established. Transcriptomic and metabolomic profiling of the hypoglossal nucleus (HMN) was conducted to identify differentially expressed genes and pathways. Dopamine receptor-related signaling was highlighted and functionally validated through pharmacological modulation and electromyographic analysis of the genioglossus muscle.

Results: One year after activation of HNS, the mean baseline apnea-hypopnea index (AHI) was reduced from 34.5 ± 12.0 to 23.5 ± 16.4 , $p < 0.05$, the mean oxygen desaturation index (ODI) decreased from $31.3 \pm 14.8/h$ to 22.1 ± 12.1 , $P < 0.05$, and the success rate of treating OSA was 52.2%. The mean baseline ESS scores differed significantly between the success ($n=13$) and failure groups ($n=14$) ($p=0.03$), while no significant correlation was found between other baseline demographic characteristics, polysomnography data, and HNS device setting parameters. TECSA occurred in patients with elevated preoperative sleepiness and varied with HNS stimulation amplitude. Complementing clinical findings, further animal model experiments demonstrated that modulation of dopamine receptors within HMN significantly influenced genioglossus muscle function, suggesting a neurochemical mechanism underlying variability in HNS efficacy.

Conclusions: An elevated preoperative Epworth Sleepiness Scale score was associated with treatment outcome, demonstrating that excessive daytime sleepiness may help predict the effects of HNS. The integration of clinical, transcriptomic, and animal model data underscores the role of dopaminergic

signaling in the regulation of upper airway muscle responsiveness via HMNs, highlighting a novel neurochemical mechanism that may inform optimization of HNS therapy and the prevention of complications.

Acknowledgments: We are deeply grateful to the Department of Otolaryngology at Charité – Universitätsmedizin Berlin and Inspire Medical Systems, Inc. for their generous collaboration and essential clinical contributions, which significantly advanced the progress of this study.

Effects of Sleep Patterns and Daytime Sleepiness on School Attendance Among Students in Elementary and Junior High Schools

R. Onishi¹, S. Ando², A. Kuriki¹, K. Furuno³, S. Handa⁴

¹Chikushi Jogakuen University, Dazaifu city, Japan, ²Fukuokaken Saiseikai Futsukaichi Hospital, Chikushino city, Japan, ³Japanese Red Cross Fukuoka Hospital, Fukuoka city, Japan, ⁴Fukuoka Mirai Hospital, Fukuoka city, Japan

Introduction: According to a Japanese national survey, the number of students who are chronically absent from elementary and junior high schools has reached approximately 350,000. Common reasons for absenteeism include “lack of motivation toward school life” and “irregular lifestyle habits.” Since an “irregular lifestyle” may be associated with irregular sleep behavior, understanding the amount and pattern of sleep and the degree of daytime sleepiness, and how it affects school attendance behavior, may provide valuable insights into the prevention and early intervention of school absenteeism. Thus, we aimed to clarify the relationship among (1) average sleep duration on weekdays and weekends, (2) the intensity of daytime sleepiness, and (3) frequency of attendance and absence in elementary and junior high school students.

Materials and methods: The survey was conducted among 929 elementary school (4th grade to 6th grade) and 332 junior high school students (1st grade to 3rd grade) between October 7 and November 1, 2024. Students were asked to digitally record their bedtimes and wake-up times for one week including weekends using an originally developed application. We analyzed the average sleep duration, as well as bedtime and wake-up time of their daily routines. Additionally, daytime sleepiness was assessed using the Japanese version of the Epworth Sleepiness Scale (JESS) and we analyzed the relation between sleepiness and absence and tardiness in junior high school students.

Results: The average sleep times in elementary school and junior high school students were 8.7±1.1 hours and 7.3±1.2. The average JESS score across the sample was 4.4 for elementary school students and 7.7 for junior high school students and 8.3% of the elementary school students and 25.9% of junior high school students scored ≥ 11, indicating excessive daytime sleepiness.

Junior high school students were divided into two groups based on their JESS scores. Group 1: JESS ≥ 11, and Group 2: JESS ≤ 10. A comparison was made between the average monthly number of absences and tardiness based on annual data, revealed that students in Group 1 had significantly more absences and instances of tardiness than in Group 2 (absence: 10.7 days vs 7.1 days: $p < 0.01$, tardiness: 7.4 days vs 4.2 days: $p < 0.01$).

The average sleep duration over one week and the JESS score showed a negative correlation ($p < 0.01$). In particular, students who averaged less than 6 hours of sleep had a significantly higher proportion of JESS scores of 11 or above.

Conclusions: In this study, it was found that sleep time was progressively shortened with age and approximately one in four junior high school students felt sleepy during the day. A higher rate of absenteeism and tardiness was observed, especially among the students who slept less than 6 hours or who felt sleepy. As the sleep habits of junior high school students were closely related to their school attendance status, screening for irregular or insufficient sleep using user-friendly application might be highly effective method to detect the abnormal sleep patterns and perform the preventive supports in order to minimize the absenteeism and tardiness.

Exploring SLEEPINESS through home monitoring with ultra long-term subcutaneous EEG and Ecological Momentary Assessment in sleepy treatment naïve obstructive sleep apnea patients starting CPAP treatment

M. Sarkez-Knudsen¹, M. Ballegaard², H. Piilgaard², E. Ahrens³, M.C. Hemmsen³, T.S. Andersen⁴, J. Bardram⁵, P. Homøe¹

¹Zealand University Hospital, Otorhinolaryngology, Koege, Denmark, ²Zealand University Hospital, Neurology, Koege, Denmark, ³T&W Engineering A/S, Allerød, Denmark, ⁴Technical University of Denmark, Applied Mathematics and Computer Science, Lyngby, Denmark, ⁵Technical University of Denmark, Health Technology, Lyngby, Denmark

Introduction: Excessive Daytime Sleepiness (EDS) is a key symptom for patients with Obstructive Sleep Apnea (OSA). Despite important limitations in the longitudinal monitoring of EDS, the Epworth Sleepiness Scale (ESS), Maintenance of Wakefulness Test (MWT), and Multiple Sleep Latency Test (MSLT) are the best available objective tests to predict EDS. Limited information exists on the day-to-day fluctuations of sleepiness symptoms from the everyday life perspective of OSA patients. The most feared is sudden sleep episodes causing traffic accidents. The following study protocol investigates the novel possibilities of Ultra Long-Term EEG (ULT-EEG) home monitoring in sleepy OSA patients with a subcutaneous implant.

We hypothesize that the high-frequency testing from ULT-EEG, in combination with Ecological Momentary Assessment (EMA), can provide the information to develop new electrophysiological monitoring of sleep propensity as an alternative to the well-established yet subjective Epworth Sleepiness Scale.

Materials and methods: This clinical exploratory and experimental study includes 15 treatment-naïve patients with severe OSA with a baseline ESS above 10. The subjects will be implanted with a two-channel subcutaneous EEG monitoring device upon inclusion and a confirmative Polysomnography (PSG) and Multiple Sleep Latency Test (MSLT). 24/7 subcutaneous EEG is recorded 6 weeks before CPAP treatment and 6 weeks during CPAP treatment. Daily assessments with the Karolinska Sleepiness Scale (KSS), Psychomotor Vigilance Task test (PVT), and a sleep/nap diary will be collected using EMA methods.

Results: Data collection in process. We present preliminary results on ULT-EEG compliance from the 12-week data collection period.

Conclusions: This study combines data collection from sleepy OSA patients' natural environments by ULT-EEG and EMA methods to obtain sleepiness metrics suitable for developing and preliminary validating the possibilities of ULT-EEG sleepiness monitoring. We aim to prove a new concept of monitoring sleepiness symptoms in OSA patients and gain new insights into CPAP-related sleepiness rehabilitation.

Acknowledgments: This study is part of the larger InnoSleep project and is primarily funded by Interreg Europe and the European Regional Development Fund.

Investigation of Sleep Architecture and Individual Traits Associated with the Discrepancy Between Subjective and Objective Sleepiness: A Retrospective Observational Study

H. Hiejima¹, M. Ozone¹, T. Kato¹, S. Mizuki¹, K. Tokame¹, M. Habukawa¹

¹Kurume University School of Medicine, Department of neuropsychiatry, Kurume city, Japan

Introduction: Excessive daytime sleepiness (EDS) is a common complaint in sleep clinics. However, some patients who report pronounced subjective sleepiness show no objective signs of sleepiness when evaluated using tools such as the Multiple Sleep Latency Test (MSLT). This discrepancy remains poorly understood and poses diagnostic challenges. While physiological assessments play an important role, they do not always reflect patients' real-world experiences. This study aimed to investigate how the discrepancy between subjective and objective sleepiness relates to sleep architecture, as measured by polysomnography (PSG), and individual characteristics. The study was approved by the Kurume University Ethics Committee (No. 22237).

Materials and methods: We retrospectively analyzed medical records of patients who visited Kurume University Hospital between 2020 and 2023 with complaints of EDS and underwent overnight PSG and daytime MSLT. From these, 153 patients (mean age: 24.8 ± 13.3 years) who had an Epworth Sleepiness Scale (ESS) score ≥11 and a mean sleep latency >8 minutes on MSLT were selected. Statistical comparisons were conducted for age, sex, PSG parameters (sleep latency, sleep efficiency, REM latency, WASO, total sleep time, and slow wave sleep [SWS] time and percentage), as well as

neurodevelopmental traits and other characteristics. Correlation, regression, and mediation analyses were performed, including stratified logistic regression by age group.

Results: The discrepancy group showed significantly higher SWS time and SWS percentage, and longer REM latency (all $p < 0.005$), with no significant differences in other PSG parameters, including WASO. No significant associations were found with questionnaire measures (BDI-II, ISI-J, ASRS, AQ-J-10, MEQ-SA). SWS% was positively correlated with MSLT latency ($r = 0.185$, $p = 0.0002$), whereas ESS showed only a minimal association ($r \approx -0.12$, $p = 0.02$, $<2\%$ variance). In multivariable models, SWS% and REM latency remained independent predictors of longer MSLT latency. However, when discrepancy was used as the dependent variable, age and AHI—but not SWS%—were significant predictors. Stratified regression revealed that discrepancy was mainly associated with SWS% in patients ≤ 18 years, whereas AHI emerged as the predictor in those ≥ 19 years. Discrepancy tended to widen with greater SWS and shrink with higher AHI. Mediation analysis further indicated that the effects of AHI and age on discrepancy were largely mediated through changes in SWS.

Conclusions: Patients who reported subjective but not objective sleepiness exhibited a favorable sleep profile with more deep sleep and longer REM latency. Although SWS was associated with longer MSLT latency, age and AHI—not SWS—were the main predictors of discrepancy. The contribution of ESS and other questionnaire-based measures was negligible. Discrepancy widened with abundant SWS and diminished with higher AHI, suggesting age-dependent mechanisms: preserved deep sleep in younger patients and respiratory disturbances in older patients. This single-center cross-sectional study relied on self-report questionnaires for patient traits and may have unmeasured confounders; multicenter studies are needed to validate these findings.

Acknowledgments: This study was supported by the “Sleep Polysomnography Databank Project” of the National Center of Neurology and Psychiatry (NCNP), Japan.

Less Sleepy, More Success: Chronotype and Insomnia Patterns Distinguish High-Achieving Adolescents

M. Sharma¹

¹Sleep Moksha, Panchkula, India

Introduction: Chronotype and sleep disorders have been linked to learning outcomes, yet data from South-Asian school settings remain sparse.

Furthermore, few studies have jointly assessed **chronotype, sleepiness, and academic achievement** using validated instruments within a real-world school context.

We examined how morningness–eveningness, subjective sleepiness, insomnia severity, and body mass index (BMI) relate to academic achievement in Indian adolescents preparing for high-stakes board examinations.

Materials and methods: This cross-sectional study included **470 students from Classes 10 to 12** enrolled in a co-educational school in North India. Participants self-reported their sleep characteristics using standardized tools: the **reduced Morningness–Eveningness Questionnaire**, the **Cleveland Adolescent Sleepiness Questionnaire**, and the **Insomnia Severity Index**. Anthropometric data (height and weight) were recorded to calculate **Body Mass Index (BMI)**. Academic performance data from final-term examinations were used to classify the top quintile of students ($n = 114$) as the **high-achiever group**.

Group comparisons were conducted between high achievers and the general cohort.

Results: High-achieving students demonstrated a significantly greater morning orientation compared to their peers ($p < 0.001$), alongside lower daytime sleepiness ($p = 0.003$) and virtually no cases of severe insomnia (1.8% vs 19.7%). Despite having a higher average BMI ($p < 0.001$), this group reported fewer sleep-related impairments. Spearman correlation analyses revealed that greater morningness was associated with both lower sleepiness ($\rho = -0.275$, $p < 0.001$) and reduced insomnia severity ($\rho = -0.239$, $p < 0.001$). Notably, sleepiness strongly correlated with insomnia symptoms ($\rho = 0.449$, $p < 0.001$), reinforcing the interdependence of circadian alignment, sleep quality, and daytime functioning in determining academic outcomes.

Conclusions: A pronounced morning chronotype, lower daytime sleepiness, and a virtual absence of severe insomnia characterised academically successful students, independent of sex distribution and despite their higher BMI. The inverse correlations between morningness and both sleepiness and insomnia underscore the protective role of circadian alignment for daytime alertness and sleep health.

These findings support implementing circadian-friendly school start times and targeted sleep-health programmes to foster academic performance in South-Asian adolescents.

Acknowledgments: We want to extend our heartfelt gratitude to all the participants who took part in this study.

Long-Term Clinical and Functional Evolution in Patients with Obstructive Sleep Apnea and Daytime Sleepiness Treated with CPAP: Results from the HYPNOSA Cohort Study

Introduction: Obstructive Sleep Apnea (OSA) associated with Excessive Daytime Sleepiness (EDS) is a highly prevalent clinical phenotype with significant impact on physical and psychological wellbeing. The HYPNOSA study aims to characterize this phenotype and evaluate the evolution of symptoms, quality of life, and physiological parameters under CPAP therapy. This abstract presents descriptive interim findings at 6, 12, and 24 months of follow-up.

Materials and methods: HYPNOSA is a prospective, multicenter observational study including 616 patients diagnosed with OSA and EDS. Patients were evaluated at baseline and followed at 6, 12, and 24 months. Collected data included demographics, respiratory sleep parameters (AHI, CT90, mean SatO₂), ESS, EuroQol-5D, FOSQ, HADS, and CPAP adherence. Analyses were conducted using R v4.4.2.

Results: The population had a mean age of 55.6±11.5 years; 65.6% were male. Baseline sleep study showed severe OSA (mean AHI: 39.5/h), oxygen desaturation (SatO₂: 91.4%) and prolonged hypoxic burden (CT90: 21.7%).

Baseline clinical scales revealed a high burden of symptoms:

- **Epworth Sleepiness Scale (ESS):** mean 10.9 (P50: 11), with most reported sleepiness while watching TV (2.06±0.95) and lying down in the morning (2.22±0.98).
- **EuroQol-5D:** moderate limitation in mobility, pain, and daily activities (mean ~1.5), with anxiety/depression as the most impaired domain.

- **FOSQ:** mean score of 92.1 ± 24.4 , with marked functional impairment; 20 of 30 items scored >3.2 (quite a bit/much), especially in concentration, household chores, and keeping pace with peers. Lowest was general activity (2.69 ± 1.1).
- **HADS:** total score 12.07 ± 7.24 , indicating frequent symptoms of anxiety and low mood.

At 6 months, improvements were substantial:

- **ESS:** 7.95 ± 4.61 , with reduction in most somnolence items.
- **EuroQol-5D:** improved to 73.5 ± 16.5 , pain remained most reported limitation.
- **FOSQ:** increased to 100.07 ± 21.3 , 29/30 items >3.4 ; lowest again was general activity (2.8 ± 1.04).
- **HADS:** reduced to 4.17, indicating low-mild psychological symptoms.
- **IAH:** decreased to 3.2/h; **CT90 fell to 0.5%;** **SatO₂ improved to 95%;** average CPAP use: 6.2 h/night.

At 12 months, this trend continued: ESS 7.19; HADS 2.04; FOSQ 101.5; EQ-5D 72.5. At 24 months (in limited data), results remained stable: ESS 6.67, HADS 0.05, FOSQ 109.7, EQ-5D 76.7. CPAP adherence was consistently above 5.3 h/night.

Conclusions: Despite being relatively young and without major comorbidities, patients with OSA and EDS present with significant functional, emotional, and quality-of-life impairment. CPAP treatment leads to rapid and sustained improvement in sleep physiology, daily functioning, and psychological wellbeing. However, some limitations—especially general activity—persist. These findings support the value of long-term follow-up and structured management in this clinical phenotype.

Pitolisant for Excessive Daytime Sleepiness in Prader-Willi Syndrome: Phase 2 Study Results and Phase 3 Clinical Trial Design

R. Bhattacharjee¹, A. Revana², J. Miller³, D. Norman⁴, D. Seiden⁵

¹Rady Children's Hospital, University of California San Diego, San Diego, United States, ²Baylor College of Medicine, Texas Children's Hospital, Houston, United States, ³University of Florida Health Shands Hospital, Gainesville, United States, ⁴Santa Monica Clinical Trials, Los Angeles, United States, ⁵Harmony Biosciences, Plymouth Meeting, United States

Introduction: Prader-Willi Syndrome (PWS) is a complex genetic disorder with symptoms that include hyperphagia, behavioral disturbances, and excessive daytime sleepiness (EDS). Pitolisant is approved in the United States for the treatment of EDS or cataplexy in adults with narcolepsy and the treatment of EDS in pediatric patients ≥ 6 years of age with narcolepsy.

Materials and methods: In a phase 2, proof-of-concept study (which was not powered to show statistical significance), patients with a confirmed diagnosis of PWS and a score ≥ 12 on the parent/caregiver version of the Epworth Sleepiness Scale for Children and Adolescents (ESS-CHAD) were randomized to receive higher-dose pitolisant, lower-dose pitolisant, or placebo (dose based on age group) for 11 weeks (3-week titration, 8-week stable-dose). The primary efficacy endpoint was change from baseline at Week 11 in ESS-CHAD score. Secondary/exploratory endpoints included the Caregiver Global Impression of Severity (CaGI-S) for EDS, Aberrant Behavior Checklist-2 (ABC-2), and Hyperphagia Questionnaire for Clinical Trials (HQ-CT; in conjunction with the Food Safe Zone Questionnaire).

Results: Among 65 enrolled patients in the phase 2 study (50.8% male), 34 (52.3%) were children (6 to <12 years), 19 (29.2%) were adolescents (12 to <18 years), and 12 (18.5%) were adults (≥ 18 years). Overall, mean (SE) change in ESS-CHAD score at Week 11 was greater in the higher-dose (-4.9 [1.23]) and lower-dose (-4.1 [1.06]) pitolisant groups compared with the placebo group (-3.7 [1.13]). There was an unusually large placebo response in the adolescent age group, due to data from a single outlier. Reductions in CaGI-S scores and HQ-CT scores were greater for pitolisant compared with placebo in the children and adult age groups. In children (6 to <12 years), mean reduction in all ABC-2 domain scores (irritability, social withdrawal, hyperactivity/noncompliance, inappropriate speech, stereotypic behavior) was greater for higher-dose pitolisant compared with placebo. The most common adverse events in pitolisant-treated patients (doses pooled) were irritability (17.4%) and anxiety (13.0%). The design of a multicenter, randomized, double-blind, placebo-controlled, phase 3 trial (TEMPO;

NCT06366464) was informed by the results of the phase 2 study. The phase 3 trial is currently enrolling approximately 130 patients ≥ 6 years of age with PWS and EDS. Patients are randomly assigned (1:1) to receive pitolisant (weight-based dosing: 8.9-44.5 mg/d) or matching placebo tablets. The primary endpoint is change from baseline at Week 11 in EDS as measured by the PROMIS-SRI (Patient-Reported Outcomes Measurement Information System - Sleep Related Impairment [Parent Proxy]). Secondary endpoints include the ESS-CHAD, CaGI-S for EDS, Clinician Global Impression of Severity (CGI-S) for EDS, ABC-2, and HQ-CT.

Conclusions: In a phase 2 proof-of-concept study, pitolisant reduced EDS in patients with PWS. Pitolisant may also reduce behavioral disturbances and hyperphagia. The ongoing phase 3 clinical trial is further evaluating the efficacy and safety of pitolisant in a larger population of patients ≥ 6 years old with PWS and EDS.

Posturographic findings in patients suffering from the Syndrome of Obstructive Sleep Apnea and Snoring

M. Milkov¹, M. Stoykov¹

¹Medical University - Varna, Dental materials science and Prosthetic Dental medicine, Varna, Bulgaria

Introduction: The Syndrome of obstructive sleep apnea and snoring (SOSAS) is a well-known socially significant disease, with severe repercussions on the quality of life of affected individuals. It is characterized by the presence of cessations in patients' breathing during sleep, leading to intermittent hypoxia and multiple awakenings. In addition to the negative impact on the cardiovascular, endocrine, respiratory, cognitive, the impact of impaired blood oxygenation on the audio-vestibular system is being intensively studied nowadays.

Materials and methods: For the period from January to December 2024, 100 patients (50 female and 50 male) with complaints of disturbed sleep, daytime sleepiness, fatigue, passed through the Sector "Audio-vestibular and Sleep Medicine" of the University Medical and Dental Center at Medical University - Varna. All patients included in the study completed both standard questionnaires for the assessment of symptoms related to sleep disorders (Berlin questionnaire, ESS), as well as those specifically developed for the purposes of the study. Information on the presence of allergies, common diseases, surgical interventions in the maxillofacial area, and medication intake was collected. A polygraphic sleep study at home was conducted. All patients were also tested on stabilometric equipment to assess their ability to maintain body balance. The information obtained was statistically analyzed using the SPSS software package.

Results: Different forms of obstructive sleep apnea, according to the values of the apnea-hypopnea index (the lowest established value was 3, the highest - 75) from the polygraph examination, the anamnesis taken and the completed sleep assessment questionnaires. SOSAS was identified in a total of 77 (76.5%) of the examined patients (45 males and 32 females). In 23 patients, only snoring was proven. Statistically significant deterioration of the dynamic postural status parameters (weight distribution between the two feet, length of the sway curve (stabilogram) and area of the maximum stability) was found in patients with a proven form of obstructive sleep apnea. A pronounced deterioration of the body balance and an increase in the values of the length of the stabilogram and the area of maximum stability were observed, with more pronounced changes being found in males.

Conclusions: Complete and thorough diagnostics of all the effects of SOSAS on patients allows for timely therapeutic measures to be taken in order to improve the quality of life of those affected.

Acknowledgments: This study is funded by the European Union-NextGenerationEU, through the National Recovery and Resilience Plan of the Republic of Bulgaria, project No. BG-RRP-2.004-0009.

Primary Efficacy and Safety Results of a Phase 2, Double-Blind, Placebo-Controlled, Proof-of-Concept, Signal Detection Study of Pitolisant in Myotonic Dystrophy

D. Seiden¹, J. Hamel², J.-D. Brisson³, H. Lochmüller^{4,5,6}, A. Puwanant⁷, D. Leung⁸, L. Gutmann⁹, A. Ade¹, G. Runyan¹, G. Nomikos¹

¹Harmony Biosciences, Plymouth Meeting, United States, ²University of Rochester Medical Center, Rochester, United States, ³Université de Sherbrooke, Québec, Canada, ⁴Children's Hospital of Eastern

Ontario Research Institute, Ottawa, Canada, ⁵The Ottawa Hospital, Division of Neurology, Department of Medicine, Ottawa, Canada, ⁶Brain and Mind Research Institute, University of Ottawa, Ottawa, Canada, ⁷Wake Forest School of Medicine, Winston-Salem, United States, ⁸Kennedy Krieger Institute, Baltimore, United States, ⁹Indiana University School of Medicine, Indianapolis, United States

Introduction: Myotonic dystrophy type 1 (DM1) is the most common muscular dystrophy in adults. DM1 presents with multi-systemic symptoms including excessive daytime sleepiness (EDS) and fatigue, which occur in up to 80-90% of patients with DM1 and can impact daily functioning as much as muscular symptoms (myotonia and muscle weakness). DM1 may have direct effects on CNS sleep regulatory circuits, with patients exhibiting signs of central sleep-wake dysregulation. Pitolisant is a histamine 3 receptor antagonist/inverse agonist approved in the US for the treatment of EDS or cataplexy in adults with narcolepsy and the treatment of EDS in pediatric patients ≥ 6 years of age with narcolepsy. The aim of this phase 2 proof-of-concept study was to evaluate the efficacy and safety of pitolisant in adults with DM1.

Materials and methods: Eligible patients were enrolled into an 11-week double-blind phase. Patients were randomized (1:1:1) to lower-dose pitolisant, higher-dose pitolisant, or matching placebo. The primary efficacy endpoint was the change from baseline to Week 11 in Daytime Sleepiness Scale (DSS) score. Additional efficacy endpoints included changes in daytime sleepiness as measured by the Epworth Sleepiness Scale (ESS) and Clinical Global Impression of Severity (CGI-S) as well as changes in the Fatigue Severity Scale (FSS). Upon completion, eligible patients had the option to enroll in an open-label extension phase.

Results: A total of 30 patients aged 18-65 with DM1 were randomized in the study. The mean change from baseline in DSS score at end of the double-blind period was -3.8 and -1.8 for the higher- and lower-dose pitolisant groups, respectively, compared with 0.0 for placebo. Clinically meaningful improvements in ESS, CGI-S, and FSS scores were also demonstrated for pitolisant. A clear and consistent dose-response was observed, with the higher-dose pitolisant group showing a greater response than the lower-dose group. The most common adverse events were headache, insomnia, and nausea.

Conclusions: Pitolisant reduced EDS in adults with DM1 in a dose-dependent manner. The safety and tolerability profile of pitolisant in patients with DM1 was consistent with the known safety profile of pitolisant.

Reduction in Sleep Inertia and Components of Daytime Sleepiness in Idiopathic Hypersomnia With Low-Sodium Oxybate Treatment in the Phase 4 DUET Study

H.P.A. Van Dongen¹, L.D. Schneider², C.M. Ruoff³, J. Dai⁴, D.A. Nichols⁴, T.L. Steininger⁴, M.T. Kirby^{5,6}, M. Whalen⁵, A. Cairns⁵, D.T. Plante⁷

¹Sleep and Performance Research Center, Washington State University Health Sciences Spokane, Spokane, United States, ²Stanford University Center for Sleep Sciences and Medicine, Palo Alto, United States, ³Center for Sleep Medicine, Mayo Clinic, Scottsdale, United States, ⁴Jazz Pharmaceuticals, Palo Alto, United States, ⁵Jazz Pharmaceuticals, Philadelphia, United States, ⁶Department of Psychiatry & Health Behavior, Medical College of Georgia at Augusta University, Augusta, United States, ⁷Wisconsin Institute for Sleep and Consciousness, University of Wisconsin-Madison, Madison, United States

Introduction: Idiopathic hypersomnia is characterised by excessive daytime sleepiness and, in many patients, sleep inertia, including prolonged difficulty awakening, repeated returns to sleep, irritability, and/or confusion. Low-sodium oxybate (LXB, Xywav[®]) is approved in the United States to treat idiopathic hypersomnia in adults and excessive daytime sleepiness or cataplexy in patients ≥ 7 years of age with narcolepsy. Jazz DUET (Develop hypersomnia Understanding by Evaluating low-sodium oxybate Treatment) was a phase 4, prospective, multicentre, single-arm, multiple-cohort, open-label study (NCT05875974) evaluating LXB treatment effectiveness for daytime and nighttime symptoms of idiopathic hypersomnia or narcolepsy. The aim of the present analysis was to estimate the magnitude and temporal dynamics of sleep inertia and components of daytime sleepiness in participants with idiopathic hypersomnia treated with LXB.

Materials and methods: DUET included the following periods: screening (with 2-week washout for oxybate users), 8-day baseline (BL), 2- to 8-week LXB titration, 2-week stable dose, 8-day end of treatment (EOT), and 2-week safety follow-up. Exploratory endpoints included Psychomotor Vigilance Test (PVT; objective measure of behavioural alertness) and Karolinska Sleepiness Scale (KSS; subjective measure of sleepiness). The PVT and KSS were administered on day 8 of BL and EOT, after overnight polysomnography. The 10-minute PVT, a reaction-time task requiring participants to respond as quickly and accurately as possible to a visual stimulus, was completed 10, 40, and 90 minutes after polysomnographically assessed awakening. The KSS, a single-item, 9-point scale ranging from “extremely alert” to “extremely sleepy, can’t keep awake” was completed within 2 minutes after awakening and immediately before and after each PVT assessment. Nonlinear, mixed-effects regression models on PVT lapses (reaction times >500ms) and KSS ratings were used to estimate objective behavioural alertness and subjective sleepiness, respectively, at awakening and 2 hours after awakening, as well as the magnitude of sleep inertia (the portion of behavioural alertness or subjective sleepiness that dissipates after awakening). The model accounted for systematic inter-individual differences and heteroskedastic error variance. *P* values are nominal.

Results: Forty-six people with idiopathic hypersomnia enrolled and took LXB for ≥ 1 night. Most enrolled participants were female (80.4%) and White (84.8%); mean (SD) age was 38.1 (11.8) years. PVT results ($n=40$) indicated improvement from BL to EOT in behavioural alertness upon awakening (PVT lapses, 16.5 to 3.1; change [95% confidence interval, CI]: -13.4 [$-19.3, -7.6$]; $P<0.0001$) and after 2 hours (9.6 to 3.0; change [95% CI]: -6.6 [$-9.6, -3.6$]; $P<0.0001$) and improvement in sleep inertia magnitude (change [95% CI]: -13.7 [$-19.8, -7.6$]; $P<0.0001$). KSS results ($n=40$) indicated reduction from BL to EOT in subjective sleepiness upon awakening (KSS rating, 6.9 to 4.4; change [95% CI]: -2.5 [$-2.9, -2.1$]; $P<0.0001$) and after 2 hours (6.2 to 4.4; change [95% CI]: -1.8 [$-2.2, -1.4$]; $P<0.0001$), and improvement in sleep inertia magnitude (change [95% CI]: -5.0 [$-5.5, -4.5$]; $P<0.0001$). Treatment-emergent adverse events were consistent with the known LXB safety profile.

Conclusions: Compared with baseline, participants with idiopathic hypersomnia on optimised LXB treatment demonstrated reduced sleep inertia magnitude, less daytime sleepiness, and increased behavioural alertness.

Acknowledgments: Funded by Jazz Pharmaceuticals.

Residual Excessive Daytime Sleepiness in CPAP-Treated OSA Patients: A Retrospective Study from a Tertiary Australian Hospital

S. Agwan¹, D. Baron¹, S. Chawla², H. Fabros², R.S. Sharma², D. Ting³, K.B. Sriram^{1,2}

¹Gold Coast University Hospital, Sleep Disorders Centre, Southport, Australia, ²Griffith University, School of Medicine and Dentistry, Gold Coast, Australia, ³Bond University, Faculty of Health Sciences & Medicine, Gold Coast, Australia

Introduction: Obstructive sleep apnoea (OSA) is a frequent cause of excessive daytime sleepiness (EDS). EDS impairs quality-of-life and can lead to motor vehicle accidents and/or workplace injuries. CPAP (continuous positive airway pressure) is the gold standard treatment for OSA but up to 22% of CPAP-treated OSA patients report residual EDS on follow-up. The causes of residual EDS are multifactorial and can be broadly categorised into: 1) ineffective CPAP treatment, 2) another sleep disorder contributing to EDS, 3) medical disorders causing EDS, and 4) persistent EDS with no clear aetiology. Identifying the underlying cause(s) of residual EDS is essential for improving treatment adherence and patient quality of life. Despite increasing awareness, there is limited real-world data on the prevalence and causes of residual EDS in CPAP-treated OSA patients in Australian clinical settings, highlighting the need for this study.

Materials and methods: This retrospective study was conducted at Gold Coast Hospital University Hospital (GCUH), a tertiary referral centre with a catchment population of over 600,000 people across South-East Queensland and Northern New South Wales regions of Australia. Medical records were reviewed for patients aged ≥ 18 years who presented to the GCUH Sleep Medicine Outpatient Clinic with an OSA diagnosis between 2019-2024 (inclusive). Residual EDS was defined as Epworth Sleepiness Scale (ESS) of >10 or patients' subjective complaint of significant residual daytime somnolence during their post-CPAP commencement clinic review. Data collected included demographics, diagnostic modality, CPAP therapy details, co-morbidities and investigations/treatments for persistent EDS.

Results: Out of 354 patients treated for OSA at our sleep clinics, 35 (10%) reported residual EDS following CPAP commencement. The median age of these patients was 58 years (IQR 53-75 years), with 60% (n=21) being male. Nearly half (46%) had chronic pain or a mental health disorder as a co-morbidity. Median ESS and Apnoea-Hypopnoea Index (AHI) at OSA diagnosis were 14 (IQR 10.5-17) and 31.7 (IQR 20.5-51), respectively. Most patients (n=20) had a home-based diagnostic study while the majority (n=24) also had a lab-based CPAP titration. Six patients required in-lab CPAP titration, and three underwent vigilance testing to assess for central hypersomnolence disorders. Multiple contributing factors were identified in eight patients, with insomnia (n=7) being the most common. Other frequent causes included mask fit issues, inadequate pressure, and CPAP discomfort. Two patients were prescribed modafinil: one had a mean sleep latency (MSL) <8mins on vigilance testing (with no sleep-onset Rapid Eye Movement periods) but also had post-traumatic stress disorder and insomnia, while the other had a normal MSL.

Conclusions: Insomnia, a common co-occurrence with OSA, was the leading contributor to post-CPAP residual EDS in our cohort. Early screening and management with cognitive behavioural therapy and sleep hygiene strategies may improve patient quality-of-life. Chronic pain and mental health co-morbidities, which were prevalent in this group, can fragment sleep and should be identified at initial screening. CPAP intolerance and mask related issues remain global challenges, and limited access to lab-based titration and sleep scientist clinics may hinder timely resolution. Overall, post-CPAP residual EDS is often multifactorial and requires a systematic assessment and individualised approach.

Sexual dysfunction in men with Obstructive Sleep Apnea: The role of self-reported sleepiness in a population-based study

E.H. Thorarinsdottir^{1,2}, A.F. Viken³, S.P. Siiak⁴, V. Schlunssen⁵, M. Lønnebotn^{6,7}, R.J. Bertelsen³, F.G. Real³, T. Gislason^{2,8}

¹Primary Health Care of the Capital Area, Reykjavik, Iceland, ²University of Iceland, Faculty of Medicine, Reykjavik, Iceland, ³University of Bergen, Department of Clinical Science, Bergen, Norway, ⁴Tartu University, Andrology Centre, Tartu, Estonia, ⁵Danish Ramazzini Centre, Department of Public Health, Research Unit for Environment, Occupation and Health, Aarhus, Denmark, ⁶University of Bergen, Department of Global Public Health and Primary Care, Bergen, Norway, ⁷Haukeland University Hospital, Department of Occupational Medicine, Bergen, Norway, ⁸Landspítali University Hospital, Department of Sleep, Reykjavik, Iceland

Introduction: Sexual dysfunction is common in middle-aged and older men and may be underrecognized in those with obstructive sleep apnea (OSA), a prevalent but often undiagnosed condition in the general population. In recent years, excessive daytime sleepiness (EDS) in OSA has been linked to increased risk of adverse health outcomes, including cardiovascular and metabolic diseases, suggesting that EDS may reflect underlying mechanisms contributing to these outcomes. However, the relationship between OSA, sleepiness, and sexual dysfunction remains unclear. This study aimed to examine the association between sexual dysfunction and OSA, with a focus on self-reported sleepiness in a population-based male sample.

Materials and methods: This cross-sectional study used data from the Respiratory Health in Northern Europe (RHINE) cohort, a population-based, multicenter study conducted in Tartu (Estonia), Reykjavik (Iceland), Bergen (Norway), and Aarhus (Denmark). It included 1,700 men (mean age 61.0 years) who completed the Aging Males' Symptoms (AMS) questionnaire and provided data on OSA-related symptoms and relevant health covariates. For a description of the RHINE cohort, see PMID: 38256560. Diagnosed OSA was based on self-report, and suspected OSA was defined using the Multivariable Apnea Prediction (MAP) index (score >0.5 = high OSA risk). Subjective sleepiness was assessed using the Epworth Sleepiness Scale (ESS >10 = "risk of dozing") and self-report of "feeling sleepy" ≥3 days per week. These indicators defined four sleepiness phenotypes: non-sleepy, risk of dozing only, feeling sleepy only, and both symptoms. Associations between OSA, sleepiness phenotypes, and sexual dysfunction were analyzed using multivariable logistic regression adjusted for age, BMI, smoking, diabetes, hypertension, cardiovascular disease, and study center.

Results: Among the 1,700 participants, 13% reported a previous OSA diagnosis, and 77% of these were receiving current OSA treatment. Among those without diagnosed OSA, 45% met criteria for suspected OSA (MAP > 0.5). Sexual dysfunction was significantly more prevalent among men with suspected or diagnosed OSA compared to those without. In multivariable logistic regression, men with suspected

OSA reporting “both risk of dozing and feeling sleepy” had the highest odds of sexual dysfunction, with adjusted odds ratios (ORs) of 4.71 (95% confidence interval [CI], 3.32–6.68) for decreased morning erections and 3.82 (95% CI, 3.09–4.71) for decreased libido. In contrast, classic OSA symptoms such as snoring, gasping, and witnessed apneas showed no associations with sexual dysfunction.

Conclusions: Subjective sleepiness is strongly associated with sexual dysfunction in men with OSA, independent of traditional cardiometabolic risk factors. The combination of an elevated ESS score and frequent self-reported sleepiness may serve as a valuable clinical marker for identifying male OSA patients at heightened risk of sexual dysfunction. Incorporating sleepiness assessments into clinical evaluations for OSA may improve recognition of men at risk for broader health consequences.

The Infamous Kleine-Levin Syndrome: An Unusual Response to Modafinil in a Teenage Female

A. Valenzuela¹, A. Nguyen², M. Chaung², D. Dominguez¹

¹Banner Health, Sleep Medicine, Mesa, United States, ²University of Arizona - College of Medicine, Phoenix, United States

Introduction: Kleine - Levin Syndrome (KLS) is a rare sleep disorder, characterized by intermittent episodes of hypersomnia that correspond with changes in cognition, mood and behavior. Here we present the case of a young patient with episodic periods of hypersomnolence suspicious for KLS. Modafinil was utilized as an abortive measure with improvement of hypersomnolence and thus far has served as a preventative measure for new episodes as well.

Materials and methods: A 16 year old female, with a history of headaches and intermittent fatigue presented to the sleep clinic for periods of sleepiness. She reported that her symptoms started approximately one year prior without notable triggers. She noted that she has prolonged periods of normal function characterized by adequate nocturnal sleep hours where she feels refreshed, awake, alert and energetic. However, at irregular times throughout the year she has “bad weeks” that can last up to a month. These challenging weeks are characterized by anterograde amnesia, mood disruption, apathy, altered perception, cognitive dysfunction and exercise intolerance. This occurred despite longer than normal sleep hours. Rare hyperphagia reported. No hypersexuality reported. She was not taking any medications.

Results: Patient was evaluated by cardiology and neurology with unremarkable diagnostic testing/imaging and referred to sleep medicine. Nocturnal polysomnogram (PSG) with subsequent daytime multiple sleep latency test (MSLT) were both unremarkable. Labs for restless leg syndrome showed low ferritin and vitamin D, both of which were adequately supplemented without improvement of episodes/symptoms. Modafinil was started during her next episode of hypersomnolence and cognitive changes. This helped resolve the episode, notably the daytime sleepiness, with improvement of cognitive function and improvement of her other symptoms as well. While on modafinil, patient has not had an episode in nearly one year.

Conclusions: Kleine-Levin syndrome is a rare condition with a male predominance of 4:1. As it is a clinical diagnosis, other neurologic, metabolic and psychiatric causes must be evaluated and ruled out first. While polysomnogram does not typically show abnormalities, this must still be performed with a daytime multiple sleep latency test to rule out other etiologies. The timing of these studies may be critical in terms of whether the patient is acutely in an episode of KLS. Treatment modalities, including sleep hygiene and/or pharmacologic therapies to target specific symptoms are quite variable with limited literature. Modafinil may prove to be a useful treatment modality as an abortive measure and even potentially preventative of future symptomatology.

Towards Human-Centric Industry 5.0: Predicting Operator Sleepiness Using Wearable Sleep Data

S. Groppo¹, M. Guagnano¹, L. Pugliese², M. Violante¹

¹Politecnico di Torino, Department of Control and Computer Engineering, Torino, Italy, ²Sleep Advice Technologies, Torino, Italy

Introduction: Excessive daytime sleepiness (EDS) affects approximately 20% of the population and is a significant contributor to workplace and vehicular accidents, as well as overall poorer health outcomes. Common causes of EDS include sleep deprivation, obstructive sleep apnea, and the use of sedating medications. Monitoring and detecting mental or physical fatigue in the workplace is crucial to maintaining both productivity and worker health. While current systems analyze biometric signals, such as eye activity and complex measurements like ECG, EMG, and EEG, this paper proposes a non-invasive model that predicts operator sleepiness based on the previous night's sleep quality. Using a validated system to predict sleep events (e.g., microsleeps, N1, N2), our approach offers an efficient way to predict operator fatigue and optimize wellbeing in industrial settings.

Materials and methods: Dataset:

The dataset includes recordings from 4 subjects (mean age: 29 ± 2 , 1 female), who wore a Garmin smartwatch running a ConnectIQ application. The application collected data over 10 consecutive days and nights for each subject.

Sleepiness Evaluation:

Sleepiness was assessed using a proprietary, validated algorithm designed to predict sleep events. This algorithm generates an Alert prior to each sleep event, with an accuracy of nearly 90% when compared to medical doctor scoring based on Polysomnography (PSG). The number of Alerts during the daytime serves as the ground truth for determining sleepiness.

Sleep Quality Evaluation:

The sleep quality of each subject was evaluated using a proprietary algorithm capable of identifying the wake-sleep transition and classifying sleep stages. This algorithm has been validated against PSG medical doctor scoring, ensuring its accuracy in measuring parameters such as sleep onset latency, arousal index, and overall sleep quality.

Machine Learning Algorithm:

To predict sleepiness, we used the XGBoost algorithm. The model takes the following sleep quality parameters as input:

- Total Sleep Time (TST): The total duration of sleep.
- Sleep Onset Latency (SOL): The time taken to fall asleep.
- Sleep Efficiency (SE): The ratio of time spent asleep versus time spent in bed.
- Arousal Index (AI): The frequency of awakenings or disturbances during sleep.
- Duration of Longest Awake after Sleep Onset (DoLA): The longest duration of wakefulness after initially falling asleep.
- Sleep Quality (SQ): A composite measure of overall sleep quality.

The output of the model is binary, predicting whether the subject, that precise day, will be "Sleepy" or "Not Sleepy." Subjects that during the day presented more than 2000 seconds in Alerts are classified as "Sleepy," while those with fewer than 2000 seconds in Alerts are classified as "Not Sleepy."

Results: The dataset has been split into 70% for training and 30% for validation.

Sleepy label generated during the validation phase:

- Precision 100%
- Recall 75%
- F1-score 86%

Not Sleepy label generated during the validation phase:

- Precision 88%
- Recall 100%
- F1-score 93%

Conclusions: This study suggests that may be possible to predict an operator's sleepiness using a noninvasive ML approach that processes sleep quality data collected from wearable devices.

Hypersomnia

Altered sleep spindle morphology in idiopathic hypersomnia

S. Mombelli^{1,2}, A.-S. Deshaies-Rugama^{1,3}, H. Blais¹, C. Thompson¹, A. Desautels^{1,4}, J. Montplaisir^{1,2}, M. Nigam^{1,4}, C. Moderie^{5,6}, J.-M. Lina¹, K. Lacourse¹, J. Carrier^{1,3}, N. Gosselin^{1,3}

¹Center for Advanced Research in Sleep Medicine, Research center of the Centre intégré universitaire de santé et de services sociaux du Nord de l'Île-de-Montréal, Montréal, Canada, ²Université de Montréal, Department of Psychiatry and Addictology, Montréal, Canada, ³Université de Montréal, Department of Psychology, Montréal, Canada, ⁴Université de Montréal, Department of Neuroscience, Montréal, Canada, ⁵McGill University, Department of Psychiatry, Montreal, Canada, ⁶Centre for Study and Treatment of Circadian Rhythms, Douglas Mental Health University Institute, Montreal, Canada

Introduction: Excessive daytime sleepiness (EDS) is the most disabling symptom of idiopathic hypersomnia (IH), profoundly impairing daily functioning and quality of life. Paradoxically, sleepiness emerges despite prolonged and apparently well-consolidated nocturnal sleep. This clinical presentation challenges conventional models linking EDS to sleep fragmentation and raises important questions regarding the integrity of sleep microarchitecture and its role in sustaining restorative processes. Within this framework, sleep spindles offer valuable insight into how thalamocortical coordination protects sleep by reducing cortical arousability. Their alteration may signal dysfunction within this network, leading to insufficient sleep restoration and contributing to EDS. Nevertheless, the morphological features of spindles remain unexplored in IH. Here, we investigated whether individuals with IH show alterations in sleep spindle density and morphology compared to healthy controls, and whether these features are associated with objective and subjective measures of EDS in IH.

Materials and methods: We retrospectively selected 62 adults with IH (mean age = 35.3 ± 10.5 years; 69.4% women) and 70 healthy controls (mean age = 35.9 ± 15.9 years; 40% women). Patients were diagnosed according to ICSD-3 criteria, based on clinical interview, questionnaires, overnight polysomnography, and the Multiple Sleep Latency Test (MSLT) with four naps. Exclusion criteria included apnea-hypopnea index ≥ 15 , psychiatric or neurological conditions, other sleep disorders, shift work, and use of medications prior to the polysomnography. Subjective EDS was measured using the Epworth Sleepiness Scale, while objective EDS was indexed by mean sleep latency on the MSLT. Automated spindle detection was performed on frontal (F3–F4) and central (C3–C4) EEG derivations during N2 and N3 sleep stages. In addition to spindle density (events/min), we extracted total count, duration (seconds), dominant and average frequency (Hz), peak-to-peak amplitude (μV), and root mean square (RMS) amplitude (μV). Group comparisons were conducted using ANCOVAs, and partial correlations assessed associations between spindle features and EDS. Sex and age were included as covariates in all analyses. Statistical significance was set at $p < 0.05$.

Results: Compared to controls, IH patients exhibited increased spindle count and density across both frontal and central derivations (all $p < 0.001$), but with significantly shorter durations ($p < 0.001$) and lower amplitudes, both in terms of peak-to-peak ($p = 0.005$ and $p = 0.006$, respectively) and RMS values ($p = 0.009$). In the frontal derivations, spindles also showed higher frequencies in IH (dominant: $p = 0.035$; average: $p = 0.032$). Furthermore, in central derivations, more severe objective EDS, as indicated by shorter MSLT latencies, correlated with smaller peak-to-peak amplitude ($r = 0.296$, $p = 0.021$) and smaller RMS amplitude ($r = 0.282$, $p = 0.029$). No associations were found between spindle features and subjective EDS.

Conclusions: These findings identify a novel electrophysiological signature in IH, characterized by paradoxically increased but morphologically impaired spindles. This pattern suggests a state of hyperstable yet functionally inefficient sleep, likely reflecting disrupted thalamocortical dynamics underlying EDS in IH.

Analysis of Case Reports about Patients with Hypersomnia Using LLMs for Data Extraction

F. Dennstädt¹, I. Filchenko¹, N. Cihoric¹

¹Inselspital, University Hospital and University of Bern, Bern, Switzerland

Introduction: Hypersomnia affects 4-5% of general population (Dauvilliers et Buguet, 2005). Its etiological causes are diverse, and the treatment strategies are challenged by the limited evidence and variable therapeutic responses. While evidence from large observational studies and clinical trials is gradually emerging, case report data remains underutilized due to its perceived low evidentiary value. Nonetheless, case reports can offer valuable insights, especially in rare or poorly understood conditions. Extracting relevant clinical information from case reports is labor-intensive. Therefore, we aimed to develop a large-scale, data-driven analysis of published case reports in patients with hypersomnia using generative artificial intelligence (AI) in the form of Large Language Models (LLMs).

Materials and methods: A comprehensive search query using relevant MeSH terms identified all hypersomnia case reports on PubMed, from which titles and abstracts were obtained. The etiology and the clinical diagnosis of hypersomnia were the primary outcome measures. A structured data extraction with 43 questions was designed to identify relevant case reports and capture patient demographics, the clinical diagnoses, and the etiology of hypersomnia, if applicable. The LLM Qwen3-32B, accessed via the general-classifier Python library, was used to answer these questions for all the identified case reports. We evaluated LLM performance on a manually labeled ground truth dataset and conducted a quantitative analysis of the LLM-extracted data.

Results: The PubMed search yielded 2431 publications. On the ground truth dataset, the LLM-based data extraction achieved an overall accuracy of 93.9%, recall of 75.7%, precision of 76.4%, and an F1-score of 76.1% across all 43 questions; an F1-score >90% was achieved for 12 questions. LLM analysis identified 908 of the 2431 publications (37.4%) as case reports on individual patients with hypersomnia. Of these patients, 38.1% (n=346) were male and 30.3% (n=275) female (sex unreported in 31.6% cases). Age distribution indicated 56.5% (n=513) adults and 21.1% (n=192) pediatric with age unreported in 22.4% cases. Key reported sleep diagnoses included hypersomnia due to a medical condition (38.1% [n=346] with 29.1% [n=101] attributed to neurodegeneration), narcolepsy (37.4%, 340 instances), Kleine-Levin-Syndrome (18.1%, 164 instances), and sleep disordered breathing (17.7%, n=161), with obstructive sleep apnea being predominant (85.7% of patients with sleep disordered breathing, n=138). Most common other causes included substance abuse (13.9%, n=126), medication-related effects (11.7%, n=106), and toxic exposures (11.5%, n=104). 28.9% (n=262) patients had multiple etiological factors for hypersomnia.

Conclusions: This is the first study to systematically analyze all case reports on a sleep disorder using LLMs. First, our study shows that LLMs can accurately extract diverse data from case reports, enabling an efficient analysis of medical literature on a large scale. Second, hypersomnia has a large etiological landscape with comorbid medical condition, autoimmune conditions, and substance abuse being the most commonly described in case reports. We will further systematically evaluate the outcomes of case reports.

Acknowledgments: Not applicable.

Introduction: Idiopathic hypersomnia (IH) is a rare, heterogeneous sleep disorder characterized by excessive daytime sleepiness. The exact prevalence of IH remains unknown due to the absence of epidemiological studies. A high proportion of IH patients (26.9-39.1%) reported a family member with excessive daytime sleepiness. In contrast to narcolepsy type 1, which is a well-defined type of central disorders of hypersomnolence, the etiology of IH is poorly understood. No susceptibility loci associated with IH have been clearly identified, despite the tendency for familial aggregation of IH.

Materials and methods: We performed a variation screening of *prepro-orexin/hypocretin* and *orexin receptor* genes, and an association study for IH in a Japanese population, with replication (598 IH patients and 9826 controls). Two forms of orexin (orexin-A and -B) are generated by cleavage of one precursor peptide, prepro-orexin. A cleavage assay was conducted using proprotein convertase subtilisin/kexin (PCSK) type 1 and PCSK2 to examine differences in cleavage efficiency between the wild-type (Gly-Lys-Arg; GKR) and mutant (Gly-Arg-Arg; GRR) peptides.

Results: We identified a rare missense variant (g.42184347T>C; p.Lys68Arg; rs537376938) in the cleavage site of *prepro-orexin* that was associated with IH (minor allele frequency of 1.67% in cases versus 0.32% in controls, $P = 2.7 \times 10^{-8}$, odds ratio = 5.36). All patients with this mutation were heterozygous carriers. Subjective sleepiness as evaluated with the Epworth Sleepiness Scale scores in unmedicated conditions and arousal index (polysomnography) were nominally higher in the orexin mutation-positive patients compared with the orexin mutation-negative patients ($P = 0.049$ and $P = 0.046$, respectively), suggesting that mutation-positive IH patients suffered more sleepiness and sleep instability. No significant association between narcolepsy (type 1 and type 2) and rs537376938 was observed. In both PCSK1 and PCSK2 assays, the mutant peptide was less processed than the wild-type peptide. We also confirmed that the uncleaved forms of orexin-A and orexin-B peptides exhibited reduced signaling through orexin receptors than mature orexin-A and orexin-B peptides.

Conclusions: These results indicate that a subgroup of IH is associated with decreased orexin signaling, which is believed to be a hallmark of narcolepsy type 1.

Acknowledgments: The main findings have been previously reported in NPJ Genomic Medicine (DOI:10.1038/s41525-022-00298-w).

Challenges in the Treatment of Narcolepsy and the Positive Impact of Acetyl-L-Carnitine: A Case-Based Review with 20-Year Follow-Up

M. Meira e Cruz¹, M. Webb²

¹Sleep Unit, Cardiovascular Center of University of Lisbon, Faculty of Medicine, Sleep Unit, Lisbon, Portugal, ²Columbia University, New York, United States

Introduction: Narcolepsy is a chronic sleep disorder marked by excessive daytime sleepiness (EDS), disrupted nocturnal sleep, and, in some cases, cataplexy. Standard treatments—including wake-promoting agents, stimulants, and sodium oxybate—often provide incomplete symptom control and may cause significant side effects. Misdiagnosis is also common, particularly with mood disorders, contributing to delayed treatment and prolonged functional impairment. Current therapies primarily target monoaminergic and GABAergic systems, yet do not address potential deficits in neuronal energy metabolism. Emerging data suggest that mitochondrial dysfunction may play a role in central hypersomnias, supporting interest in metabolic modulators such as acetyl-L-carnitine (ALCAR). We present a case of treatment-resistant narcolepsy in which low-dose ALCAR supplementation resulted in a marked and sustained improvement in wakefulness, highlighting its potential as an adjuvant therapeutic strategy.

Materials and methods: A comprehensive case-based review was conducted using a detailed, longitudinal clinical history of a 50-year-old female patient diagnosed with narcolepsy following over 15 years of misdiagnosed mood disorder. Data include pharmacological regimens, objective sleep

testing, adverse effects, and patient-reported outcomes. The impact of low-dose ALCAR (250 mg/day) on wakefulness, symptom severity, and quality of life was documented over a 6-month period.

Results: The patient experienced persistent excessive daytime sleepiness and functional decline despite multiple treatment attempts over two decades. Initial pharmacologic management included antidepressants, Modafinil, Armodafinil, Adderall, Concerta, Jornay, Vyvanse, and sodium oxybate (Xyrem). Many of these treatments led to intolerable side effects—including severe gastrointestinal symptoms, Barrett's esophagus, and psychiatric distress—or failed to provide sustained benefit. Xyrem, though initially discontinued due to severe adverse reactions such as vomiting, shivering, and anxiety, was later successfully reintroduced beginning at a very low dose (0.25 g nightly) and gradually titrated up. The patient eventually stabilized on a regimen of 2.25 g of Xyrem taken twice nightly, combined with 125 mg of Modafinil daily.

This combination extended the patient's functional wake window to approximately four hours. In early 2025, the patient began taking 250 mg of acetyl-L-carnitine (ALCAR) each morning. This addition was associated with a further and sustained increase in her wakefulness window—from four to approximately six hours—with a marked reduction in the need for daytime napping and no reported side effects. The patient described significant improvements in alertness, daily functioning, and overall quality of life. Attempts to increase ALCAR beyond 250 mg/day resulted in undesirable overactivation, affirming the effectiveness of the lower dose. A follow-up self-observation revealed that accidental omission of ALCAR for one week led to a noticeable recurrence of brain fog and excessive sleepiness, which resolved upon resuming the correct supplement. This unintentional interruption served to reinforce the subjective benefit attributed to ALCAR.

Conclusions: This case highlights the multifaceted challenges in narcolepsy management and proposes acetyl-L-carnitine as a potential adjuvant therapy in refractory cases. Given its safety profile and observed benefit in this case, ALCAR warrants further investigation through controlled clinical trials.

Clinical Characterization of Patients with Abnormal Multiple Sleep Latency Test: A 10-Year Cohort Study

N. Badillo^{1,2}, A. Krieger^{2,3,4,5}

¹Weill Cornell Medicine, Clinical Translational Science Center, New York, United States, ²Weill Cornell Medicine, Center for Sleep Medicine, New York, United States, ³Weill Cornell Medicine, Department of Neurology, New York, United States, ⁴Weill Cornell Medicine, Department of Genetic Medicine, New York, United States, ⁵Weill Cornell Medicine, Department of Medicine, New York, United States

Introduction: The Multiple Sleep Latency Test (MSLT) remains the gold standard diagnostic tool for central disorders of hypersomnolence, yet comprehensive characterization of patients with abnormal results is limited. We analyzed a decade of MSLT data from a diverse urban academic sleep center to identify distinctive clinical, polysomnographic, and functional profiles that differentiate Narcolepsy Type 1 (NT1), Narcolepsy Type 2 (NT2), and Idiopathic Hypersomnia (IH), aiming to enhance diagnostic precision in these challenging conditions.

Materials and methods: We retrospectively analyzed 893 consecutive patients who underwent polysomnography and MSLT at Weill Cornell Center for Sleep Medicine (2010-2020). Patients were classified according to ICSD-3 criteria as having normal MSLT (n=492), IH (n=294), Narcolepsy (n=107). Narcolepsy was further classified based on the presence of cataplexy. Comprehensive assessment included demographic data, Epworth Sleepiness Scale (ESS), Berlin questionnaire, detailed psychiatric and medical comorbidity profiles, medication usage patterns, polysomnographic metrics, and functional parameters. All subjects underwent an attended polysomnography (PSG) on the night preceding the MSLT protocol. Statistical analyses employed ANOVA and chi-square tests with significance at $p < 0.05$.

Results: Patients with abnormal MSLT demonstrated distinct clinical profiles beyond diagnostic criteria. NT1 patients had the most severe objective sleepiness (mean sleep latency: 4.51 ± 1.96 min) and highest ESS scores (14.7 ± 4.7 vs. 11.6 ± 5.1 in those with normal MSLT, $p < 0.0001$), yet showed significantly better functional outcomes with higher employment rates (78.6% vs. 47.6% in controls, $p = 0.0065$) and physical activity (52.2% engaged in regular exercise vs. $< 30\%$ in other groups, $p < 0.001$). In terms of self-reported psychiatric comorbidities, NT1 patients had significantly higher rates of anxiety (50.0%), depression (53.6%), and cognitive symptoms (memory loss: 21.4%) compared to other groups ($p < 0.001$). Sleep architecture analysis of MSLT revealed narcolepsy groups had significantly increased REM sleep percentage ($\sim 23\%$ vs. 11% in controls, $p < 0.0001$) and shortened sleep onset latency (NT1:

8.3 min; NT2: 6.0 min vs. controls: 35.2 min, $p < 0.0001$). IH patients demonstrated intermediate polysomnographic abnormalities but reported the highest rates of lack of energy (81.7%, $p < 0.0001$) and longest nap durations (18.8 minutes vs. 10.5 minutes in patients with normal MSLT findings). Caffeine sensitivity was significantly higher in NT1 (25.0%) and IH (21.4%) compared to NT2 (5.2%, $p = 0.0021$), suggesting distinctive pathophysiological mechanisms.

Conclusions: This comprehensive characterization reveals that clinical phenotypes of NT1, NT2, and IH extend significantly beyond standard diagnostic parameters. The paradoxical finding of better functional capacity in NT1 patients with severe objective sleepiness suggests complex compensatory mechanisms worthy of further investigation. The distinct patterns of psychiatric comorbidities, sleep architecture signatures, and functional outcomes provide valuable additional markers that can enhance diagnostic accuracy and inform targeted management strategies. These findings underscore the importance of holistic clinical assessment beyond isolated MSLT parameters when evaluating and treating patients with suspected central disorders of hypersomnolence.

Acknowledgments: We thank the staff and patients of the Weill Cornell Center for Sleep Medicine for their contributions. Supported by NIH/NCATS Grant #2TL1-TR-2386 and Weill Cornell Clinical Translational Science Center (CTSC).

Clinical Significance of Fractional Exhaled Nitric Oxide (FeNO) in Narcolepsy Patients

Y. Liu¹, W. Guo², F. Wei², X. Dong¹, F. Han¹

¹Peking university people's hospital, sleep center, Beijing, China, ²State Key Laboratory of Advanced Materials for Intelligent Sensing, GRINM Group Co, Beijing, China

Introduction: Narcolepsy is characterized by excessive daytime sleepiness, often accompanied by obesity and obstructive sleep apnea (OSA). Airway inflammation in OSA and obesity has been described and can be assessed by measuring the biomarker fractional exhaled nitric oxide (FeNO). In this preliminary study, we explored the significance of FeNO measurement in patients with narcolepsy.

Materials and methods: This study was a prospective and in-hospital population-based study. We enrolled patients with narcolepsy and compared them with patients with OSA and insomnia. Patients underwent pulmonary function tests, FeNO measurement, arterial blood gas analysis, polysomnography, and multiple sleep latency tests. All patients had eosinophil counts, and some underwent IgE testing. FeNO was measured daily during hospitalization, including before and after ventilator and pharmacological treatments.

Results: A total of 90 patients were included, divided into narcolepsy ($n = 30$), OSA ($n = 30$), and insomnia ($n = 30$) groups. The median apnea-hypopnea index (AHI) in the narcolepsy group was 16 ± 4.5 , with a mean age of 50.9 years and 29% females. Among narcolepsy patients, 45% were diagnosed with OSA, of which 53% had moderate to severe disease. FeNO levels were significantly higher in patients with moderate to severe OSA compared to those with no or mild OSA ($P = 0.024$). FeNO was positively correlated with the apnea-hypopnea index ($r = 0.65$, $p < 0.001$) and the lowest blood oxygen saturation ($r = 0.54$, $p < 0.001$). Among the 37 patients in the OSA group who underwent continuous positive airway pressure (CPAP) titration and treatment, successful titration was associated with lower nocturnal FeNO elevation (7.2 ± 3.3 vs. 11.0 ± 4.3 , $p = 0.02$). FeNO levels decreased after 1-4 days of CPAP treatment (11.7 ± 4.4 ppb, $p < 0.001$). In narcolepsy patients with OSA, FeNO did not decrease with AHI reduction after CPAP treatment compared to the OSA group. Pharmacological treatment significantly improved daytime sleepiness in narcolepsy patients but did not significantly change FeNO levels.

Conclusions: FeNO was not significantly correlated with daytime sleepiness in narcolepsy and did not change with CPAP treatment. FeNO levels were elevated in OSA patients and correlated with disease severity, decreasing after positive airway pressure treatment. This study supports the role of upper airway inflammation in the pathogenesis of OSA and suggests that FeNO may be useful for monitoring the effectiveness of CPAP treatment. The correlation between FeNO and daytime sleepiness requires further investigation.

Data-Driven Identification of OSA Subtypes through Endotypic Clustering in Multi-Cohort Population Studies

S.J. Lee¹, H.K. Ahn^{1,2}, Y.H. Na^{1,2}, Y.G. Lee^{1,2}, H.K. Lee^{1,2}, H.W. Shin^{1,2,3,4}

¹Obstructive Upper Airway Research Laboratory, the Department of Pharmacology, Seoul National University College of Medicine, Seoul, Korea, Republic of, ²Department of Biomedical Sciences, Seoul National University College of Medicine, Seoul, Korea, Republic of, ³Department of Otorhinolaryngology-Head and Neck Surgery, Seoul National University Hospital, Seoul, Korea, Republic of, ⁴OUaR LaB, Inc, Seoul, Korea, Republic of

Introduction: Obstructive sleep apnea (OSA) is a physiological and clinically heterogeneous disorder. Conventional severity metrics such as the Apnea-Hypopnea index (AHI) provide limited insight into underlying pathophysiological mechanisms. Four endotypic traits—loop gain (instability of ventilatory control), muscle compensation (upper airway dilator response), pharyngeal collapsibility (airway collapse tendency during sleep), and arousal threshold (Tendency to wake up easily in response to respiratory disturbances)—capture key physiological determinants of OSA. These traits support mechanistic subtyping beyond AHI. In this study, we performed unsupervised clustering of endotypic traits in large population-based cohorts to define physiologically distinct OSA subtypes and assess their clinical significance.

Materials and methods: We analyzed data from 14,643 participants across four population-based cohorts: Korea Image-based Sleep Study (KISS, n = 6,661), Sleep Heart Health Study (SHHS, n = 3,964), the Osteoporotic Fractures in Men Study (MrOS, n = 2,280), and the Multi-Ethnic Study of Atherosclerosis (MESA, n = 1,738). Four validated endotypic traits were estimated using the PUP framework with previously published techniques. After Z-score standardization, K-means clustering was applied, and the optimal number of clusters was determined using the Elbow method, Calinski-Harabasz index, and Davies-Bouldin index. AHI was excluded from clustering but analyzed along with polysomnographic, demographic, and endotypic variables after clustering. To assess the magnitude of between-cluster differences, effect sizes were calculated using Cohen's d (small: d=0.2, medium: d=0.5, large: d=0.8).

Results: Unsupervised clustering of four endotypic traits identified four physiologically distinct OSA subtypes (Cluster A: n = 7,843; B: n = 4,194; C: n = 1,738; D: n = 868). Demographic and polysomnographic measures showed clear gradients: gender, BMI, arousal index, AHI, obstructive and central apnea duration, and hypoxic burden increased from A to D, while sleep efficiency and mean oxygen saturation decreased. Effect size analysis indicated large between-cluster differences in arousal index, obstructive apnea duration, and oxygen saturation; medium effects in age, central apnea duration, and hypoxic burden; and only small effects in gender, BMI, WASO, sleep efficiency, central apnea index, and AHI.

Conclusions: Endotype-based clustering revealed four physiologically and clinically distinct OSA subtypes. These subtypes reflect underlying differences in ventilatory control, arousal threshold, and airway collapsibility, providing a mechanistic alternative to conventional AHI-based classification. This framework supports more precise phenotyping and may support the development of personalized treatment strategies for OSA.

Discrepancy between subjective and objective sleepiness in adolescents is associated with neurodevelopmental disorders

Y. Oka¹, O. Munkhjargal², T. Higaki²

¹Ehime University, Center for Sleep Medicine, Ehime, Japan, ²Ehime University, Department of Pediatric and Adolescent Therapeutic and Developmental Education, Ehime, Japan

Introduction: Lack of correlation between subjective and objective measurements of daytime sleepiness is common. Possible predictors of the discrepancy between subjective and objective sleepiness were examined in adolescents.

Materials and methods: Two hundred and eleven pediatric patients (aged 10-18 years) with various sleep disorder symptoms were evaluated for subjective and objective sleepiness. Subjective sleepiness was defined as the scores of 11 or more on the Japanese version of Epworth Sleepiness Scale and objective sleepiness was defined as mean sleep latency of 8.0 min or less on the Multiple Sleep Latency

Test. Patients were then classified as concordantly sleepy (CS), objectively sleepy (OS), subjectively sleepy (SS), and non sleepy (NS). Discrepancy-related factors were identified with multivariable logistic regression analysis.

Results: Discrepancy between subjective and objective sleepiness was observed in 46.4% of the patients. When the CS group was set as the reference in the multivariable logistic regression analysis, younger age (odds ratio (OR)=0.75, 95% confidence interval (CI): 0.58 to 0.97), lower sleep efficiency (OR=0.93, 95% CI: 0.87 to 0.99), and neurodevelopmental disorders (OR=7.54, 95%, CI: 2.43 to 23.38) were significantly associated with subjective sleepiness. When the NS group was set as the reference, later bedtime (OR=2.56, 95% CI: 1.28 to 5.15) and neurodevelopmental disorders (OR=4.12, 95% CI: 1.30 to 12.99) were associated with subjective sleepiness. In subgroup analyses on autism spectrum disorders (ASD) and attention deficit hyperactivity disorders (ADHD), only ASD (SS vs. CS: OR=17.23, 95% CI: 3.46 to 85.9; SS vs. NS: OR=5.36, 95% CI: 1.43 to 20.03) exhibited statistical significance in the multivariable regression model. In contrast, ADHD was not related with discrepancy.

Conclusions: Nearly half of the patients exhibited discrepancy between subjective and objective sleepiness which need to be taken into consideration in the management of hypersomnia. Significant factors related to subjective discrepancy included: age, delayed bedtimes, and neurodevelopmental disorders in the adolescent population.

Does Kleine-Levin Syndrome Have Circadian Dysfunction?

S. Wu¹, Y. Liu¹, L. Xu¹, Q. Ding¹, F. Xiao¹, Y. Zuo¹, M. Wang¹, Z. Feng¹, H. Wang¹, X. Dong¹, F. Han¹

Introduction: Kleine-Levin Syndrome (KLS) involves periodic hypersomnia relapses and debilitating neurobehavioral disturbances, yet the existence of circadian rhythm dysfunction remains debated.

Materials and methods: We conducted a study integrating between-group comparisons with a within-subject design. Circadian rhythms were evaluated under a modified constant routine protocol in 22 KLS patients (mean age 23.5 ± 15.1 years) and 48 age-, sex-, and BMI-matched healthy controls (mean age 20.8 ± 6.2 years). Habitual sleep-wake patterns were assessed via wrist-worn actigraphy. Endogenous circadian markers—including phase [dim light melatonin onset (DLMO), core body temperature minimum (CBTmin)], amplitude, and MESOR—were derived from 24-hour melatonin and CBT profiles. Importantly, a subgroup of six KLS patients was evaluated in both remission and relapse states.

Results: Between-group comparisons revealed no significant differences in sleep-wake patterns, circadian phase markers (e.g., DLMO), amplitude, or MESOR between KLS patients and healthy controls. The one exception was a statistically lower baseline melatonin level in the KLS relapse group compared to controls (1.9 ± 1.1 vs. 3.2 ± 1.9 pg/mL, $p=0.007$), though this difference is unlikely to be clinically significant. In contrast, the within-subject paired analysis revealed a significant and dynamic phase advance during relapse. Specifically, DLMO advanced by a mean of 1.4 hours ($p=0.031$) and CBTmin advanced by a mean of 1.9 hours ($p=0.019$). In contrast to this phase shift, there were no significant changes in the amplitude or MESOR for either melatonin or CBT between the remission and relapse states. This marked phase shift in KLS patients contrasted with the high circadian stability observed in controls assessed twice.

Conclusions: KLS is not associated with persistent abnormalities in circadian phase, amplitude, or MESOR. Instead, the disorder is characterized by a distinct and dynamic phase advance during symptomatic relapses. These findings provide novel insight into the circadian pathophysiology of KLS, highlighting the circadian system's phase-shifting mechanism as a potential therapeutic target.

⁴Robert Debré Hospital, National Reference Center for Narcolepsies and Hypersomnia, Fédération Pédiatrique des Pathologies du Sommeil, Paris, France

Introduction: Narcolepsy type 1 (NT1) and idiopathic hypersomnia (IH) are central disorders of hypersomnolence characterized by excessive daytime sleepiness and cognitive complaints. While NT1 has been associated with altered executive function and enhanced creativity, intelligence quotient (IQ) remains understudied in adults with NT1 and has never been systematically assessed in IH. This study aimed to evaluate IQ in adults with NT1 and IH compared to healthy controls, using a standardized measure of cognitive ability.

Materials and methods: We conducted a prospective, controlled study including 30 adults with NT1, 30 with IH, and 30 age-, sex-, and education-matched healthy controls, recruited at the French National Reference Center for Narcolepsy and Hypersomnia. Participants completed the Wechsler Adult Intelligence Scale – Fourth Edition (WAIS-IV), assessing Full Scale IQ (FSIQ) and four cognitive domains: Verbal Comprehension, Perceptual Reasoning, Working Memory, and Processing Speed.

Results: On the Full Scale IQ, participants with IH (mean $\pm$ SD: 113.6 ± 14.3) and NT1 (104.1 ± 14.3) had scores similar to those of healthy controls (108.4 ± 17.0). One of the four indices, the Working Memory Index, was globally different between the three groups (IH: 109.0 ± 17.1 ; NT1: 99.0 ± 15.8 ; Control: 102.3 ± 13.4 , $P = 0.04$), with a trend for IH participants to have higher scores than NT1 participants (but $P = 0.04$). Of the subtests, Information, Visual Puzzle, and Digit Span tended to differ between the three groups, with no other differences between two groups. Higher IQ scores were moderately correlated with more years of education (but not with disease course or treatment). Pretest fatigue (but not Epworth Sleepiness Score) predicted poorer performance on the Working Memory Index.

Conclusions: Adults with NT1 and IH have normal intellectual functioning comparable to healthy controls. Despite subjective cognitive complaints, particularly in NT1, their IQ performance indicates preserved cognitive potential. These findings support the view that individuals with hypersomnolence disorders can achieve normal academic and professional outcomes, emphasizing the importance of recognizing their intact intellectual capabilities in clinical and educational contexts.

Acknowledgments:

We would like to thank all the participants who generously gave their time to take part in this study. We are particularly grateful to the patients with narcolepsy type 1 and idiopathic hypersomnia who shared their experiences and contributed to advancing knowledge about these rare conditions. We also thank the healthy volunteers for their participation and support.

We acknowledge the dedicated staff at the National Reference Center for Narcolepsy and Hypersomnia at the Pitié-Salpêtrière University Hospital for their assistance with patient recruitment, clinical evaluations, and logistical support. Special thanks to my colleagues who follow patients with professionalism and care.

Finally, we are grateful to our colleagues and collaborators for their constructive feedback during the design and interpretation of the study.

Investigating GABA and Glx in Central Hypersomnolence Disorders: A Multicenter Harmonized Spectroscopy Study

⁸Amsterdam Neuroscience, Compulsivity Impulsivity and Attention, Amsterdam, Netherlands

Introduction: Central disorders of hypersomnolence (CDH), including narcolepsy type 1 (NT1), narcolepsy type 2 (NT2), and idiopathic hypersomnia (IH), are characterized by excessive daytime sleepiness. NT1 is biologically defined by low or absent cerebrospinal fluid (CSF) hypocretin levels, but distinguishing NT2 from IH remains challenging due to the lack of reliable biomarkers. While dysfunction in default mode network (DMN) regions such as the medial prefrontal cortex (mPFC) and posterior cingulate cortex (PCC) has been implicated, neurochemical alterations in these regions remain poorly understood. Glutamate plus glutamine (Glx) and gamma-aminobutyric acid plus macromolecules (GABA+) may reflect altered excitatory-inhibitory signaling in CDH. However, it remains unclear whether the observed neurometabolic changes reflect stable disease traits or transient effects related to sleep-wake state, such as sleep deprivation. Moreover, the relationship between neurometabolite levels and clinical measures of sleepiness and sleep quality in CDH is still poorly understood.

Materials and methods: Using harmonized multi-center 3 Tesla MRI, we acquired MEGA-PRESS spectroscopy from both the mPFC and PCC, to quantify Glx and GABA+ in patients with NT1 (n=20), NT2 (n=19), or IH (n=28), and in healthy controls (n=21). Healthy controls were scanned in both well-rested and partially sleep-deprived conditions (maximum four hours of permitted sleep). Metabolites levels were quantified using Osprey, providing water-scaled and tissue-corrected absolute concentrations, as well as values normalized to total creatine (tCr). Group comparisons were performed using ANCOVA, comparing patient groups separately with rested and sleep-deprived controls. Within-subject effects of sleep deprivation were tested in controls using linear mixed-effects models. Partial correlations in the patient group were computed between metabolite levels and clinical measures: Epworth Sleepiness Scale (ESS), Pittsburgh Sleep Quality Index (PSQI), and multiple sleep latency test (MSLT). All statistical analyses were adjusted for site, age, and sex.

Results: No significant differences in Glx or GABA+ were observed when comparing CDH patient groups with rested controls. However, Glx/tCr ratios were significantly higher in sleep-deprived controls compared to all three patient groups in the PCC ($F(3,32)=10.96$, $p<0.001$). These findings were corroborated by linear mixed-effects models, which confirmed increased Glx/tCr in mPFC in healthy controls when partial sleep-deprived versus well-rested ($p = 0.03$). Across CDH patients, lower absolute Glx in PCC was associated with greater daytime sleepiness (ESS: $r=-0.52$, $p=0.0051$), while higher Glx/tCr ratios in PCC correlated with poorer sleep quality (PSQI: $r=0.44$, $p=0.0224$) and shorter sleep latency (MSLT: $r=-0.53$, $p=0.0102$). In mPFC, higher GABA+ levels were associated with shorter MSLT sleep latency ($r=-0.27$, $p=0.0424$).

Conclusions: We found no significant differences in Glx or GABA+ concentrations between the three CDH patient groups and well-rested healthy controls, suggesting that trait-like neurometabolic alterations in DMN regions may be subtle or absent. Notably, Glx/tCr ratios increased following partial sleep deprivation in healthy controls, potentially reflecting a state-dependent neurochemical response specific to acute rather than chronic sleepiness. Furthermore, associations between Glx and GABA+ levels and clinical measures of sleepiness and sleep quality suggest that individual variability in disease severity may be captured by these metabolites, supporting their potential as candidate biomarkers in CDH.

Limitations of the MSLT and Predictive Diagnostic Factors in Patients with Hypersomnolence

S. Kim¹, Y.-C. Kim¹, Y.H. Um¹, T.-W. Kim¹, H.J. Seo¹, J.-H. Jeong¹, S.-C. Hong¹

¹St.Vincent's Hospital, The Catholic University of Korea, Department of Psychiatry, Suwon, Korea, Republic of

Introduction: Narcolepsy is a neurological sleep disorder characterized by hypersomnolence, sleep fragmentation, and rapid eye movement(REM) sleep dissociation. However, the classifications of central disorders of hypersomnolence remain dynamic and debated. Some research has shown that sleep stage sequences during naps with sleep onset rapid eye movement(SOREM) periods differ significantly between patients with narcolepsy type 1 (NT1), narcolepsy type 2 (NT2), and idiopathic hypersomnia (IH). We hypothesize that SOREMP sequences, or the occurrence of SOREMPs in the early phase, may influence diagnostic changes.

Materials and methods: We selected patients who visited St. Vincent's Hospital between 2002 and 2023 for daytime sleepiness and underwent the multiple sleep latency test (MSLT) more than twice. Patients were divided into five groups: NT1, NT2, IH, REM dysregulation(REMD), and normal. We

analyzed diagnostic changes, SOREMPs in the first nap, and the duration of mean sleep latency using logistic regression analysis.

Results: A total of 126 patients were included (66 NT1, 30 NT2, 16 IH, 8 REM dysregulation, and 6 normal). Of these, 39 patients (30.7%) had changes in their diagnosis. The number of SOREMPs in the first MSLT was statistically significant ($p = 0.028$, $OR = 0.33$). The occurrence of SOREMPs during the first nap of the second MSLT also showed a significant association with diagnostic changes ($p < 0.001$, $OR = 0.05$).

Conclusions: This study confirms the utility of MSLT in diagnosing NT1 patients, though it has limitations in diagnosing other hypersomnolence disorders. The presence and number of SOREMPs in the first nap of the MSLT appear to influence subsequent diagnostic changes. Further studies with larger sample sizes and more structured designs are needed.

Long sleep duration and autonomic function: A systematic review

S. Park¹, J. Logan¹

¹University of Virginia, School of Nursing, Charlottesville, United States

Introduction: Long sleep has been linked to increased cardiovascular disease (CVD) risks, yet the underlying autonomic mechanisms remain underexplored compared to other physiological pathways. Most existing studies on sleep and autonomic function have focused primarily on sleep deprivation or insomnia. This systematic review aimed to investigate how long sleep duration is defined in current studies and how long sleep duration is associated with autonomic function outcomes across populations.

Materials and methods: Structured searches were conducted in PubMed, Embase, Web of Science, Scopus, and CINAHL for articles published in English with full text before April 2025. Search terms included “long sleep” or “long sleep duration” and “autonomic function” or “autonomic nervous system.” Studies were excluded if they treated sleep as a continuous variable without an explicit long sleep category or if conducted in non-human populations. The JBI critical appraisal checklist for systematic reviews and research syntheses was used for quality assessment.

Results: A total of 9 studies were included. Most were cross-sectional (78%), involving adolescents (22%), healthy adults (22%), and older adults (44%). Six studies (67%) used the PSQI to measure subjective sleep duration, while objective measurements predominantly utilized wrist-worn actigraphy devices (also 67%); one study used direct observation by medical staff. Definitions of long sleep varied: ≥ 7 hours (22%), ≥ 8 hours (22%), and ≥ 9 hours (56%). Autonomic function was mostly measured using heart rate variability (HRV) with short-term (1-5 minute) lead I ECG recording, as well as muscle sympathetic nerve activity, and orthostatic heart rate tests. Frequency-domain indices (total power, LF-HRV, HF-HRV, LF/HF ratio) and time-domain indices (SDNN, RMSSD) were frequently reported. Cross-study comparisons suggested that older long sleepers were more likely to have a higher risk of cardiac vagal control decline compared to healthy adults or adolescents, except for adolescents with mental illness. One study using both subjective and objective assessments found that self-reported long sleep duration was significantly associated with reduced parasympathetic withdrawal during orthostatic challenges, whereas objectively measured long sleep duration showed no such association.

Conclusions: This review highlights the inconsistency in definitions of long sleep duration, ranging from ≥ 7 hours to unclassified longer durations. In older adults and adolescents with mental illness, long sleep duration was associated with impaired autonomic function. Although objective measures are more accurate for assessing sleep duration, subjective and objective sleep measures capture different aspects of sleep. Therefore, the choice to use both should be carefully considered based on the study's aims. Future studies should establish optimal cutoffs to define long sleep duration and adopt consistent autonomic measurement protocols to inform interventions targeting sleep for cardiovascular risk reduction. It would also be meaningful to identify which combination of autonomic function indices best predicts overall autonomic health.

Machine Learning Classification of Idiopathic Hypersomnia and Narcolepsy: Novel Clinical Predictors from a Decade-Long Urban Academic Sleep Center

N. Badillo^{1,2}, A. Krieger^{2,3,4,5}

¹Weill Cornell Medicine, Clinical Translational Science Center, New York, United States, ²Weill Cornell Medicine, Center for Sleep Medicine, New York, United States, ³Weill Cornell Medicine, Department of Neurology, New York, United States, ⁴Weill Cornell Medicine, Department of Genetic Medicine, New York, United States, ⁵Weill Cornell Medicine, Department of Medicine, New York, United States

Introduction: Differentiating idiopathic hypersomnia (IH) from narcolepsy remains challenging despite established polysomnographic criteria. The Multiple Sleep Latency Test (MSLT) and polysomnography (PSG), while considered gold standards, present limitations in accessibility, cost, and interpretation variability. We investigated whether machine learning using multi-modal clinical data could improve diagnostic accuracy and identify novel predictors for these disorders.

Materials and methods: We retrospectively analyzed 19,398 records from Weill Cornell Center for Sleep Medicine (2010-2020) in New York City. From 893 patients with PSG and MSLT, we identified 294 with IH (32.9%), 107 with narcolepsy (12.0% Type 1 & 25.2% Type 2), and 492 with normal MSLT results (55.1%). Data preprocessing included normalization, imputation, and feature extraction from clinical questionnaires (Epworth Sleepiness Scale, Berlin Questionnaire), PSG metrics (sleep architecture, respiratory events), and MSLT parameters (sleep/REM latencies, SOREMPs). Seven machine learning algorithms were evaluated with various dimensionality reduction techniques (PCA, t-SNE, UMAP), with model performance assessed through 5-fold cross-validation. Random Forest with t-SNE demonstrated superior performance (accuracy: 81.7%, AUC: 0.912, F1: 0.813) and was used to identify novel predictive features through correlation analysis.

Results: Our t-SNE approach significantly outperformed other techniques (t-SNE: ~82% accuracy vs. PCA: 53%, UMAP: 56%). The model identified key predictors across multiple domains: (1) validated sleepiness measures (ESS Total: 0.013, specific ESS questions: 0.006-0.008); (2) sleep timing variables (weekday bedtime: 0.180, sleep onset latency: 0.161-0.180); and (3) lifestyle factors (coffee consumption: 0.007, alcohol consumption: 0.366-0.517, occupation active [movement/non-sedentary] : 0.317-0.462, need alarm clock [to wake up from sleep] : 0.283-0.431). Clinical phenotyping showed NT1 patients had the highest ESS scores (14.7±4.7) and unexpected characteristics including highest rates of occupational engagement (78.6% vs. 39.2% NT2, 51.7% IH) and distinctive comorbidity patterns (anxiety: 50.0%, depression: 53.6%, anemia: 21.4%).

Conclusions: Our machine learning approach identifies previously unreported behavioral and clinical markers that enhance differential diagnosis of hypersomnolence disorders. This large cohort from a diverse urban population demonstrates that diagnostic algorithms incorporating both traditional and novel predictors can achieve >80% accuracy, potentially reducing reliance on resource-intensive sleep studies. The identification of previously overlooked clinical predictors opens possibilities for more accessible screening tools and personalized management approaches, particularly valuable for reducing the substantial diagnostic delays (often 8-15 years) currently observed in these disorders.

Acknowledgments: We thank the staff and patients of the Weill Cornell Center for Sleep Medicine for their contributions. Supported by NIH/NCATS Grant #2TL1-TR-2386 and Weill Cornell Clinical and Translational Science Center (CTSC).

Metabolomic Profiling of Kleine-Levin Syndrome In and Out of Episode using Liquid Chromatography-Mass Spectrometry

L. Xu¹, S. Yue¹, J. Li², X. Liu², G. Xu², F. Han¹

¹Peking University People's Hospital, Beijing, China, ²CAS Key Laboratory of Separation Science for Analytical Chemistry, Dalian, China

Introduction: Kleine-Levin syndrome (KLS) is a rare episodic hypersomnia disorder lacking diagnostic biomarkers and mechanistic insights. This study utilized liquid chromatography-mass spectrometry (LC-MS) to profile serum and cerebrospinal fluid (CSF) metabolomes in KLS patients, aiming to identify diagnostic biomarker panels and elucidate metabolic changes across symptomatic (in-episode) and asymptomatic (out-of-episode) phases.

Materials and methods: We enrolled 74 KLS patients (mean age: 19.2 ± 11.4 years; 68.9% male) diagnosed at the Sleep Division, Peking University People's Hospital (2004–2021). Samples included 50 in-episode and 56 out-of-episode serum samples, plus 27 in- and 27 out-of-episode CSF samples. Serum from 64 healthy controls served as reference. Untargeted LC-MS metabolomics/lipidomics

profiling was performed, followed by KEGG-based pathway analysis. A novel SVM-RFE (Support Vector Machine-Recursive Feature Elimination) algorithm identified KLS-associated metabolic features, with binary logistic regression screening diagnostic markers. Cross-fluid metabolic dynamics were analyzed in 19 patients with paired serum-CSF samples.

Results: LC-MS identified 559 serum metabolites and 334 lipids with robust data quality. A six-marker serum panel (carnitine C10:3, 3-hydroxybutyrate, decanoic acid [FFA 10:0], glycochenodeoxycholic acid [GCDCA], phenylalanylphenylalanine [Phe-Phe], SM [d18:1_24:1]) achieved an AUC of 0.950 (sensitivity: 0.854; specificity: 0.923). In serum, metabolic dysregulation in KLS during in-episodes and out-of-episodes primarily involves phenylalanine metabolism, glycerophospholipid metabolism, and steroid hormone biosynthesis pathways. CSF metabolic profiles show systemic suppression of amino acid metabolism, with significant reductions in branched-chain amino acids (valine, leucine) and aromatic amino acids (tryptophan), alongside decreased levels of pyruvate (a key tricarboxylic acid cycle intermediate) and pipercolic acid (a lysine metabolite). Serum/CSF relative abundance ratios for the same metabolites in individual subjects revealed elevated ratios for tryptophan and phenylalanine, suggesting potential dysfunction in the active transport system.

Conclusions: This study identified a serum biomarker panel for KLS diagnosis and, for the first time, characterized CSF metabolic shifts between in- and out-of-episode. The mechanism of KLS may be associated with the impairment of the active transport system, the disruption of the blood-brain barrier, and the central neuroinflammatory response.

Multimodal digital assessments of hypersomnia with an instant messaging program

Y. Liu¹, L. Xian¹, Y. Wang¹, P.S. Lo¹, C.C.W. Cheng¹, K.Y. Chan¹, N.Y. Chan¹, S.X. Li^{2,3}, J.W.Y. Chan¹, Y.K. Wing^{1,4}, T.M.H. Li¹

¹Li Chiu Kong Family Sleep Assessment Unit, The Chinese University of Hong Kong, Department of Psychiatry, Hong Kong, China, ²The University of Hong Kong, Department of Psychology, Hong Kong, China, ³The State Key Laboratory of Brain and Cognitive Sciences, The University of Hong Kong, Hong Kong, China, ⁴Li Ka Shing Institute of Health Sciences, Faculty of Medicine, The Chinese University of Hong Kong, Hong Kong, China

Introduction: Hypersomnia, characterized by prolonged sleep duration and/or daytime sleepiness, is a common symptom in depression. While hypersomnia assessments rely on self-report, clinical appraisal, and polysomnography (PSG), patients with hypersomnia may present with a wide range of behavioral expressions that may not be captured well by traditional assessments, e.g., trouble concentrating and anxiety, which, however, were correlated with specific linguistic and acoustic features. Advances in digital health have enabled ecologically valid and continuous monitoring through multimodal assessment. As prior studies have validated speech features as reliable markers, this study investigates hypersomnia symptoms in a Hong Kong youth sample using a Telegram-based speech-based ecological momentary assessment (EMA) that collects audio data, aiming to identify behavioral markers and evaluate the effectiveness of automated feature extraction via machine learning and deep learning models.

Materials and methods: This is part of an ongoing study on depression detection using EMA, which initially recruited 328 youth participants. Among those who completed the study (n=300, 19% with depression), 26 individuals had hypersomnia symptoms (mean age: 20.64; 75.18% female), identified via the post-EMA outcomes of the Structured Clinical Interview for the Hamilton Depression Rating Scale with Atypical Depression Supplement (SIGH-ADS 2003), and the remaining 274 did not exhibit hypersomnia symptoms (mean age: 21.12; 84.62% female). Within the hypersomnia group, 17 reported ≥ 1 -hour sleep extension, and 9 reported ≥ 2 -hour increases. Exclusion criteria included a history of neuropsychiatric disorders (other than depression and anxiety), any voice, speech, or language disorder, or being deemed unable to provide informed consent. Over seven days, participants completed twice-daily mood assessments, with a minimum compliance rate of 70% required for inclusion. From the resulting voice recordings, a domain-specific pipeline extracted 84 interpretable acoustic and linguistic features, incorporating both static and temporal dynamics. To model complex feature interactions and latent structures, classification of hypersomnia symptoms was performed using the state-of-the-art machine learning algorithms with five-fold cross-validation and SMOTE applied for class balancing.

Results: With age, gender, and depression symptom controlled, patients with hypersomnia symptoms demonstrated significant differences in acoustic features, including higher short-term pitch variability

($P=.04$), reduced short-term loudness variability ($P=.003$), and a lower rate of change in the power spectrum ($P=.01$), indicating reduced speech energy and psychomotor slowing. Linguistic analysis revealed an increased short-term fluctuation in the use of negation words ($P=.04$), and an increased risk-related words usage variability ($P=.02$), reflecting disrupted affective or cognitive regulation. Combining acoustic, linguistic modalities, and demographic information, the Multilayer Perceptron and Long Short-Term Memory (LSTM) model achieved an F1-score of 0.74 for binary classification (sensitivity=0.35; specificity=0.71) between hypersomnia and other participants, and an F1-score of 0.76 for the multi-class classification.

Conclusions: Digital assessment using speech and language features offers a scalable, ecological approach to identify hypersomnia symptoms. Our findings reveal distinct acoustic and linguistic markers associated with hypersomnia and demonstrate the feasibility of automated classification, supporting early detection.

Nap-Related Variability of MSLT in Central Disorders of Hypersomnolence, Insufficient Sleep, and Delayed Sleep-Wake Phase Disorder

J. Johnson¹, J. Bena², S. Morrison², M.L.D. Araujo¹, S. Thanaviratananich¹, N. Foldvary-Schaefer¹

¹Cleveland Clinic, Sleep Disorders Center, Cleveland, United States, ²Cleveland Clinic, Department of quantitative health sciences, Cleveland, United States

Introduction: Multiple Sleep Latency Testing preceded by polysomnography (PSG-MSLT) is the standard evaluation for patients with suspected central disorders of hypersomnolence (CDH). The validity of MSLT depends on adequate sleep prior to testing and proper alignment of test time with the patient's circadian rhythm. Insufficient sleep syndrome (ISS) and delayed sleep-wake phase disorder (DSWPD) can be associated with abnormal MSLT potentially leading to misdiagnosis. We analyzed nap-to-nap variability in MSLT parameters in patients with CDH, ISS and DSWPD to elucidate variations in nap patterns by clinical diagnosis.

Materials and methods: This retrospective cohort included 1,474 patients who underwent PSG-MSLT for hypersomnolence (January 2003-August 2024) at Cleveland Clinic. Patients were classified as narcolepsy type 1 (NT1), narcolepsy type 2 (NT2), idiopathic hypersomnia (IH), ISS and DSWPD based on physician clinical diagnosis. Those with hypersomnolence due to other conditions (e.g., OSA, psychiatric disease; $n=618$) or undifferentiated hypersomnia ($n=227$) were excluded. Nap-to-nap variability in sleep latency (SL), sleep onset REM periods (SOREMPs) and REM latency (REML) was assessed across diagnostic groups. Kruskal-Wallis, ANOVA, and Chi-square tests with Bonferroni corrections were used for patient and overall measures, while linear and logistic mixed effect models were used to evaluate trends and overall differences across naps.

Results: Of 676 patients (33.1 ± 13.5 years, 75.4% female), 90(13.3%) had NT1, 155(22.9%) NT2, 313(46.3%) IH, 55(8.1%) ISS, and 63(9.3%) DSWPD. While groups did not differ in age, proportion of females was higher in IH than NT2 and ISS (81.8% vs. 70.3%; 63.6%; $p=0.007$). More Caucasians had IH than NT1 or NT2 (79.4% vs. 63.3%; 65.8%; $p=0.003$). Mean sleep latency (MSL) was shortest in NT1 and longest in DSWPD (NT1 median [IQR]: 3.8[2.1,6.7]; NT2:5.0[3.2,7.1]; IH:7.4[5.1,9.9]; ISS:10.0[5.8,14.6]; DSWPD:12.8[9.3,15.8] min; $p<0.001$). Prevalence of ≥ 2 SOREMPs (%) was higher and REML (mean $\pm$ sd) shorter in NT1 and NT2 than other groups [NT1(84.4%, 9.4 ± 5.5); NT2(74.3%, 12.5 ± 4.4); IH(1.6%, 17.2 ± 2.7); ISS(20%, 15.2 ± 4.2); DSWPD(12.7%, 16.2 ± 3.4); all $p < 0.001$]. SL trajectories varied by group ($trend p < 0.001$). ISS and DSWPD showed increasing SL across trials, with the change being smaller for IH (ISS:slope = 0.92[95% CI:0.57,1.28]; DSWPD:0.97[0.64,1.30]; IH:0.61[0.46,0.76]; all $p < 0.001$). NT1 and NT2 showed stable SL across trials. (NT1:slope = 0.04[95% CI: -0.23,0.32], $p=0.76$; NT2:0.18(-0.03,0.39), $p=0.09$). Nap-level trends of SOREMP trajectories varied by group ($trend p=0.04$). ISS and DSWPD showed declining odds of SOREMPs across trials (ISS:OR = 0.65[95% CI:0.51,0.84], $p < 0.001$; DSWPD:0.69[0.53,0.90], $p=0.007$). NT1 and NT2 showed consistently high and IH consistently low SOREMP frequency (NT1:OR = 0.94[95% CI:0.82,1.08], $p=0.39$; NT2:0.91[0.82,1.01], $p=0.073$; IH:0.87[0.74,1.02], $p=0.091$). REML trajectories also varied across groups ($trend p=0.006$). NT2 and ISS showed increasing REML across trials (NT2:slope = 0.23[95% CI:0.04,0.43], $p=0.019$; ISS:0.67 [0.34,0.99], $p < 0.001$). NT1 showed stable short REML; IH and DSWPD stable long REML

(NT1:slope = 0.23[95% CI: -0.02,0.49], $p=0.075$; IH:0.02[-0.12,0.16], $p=0.78$; DSWPD:0.24[-0.07,0.54], $p=0.13$).

Conclusions: ISS and DSWPD demonstrated progressively increasing SL and declining SOREMP occurrence across successive naps, suggesting influence of fluctuating sleep pressure or circadian misalignment. In contrast, NT1, NT2, and IH exhibited stable SL and consistent SOREMP patterns, indicating persistent hypersomnolence. These findings underscore the utility of nap-by-nap MSLT analysis in differentiating CDH from ISS and DSWPD.

Neurobehavioral features in central hypersomnia disorders: preliminary results of subjective and objective measures

A. Frijó¹, C. Leitner¹, S. Mombelli^{2,3}, F. Casoni¹, P. Proserpio¹, C. Liguori⁴, L. Ferini-Strambi^{1,5}, A. Galbiati^{1,5}

¹Sleep Disorders Centre, Department of Clinical Neurosciences, Neurology, IRCCS San Raffaele Scientific Institute, Milan, Italy, ²Department of Psychiatry and Addictology, Université de Montréal, Montreal, Canada, Montréal, Canada, ³Center for Advanced Research in Sleep Medicine, Research center of the Centre intégré universitaire de santé et de services sociaux du Nord de l'Île-de-Montréal, Montreal, Canada, Montréal, Canada, ⁴Sleep Medicine Center, Department of Systems Medicine, University of Rome Tor Vergata, Rome, Italy, ⁵Department of Psychology, "Vita-Salute" San Raffaele University, Milan, Italy

Introduction: Central disorders of hypersomnolence (CDH), such as narcolepsy and idiopathic hypersomnia, are characterized not only by excessive daytime sleepiness but also by cognitive impairments, mood disturbances, and autonomic dysregulation. Despite their clinical relevance, the interplay between these dimensions remains poorly understood, particularly in terms of how subjective experiences relate to objective physiological and behavioral measures. This study explores the relationship between depressive symptoms, autonomic arousal, and neurobehavioural performance in patients with CDH, integrating subjective and objective measures.

Materials and methods: Nineteen patients with CDH (M/F 7/12; mean age 29.15±8.49 years) and sixteen healthy controls (M/F 7/9; mean age 27.65±7.53 years) were recruited. Patients were diagnosed according to ICSD- 3-TR criteria, based on clinical interview, overnight polysomnography, and the Multiple Sleep Latency Test with four naps. Subjective measures included the Epworth Sleepiness Scale (ESS) for daytime sleepiness and the Patient Health Questionnaire-9 (PHQ-9) for depressive symptoms. Objective measures included pupillometry, assessing baseline pupil diameter and the pupil light reflex (PLR), and the Psychomotor Vigilance Test (PVT) which evaluates sustained attention and response speed. Group comparisons were conducted using Mann-Whitney U tests for non-parametric variables. Spearman correlations were used to explore associations between subjective and objective measures. Statistical significance was set at $p < 0.05$.

Results: ESS scores were significantly higher in CDH patients compared to controls ($W = 20.500$, $p < .001$), as were PHQ-9 scores ($W = 31.500$, $p < .001$). No significant differences emerged between groups in pupillometry parameters or PVT performance. Interestingly, depressive symptoms (PHQ-9) were negatively correlated with PLR latency (i.e., time between light stimulus and pupil constriction onset) ($r = -0.723$, $p = 0.018$). Additionally, a significant negative correlation was found between PVT anticipations and baseline pupil diameter ($r = -0.648$, $p = 0.023$).

Conclusions: The results reveal a dissociation between subjective and objective neurobehavioral markers in individuals with CDH. While subjective sleepiness clearly distinguished patients from healthy controls, objective indices of vigilance and autonomic reactivity did not show significant group differences. Importantly, depressive symptoms were more pronounced in the CDH group, highlighting the potential impact of psychiatric comorbidities that warrants further investigation. The significant negative correlation between PHQ-9 scores and PLR latency suggests that higher depressive symptoms are associated with a faster pupillary constriction response, potentially reflecting altered autonomic regulation. Additionally, the observed association between larger baseline pupil diameter and increased PVT anticipations indicates that higher resting arousal levels may be linked to more impulsive behavior during vigilance tasks. This finding could reflect a compensatory mechanism or a dysregulation in arousal systems affecting inhibitory control. Overall, the study confirms the prominent subjective burden of sleepiness and depression in patients with CDH, despite the absence of consistent objective impairments. These results underscore the need to integrate multimodal assessment tools to

better capture the complexity of CDH and inform more personalized and effective therapeutic strategies.

Prevalence, clinical, and sleep laboratory characteristics among patients presenting with excessive daytime sleepiness in Thailand, a tertiary care setting

P. Nuengjumnong¹, C. Pimolsri², W. Chotinawattarakul³

¹Faculty of Medicine Siriraj Hospital, Mahidol University, Medicine, Bangkok, Thailand, ²Faculty of Medicine Siriraj Hospital, Mahidol University, Siriraj Sleep Center, Bangkok, Thailand, ³Faculty of Medicine Siriraj Hospital, Mahidol University 2, Siriraj Sleep Center, Bangkok, Thailand

Introduction: Excessive daytime sleepiness (EDS) is a significant clinical issue associated with high morbidity, including increased risk of accidents, impaired cognitive performance, and mood disturbances. In Thailand, research on hypersomnolence disorders remains limited. This study aimed to determine the prevalence, clinical features, and sleep laboratory characteristics of patients presenting with EDS at Siriraj Hospital.

Materials and methods: This retrospective study analyzed data from patients who presented with EDS and underwent a Multiple Sleep Latency Test (MSLT) at the Siriraj Sleep Center between January 2018 and December 2023. The primary outcome was the prevalence of hypersomnia disorders. Secondary outcomes included clinical features and sleep laboratory findings.

Results: A total of 99 patients were included in the analysis. Of these, 45.5% were male. The average age was 32 years, the total sleep time was 7.53 ± 1.17 hours, and the mean Epworth Sleepiness Scale (ESS) score was 12.17 ± 5.87 , with significant differences observed among narcolepsy (NC), idiopathic hypersomnia (IH), and sleep insufficiency and others groups ($p = 0.033$) which significant 2-group comparison of idiopathic hypersomnia and others group. The most common diagnosis was sleep insufficiency ($n=18$), followed by obstructive sleep apnea (OSA; $n=15$), idiopathic hypersomnia ($n=14$), and narcolepsy ($n=12$).

Conclusions: Clinical presentations of disorders of hypersomnolence were usually overlapped and most were nonspecific. Objective testing with PSG and MSLT were essential for making a precise diagnosis.

Acknowledgments: Siriraj Sleep Center, Thailand

Risk of Sodium-Associated Negative Clinical Outcomes in Individuals With Idiopathic Hypersomnia in the United States: A Real-World Analysis

S.C. Markt¹, C. Drachenberg¹, P.R. Taub², L.A. Surkin³, K. Easson⁴, J.K. Alexander¹, P. Gagnon-Sanschagrin⁴, M. Whalen⁵, R. Bellefleur⁴, S. Beaty¹, M. Levesque-Leroux⁴, A. Guérin⁴, R.J. Kovacs⁶

¹Jazz Pharmaceuticals, Palo Alto, United States, ²Division of Cardiovascular Medicine, University of California San Diego, San Diego, United States, ³CardioSleep Diagnostics, Greenville, United States, ⁴Analysis Group ULC, Montreal, Canada, ⁵Jazz Pharmaceuticals, Philadelphia, United States, ⁶Cardiology Division, Indiana University School of Medicine, Indianapolis, United States

Introduction: Individuals with idiopathic hypersomnia (IH) experience an elevated prevalence of cardiovascular, cardiometabolic, and renal comorbidities which may be exacerbated by excess sodium. This study aimed to assess the risk of sodium-associated negative clinical outcomes (NCOs) among individuals with IH compared with those without IH, and to evaluate whether risk is further elevated among individuals with pre-existing sodium-associated risk factors.

Materials and methods: Komodo Research Data (01/01/2016–31/01/2024) were used to retrospectively identify US individuals diagnosed with IH (*index*: first-observed IH diagnosis), and a cohort of individuals without IH (*index*: randomly selected date within ≥ 48 months of continuous plan eligibility), using a 1:5 ratio of individuals with and without IH. All individuals were required to have ≥ 12 months' continuous enrolment in both the pre- and post-index periods. Entropy balancing was used to balance demographic characteristics (age, sex, race/ethnicity, US region of residence, health plan type, index year) at index between cohorts. The IH cohort was stratified into higher-risk (≥ 1 sodium-associated risk factor during the 12-month pre-index period) and lower-risk (no risk factors in the pre-index period) subgroups. Sodium-associated NCOs were defined through pragmatic literature review and clinical expert discussion and were categorised as cardiovascular (hypertension, heart failure,

stroke, transient ischaemic attack, major adverse cardiovascular event [MACE; ie, heart failure, stroke, myocardial infarction, unstable angina, or coronary revascularisation procedures]), cardiometabolic (oedema), and renal (proteinuria, chronic kidney disease, kidney failure) conditions. Development of incident NCOs or progression of NCOs were identified during the post-index period. Hazard ratios (HRs) and 95% confidence intervals (CIs) were calculated for each NCO using weighted and unweighted Cox proportional hazards model to compare 1) the IH and non-IH cohorts and 2) the higher- and lower-risk IH subgroups.

Results: After balancing, demographics were similar between the IH (n=11,951) and non-IH (n=59,755) cohorts (mean [standard deviation] age: 41.7 [15.7] vs 41.8 [16.0] years, respectively; 66.4% female in both cohorts). Individuals with IH had a higher risk (HR [95% CI]) of any NCO versus individuals without IH (1.71 [1.64–1.77]). Specifically, risk (HR [95% CI]) of hypertension (1.68 [1.61–1.76]), MACE (1.49 [1.30–1.71]), oedema (1.75 [1.58–1.93]), and renal NCOs (1.42 [1.29–1.57]) was higher in individuals with versus without IH. Among individuals with IH, 63.1% were defined as higher-risk (n=7542). Higher-risk individuals had an increased risk (HR [95% CI]) of any NCO relative to lower-risk individuals (1.68 [1.56–1.81]). Further, higher-risk individuals had increased risk (HR [95% CI]) of hypertension (1.36 [1.26–1.47]), MACE (15.63 [8.31–29.39]), oedema (7.17 [5.29–9.72]), and renal NCOs (6.59 [4.89–8.89]) versus lower-risk individuals.

Conclusions: Individuals with IH have an elevated risk of developing incident or experiencing progression of cardiovascular, cardiometabolic, and renal NCOs versus individuals without IH. Many individuals with IH had pre-existing sodium-associated risk factors, for whom the risk of NCOs was particularly heightened. These results emphasise the need to reduce sodium intake and mitigate the risk of NCOs among individuals with IH, especially for those with pre-existing comorbidities.

Sleep Actigraphy in Participants With Narcolepsy or Idiopathic Hypersomnia Taking Low-Sodium Oxybate: Results From the DUET Study

N. Foldvary-Schaefer¹, R.B. Sangal^{2,3}, K. Maski⁴, D.A. Nichols⁵, T.L. Steininger⁵, J. Dai⁵, M.T. Kirby^{6,7}, M. Whalen⁶, A. Cairns⁶, D.T. Plante⁸

¹Sleep Disorders Center, Department of Neurology, Cleveland Clinic, Cleveland, United States, ²Sleep & Attention Disorders Institute, Sterling Heights, United States, ³Oakland University William Beaumont School of Medicine, Rochester, United States, ⁴Department of Neurology, Boston Children's Hospital, Boston, United States, ⁵Jazz Pharmaceuticals, Palo Alto, United States, ⁶Jazz Pharmaceuticals, Philadelphia, United States, ⁷Department of Psychiatry & Health Behavior, Medical College of Georgia at Augusta University, Augusta, United States, ⁸Department of Psychiatry, University of Wisconsin–Madison, Madison, United States

Introduction: Actigraphy provides an empirical, noninvasive, continuous method for monitoring sleep patterns in real-world settings. Jazz DUET (Develop hypersomnia Understanding by Evaluating low-sodium oxybate Treatment) was a phase 4, prospective, multicentre, single-arm, multiple-cohort, open-label study (NCT05875974) evaluating effectiveness of low-sodium oxybate (LXB; Xywav®) on daytime and nighttime-related signs and symptoms in participants with narcolepsy or idiopathic hypersomnia.

Materials and methods: DUET included a screening period (with 2-week washout for oxybate users), 8-day baseline (BL) period, 2- to 8-week LXB titration period, 2-week stable-dose period (SDP), 8-day end-of-treatment (EOT) period, and 2-week safety follow-up period. Participants wore a wrist actigraphy device (GENEActiv; 3-axis accelerometer, measurement frequency set to 20 Hz for continuous recording up to 30 days) during BL, SDP, and EOT. Exploratory outcomes (from BL to EOT; uncontrolled for multiplicity) included total nocturnal sleep duration, number of awakenings, sleep onset latency (SOL), and wake after sleep onset (WASO). Least-squares means (LSM) were adjusted for BL values using ANCOVA.

Results: Fifty-five participants with narcolepsy and 46 with idiopathic hypersomnia enrolled and took LXB for ≥1 night; 13 narcolepsy participants transferred to a different cohort (analysed separately); 34 and 40 completed the study, respectively. In narcolepsy and idiopathic hypersomnia cohorts, respectively, participants were mostly female (72.7%; 80.4%) and White (80.0%; 84.8%), with a mean (SD) age of 33.4 (12.9) and 38.1 (11.8) years. Participants with evaluable actigraphy data at BL and EOT (≥5 of 8 days in each) were n=22 (narcolepsy) and n=32 (idiopathic hypersomnia); missing data were due to device failures, insufficient wear time, and electronic capture/transfer errors. Mean (SE) total

nocturnal sleep duration (minutes) was similar from BL to EOT for narcolepsy (418.7 [16.5] to 397.4 [18.8], LSM [SE] change, -21.3 [15.8], $P=0.1949$), and reduced for idiopathic hypersomnia (410.6 [11.8] to 386.0 [11.0], LSM change [SE] -24.6 [7.7], $P=0.0035$). Mean (SE) number of awakenings reduced from BL in both cohorts: narcolepsy, 22.4 (1.0) to 18.6 (0.9), LSM change (SE), -3.8 (0.9), $P=0.0003$; idiopathic hypersomnia, 21.4 (0.9) to 18.0 (1.0), LSM change (SE), -3.4 (0.6), $P<0.0001$. Mean (SE) SOL (minutes) showed no change in narcolepsy (8.6 [1.4] to 12.7 [2.5], LSM change [SE], 4.1 [2.5], $P=0.1204$) and increased from BL in idiopathic hypersomnia (5.7 [0.9] to 10.3 [1.6], LSM change [SE], 4.6 [1.6], $P=0.0073$). Mean (SE) WASO duration (minutes) reduced from BL in narcolepsy (179.0 [11.9] to 160.5 [7.3], LSM change [SE], -18.5 [7.4], $P=0.0211$) and showed no change in idiopathic hypersomnia (161.8 [5.4] to 137.7 [9.1], LSM change [SE], -10.8 [8.7], $P=0.2244$). Treatment-emergent adverse events were consistent with the known safety profile of LXB.

Conclusions: Based on actigraphy, participants with narcolepsy taking LXB showed decreased awakenings and WASO duration, suggesting less disrupted sleep with treatment, compared with BL (off-treatment). Participants with idiopathic hypersomnia taking LXB showed decreased total nocturnal sleep time, and fewer awakenings, which may reflect more restorative sleep. These results augment previously reported polysomnography findings in these participants, adding to the established effectiveness of LXB treatment for narcolepsy and idiopathic hypersomnia.

Sleep architecture with low-sodium oxybate treatment in idiopathic hypersomnia: results from the DUET study

A. Cairns¹, R.K. Bogan², N. Foldvary-Schaefer³, D.A. Nichols⁴, T.L. Steininger⁴, D.S. Fuller¹, J.K. Alexander⁴, D.T. Plante⁵

¹Jazz Pharmaceuticals, Philadelphia, United States, ²University of South Carolina School of Medicine, Columbia, United States, ³Sleep Disorders Center, Neurological Institute, Cleveland Clinic, Cleveland, United States, ⁴Jazz Pharmaceuticals, Palo Alto, United States, ⁵University of Wisconsin–Madison, Madison, United States

Introduction: Jazz DUET (Develop hypersomnia Understanding by Evaluating low-sodium oxybate Treatment) was a phase 4, prospective, multicentre, single-arm, multiple-cohort, open-label study (NCT05875974) evaluating the effectiveness of low-sodium oxybate (LXB; Xywav[®]) treatment on daytime and nighttime-related signs and symptoms, including polysomnography (PSG)-based sleep architecture, in participants with idiopathic hypersomnia or narcolepsy. This abstract includes results from the idiopathic hypersomnia cohort.

Materials and methods: DUET included a screening period (2-week washout for current oxybate users), 8-day baseline period (BL; with overnight PSG and assessments on day 8), 2- to 8-week LXB titration period (participants initiated LXB treatment with individualised dosing adjustments to achieve their optimal dosage), 2-week stable-dose period (SDP), 8-day end-of-treatment period (EOT; with overnight PSG and assessments on day 8), and 2-week safety follow-up. Nocturnal PSGs were scheduled using an *ad libitum* protocol, allowing a minimum of 10 hours in bed, unless the participant naturally awakened earlier; bedtime was determined by habitual bedtime. PSG recordings were centrally scored. Exploratory PSG endpoints were analysed in the idiopathic hypersomnia cohort completer set; least squares mean (LSM) changes were adjusted for baseline values. Total shifts from deeper to lighter sleep/wake stages were defined as N1/N2/N3/REM to wake and N2/N3/REM to N1. P values were uncontrolled for multiplicity and therefore considered nominal.

Results: Forty-six participants with idiopathic hypersomnia enrolled and took ≥ 1 LXB dosage (safety set); 40 completed the study (completer set). In the safety set, most participants were female (80%) and White (85%) with a mean (SD) age of 38.1 (11.8) years. In the completer set, mean (SE) total sleep time (TST) at BL and EOT was 467.5 (17.7) and 413.4 (15.5) minutes, respectively (LSM change [95% CI], -54.1 [-81.3, -26.9]; $P=0.0003$). Mean (SE) total number of shifts from deeper to lighter sleep/wake stages at BL and EOT was 60.9 (4.8) and 43.7 (4.3), respectively (LSM [95% CI]: -17.1 [-23.7, -10.5]; $P<0.0001$). Mean (SE) time spent in N1 sleep at BL and EOT was 47.8 (4.1) and 33.0 (3.5) minutes (LSM [95% CI]: -14.8 [-20.3, -9.3]; $P<0.0001$), percentage of sleep stage per TST was 10.3% and 8.0% ($P=0.0017$); in N2 sleep, 270.0 (10.2) and 225.8 (11.5) minutes (LSM [95% CI]: -44.3 [-66.7, -21.9]; $P=0.0003$), 58.5% and 54.2% ($P=0.0286$); in N3 sleep, 51.9 (5.6) and 92.5 (8.5) minutes (LSM [95% CI]:

40.6 [25.8, 55.4]; $P < 0.0001$), 11.2% and 22.8% ($P < 0.0001$); and in REM, 97.7 (7.4) and 62.1 (5.6) minutes (LSM [95% CI]: -35.7 [-46.0, -25.3]; $P < 0.0001$), 20.0% and 15.0% ($P < 0.0001$).

Conclusions: Participants with idiopathic hypersomnia treated with open-label LXB demonstrated reduced TST on *ad libitum* PSG versus BL, with corresponding increases in N3 sleep, decreases in N1, N2, and REM, and reduced stage shifts. These results suggest a potential correction of the underlying differences in sleep architecture between people with idiopathic hypersomnia and controls that have been described previously in a meta-analysis. These findings also represent the first evaluation of the impact of LXB treatment on PSG sleep architecture in individuals living with idiopathic hypersomnia.

Tonic immobility evaluation in patients with primary hypersomnias with motor paralysis triggered by emotions

B. Sarmieiro¹, L. Catarina Lima Portugal¹, C. Martins Correa da Silva²

¹Rio de Janeiro State University, Neurophysiology Lab, Physiologic Department, Biomedic Center (IBRAG), Rio de Janeiro, Brazil, ²Rio de Janeiro State University, Neurology, Rio de Janeiro, Brazil

Introduction: Tonic immobility (TI) is characterized by a reversible, intense state of motor inactivity and reduced responsiveness exhibited by many vertebrates when facing situations of extreme fear or inescapable threat. This behavior is considered the last defense mechanism in the context of potential overwhelming danger. TI has also been studied as a common response in humans with post-traumatic stress disorder (PTSD), particularly in victims of sexual assault. Patients with narcolepsy experience a motor phenomenon called cataplexy that is triggered by emotions. While typical cataplexy is associated with hypocretin deficiency and the presence of HLA-DQB1*06:02, which are features of narcolepsy type 1, atypical cataplexy can occur in both narcolepsy type 1 (NT1) and type 2 (NT2). Its underlying mechanisms remain unclear, but psychiatric factors are considered one of the primary suspected causes.

Materials and methods: Patients with primary hypersomnia were previously diagnosed with NT1, NT2 and Idiopathic Hypersomnia (IH) according to ICSD-3 criteria. They were classified into NT1 and NT2 based on cerebrospinal fluid (CSF) hypocretin levels—low in NT1 and normal in NT2. All patients underwent genetic testing for high-definition HLA types. Those presenting with cataplexy, atypical cataplexy, or other motor phenomena triggered by emotions with paralysis were evaluated for trauma history, presence of PTSD and depression, and signs of TI. To assess trauma history, the Life Events Checklist-5 (LEC-5) was used. This assessment was followed by the Tonic Immobility Scale (TIS) to evaluate the TI response during or immediately after the worst traumatic (TIS trauma) experience and during episodes of motor phenomena triggered by emotions (TIS Motor Paralysis). To gain further insight into their mental health, two additional psychometric scales were administered: the PTSD Checklist for DSM-5 (PCL-5) and the Patient Health Questionnaire-9 (PHQ-9).

Results: Of the 68 patients with primary hypersomnia, 25 patients who reported emotion-triggered motor events with paralysis were included. Of these, 14 had NT1 (low hypocretin); all were positive for HLA-DQB1*06:02. Eight had normal hypocretin (6 NT2 and 2 IH) and three had no hypocretin data. Typical cataplexy, considered present if the patient presented symptoms with laughter lasting less than 2 minutes, was present in 12 patients with NT1, while atypical episodes, involving only negative emotions, asymmetrical or lasting more than 5 minutes, were reported by all NT2 and IH patients. Comparing TIS trauma and TIS motor paralysis we found a greater positive correlation (Pearson coefficient) in the group with atypical cataplexy ($r^* = 0.8$, CI = 0.44-0.94, $p = 0.0006$) than in the group with typical cataplexy ($r^* = 0.64$, CI 0.11-0.89, $p = 0.012$). Using the t test, we also found significantly higher scores in TIS trauma ($p = 0.04$) and TIS motor paralysis (0.03) in the group with atypical cataplexy compared to typical cataplexy.

Conclusions: This is the first study to assess tonic immobility (TI) symptoms in primary hypersomnia patients categorized by biomarkers such as hypocretin levels and HLA status. These results open a discussion about the pathophysiology of atypical motor phenomena triggered by emotions with paralysis that are not related to hypocretin deficiency.

Acknowledgments: Thanks to Prof. Emmanuel Mignot for the hypocretin measurements of the research.

Insomnia

Aberrant Effective Connectivity Within and Between the Default Mode Network, Executive Control Network and Salience Network in Chronic Insomnia Disorder – towards identifying the hyperarousal state

T. Georgiev¹, R. Paunova², T. Zdravkova², K. Avramov², A. Draganova², K. Terziyski¹

¹Medical University - Plovdiv, Pathophysiology, Plovdiv, Bulgaria, ²Medical University - Plovdiv, Plovdiv, Bulgaria

Introduction: The hyperarousal hypothesis is a key conceptual model for the pathogenesis of chronic insomnia disorder (CID). The model is based on the observed persistent state of physiological, cognitive, and emotional hyperactivation in CID patients, but its neurofunctional mechanisms are not fully understood.

Resting state functional MRI studies in CID patients have demonstrated altered functional connectivity (FC) in the default mode network (DMN), executive control network (ECN) and salience network (SN), which are involved in self-referential processing, internal mentation, emotional plasticity, and goal-directed attention.

While FC offers insights into co-activation patterns among brain regions, it does not provide directionality or causality of these interactions. In contrast, effective connectivity (EC) describes the influence of one brain region over another, incorporating temporal and causal effects of the regions in a neural circuit.

We hypothesized that effective connectivity between key nodes of the DMN, ECN and SN is disrupted in individuals with CID, impairing the SN's ability to modulate and “switch” between DMN and ECN, as the neurofunctional substrate of the hyperarousal state in CID.

Materials and methods: We recruited 31 CID patients, compliant with the ICSD-II/TR criteria, and 24 age-, sex-, and education-matched healthy controls (HC). All participants filled out Insomnia severity index (ISI), Beck depression inventory (BDI) and Epworth sleepiness scale (ESS) and were scanned on a 3T MRI system, obtaining structural and functional data. SPM 12 (Statistical Parametric Mapping) was used to analyse the results. Spectral dynamic causal modelling (spDCM) was applied to the chosen regions of interest (ROIs) within and between the DMN, SN and ECN. One-sample test was used to define the connections significantly different from zero within each group, and two-sample test was performed to determine the connections significantly different between both groups. Two-stage false discovery rate correction was applied.

Results: There were three significant connections, present only in the CID group – suppressive from the dorsolateral prefrontal cortex (DLPFC) to the right hippocampus (HippR) (-0.110 ± 0.258 , $p=0.035$), excitatory from the dorsomedial prefrontal cortex (DMPFC) to the ventromedial prefrontal cortex (VMPFC) (0.206 ± 0.342 , $p=0.018$), and excitatory from the common medial prefrontal cortex (MPFC) to the right anterior insula (AIR) (0.067 ± 0.172 , $p=0.019$). The analysis in the control group revealed two significant excitatory connections – from the posterior cingulate cortex (PCC) to AIR (0.148 ± 0.242 , $p=0.001$), and from precuneus to PCC (0.441 ± 0.388 , $p=0.033$), which are absent in the patients' group. In addition, CID patients scored higher on the ISI (18 ± 4.00 vs 4 ± 2.85 , $p < 0.001$) and BDI (13 ± 7.57 vs 5 ± 4.72 , $p < 0.001$) questionnaires compared to HC. Significant negative correlations between DLPFC to HippR connectivity and both ISI ($\rho = -0.507$, $p < 0.001$) and BDI ($\rho = -0.272$, $p < 0.05$) scores were identified.

Conclusions: Our results indicate that effective connectivity among the DMN, ECN and SN is altered in individuals with CID. Disruptions within the DMN and between the DMN, SN and ECN reflect an impaired ability to appropriately shift between internally and externally directed cognitive states—an imbalance potentially underlying the hypervigilant state of CID.

Acknowledgments: This study was funded by the Medical University of Plovdiv, Bulgaria.

Actigraphy-Derived Circadian Rhythm Patterns as the Predictors of Anxiety and Depression in Individual with Insomnia Symptoms: Results of Principal Component Analysis

M. Zhou¹, C.X. Chen¹, W.I. Ao¹, S.X.T. Wang¹, C.C.H. Sin¹, S. Xie¹, S. Chen¹, J.W.Y. Chan¹, Y.K. Wing², N.Y. Chan¹

¹The Chinese University of Hong Kong, Department of Psychiatry, Li Chiu Kong Family Sleep Assessment Unit, Shatin, Hong Kong, SAR of China, ²The Chinese University of Hong Kong, Department of Psychiatry, Li Chiu Kong Family Sleep Assessment Unit, and Faculty of Medicine, Li Ka Shing Institute of Health Sciences, Shatin, Hong Kong, SAR of China

Introduction: Emerging evidence links insomnia, circadian rhythm disruption, and mood disorders like anxiety and depression. However, the specific associations between disrupted circadian patterns and mood disorders in insomnia are not well understood. This study examined these relationships in adults with insomnia symptoms.

Materials and methods: Participants were community-dwelling residents from Hong Kong with insomnia (Insomnia Severity Index, ISI ≥ 10), excluding those with comorbid Major Depressive Disorder (MDD) and anxiety disorders. They completed 7-day wrist actigraphy using the ActiGraph GT3X, and mood disorders were assessed via the Structured Clinical Interview for DSM-5 Disorders (SCID-5). Six circadian rhythm parameters were extracted to assess rhythm stability, fragmentation, and day-night activity distribution, including Interdaily Stability (IS), Intradaily Variability (IV), average activity intensity and onset time of the lowest 5-hour nocturnal period (L5, L5hr), and the highest 10-hour diurnal period (M10, M10hr). Principal Component Analysis (PCA) was applied for dimensionality reduction, with components explaining more than 15% of the variance retained, supported by the elbow point in the scree plot. Multivariate logistic regression (adjusting for sex, age, education, marital status, employment, income, BMI, ISI score, and sleep duration) examined associations between circadian dimensions and MDD and Generalized Anxiety Disorder (GAD). To validate the findings, XGBoost models were used, with SHAP values determining feature importance and contribution.

Results: A total of 267 participants (Mean age: 43.4 years, 20.6% male) were included. Among them, 17 (6.4%) had GAD and 18 (6.7%) had MDD. Based on PCA, three principal components were extracted: Dimension 1 (Dim.1, 31.6% of variance), Dim.2 (22.4%), and Dim.3 (19.5%), together accounting for 73.5% of the total variance. Dim.1 was characterized by a delayed circadian phase (M10hr, L5hr), high IV, low IS, and lower daytime activity (M10), reflecting a delayed, unstable, and disorganized rhythm pattern. Dim.2 showed a delayed circadian phase with high IS and low IV, indicating a delayed yet well-consolidated rhythm structure. Both higher Dim.1 and Dim.2 were associated with younger age. Dim.3 was associated with elevated daytime and nighttime activity levels and low IS, suggesting reduced day-night differentiation. Results showed that Dim.1 was significantly associated with a higher probability of MDD (OR = 1.61, 95% CI: 1.12–2.31), and Dim.2 with GAD (OR = 1.69, 95% CI: 1.09–2.64). The XGBoost models showed good predictive performance, with AUCs of 0.88 for MDD and 0.78 for GAD. SHAP values indicated higher Dim.1 values were correlated with higher risk of MDD, and higher Dim.2 with higher risk of GAD.

Conclusions: The concurrence of insomnia and a delayed, irregular and disorganized circadian rhythm pattern were associated with higher risk of MDD, while that of insomnia with a delayed but regular circadian pattern are associated with higher risk of GAD. Future research is needed to determine whether treating different subtypes of circadian rhythm patterns in insomnia could alleviate mood symptoms and even prevent the onset of mood disorders.

A Multidimensional Risk Model for Sleep Disturbances in Psychosomatic Rehabilitation Patients

J. Faber¹, P. Bommersbach², A.A. Schlarb¹

¹Bielefeld University, Bielefeld, Germany, ²Eifelklinik Manderscheid, Manderscheid, Germany

Introduction: Sleep disturbances and insomnia are highly prevalent among patients in psychosomatic rehabilitation. With high comorbidity and complex health profiles, these patients are especially vulnerable to chronic insomnia. This study aimed to develop a theoretical model integrating diverse risk and protective factors influencing sleep outcomes in this vulnerable group.

Materials and methods: A randomized sample of 356 patients (mean age = 49.04, SD = 9.96; 51.2% female) was drawn from a pool of 2,179 admissions. At admission, participants completed standardized assessments on sleep quality, insomnia, mental and physical health, and lifestyle factors.

Results: Poor sleep quality affected 81.1% of patients, and 64.1% met criteria for insomnia. Regression and path analyses identified mental and physical health, stress, lifestyle behaviours, and environmental factors as significant predictors of sleep outcomes (sleep quality: $F[13,150] = 4.401, p < .001$; insomnia: $\chi^2[13] = 25.842, p = .018$). Somatic complaints emerged as the most robust single predictor.

Conclusions: Findings support a comprehensive, multidimensional model of sleep disturbances that accounts for psychological, physiological, and behavioural factors. These insights highlight the need for integrated treatment strategies in psychosomatic rehabilitation settings.

Analysis of the clinical effect of pulsed electromagnetic field on primary insomnia

J. Chen¹, Y. Tian², Q. Ma²

¹The Xuanwu Hospital Capital Medical University, Beijing, China, ²The First Hospital of Hebei Medical University, neurological department, Shijiazhuang, China

Introduction: To investigate the therapeutic effect of pulsed electromagnetic fields (PEMFs) on primary insomnia.

Materials and methods: A total of 120 patients with primary insomnia admitted to the The First Hospital of Hebei Medical University from January to December 2021 were randomly divided into conventional treatment and sham stimulation group (control group) and conventional treatment and PEMFs stimulation group (PEMFs group), with 60 patients in each group. Before and after 2 weeks of treatment, Pittsburgh Sleep Quality Index (PSQI) was used to evaluate the sleep quality, and Insomnia Severity Index (ISI) was used to evaluate the severity of insomnia.

Results: The total effective rate of PEMFs group was higher than that of control group [81.67% (49/60) vs. 41.67% (25/60); $\chi^2 = 20.306, P = 0.000$]. After treatment, the total PSQI score ($F = 228.729, P = 0.000$), sleep quality ($F = 87.291, P = 0.000$), time to fall asleep ($F = 181.842, P = 0.000$), sleep time ($F = 143.355, P = 0.000$) and ISI score ($F = 361.348, P = 0.000$) of the 2 groups were significantly lower than those before treatment. PSQI total score ($F = 13.297, P = 0.000$), sleep quality ($F = 7.573, P = 0.007$), time to fall asleep ($F = 9.776, P = 0.002$), sleep time ($F = 8.566, P = 0.004$), and ISI score ($F = 5.350, P = 0.000$) in PEMFs group after treatment were significantly lower than those of the control group.

Conclusions: PEMFs are safe and effective in the treatment of patient with primary insomnia, which can significantly improve the sleep quality, and can be used as a non - drug treatment for patients with primary insomnia.

A new model of care for men with depression and co-occurring insomnia in primary care: A feasibility and acceptability trial

J. Haycock¹, A. Reynolds¹, R. Adams^{1,2}, N. Lovato¹

¹Flinders University, Flinders Health and Medical Research Institute: Sleep Health, Adelaide, Australia,

²Southern Adelaide Local Health Network, SA Health, Respiratory and Sleep Services, Adelaide, Australia

Introduction: Mental health disorders are very common in men and 75% of suicides are in men. Despite this, men frequently do not seek help for mental health, and depression in men is often unmanaged.

Ninety percent of men with depression experience insomnia, but insomnia is completely neglected in depression management. As men may be more comfortable talking about their sleep than mental health, insomnia is a way to “open the door” on mental health for men. Research shows that psychological treatment of insomnia has a large therapeutic benefit on depression and reduces suicidal ideation. This aim of this research program was to implement a feasibility and acceptability trial for a scalable, cost-effective new model of care for men suffering depression and co-occurring insomnia.

Materials and methods: Male patients (aged 18-80 years) with probable insomnia disorder (Sleep Condition Indicator (SCI) total score ≤ 16 and symptoms present for at least 3 months), and depressive symptoms (Patient Health Questionnaire (PHQ-9) score ≥ 5) were invited to take part in a treatment study conducted within primary care. Participants were offered nurse delivered Brief Cognitive

Behavioural Therapy for insomnia (CBTi) which included 4 weekly sessions of 30-45 minutes, which has strong supporting evidence for the treatment of insomnia when tailored for primary care. Participants completed the SCI and PHQ-9 at pre-treatment and 3-month follow up. To date, 19 participants have completed 3-month follow-up. Semi structured qualitative interviews were conducted with practice staff and patients to explore their experiences of the treatment and suggestions for future development, to identify potential barriers and facilitators to delivery of the treatment program in primary care.

Results: A total of 28 men participated in this study (Age mean=56.1 years, SD=17.0). Baseline scores prior to treatment indicate probable insomnia disorder (SCI mean=8.5, SD=4.9) and moderate depression (PHQ-9 mean=13.5, SD=5.1). Data from the 19 men who have completed 3-month follow-up to date indicate significant improvements in insomnia symptoms from pre (SCI mean=9.8, SD=4.4) to post treatment (SCI mean=21.5, SD=4.6, $p<.001$). Depressive symptoms also improved from pre (PHQ-9 mean=13.0, SD=5.3) to post treatment (PHQ-9 mean=5.1, SD=3.7, $p<.001$). These improvements were also clinically meaningful for both insomnia symptoms (mean change 11.6; Reliable Change Index [RCI]=7) and depression (mean change 7.9; Minimal Clinically Important Difference [MCID]=5). The semi-structured interviews highlighted that nurse time and GP support were critical to the positive patient experience and engagement in the treatment.

Conclusions: Treating insomnia has a positive impact on both sleep and depressive symptoms in men with comorbid depression and insomnia. Preliminary results show the delivery of nurse based CBTi is both acceptable and feasible within primary care. Further research needs to consider funding models to allow for early detection and treatment of co-occurring depression and insomnia.

An investigation of lighting interventions to modify sleep quality in University students

K. Sexton-Radek¹

¹Elmhurst University, Psychology, Elmhurst, United States

Introduction: Sleep quality in young adult university students is poor, with fragmented sleep, long sleep onset latencies, and reduced total sleep time. The common influential factors of social and work schedules and stress have been identified as triggers and outcomes of poor sleep. The known role of lighting's influence on the circadian rhythm is also a significant factor in young adult university students' sleep with their dependence on electronic devices, thus constantly stimulating visual neuromuscular pathways when checking their social media. The aim of the investigation was twofold: to measure adherence to abstaining from electronics one hour before bedtime and the utility of exposure to lighting that facilitates relaxation and focus.

Materials and methods: This IRB-approved study invited participants from a midwestern university to participate in the survey in exchange for course credit. Seven undergraduates with a mean age of 20.9 years participated in the study. There were four females and three males. All participants were interviewed using a standard sleep history intake interview and were requested to keep a sleep log for two weeks. A random assignment of lighting conditions was given, and each participant returned to their residence hall room at two assigned times for twenty minutes of light exposure in the room. The rooms were measured by a light meter, and an app-controlled bright bulb and lamp were provided with the lighting assignment. A calm, focused, and ordinary lighting exposure was assigned mid-morning for twenty minutes and again in midafternoon.

Results: The participants were generally mildly sleep deprived, with an average at the onset of the study of 68% sleep efficiency. At the end of week one, the average sleep efficiency was 72%, and after week two, the average sleep efficiency was 77%. A statistically significant chi-square index was obtained in comparing the calm lighting condition and sleep efficiency but not with the focus or ordinary lighting conditions. On study evaluation forms, participants rated the morning lighting time and morning lighting condition of calm lighting settings as highly favorable at 94%. The degree of sleepiness, a positive history of transient insomnia centered on the anticipation of stressful events such as an exam variable, and a favorable rating of the focus lighting condition was associated as measured nonparametric correlation. All participants reported compliance with no electronics one hour before bedtime.

Conclusions: Young adult university students have poor sleep health. The commonly reported factors of extreme social schedules, devaluing sleep, and stress influence and result from poor sleep health. It

is plausible that a lighting variable proposed to sleepers may be helpful, much like the sleep hygiene lists. Modifying one's lighting exposure to alter the activation experienced throughout the day may be a valuable and easy intervention for the young adult university student. The reliance on electronics becomes an asset here, where the lighting levels could be checked before sitting in that zone for twenty minutes. The study is planned to continue, and with more participants, the effects of lighting on sleep quality in young adult university students will be further examined.

A pilot survey of Australian health professionals on melatonin use in typically developing children with chronic insomnia

V. Saddi¹, D. Van², A. Teng³

¹Sydney Children's Hospital/Bankstown Lidcombe Hospital/University of New South Wales, Sleep Medicine, Sydney, Australia, ²Bankstown Lidcombe Hospital, Paediatrics, Sydney, Australia, ³Sydney Children's Hospital/ University of New South Wales, Sleep Medicine, Sydney, Australia

Introduction: Although melatonin is commonly used in children with insomnia, data regarding its prescription practices in Australia are scarce. This pilot survey aims to describe melatonin use by a cohort of Australian health professionals in typically developing children with chronic insomnia.

Materials and methods: A cross-sectional open survey was administered to a cohort of Australian health professionals electronically across three states (NSW, Victoria and Queensland), collecting information about melatonin prescribing practices in typically developing children. Participants were recruited at a paediatric conference event. Data collection included the following variables: patient age range, dosages used, time of administration, treatment duration, association with other treatments, perceived efficacy, and side effects. Data are expressed as a percentage of total responses

Results: A total of 101 health professionals responded to the survey. This included 48 Paediatricians, 45 General Practitioners and 8 Psychiatrists. Majority (95.4%) used melatonin in clinical practice. Melatonin was prescribed in all ages (including under 2 years of age), but most frequently used in those aged 10 years and over (54.2%). The most common indication was difficulty falling asleep (84.9%). Other prominent indications included parental request (26.4%), anxiety (21.7%), daytime irritability (9.4%) and movements in sleep (7.5%). Most combined use of melatonin with good sleep habits (92.4%). Other prominent medications used consisted of clonidine (31.4%), antihistamine (16.2%) and tricyclic antidepressants (10.5%). Many practitioners continued melatonin use for over 3 months duration (34.3%), with some electing to continue until sleep improved (21.9%). A total of 28.6% participants reported any side effects related to melatonin. These were mild and included headaches, nightmares, vivid dreams, bed wetting, tiredness, daytime somnolence, parasomnias and worsening daytime behaviour. A significant percentage (41%) of participants have ever recommended that patients purchase melatonin from overseas.

Conclusions: This pilot survey demonstrates that no clear consensus exists about the use of melatonin in typically developing children among the surveyed participants. There is a need for clear guidance and further education with the development of an Australia-wide guideline to rationalise and optimise the use of melatonin in children.

App-delivered sleep therapy for older individuals with insomnia (The ASTEROID Study): A randomised controlled trial

C. Gordon^{1,2}, M. Rahimi², C. Hoyos^{1,2}, J. Chapman^{1,2}, D. Bartlett^{1,2}, N. Marshall^{1,2}, N. Glozier³, S. Naismith⁴, H. LaMonica³, R. Grunstein^{1,2,5}

¹Macquarie University, Faculty of Medicine, Health and Human Sciences, Sydney, Australia, ²Woolcock Institute of Medical Research, CIRUS Centre for Sleep and Chronobiology, Sydney, Australia, ³University of Sydney, Sydney Medical School, Sydney, Australia, ⁴University of Sydney, Healthy Brain Ageing Program, Sydney, Australia, ⁵Royal Prince Alfred Hospital, Sydney Local Health District, Sydney, Australia

Introduction: Behavioural therapy for insomnia using sleep restriction is a decompartmentalised form of CBTi but has not been tested in older adults with insomnia. This study investigated the efficacy of digital behavioural therapy for insomnia (dBTi) compared to digital sleep health education (active

control) at reducing insomnia symptoms (Insomnia Severity Index: ISI) in older adults with insomnia at 8 weeks.

Materials and methods: The ASTEROID study was a 2-arm single-blind, randomised controlled trial. Participants were randomised to either dBTi or sleep health education. Recruitment was online and participants were ≥ 60 years, had an ISI ≥ 10 and access to a smartphone. Exclusion criteria: shift workers, recent travel (>2 h time zone), serious medical or psychiatric conditions, high risk of sleep disorders, and recent psychotherapy for insomnia (~ 12 months). The intervention (dBTi) was delivered using SleepFix, a mobile application providing sleep restriction over 6 weeks and the control consisted of three bi-weekly digital modules about sleep, insomnia and strategies to improve sleep. The primary endpoint was ISI at 8 weeks, with follow-up at 16 and 26 weeks. Secondary outcomes were sleep quality, fatigue, sleepiness, anxiety and depressive symptoms. All analyses were conducted using intention-to-treat. Registration NCT05067569.

Results: Between September 2022 and November 2023 we randomised 273 participants to dBTi ($n=136$) or sleep education ($n=137$). The mean age was 67.9 ($SD \pm 5.6$) years, with 223 (81.7%) females, most were retired ($n=166$, 61%) and had a baseline ISI of 17.2 ± 4.4 . The mean ISI was significantly lower in the dBTi group compared to control at 8 weeks ($p < 0.001$; 10.5 [95% CI $9.2-11.9$] vs 14.1 [$13.1-14.9$]). There were further reductions in ISI at weeks 16 and 26 in the dBTi group compared to control (all $p < 0.001$; week 26: 8.6 [$7.1-10.2$] vs 13.7 [$12.9-15.4$]). The dBTi group also showed improved secondary outcomes at all time points compared to control, except for anxiety symptoms at 26 weeks ($p=0.184$). There was a higher attrition rate in the dBTi group ($n=56$ completers) compared to the control ($n=72$) at 26 weeks.

Conclusions: We have shown sleep restriction therapy administered using a digital therapeutic reduces insomnia symptoms in older people with insomnia and has positive effects on sleep, daytime symptoms and depressive symptoms. Digital-based sleep restriction therapy could be implemented as a first-line treatment in a stepped care model or with psychologist supervision to increase patient accessibility.

Acknowledgments: We would like to acknowledge all the participants in this study.

Applying Tinnitus Retraining Principles to COMISA Desensitisation/Habituation Programs

R. Clancy¹

¹St Luke's Care Hospital; Bondi Respiratory & Sleep; Sydney Sleep Centre; Let Sleep Happen, Psychology, Bondi Junction, Australia

Introduction: COMISA, the co-occurrence of insomnia and obstructive sleep apnea (OSA), poses unique challenges, as CPAP therapy often exacerbates insomnia due to aversive sensations like claustrophobia (mask discomfort) and suffocation (continuous air pressure). Jastreboff and Hazell (2008) note that over 75% of tinnitus sufferers naturally habituate to intrusive sounds, becoming unaware over time unless consciously focusing. This selective perception principle underpins tinnitus retraining therapy (TRT), using white noise to desensitize patients. Similarly, a graded desensitization program for COMISA can habituate patients to CPAP sensations and insomnia hypervigilance-provoking sounds (eg distracting sounds nearby), reducing hypervigilance, insomnia severity (correlated with ISI) and improving CPAP adherence.

Materials and methods: Jastreboff and Hazell's TRT program posits that tinnitus becomes problematic due to selective perception, where emotional significance amplifies awareness. TRT uses CBT to reframe tinnitus as neutral and sound therapy (white noise at decibels slightly above perceived loudness of tinnitus) to facilitate habituation. Over time, patients perceive tinnitus only when intentionally focused, as the brain filters it out. For COMISA, CPAP sensations (Q3: claustrophobia, Q4: suffocation) and sounds (Q7: hissing) are analogous to tinnitus, amplified by hypervigilance common in insomnia. The 8-item COMISA questionnaire identifies specific aversions (e.g., Q5: mask intolerance, Q6: nasal blockages), with higher scores (0–10, strongly disagree to agree) indicating greater distress, correlating with ISI. A TRT-inspired program can desensitize patients by gradually exposing them to CPAP sensations and sounds, reframing them as non-threatening, and fostering habituation to improve sleep quality and CPAP adherence.

A 12-week graded desensitization program for COMISA adapts TRT's sound therapy and CBT principles to address CPAP aversions, using the COMISA questionnaire to tailor interventions. The goal is to reduce selective perception of claustrophobia, suffocation, and mask-related sounds, enabling habituation akin to tinnitus management.

Administer COMISA questionnaire (Q1–Q8, 0–10) and ISI to identify aversions (e.g., Q3: claustrophobia, Q7: hissing) and insomnia severity. Fit CPAP mask with optimal seal; note nasal/sinus issues (Q6). CBTi and Reframing (Weeks 1–2): Educate on core sleep hygiene, stimulus control method & Bed Restriction principles, and education on selective perception: CPAP sensations are amplified by insomnia-related hypervigilance, like tinnitus. Reframe mask sensations as neutral (e.g., “Air pressure supports breathing, not threat of suffocation”), referencing Q4 responses. Graded Sensory Exposure (Weeks 3–6): Air Pressure Introduction, with respiratory specialist's help, setting CPAP machine at low pressure increasing durations, monitoring 'suffocation' scores. Sound Exposure: Introduce white noise/raindrops/fan via phone/electronic device to reduce focus on external sounds of traffic or bed environment & “bat away” ruminative or obsessive thoughts, fading over time as alternative association develops & habituation occurs.

Results: pending preliminary patients' data (July 2025)

Conclusions: By adapting TRT's principles, COMISA sufferers can condition positive CPAP associations & reducing insomnia severity and improving adherence. The desensitization program leverages graded exposure to aversive auditory/proprioceptive stimuli, mirroring tinnitus habituation, where sufferers can learn to ignore perceived threatening signals. Questionnaire-guided interventions target specific aversions (Q1–Q8) & build agency. Future studies should validate outcomes, correlating reduced COMISA scores with ISI, supporting CBTi approaches for COMISA management.

A prospective study of the impact of the natural course of insomnia symptoms on work productivity

Y. Takano¹, Y. Inoue¹

¹Tokyo Medical University, Department of Somnology, Tokyo, Japan

Introduction: The economic losses due to insomnia symptoms account for 91% of presenteeism and absenteeism. Numerous epidemiological studies have consistently reported that the presence of insomnia symptoms is associated with presenteeism and absenteeism. However, since the previous studies were cross-sectional studies, the causal relationship remains unclear. This study aims to clarify the impact of the natural course of insomnia symptoms on presenteeism and absenteeism.

Materials and methods: This study included 4242 daytime workers who attended the annual medical check-up in both 2018 and 2019 (11–12-month follow-up rate is 73.5%). In this study, the presence or absence of insomnia symptoms was asked with a single question, “Do you have insomnia symptoms?”, and the response was either “Yes” or “No”. They were categorized into four groups: normal (No-No; n = 3032, 71.5%), new onset (No-Yes; n = 329, 7.8%), recovery (Yes-No; n = 300, 7.1%), and persistent (Yes-Yes; n = 581, 13.7%). Presenteeism was assessed by asking about work performance in the past month, rated on a scale of 0% (“total lack of performance”) to 100% (“no lack of performance”) in 10% increments, while absenteeism was asked about the number of days absent due to injury or illness in the past month. Statistical analysis method used a linear mixed model (LMM), with group (normal, new onset, recovery, and persistent), time (baseline and follow-up), group*time (interaction) as independent variables, and demographic, workplace, comorbidity factors as covariates.

Results: The result of LMM showed that a significant interaction effect on presenteeism ($\chi^2(3) = 4.73$, $p = 0.003$). Post hoc comparison showed that presenteeism score in the new onset group was significantly lower at follow-up than at baseline. At the follow-up, the persistent group had significantly lower presenteeism score than all other groups, and the new onset group had significantly lower presenteeism score than the recovery and normal groups. The result of LMM showed no significant interaction effect on absenteeism ($\chi^2(3) = 0.61$, $p = 0.61$), but main effect of the group was significant. In the post hoc, the persistent group had significantly higher absenteeism than the normal group.

Conclusions: The presence of insomnia symptoms leads to an immediate worsening of presenteeism, which subsequently becomes chronic, whereas recovery from insomnia symptoms leads to an immediate improvement in presenteeism. Our study revealed a causal relationship between insomnia symptoms and presenteeism. In contrast, the persistence of insomnia symptoms is associated with chronic absenteeism, suggesting that there may be a potential time lag between the onset of insomnia symptoms and the development of absenteeism.

A Small-World Network Study on Acupuncture Treatment for Chronic Insomnia

M. Xia¹, L. Li¹, Z. Liu¹, Y. Chen¹

¹Yueyang Hospital of Integrated Traditional Chinese and Western Medicine, Shanghai University of Traditional Chinese Medicine, Shanghai, China

Introduction: Insomnia is the dissatisfaction with sleep duration and quality despite adequate opportunities and environment, affecting daytime functionality. Global insomnia rates are rising, with prevalence up to 12%-20%. Chronic insomnia increases risks for cardiovascular disease, cognitive and emotional disorders, metabolic issues, and even cancer. Addressing insomnia has become vital. Functional Magnetic Resonance Imaging (fMRI) is a key non-invasive method to study the brain's response to acupuncture, a current research focus. This project combines Acupuncture and fMRI to investigate acupuncture's effects on brain networks in chronic insomnia, using the Small-World Network method to explore specific acupuncture points' impact.

Materials and methods: Totally 30 insomnia subjects were randomly divided into the treatment group and the control group. (1:1). 15 healthy subjects were recruited to match insomnia patients with age, gender and education level. After enrollment, T1 images and Bold were taken from all subjects using 3.0T magnetic resonance (SIEMENS MAGNETOM Verio Syngo MR B17, Germany) and a 32-channel cranial coil. Based on MATLAB2013b (Mathworks, Natick, MA, USA), through SPM12 software for data pre-processing, the large-scale brain functional network was constructed by GREYNET software, and the images were presented by Brain Net Viewer software. The differences of global attributes and node attributes of the brain network between the two groups were compared, the three sets of square difference analysis, the statistical differences of network measures between the groups were compared, and the paired T-test was used to analyze the changes of network measures.

Results: Compared with healthy controls, the small-world attribute of insomnia patients is weakened. Acupuncture treatment in both the treatment group and the control group could enhance the small-world attribute, clustering coefficient, shortest path and network efficiency of insomnia patients. Compared with before treatment, the difference was statistically significant ($P < 0.05$). Acupuncture treatment in treatment group and control group can significantly improve PSQI, ISI and brain network efficiency has a negative correlation. Compared with the control group, the difference was statistically significant ($P < 0.05$). In the two groups, the efficiency of acupuncture intervention in insomnia network was enhanced: dorsolateral superior frontal gyrus L, orbital middle frontal gyrus R, anterior cingulate and paracentric gyrus L, cuneus lobe L, paracentral lobule L; Hippocampus L and amygdala L were significantly enhanced in treatment group. Treatment group may play a role in treating insomnia and improving the state of liver fire and heart disturbance through brain regions such as hippocampus, amygdala and anterior cingulate gyrus, which are the important brain regions for the treatment of insomnia.

Conclusions: Acupuncture treatment can enhance the small-world attribute of insomnia patients. Acupuncture treatment in treatment group can significantly change the negative correlation between PSQI, ISI and brain network efficiency in insomnia patients. Brain regions such as the hippocampus, amygdala, and anterior cingulate gyrus may be important target regions for acupuncture treatment of insomnia. This research contributes to a deeper understanding of the pathophysiological mechanisms of insomnia, reveals the association between insomnia symptoms and the structure and function of brain networks, and provides clues for formulating personalized acupuncture treatment plans for insomnia patients.

Association between insomnia disorder and healthcare resource utilization in the United States military health system

V. Capaldi¹, K. Werner¹, J. Herrin², B. Stryckman³, S. Williams⁴, W. Funk⁵, J. Albrecht³, E. Wickwire³

¹Uniformed Services University of the Health Sciences, Bethesda, United States, ²Yale University School of Medicine, New Haven, United States, ³University of Maryland School of Medicine, Baltimore, United States, ⁴Defense Health Headquarters, Falls Church, United States, ⁵Kennell and Associates, Inc., Falls Church, United States

Introduction: Insomnia disorder is common among U.S. military Service Members and negatively impacts health and military readiness. Among civilians, insomnia is associated with substantial economic burden; yet, little is known about the economic burden of insomnia within the US Military Health

System (MHS). The MHS is a large, integrated healthcare delivery system with worldwide operations and thus ideal for health services research. The purpose of this study was to determine the association between insomnia disorder and healthcare resource utilization in the MHS.

Materials and methods: Our data source was the Military Data Repository (MDR) between years 2016-2021. This large data repository includes encounter, procedure, medication, and durable medical equipment information for Active-duty military personnel, military dependents, National Guard, and Reserves. Demographic and military information was obtained from the MDR. Inclusion criteria were age <65 years, active-duty military personnel, 12 months of continuous enrollment before and after first insomnia diagnosis (i.e., the index date), and no evidence of insomnia during the 12 months prior to first diagnosis. Insomnia and comorbid medical and psychiatric conditions were defined based on International Classification of Disease-10th Edition codes. Beneficiaries with insomnia were matched 1:1 with non-insomnia controls on >20 demographic, military, and medical and psychiatric comorbidity variables. Mixed effects models were used to compare non-insomnia related healthcare resource utilization (HCRU) between groups across multiple points of service: outpatient, inpatient, and emergency department (ED).

Results: The final sample included 40,978 MHS beneficiaries with insomnia and 40,978 matched non-insomnia controls. Most (35.9%) beneficiaries with insomnia were between ages 25-34 years, and 20.7% were women. 4.2% of beneficiaries with insomnia had one comorbid medical or psychiatric condition, and 1% had >2 comorbid conditions. Relative to matched non-insomnia controls, beneficiaries with insomnia demonstrated greater 12-month HCRU at every point of service (all P values <0.001). The incident rate ratio for non-insomnia inpatient visits was RR (95% CI) = 1.96 (1.85,2.08); for non-insomnia outpatient visits was 2.24 (2.23,2.24); and for non-insomnia related ED visits was 1.60 (1.57,1.63).

Conclusions: Insomnia is associated with substantially increased healthcare resource utilization in the US military health system. Future research should seek to advance personalized medicine approaches to improve outcomes of evidence-based insomnia care.

Acknowledgments: Funding: U.S. Department of Defense HT94022210006.

Association between symptoms of depression and insomnia

T. Toncar¹, L. Rosenblum¹, M. Glos¹, T. Penzel¹, I. Fietze^{1,2}

¹Charité-Universitätsmedizin Berlin, Center for Sleep Medicine, Berlin, Germany, ²The Fourth People's Hospital of Guangyuan City, Department of Medicine, Guangyuanchina, China

Introduction: Patients with insomnia who have trouble to fall asleep or / and to maintain sleep quite often also report symptoms beyond like those of depression or daytime sleepiness. The consideration of these variables can be helpful in phenotyping, treatment planning and evaluation of insomnia. The aim of the present study was to explore factors or factor combinations that are related to the severity of insomnia.

Materials and methods: From n= 175 (f= 108) patients diagnosed with insomnia (mean age: 46.4± 14.5 yrs, range 18 - 83 yrs) demographic and anamnestic variables, sleep questionnaires (ISI, ESS, RLS-DI, Stop-Bang), and revised Beck Depression Inventory (BDI-II) are recorded. Responses of the 21 items of BDI-II were evaluated statistically using an exploratory factor analysis. This analysis identified possible predictors of the depression symptoms that contribute to the insomnia severity and complaints. To verify these, they were examined using regression analysis to predict insomnia symptoms. The study was approved by the local Ethics Committee of the Charité-Universitätsmedizin Berlin. Participants have given written informed consent.

Results: The mean ISI-Score was 18.8 ± 0.3 and the mean total BDI-II-Score was 12.3 ± 0.6. There was a positive correlation between ISI-Score and BDI-II-Score (r= .418, p <.001). Factor analysis of BDI-II revealed two latent factors: "pessimism" and "tiredness or fatigue" (p < .001). Linear regression revealed a significant correlation between the identified BDI-II factor "tiredness or fatigue" and the severity of insomnia (r = .55, p < .001). Pessimism and ISI-Score did not show significant correlation (r = .16, p < .05).

Conclusions: The mean ISI-Score was 18.8 ± 0.3 and the mean total BDI-II-Score was 12.3 ± 0.6. There was a positive correlation between ISI-Score and BDI-II-Score (r= .418, p <.001). Factor analysis of BDI-II revealed two latent factors: "pessimism" and "tiredness or fatigue" (p < .001). Linear regression revealed a significant correlation between the identified BDI-II factor "tiredness or fatigue" and the

severity of insomnia ($r = .55, p < .001$). Pessimism and ISI-Score did not show significant correlation ($r = .16, p < .05$).

Association of medications commonly used for insomnia (MCUFI) with abnormal physical activity patterns: A Deep Learning Study Based on NHANES 2003-2006 Database

S. Zheng¹, W. Zeng², B. Zhang¹

¹Nanfang Hospital, Southern Medical University, Department of Psychiatry, Guangzhou, China,

²Nanfang Hospital, Southern Medical University, Department of Radiology, Guangzhou, China

Introduction: Medications commonly used for insomnia (MCUFI) are widely regarded as an initial approach by clinicians, with high risk of physical activity(PA) impairment. No large-scale studies have explored the effect of MCUFI on PA patterns assessed by longitudinal objective PA data.

Materials and methods: This study aims to evaluate the PA patterns in MCUFI group, and establish a series of classification models for MCUFI usage with reshaped three-dimensional spatiotemporal PA data, using a multi-layer network based on the Convolutional Long Short-Term Memory (Conv-LSTM) architecture. The deep learning classifiers were developed and validated by internal cross-validation and independent test set. SHapley Additive exPlanations (SHAP) method was used to quantify the relative importance of each time point in the models.

Results: A total of 14,631 participants were included in this study, using the National Health and Nutrition Examination Survey (NHANES) dataset. The MCUFI group demonstrated significantly reduced intensity across all time periods (all $p < 0.001$). Specifically, the group showed a slower growth rate in PA from nighttime to daytime ($p < 0.001$) and a slower decrement rate from daytime to nighttime ($p < 0.001$). Within the MCUFI group, males showed higher activity intensity only during daytime compared to females ($p = 0.028$). Participants using benzodiazepines had significantly reduced intensity than those using other types of MCUFI ($p < 0.001$). The Conv-LSTM model demonstrated robust classification performance across multiple tasks. Particularly, the model achieved moderate performance in detecting MCUFI use (area under the curve, 0.745 [95% CI, 0.728–0.763] for the validation set and 0.700 [95% CI, 0.691–0.710] for the test set).

Conclusions: This study has confirmed the association between MCUFI usage and abnormal PA patterns, with variations observed in gender and type of MCUFI. Further, a series of interpretable deep learning classification models have been established, demonstrating moderate performance.

Association of Personality Profiles with Sleep Disturbance, Depression and Anxiety in Individuals with Insomnia Disorder: A Latent Class Analysis

H.L. Lam¹, C.X. Chen¹, M. Zhou¹, W.I. Ao¹, S.X. Li^{2,3}, J.W.Y. Chan¹, Y.K. Wing^{1,4}, N.Y. Chan¹

¹Li Chiu Kong Family Sleep Assessment Unit, Department of Psychiatry, The Chinese University of Hong Kong Shatin, Hong Kong SAR, Hong Kong, Hong Kong, SAR of China, ²Sleep Research Clinic & Laboratory, Department of Psychology, The University of Hong Kong, Hong Kong, Hong Kong, SAR of China, ³The State Key Laboratory of Brain and Cognitive Sciences, The University of Hong Kong, Hong Kong, Hong Kong, SAR of China, ⁴Li Ka Shing Institute of Health Sciences, Faculty of Medicine, The Chinese University of Hong Kong, Shatin, Hong Kong SAR, Hong Kong, Hong Kong, SAR of China

Introduction: Insomnia disorder is highly comorbid with psychiatric disorders, such as anxiety and depression. Certain personality trait profiles have been identified as transdiagnostic risk factors for co-occurrence and increased severity of psychiatric disorders. However, empirical research exploring personality profiles in individuals with insomnia and their relationship with insomnia severity and mood symptoms remains limited. The present study aims to understand the relationship between personality profiles and depression, anxiety, insomnia severity, and well-being in individuals with insomnia disorder.

Materials and methods: 218 Chinese participants who underwent Diagnostic Interview for Sleep Patterns and Disorders(DIS) and the Structured Clinical Interview for DSM Disorders(SCID) to screen for sleep and psychiatric disorders, respectively were recruited from the community study in Hong Kong and. All Participants (Mean age=46 yrs $\pm$ 14.93; female: 76.6%; Presence of comorbid psychiatric disorder: 35.3%) has completed questionnaires including the Big Five Inventory(BFI) for personality

traits, symptoms of anxiety, depression, and insomnia, well-being measurement including quality of life, and other insomnia-related measures such as excessive daytime sleepiness, sleep reactivity, sleep hygiene, and rumination. The subjects also completed 7-day sleep diary recording of their sleep-wake patterns, including total sleep duration(TST), sleeptime(ST), wake after sleep onset(WASO), sleep onset latency(SOL), and waketime(WT). Latent class analysis(LCA) was used to identify personality subgroups controlling for age, sex, and psychiatric history. ANOVA was further conducted to investigate the between-subject differences of sleep and mood-related outcomes in personality subgroups.

Results: LCA identified three subgroups characterized as vulnerable, typical, and resilient profiles. The vulnerable group (9.2%) exhibited significantly higher neuroticism($N: 4.07 \pm 0.338$) and lower conscientiousness($C: 2.55 \pm 0.491$), agreeableness($A: 3.01 \pm 0.532$), openness to experience($O: 2.48 \pm 0.639$), and extraversion($E: 1.95 \pm 0.516$), while the resilient group (23.4%) showed the opposite pattern ($N: 2.49 \pm 0.488$; $C: 3.97 \pm 0.348$; $A: 3.94 \pm 0.399$; $O: 3.50 \pm 0.661$; $E: 3.05 \pm 0.561$). The typical group (67.4%) scored nearly average on all traits ($N: 3.30 \pm 0.469$; $C: 3.30 \pm 0.525$; $A: 3.35 \pm 0.399$; $O: 3.11 \pm 0.524$; $E: 2.63 \pm 0.498$). The vulnerable group demonstrated significantly higher insomnia severity ($F[2,215]=9.08$, $p<0.001$), more depressive ($F[2,215]=16.9$, $p<0.001$) and anxiety symptoms ($F[2,215]=24.9$, $p<0.001$), lower quality of life ($F[2,215]=19.3$, $p<0.001$), compared to typical group, then followed by resilient group. Vulnerable group also reported significantly higher mental fatigue ($F[2,215]=3.15$, $p=0.045$), greater daytime sleepiness ($F[2,215]=3.35$, $p=0.037$), and sleep reactivity to stress ($F[2,215]=5.16$, $p=0.006$) compared to Resilient group only. Resilient group has significantly less rumination ($F[2,215]=12.2$, $p<0.001$) and better sleep hygiene ($F[2,215]=3.61$, $p=0.029$) compared to the other groups while typical and vulnerable group had no significant difference. No significant difference were found in all variables related to sleep-wake patterns among three groups.

Conclusions: High Neuroticism along with low extraversion, agreeableness, conscientiousness, and openness to experience are associated with increased risk of sleep and mood disturbance among individuals with insomnia disorders, suggesting the existence of subgroups within the insomnia population. These findings indicate the need for further phenotyping subgroups of insomnia in order to develop personalized treatment for insomnia.

Introduction: Growing evidence suggests that insomnia symptoms are associated with heightened impulsive behaviors and altered decision-making patterns. However, there remains limited research regarding the link between objectively measured sleep and decisional impulsivity, a form of decision-making characterized by the acceptance of undue uncertainty, or failure to adapt to environmental changes. According to the dual systems model, since the developing brain is characterized by the imbalance of increased reward-seeking and immature impulse control, inadequate sleep may exacerbate one's propensity to hasty decision making during late adolescents and early young

adulthood. This study aimed to explore the associations of objective and subjective sleep with trait impulsivity and decision-making, specifically performance on a probabilistic reasoning task, in youth.

Materials and methods: Youth participants aged 18-25 were recruited and were invited to complete a battery of self-report questionnaires including Insomnia Severity Index (ISI) for insomnia severity, Pittsburgh Sleep Quality Index (PSQI) for sleep quality, and the Barratt Impulsiveness Scale (BIS) for trait impulsivity. Objective sleep was prospectively assessed over seven nights using wrist actigraphy. Probabilistic reasoning was measured by a behavioral task (beads task) with two scenarios (easy, less uncertainty vs. intermediate, more uncertainty). Multiple regression analyses were used to examine the association of subjective and objective sleep parameters with self-reported impulsivity and probabilistic reasoning task performance.

Results: Thirty-seven participants (mean age: 18.5 ± 1.71 years, female: 62.3%) were included in the study. Multiple regression analyses showed that actigraphy-estimated wake after sleep onset (WASO) was significantly and negatively associated with beads task performance in the easy scenario ($\beta = -0.79$, $p = .036$), even after controlling for subjective sleep (ISI and PSQI scores), suggesting that increased nocturnal wake time after sleep onset was associated with fewer beads drawn before decision-making, reflecting a more impulsive, jumping-to-conclusions reasoning style. No significant association was found between WASO and performance in the intermediate scenario with more uncertainty. Additionally, there were no significant associations observed between other objective sleep parameters (Sleep Onset Latency, Total Sleep Time, Sleep Efficiency) or subjective sleep measures (ISI, PSQI) and task performance in either scenario. Furthermore, objective or subjective sleep parameters were not significantly associated with trait impulsivity, as measured by BIS.

Conclusions: Disrupted sleep, characterized by objectively measured increased nocturnal awakenings, was significantly associated with more impulsive decision-making. On the other hand, subjective reports of insomnia symptoms and sleep quality were not linked to decision-making performance. Further research should consider exploring underlying mechanisms and examining sleep macro- and micro-structure in relation to decision-making and impulsivity in youth.

Acknowledgments: This work was supported by Hong Kong Research Grants Council under the General Research Fund (Ref. 17619123, awarded to SX Li).

Audio neuromodulation to treat insomnia in adults: an observational study

J. Sackier¹, N. Guest², E. Dsouza³

¹Private Practice, London, United Kingdom, ²Timperley NHS General Practice, Altrincham, United Kingdom, ³City of London School, London, United Kingdom

Introduction: Insomnia affects 31% of adults,¹ incidence rates varying by population^{2,3}, profession⁴, age, co-morbidities and other factors⁵. Characteristics vary⁶, with major impacts on daily functioning, mental and physical health⁷. Standard therapies include sleep hygiene⁸, CBT⁹, and medication¹⁰ but provide inconsistent benefits. Neuromodulation, including TMS, tDCS and cranial nerve stimulation have yielded variable results.¹¹ We designed a pilot study of an audio neuromodulation device to ascertain if sleep quality could be improved.

Materials and methods:

A non-prescription audio neuromodulator (SleepEngine™, Cambridge Sleep Sciences Ltd., 115B Innovation Drive, Oxfordshire, OX14 4RZ, UK) previously showed positive results in adults self-reporting insomnia¹². The device emits rhythmic pulsed sounds hypothesized to promote better sleep, sequenced for 6 – 8 hours and masked by white noise. To assess its effect under monitored conditions, a prospective observational study was conducted after ethical review. One British NHS General Practitioner recruited 20 participants (16 females, 4 males; mean age 51.19, range 22–67) reporting over six months of insomnia, unresponsive to other measures. Exclusion criteria included BMI >35, sleep apnoea, systemic neurologic disease, chronic pain, depression, anti-psychotic medication use, recreational drug use, or any disease likely to impair sleep. No new sleep-related interventions could be introduced during the study.

After a one-week baseline, participants used the device nightly with the sound profile in the same format for 12 weeks, followed by 8 weeks washout after device withdrawal. The primary endpoint was the Pittsburgh Sleep Quality Index (PSQI) at weeks 0, 12, and 20. PSQI scores range from 0–21, with

higher scores indicating worse sleep¹³. Secondary outcomes included sleep diaries, a patient reported sleep score (1 = poor, 5 = excellent) and qualitative feedback.

Results: No significant differences were seen between sex, age or other characteristics. Baseline mean PSQI was 11.15 (range 4–16) and declined significantly over time. Between baseline and end of treatment, there was a statistically significant reduction (mean difference paired t-test; $p = 0.0000204$). A further significant improvement was observed between end of treatment and end of washout ($p = 0.0371$), and the overall reduction from week 0 to 20 was highly significant ($p = 0.000000124$). From baseline to week 16, Wilcoxon signed-rank test revealed a statistically significant reduction in time to fall asleep ($p = 0.00053$) from 0.96 (0.23 – 3.5) to 0.58 (0.1 – 1.39) hours.

Nighttime awakenings showed a non-significant trend toward reduction during the same period from median 2.07 (range 0.57 – 6.43) vs. 1.72 (0 – 6.57) respectively; $p = 0.056$.

Participants experienced a significant reduction in time spent awake during the 12-week study period decreasing from 1.18 hours (range 0.11 – 4.14) to 0.33 hours (0.01 – 2.14), respectively; $p = 0.00039$ (paired t-test)

Patient reported sleep scores improved significantly from baseline to end of week 12 from median 2.64 (1.0 – 3.85) to 3.86 (2.86 – 5.0) respectively; $p = 0.00016$, (paired t-test).

Conclusions: No adverse effects from device use were reported, and participants expressed interest in continuing device use after the trial. These findings suggest a progressive improvement in sleep quality across the study period and these encouraging results merit further investigation.

Brain Network Study of Transcranial Plasma Therapy for Chronic Insomnia

Q. Ma¹, L. Li¹, Y. Ren¹

¹The First Hospital of Hebei Medical University, neurological department, Shijiazhuang, China

Introduction: This study intends to explore the characteristic brain network changes in patients with chronic insomnia (CI) by studying transcranial magnetic stimulation combined with electroencephalogram monitoring (TMS-EEG) and resting-state functional magnetic resonance imaging (rs-fMRI) in patients with chronic insomnia (CI) and normal people; our team's previous experiments confirmed that low-temperature plasma (LTP) stimulation may be a new non-invasive neuromodulation technique. Therefore, we intend to observe the therapeutic effect of LTP stimulation on CI patients, and explore the mechanism of LTP stimulation in the treatment of CI based on TMS-EEG and rs-fMRI techniques.

Materials and methods: Thirty-five CI patients (CI group) and 20 healthy volunteers (HC group) were selected for TMS-EEG and rs-fMRI data acquisition. Subsequently, 35 CI patients were randomly assigned to LTP stimulation group (LTP group, 20 cases) and sham stimulation group (Sham group, 15 cases). Each group was intervened for 14 days and 40 minutes a day. The two groups of patients were evaluated by sleep-related scales at baseline, after intervention and 1 month follow-up, and TMS-EEG and rs-fMRI data were collected after intervention.

Results: 1.1) In the early stage of stimulation, the information outflow in the bilateral prefrontal cortex (Fp1, Fp2) decreased in the CI group; in the late stage, the information flow in the left prefrontal region (FP1) increased. 2) The functional connectivity between right ventromedial prefrontal cortex (vmPFC) and bilateral frontal area, bilateral posterior cingulate gyrus and bilateral cerebellum was significantly decreased in CI group. The functional connectivity between right vmPFC and bilateral cingulate gyrus and bilateral insula was significantly enhanced ($P < 0.05$). 2.1) Compared with the baseline, the scores of the LTP group were significantly lower after intervention and at one-month follow-up ($P < 0.001$). 2) In the early stage of stimulation, the information outflow in the left frontal lobe (F3) was reduced in the LTP group; in the late stage of stimulation, the information flow in the left prefrontal region (FP1) increased. 3) In the LTP group, the functional connectivity between the right vmPFC and the left medial superior frontal gyrus and the left anterior cingulate gyrus was significantly enhanced ($P < 0.05$).

Conclusions: 1. CI patients have abnormal network connections between the prefrontal lobe and the temporal lobe and occipital lobe over time. The right vmPFC of CI patients had weakened connection with the executive control network and enhanced connection with the salience network. The connection with bilateral cerebellum was weakened. 2. LTP stimulation can improve insomnia in patients, and the effect can last for at least 1 month. 3. LTP treatment can reverse the abnormal changes of EEG network and make the network connection return to normal. Further, LTP treatment

may improve insomnia symptoms by enhancing the connection strength between the right vmPFC and the salience network and the default mode network.

Can a Hug Improve Sleep? A Randomized Controlled Trial of Partner Embrace in Individuals with Insomnia Symptoms

X.X. Wang¹, J.J. Liu¹

¹Peking University, School of Nursing, Beijing, China

Introduction: Insomnia is a highly prevalent sleep disorder, associated with increased risks of physical and mental health problems. Recent evidence from our team suggests that couple relationship quality plays an important role in shaping sleep outcomes. Enhancing relational quality may therefore represent a novel, non-pharmacological strategy to alleviate insomnia symptoms. Hugging, as a common form of affective touch, has been theoretically linked to improved relational well-being. Based on this, we hypothesized that partner hugging could improve insomnia symptoms by enhancing relationship quality and reducing stress.

Materials and methods: This randomized controlled trial compared the effects of sleep hygiene education alone (n = 59) versus sleep hygiene education plus daily partner hugging (n = 59) on insomnia symptoms (primary outcome), as well as sleep quality, couple relationship quality, depression, anxiety, and stress (secondary outcomes). Participants were adults (ISI score ≥ 10) cohabiting with a stable partner ≥ 5 days per week, recruited via social media from December 27, 2024, to April 7, 2025. Assessments were conducted at baseline, post-intervention, and 1-month follow-up. Sleep hygiene education consisted of a 20-minute online session. The hugging intervention involved three 20-second hugs daily (morning, after work, and bedtime) for one month. The primary analysis followed the intention-to-treat principle; per-protocol analysis was conducted for sensitivity testing. Missing data were not imputed. Generalized Estimating Equations (GEE) were used to analyze between-group differences over time.

Results: A total of 118 participants (mean age = 38.27 years, SD = 10.66; 73.9% female) were included. Compared to sleep hygiene education alone, the hugging group showed significantly greater improvement in subjective sleep quality at post-intervention (Cohen's d = 0.63; 95% CI: 0.24 to 1.03), though this effect was not sustained at 1-month follow-up. While no significant between-group differences were found for other secondary outcomes, participants in the hugging group reported significant reductions in perceived stress both at post-intervention and 1-month follow-up compared to baseline (Cohen's d = -0.69 and -0.89, respectively). These findings were robust in sensitivity analyses. Notably, intimacy scores were higher in the hugging group at the 1-month follow-up.

Conclusions: This study suggests that partner hugging may serve as a simple, low-cost, and scalable intervention to improve sleep quality among individuals with insomnia, potentially by reducing stress and enhancing relational intimacy. These findings highlight the therapeutic potential of affective physical contact in sleep health interventions.

Changes in insomnia severity and psychological distress in a community cohort completing THIS WAY UP digital sleep intervention

M. Jackson¹, H. Sanjavini¹, C. Shiner^{2,3}, A. Mahoney^{2,3}, E. Mason^{2,3}

¹Monash University, School of Psychological Sciences, Melbourne, Australia, ²St Vincent's Hospital, Clinical Research Unit for Anxiety and Depression, Sydney, Australia, ³University of New South Wales, Sydney, Australia

Introduction: Insomnia is the most common sleep disorder, affecting 10-15% of the population and contributes to poor mental and physical health outcomes. Cognitive behavioural therapy is considered the gold standard treatment for insomnia, however access to this therapy is challenging. Digital interventions for insomnia are becoming increasingly popular to overcome accessibility barriers. The effectiveness of, and adherence to, these programs across different age groups is currently unknown. This study aimed to examine the effectiveness of a digital CBT-I program on insomnia severity and psychological distress across the lifespan, and explore age-related differences in program completion rates.

Materials and methods: The sample comprised of 9,567 participants who enrolled in the Managing Insomnia program on the ThisWayUp website (www.thiswayup.org.au) between January 2022 and December 2023. The Managing Insomnia program includes four online self-directed lessons. Participants completed the Insomnia Severity Index (ISI) and the Kessler 10-item Psychological Distress scale (K-10) before each lesson of the intervention.

Effect on ISI and K-10 outcomes were observed by running linear mixed models with age group (18-25, 26-39, 40-65, 66-79, and 80+), timepoint (Lesson 1, Lesson 4) and age group and timepoint interaction as fixed effects and participant ID as random effect. Chi-squared analyses were conducted to examine differences in completion rates between groups at each timepoint.

Results: Moderate to large effect size reductions in ISI were observed across the lifespan ($p < 0.001$; $g = 0.56 - 1.01$) with change of at least 4 points (MCID) on ISI. Effects of treatment on insomnia symptom severity significantly differed by age group; the 26-39 year olds had a faster improvement in ISI compared to all other age group, except participants 80+ years ($F(df) = 24.12 (4)$; $p < 0.001$).

Significant but small effect size reductions in K-10 were observed across the lifespan ($p < 0.001$; $g = -0.11 - 0.16$), but did not differ significantly across age groups ($F(df) = 12.24 (4)$; $p = 0.02$). There were significant differences ($p < 0.001$) in program completion rates between age groups at all timepoints. Older adults (aged 66 and above) were 2-3 times more likely to complete all 4 modules compared to 18-39 year olds.

Conclusions: This self-directed internet-based CBT for Insomnia program resulted in significant improvements in insomnia symptom severity and psychological distress across all age groups. In particular the trajectory of improvement in younger adults was faster than other age groups. Importantly, older adults were more likely to complete the program compared to younger age groups. This study lends support to the recommendations implementation of digital interventions for sleep in older adults.

Characteristics and Relationship of Cognitive and Physiological Hyperarousal in Patients with Insomnia: A Primary Study

L. Yang¹, L. Meng², F. Meng³, Z. Li²

¹Beijing Anding Hospital, Capital Medical University, Beijing, Beijing, China, ²Beijing Anding Hospital, Capital Medical University, Beijing, Beijing, China, ³Beijing Anding Hospital, Capital Medical University, Beijing, Beijing, China

Introduction: To investigate the factors influencing arousal characteristics and hyperarousal in patients with insomnia, and to explore the relationship between physiological and cognitive hyperarousal. By supplementing the existing hyperarousal model, the research seeks to provide theoretical foundations for developing targeted clinical interventions

Materials and methods: This study enrolled 56 patients diagnosed with insomnia disorder at Beijing Anding Hospital outpatient clinic between May 2024 and March 2025. Of these, 40 patients were randomly assigned to either the experimental or control group using a randomized controlled allocation table, while 20 community-recruited healthy controls were included. Demographic data were collected through a self-designed general information questionnaire. All participants underwent baseline and 4-week assessments of heart rate variability (HRV), Pittsburgh Sleep Quality Index (PSQI), Dysfunctional Beliefs and Attitudes about Sleep Scale-Chinese Version (DBAS-CV), Pre-Sleep Arousal Scale (PSAS), Beck Anxiety Inventory (BAI), Beck Depression Inventory (BDI), Morningness-Eveningness Questionnaire-5 (MEQ-5), and Anxiety Sensitivity Index-3 (ASI-3). The experimental group received weekly sleep hygiene education and mindfulness-based exercises over four weeks, with assessments conducted at baseline and weekly intervals (1st, 2nd, 3rd, and 4th week). HRV measurements were obtained pre- and post-mindfulness intervention. Statistical analyses were performed using SPSS 26.0. Continuous variables were reported as mean $\pm$ standard deviation, and categorical variables as frequency and percentage composition. Linear mixed-effects models were applied to analyze the temporal relationship between mindfulness intervention and immediate HRV changes in patients, with statistical significance defined as $p < 0.05$.

Results: The baseline analysis revealed that patients with insomnia exhibited significant hyperarousal compared to the healthy control. Statistically significant differences ($p < 0.05$) were observed in the PSAS physiological dimension (16.30 ± 4.94 vs 11.25 ± 0.49), PSAS cognitive dimension (26.98 ± 6.80 vs 13.25 ± 4.51), and daytime HRV metrics (RMSSD: 33.41 ± 1.70 vs 52.75 ± 3.22 ; SDNN: 34.02 ± 1.78 vs

51.05±3.80). Path analysis demonstrated that BAI directly drove physiological hyperarousal ($\beta=0.398$, $p=0.002$), while difficulty falling asleep (PSQI2), short sleep duration (PSQI3), and daytime dysfunction (PSQI7) indirectly exacerbated cognitive hyperarousal through maladaptive cognition. Dysfunctional beliefs about sleep (DBAS) emerged as a key moderating variable, significantly reducing cognitive arousal levels ($\beta=-0.242$, $p=0.021$).

The intervention study demonstrated that after a 4-week mindfulness-based intervention, the experimental group showed a significant reduction in total PSQI scores (14.40±2.80 vs 9.05±3.55, $p<0.001$) and improvement in the cognitive arousal dimension (28.15±7.03 to 20.20±6.92, $p=0.001$), while the improvement in physiological arousal dimension did not reach statistical significance (17.45±4.68 to 15.05±7.04, $p=0.22$). Dynamic HRV monitoring revealed that even a single mindfulness session induced significant autonomic regulatory effects: a heart rate reduction of 3.86 bpm ($p<0.0001$), SDNN elevation of 5.83 points ($p=0.004$), and stress index (PSI) decrease of 9.58 points ($p=0.032$). However, cumulative effects over the 4-week intervention period failed to attain statistical significance ($p>0.05$).

Conclusions: (1) Insomnia patients exhibited 24-hour hyperarousal states across physiological, cognitive, and emotional domains;(2) Anxiety and dysfunctional beliefs about sleep emerged as primary determinants influencing somatic and cognitive hyperarousal;(3) A bidirectional interaction existed between somatic and cognitive hyperarousal, modulated by anxiety and dysfunctional sleep-related beliefs, while simultaneously demonstrating relative inter-dimensional dissociation between somatic and cognitive hyperarousal manifestations.

Circadian rhythm timing and associations with sleep symptoms in insomnia disorder

H. Scott¹, N. Lovato^{1,2}, M. Comas³, D. Bartlett^{4,5}, R. Grunstein^{4,5,6}, L. Lack¹, C.J. Gordon^{4,5}

¹Flinders University, Flinders Health and Medical Research Institute: Sleep Health, Adelaide, Australia,

²Flinders University, National Centre for Sleep Health Services Research: A NHMRC Centre of Research Excellence, Adelaide, Australia, ³Araba University Hospital, Sleep Unit, Vitoria-Gasteiz, Spain,

⁴Macquarie University, Woolcock Institute of Medical Research, Sydney, Australia, ⁵Macquarie University, Faculty of Medicine, Health and Human Sciences, Sydney, Australia, ⁶Royal Prince Alfred Hospital, Sydney, Australia

Introduction: Circadian rhythmicity is intricately intertwined with sleep timing and continuity but it may be altered in people with insomnia disorder. This study tested whether the timing of melatonin onset is associated with sleep symptoms in insomnia disorder.

Materials and methods: In total, 128 people diagnosed with insomnia disorder were recruited. Participants completed daily sleep diaries and wore an actigraph for up to 14 days prior to an in-laboratory sleep study. Participants underwent salivary melatonin collection to estimate dim-light melatonin onset (DLMO) on the following night. Regressions and analyses of variances on DLMO tertile groups tested associations between melatonin timing (DLMO, phase angle differences calculated as DLMO minus each sleep timing variable) with sleep timing and continuity variables derived from sleep diaries and actigraphy.

Results: There were significant associations between DLMO timing and sleep timing (sleep onset time and wake time from diaries, bedtime from diaries and actigraphy), $r_{(s)}=0.27 - 0.37$, but not with sleep continuity (e.g., sleep latency, wake after sleep onset, sleep duration). The phase angle between sleep onset time and DLMO was associated with sleep latency, sleep duration, and sleep efficiency, $r_{(s)}=-0.32 - 0.41$. Participants with a longer sleep onset time phase angle ($>3h$) had longer sleep latencies (*Mean diff*=43.2 mins, *SE*=13.0, $p=0.004$) and shorter sleep durations (*Mean diff*=-65.7 mins, *SE*=20.8, $p=0.006$) than participants with a shorter phase angle ($<2h$). Other phase angles (DLMO and mid-sleep, wake time) were not consistently associated with sleep.

Conclusions: Melatonin onset timing influences sleep timing in insomnia disorder. Larger phase angle differences between sleep onset and DLMO are linked to poorer sleep continuity. These findings highlight the importance of considering circadian alignment and its impact on sleep in understanding the pathophysiology of insomnia and in developing targeted treatment interventions.

Clinical Features and Cortical and Cognitive Arousal in Adolescents with Insomnia and Objective Short Sleep Duration

Y.L. Wong¹, H.F. Sit¹, X. Li¹, R. Wang¹, J.W.Y. Chan², N.Y. Chan², Y.K. Wing², C.A. Espie³, S.X. Li^{1,4}

Introduction: Adolescence is a critical developmental stage characterized by biological and psychosocial changes that may increase one's risk for sleep and mental health problems. Insomnia, a common issue among adolescents, is often associated with impaired daytime functioning and poor mental health. Previous studies suggested that objective short sleep duration (ISSD) is a marker of biological severity in insomnia, associated with heightened cortical arousal, increased medical problems, and poorer treatment prognosis. However, the clinical profile and underlying mechanism of ISSD remained unclear, especially in adolescents. This study aimed to examine the differences in clinical features, cortical and cognitive arousal in adolescents with ISSD.

Materials and methods: Seventy-eight adolescents aged 12-20 were recruited, including 59 adolescents with DSM-5 insomnia disorder and 19 healthy sleepers (HS) with self-reported 7-10 hours of sleep per night. Participants underwent a clinical interview, completed self-report questionnaires and 2-night laboratory-based polysomnographic (PSG) assessments, with the first night serving as the adaptation night. Insomnia Severity Index (ISI) and Pittsburgh Sleep Quality Index (PSQI) measured insomnia severity and sleep quality. Pre-sleep Arousal Scale (PSAS) measured somatic and cognitive arousal. Children's Depression Rating Scale-Revised (CDRS-R) measured clinician-rated depression symptoms. Insomnia participants with total sleep time less than 7 hours as measured by PSG were categorized as ISSD, and the rest were categorized as insomnia with normal sleep duration (INSD).

Results: One participant was excluded due to PSG technical issues, leaving 77 participants (mean age 17.68 and 58% female) for analysis (ISSD, $n = 18$; INSD, $n = 40$). The results showed ISSD had poorer PSG-based sleep efficacy compared to INSD ($p < .05$). Both INSD and ISSD groups showed more severe clinician-rated depressive symptoms and insomnia symptoms, poorer subjective sleep quality, and higher cognitive and somatic arousal compared to HS (*all* $ps < .001$), but there were no significant differences in these measures between the two groups. INSD showed heightened high-frequency power band (Beta-1, 15-25 Hz) compared to HS during the N1 stage and exhibited more low-frequency power band (Alpha, 8-12.5 Hz) during the N3 stage compared to ISSD (*all* $ps < .001$). ISSD had heightened high-frequency band power (Beta-2, 25-35 Hz) during Rapid Eye Movement (REM) sleep compared to INSD ($p = .03$) and HS ($p = .05$). A significant positive association between cognitive and cortical arousal was found in the ISSD ($B=0.655, p=.001$), but not in INSD ($B=-0.165, p=.176$) and HS ($B=-0.103, p=0.718$). No significant differences were found in the association between somatic and cortical arousal across groups (*all* $p>.05$).

Conclusions: ISSD is characterized by heightened high-frequency beta activity during REM sleep and a positive correlation between cortical and cognitive arousal, highlighting a distinct insomnia phenotype with biological differences. It provides physiological evidence to differentiate the mechanisms between phenotypes. Future research should explore tailored interventions and examine the implications of different insomnia phenotypes in treatment response.

Clinical subtypes of co-morbid insomnia and obstructive sleep apnea (COMISA): Results of a cluster analysis

Y. Shi¹, X. Feng¹, F. Hao¹, Y. Nie¹, L.D. Sanford², M.V. Vitiello³, X. Tang¹

¹Sleep Medicine Center, Mental Health Center, West China Hospital, Sichuan University, Chengdu, China, ²Sleep Research Laboratory, Center for Integrative Neuroscience and Inflammatory Diseases, Pathology and Anatomy, Eastern Virginia Medical School, Norfolk, United States, ³Department of Psychiatry and Behavioral Sciences, University of Washington School of Medicine, Seattle, United States

Introduction: Variations in the bidirectional relationship between obstructive sleep apnea (OSA) and insomnia in co-morbid insomnia and OSA (COMISA) may form distinct subtypes of COMISA, which have not been previously characterized. This study aims to identify and characterize subtypes of COMISA and assess their association with risks of physical (metabolic syndrome and high CVD risk) and mental (depression and anxiety) disorders.

Materials and methods: Participants were a community-recruited COMISA cohort with an initial sample size of 445 potential subjects that yielded 256 individuals who met diagnosis for COMISA and who were used to identify subtypes using a two-step clustering methodology. Demographics and multidimension clinical characteristics were collected and compared among obtained subtypes. Logistics models were used to evaluate whether these subtypes were associated with cardiometabolic and mental disorders. A clinical cohort of 1816 COMISA patients was used to validate the determined clusters applying the same two-step clustering methodology.

Results: Cluster analysis yielded three clusters (COMISA subtypes): “moderate OSA and moderate insomnia” (cluster 1), “moderate OSA and severe insomnia” (Cluster 2) and “severe OSA and moderate insomnia” (Cluster 3), consisting of 58.2%, 21.9% and 19.9% of the entire cohort, which was validated using the clinical COMISA cohort. The clusters differed significantly on a variety of clinical measurements, including blood indicators related to cardiometabolic risk, inflammation and liver function, depression symptoms, and encephalogram (EEG) spectral power. Cluster 2 was associated with elevated risk of moderate-to-severe depression symptoms, while Cluster 3 was associated with increased risk of CVD and metabolic syndrome.

Conclusions: COMISA patients were found to form three clusters or subtypes. These subtypes were differentially associated with increased risk of cardiometabolic illnesses and depression. These findings provide important preliminary evidence of the existence of phenotypes of COMISA which are likely to have clinical relevance and provide a foundation in precision medicine for treatment of COMISA.

Co-Designing a Sleep Hygiene eBook for Young People with and without Learning Disabilities: A Qualitative Focus Group Study

M. Ravikumar¹, E. Rogers¹, L. Sharpe², K. Morgan¹, I. Hartescu¹

¹Loughborough University, School of Sports Exercise and Health Science, Loughborough, United Kingdom, ²University of Lincoln, School of Psychology Sport Science & Wellbeing, Lincoln, United Kingdom

Introduction: Individuals with learning disabilities (LD) often face significant health inequalities, including poorer sleep quality, compared to the general population. While improved sleep hygiene could help address these sleep problems, there are limited evidence-based and accessible resources available to support younger people and those with LD adopt the basic principles of sleep hygiene practice. Current resources are often unregulated, outdated, or target only caregivers to interpret. In collaboration with intended users and stakeholders this project co-designed an evidence-based e-book resource appropriate for younger people with and without LD, and caregivers.

Materials and methods: Using a purposive sampling approach 18 participants (13 male; mean age = 25 years) were recruited for this qualitative study (8 individuals with diagnosed learning disabilities/difficulties and 10 caregivers). Focus groups were conducted online, were audio-recorded with consent, and lasted an average of 75 minutes (range 68-81 minutes). Based on relevant literature a semi-structured interview guide was developed addressing issues of sleep initiation and maintenance, barriers to sleep, and the impact of sleep on daytime functioning. Data were analysed using reflexive thematic analysis (Braun & Clarke, 2006; Byrne, 2022). The interviews were transcribed verbatim, and NVivo software (Version 1.3.535) was used for data storage, coding, and analysis.

Results: Thematic analysis identified four key themes: (1) Bedtime Patterns and Sleep Cues, (2) Creating a Relaxing Sleep Environment, (3) Sleep Disruptors and Adaptation, and (4) Sleep Management through Routines and Guidance. Participants discussed their bedtime routines and the specific sleep cues they relied on, such as particular activities or environmental signals that indicated the start of sleep preparation. Dim lighting, soft bedding, quiet surroundings, pre-sleep emotional regulation, and anxiety and stress reduction were independently identified as important for sleep promotion. Individuals with

LD presented a need for clearer, more accessible sleep hygiene advice. This feedback emphasised the difficulty of applying generic sleep hygiene recommendations without modification. Following the analyses, key themes were matched against current evidence-based sleep hygiene advice, and a set of simplified principles were agreed. These principles were then used to inform a pictorial, accessible e-book focussing on actionable 'rules' for better sleep. Drafts of the "Sleep Smart" e-book were then considered by a sample of professional and non-professional users whose feedback resulted in the final version.

Conclusions: Through direct engagement with end users, insights were gained which informed the creation of a tailored sleep hygiene e-booklet. Focus group discussions underscored the necessity for a resource that is accessible to younger people with below-average reading age, but nevertheless of value to caregivers, younger people generally, and clinicians. The "Sleep Smart" e-booklet provides practical, relevant guidance aimed at improving sleep quality and overall well-being for individuals with learning disabilities and learning difficulties.

Acknowledgments: The project was funded by the Medical Research Council, UK (MRC Public Engagement) and supported by Loughborough University. We thank all focus group participants for sharing their experiences and insights. The final booklet can be downloaded here: www.ncsem-em.org.uk/sleep-smart.

Cognitive-Emotional Traits and Sleep Mental Content Features in Insomnia: Associations With Mental Content Recall and Subjective Sleep Quality

E. Cini¹, F. Berra¹, F. Bolengo¹, L. Ferini-Strambi^{1,2}, A. Galbiati^{2,1}

¹Vita-Salute San Raffaele University, Psychology, Milan, Italy, ²IRCCS San Raffaele Scientific Institute, Clinical Neurosciences, Neurology, Milan, Italy

Introduction: The relationship between Insomnia Disorder (ID), sleep perception, and nocturnal mentation -including both recall and qualitative content- remains insufficiently understood. While ID is consistently associated with altered sleep perception and more negatively toned mental activity, findings regarding recall frequency and the qualitative features of nocturnal mentation are still mixed and underexplored. This study aimed to examine whether, and how, insomnia symptoms and cognitive-emotional traits influence the recall and content of nocturnal mentation, and whether these variables predict individual differences in subjective sleep perception.

Materials and methods: Twenty-six participants (age= 29.58 ± 6.5; 14F/12M) were assigned to two groups based on their Insomnia Severity Index (ISI) scores: 13 with ID symptoms (ISI ≥ 12) and 13 controls (ISI ≤ 7). Over 14 consecutive days, participants completed a Sleep Diary and a Mental Content Diary within 15 minutes of awakening. The Sleep Diary assessed subjective sleep parameters, including perceived depth and restorativeness. The Mental Content Diary captured the presence, recall, and qualitative features of nocturnal mental activity, rated for emotional, perceptual, and thought-like characteristics. Participants also completed the Difficulties in Emotion Regulation Scale (DERS), Ruminative Response Scale (RRS), and the Penn State Worry Questionnaire (PSWQ).

Results: No significant group differences in recall frequency emerged. However, participants with insomnia symptoms reported significantly lower perceived sleep depth ($p=.015$) and restorativeness ($p=.038$) than controls. Spearman correlations showed that recall frequency was negatively associated with rumination ($r=-.526$; $p=.006$) and with difficulties maintaining goal-directed behavior under negative emotion (DERS-Goals; $r=-.42$; $p=.030$). Higher levels of worry were associated with more perceptual ($r=.525$; $p=.006$), emotional ($r=.425$; $p=.030$), and realistic ($r=.425$; $p=.030$) features of mentation, while greater impulse control difficulties (DERS-Impulse Control) were linked to more perceptual content ($r=.396$; $p=.045$). A multiple linear regression showed that perceived sleep depth was significantly predicted by group status (ID symptoms; $\beta=-.889$; $p=.002$) and the presence of thought-like mentation ($\beta=-.310$; $p=.024$), explaining 39.4% of the variance ($R^2=.394$). Sleep restorativeness was also predicted by group (ID symptoms; $\beta=-.615$; $p=.032$), but not by any mental content features.

Conclusions: This study provides new insights into the interplay between cognitive-emotional traits, nocturnal mental content, and subjective sleep perception in individuals with and without ID symptoms. Although mental content recall and features did not differ between groups, individuals with ID symptoms perceived their sleep as significantly less deep and restorative. Importantly, this negative perception was not associated with the emotional intensity of mental content, but rather with its

thought-like quality, supporting theoretical models that link heightened nocturnal cognition to altered sleep perception. Unlike clinical status, cognitive-emotional traits emerged as significant correlates of nocturnal mentation, with worry and impulse control difficulties associated with more perceptual, emotional, and realistic content. While rumination and reduced ability to stay focused on goals during negative emotional states were linked to diminished recall. Overall, these findings highlight the clinical relevance of integrating nocturnal mentation characteristics and individual cognitive-emotional profiles in the clinical assessment of insomnia, suggesting that mental content during sleep may represent a meaningful marker of disrupted sleep experience.

Cognitive Function and Frontotemporal Functional Connectivity in Patients with Major Depressive Disorder and Comorbid Insomnia Symptoms: A Cerebral Hemodynamics Perspective

X. Song¹, X. Lu¹, Y. Zhang¹, Q. Zhong¹, S. Lai¹, Y. Liang¹, D. Wei¹, M. Zhang¹, S. Zhong¹, Y. Jia¹

¹Department of Psychiatry, First Affiliated Hospital, Jinan University, Guangzhou, China

Introduction: The underlying mechanism of major depressive disorder (MDD) with insomnia symptoms (IS) is still unclear. Our research is aimed to investigate the changes in the frontotemporal functional connectivity and cognitive function in patients with MDD and comorbid IS.

Materials and methods: We recruited 82 patients with MDD, including 50 comorbid with IS (MDD-IS), 32 without insomnia (MDD-nIS), and 35 healthy controls (HCs). The MATRICS Consensus Cognitive Battery (MCCB) was used to assess their cognitive function, and a resting-state functional near-infrared spectroscopy (fNIRS) was applied to measure the intensity of their frontotemporal functional connectivity (FC).

Results: A comparative cognitive function analysis showed both MDD-IS and MDD-nIS groups had significantly more impairments than the HC group in multiple domains: information processing speed, attention/vigilance, working memory, verbal learning, visual learning, and reasoning/problem-solving (all with $p < 0.001$, except reasoning/problem-solving with $p = 0.008$). In social cognition, the MDD-IS group had more pronounced impairments than the MDD-nIS group, which also performed worse than the HC group ($p < 0.001$). Using fNIRS, distinct frontotemporal and interregional functional connectivity (FC) changes were found among MDD subgroups differentiated by sleep disturbance. Compared to MDD-nIS and HC groups, the MDD-IS group exhibited significant frontotemporal hypoconnectivity ($p = 0.02$), with specific deficits in four pathways: left triangular part-left premotor cortex ($p = 0.010$), right triangular part-left oculomotor cortex ($p = 0.018$), right triangular part-right premotor cortex ($p = 0.026$), and left oculomotor cortex-right premotor cortex ($p = 0.003$). Further analysis revealed additional dysconnectivity between prefrontal and premotor regions in MDD-IS patients compared to HC, involving connections between left and right dorsolateral prefrontal cortex (DLPFC) and right premotor cortex ($p = 0.002$ and $p = 0.017$, respectively). Subgroup-specific reductions were observed in MDD-IS patients compared to MDD-nIS, particularly in connectivity between the left triangular part and left oculomotor cortex ($p = 0.049$), and between left oculomotor and left premotor pathways ($p = 0.034$). Notably, both MDD subgroups showed impaired connectivity between the right oculomotor and right premotor regions compared to HC ($p = 0.004$), indicating this pathway may be a transdiagnostic neural signature of MDD. Correlation analyses showed significant associations between cognitive performance and interregional FC in the MDD-IS subgroup. Verbal learning capacity was positively correlated with connectivity between the left oculomotor and right premotor cortices. Visual learning performance demonstrated coordinated neural coupling through four pathways: left DLPFC-right premotor cortex, left triangular part-left oculomotor cortex, right DLPFC-right premotor cortex, and left oculomotor-right premotor cortex. Reasoning and problem-solving abilities were positively associated with connectivity patterns between the left triangular-left oculomotor and left triangular-left premotor regions.

Conclusions: These findings indicate that MDD patients with sleep disturbances exhibit characteristic cognitive impairments potentially linked to dysfunctions in frontotemporal and oculomotor-premotor networks. This research advances our understanding of the neural circuits through which sleep disturbances affect cognitive phenotypes in depression, and the related FC patterns could serve as potential biological markers and therapeutic targets.

Cognitive Impairment in Obesity Individuals With and Without Insomnia: The Role of Cortisol Dysregulation

Y. Zhang¹, S. Yan¹, X. Song¹, D. Huang¹, X. Lu¹, S. Zhong¹, Y. Jia¹

¹First Affiliated Hospital of Jinan University, Department of Psychiatry, Guangzhou, China

Introduction: This study aimed to investigate the impact of insomnia on cognitive impairment in individuals with obesity, compare cognitive performance between obese patients with and without insomnia, and explore the potential role of cortisol levels in this association.

Materials and methods: A total of 50 obese participants (BMI ≥ 30 kg/m², aged 18–65 years) were recruited and divided into an insomnia group (n=24) and a non-insomnia group (n=26), with 30 healthy-weight controls (BMI 18.5–24.9 kg/m², no insomnia) included for comparison. Cognitive function was assessed using the MATRICS Consensus Cognitive Battery (MCCB), information processing speed, attention/alert working memory, verbal learning, visual learning, reasoning/problem-solving, social cognition, and total cognition. Plasma cortisol levels were measured at 8:00 AM. Group differences were analyzed using analysis of covariance (ANCOVA) adjusted for education level, and correlation analyses were performed to evaluate associations between cortisol levels, cognitive performance, and clinical variables.

Results: The obesity-with-insomnia group exhibited significantly lower performance in processing speed (p=0.021), verbal learning (p=0.009), and composite cognitive scores (p=0.004) compared to the non-insomnia group, with both obese groups performing worse than healthy controls (all p<0.01). Plasma cortisol levels were significantly elevated in the insomnia group (p<0.001), while no difference was observed between the non-insomnia and control groups. Correlation analyses revealed positive associations between insomnia severity and cortisol levels (r=0.308, p=0.006), as well as between cortisol levels and BMI (r=0.400, p<0.001).

Conclusions: Insomnia may exacerbate cognitive impairment in individuals with obesity, potentially linked to dysregulated cortisol activity. These findings highlight the importance of addressing sleep disorders in obesity management to mitigate cognitive decline.

COMISA in Heart Failure: Greater Impact and Worse clinical Outcomes Compared with Isolated Sleep Disorders

M. Meira e Cruz¹, M. Kryger², F. Pinto¹

¹Faculdade de Medicina da Universidade de Lisboa (CCUL@RISE), Cardiovascular Center of University of Lisbon, Lisbon, Portugal, ²Yale School of Medicine, New Haven, Connecticut, United States

Introduction: We aimed to evaluate the clinical impact of COMISA on patients with HF, compared to insomnia or sleep apnea alone, and to test the hypothesis that COMISA confers greater risk to HF outcomes than isolated sleep disorders.

Materials and methods: A retrospective cohort analysis was performed using open-access national health data and published studies. HF patients were identified from Portuguese health records (e.g. hospital discharge registries and mortality data), and classified into three groups based on co-diagnoses: Insomnia-only, Sleep Apnea (SA)-only, and COMISA (both insomnia and SA). Prevalence of insomnia and OSA in HF across age strata was estimated using Portuguese epidemiological sources (including INSA/SNS reports and the EPICA heart failure study). Key outcomes (e.g. HF hospitalizations, major adverse cardiac events [MACE], and all-cause mortality) were compared between groups over a follow-up period. Cox proportional hazards models adjusted for age, sex, and comorbidities were used to assess the association of COMISA with outcomes, and interaction analyses were performed to examine differences by age group.

Results: Among Portuguese HF patients (spanning young adult to ≥ 80 years), insomnia and OSA were each highly prevalent, and a notable proportion (approximately 20%) had co-morbid COMISA. Patients with COMISA had more severe HF symptoms and worse New York Heart Association functional class at baseline than those with insomnia-only or SA-only (P < 0.01). Over a median follow-up of 3 years, the COMISA group showed a higher rate of HF-related acute decompensations and MACE compared to the other groups. In multivariate analysis, COMISA was associated with a significantly elevated risk of composite cardiac events (hazard ratio ~ 2.3 vs. no-sleep-disorder, P < 0.005), exceeding the risk observed with insomnia-only or SA-only. COMISA patients had roughly double the yearly HF

hospitalization rate of those with a single sleep disorder. All-cause and cardiovascular mortality tended to be higher in COMISA as well, although not statistically significant after adjustment. Age-stratified results revealed that the detrimental impact of COMISA was most pronounced in middle-aged HF patients: for example, in patients <70 years old, COMISA was linked to a four-fold increase in MACE risk. In older HF patients (≥ 70), insomnia and OSA remained frequent, but the COMISA-related risk increment was more modest. These findings align with recent cohort data in non-HF populations showing that COMISA amplifies cardiac risk (e.g. doubling MACE incidence). Epidemiologically, the analysis confirmed that insomnia and OSA often coexist in HF: while only ~0.9% of Portuguese adults ≥ 25 are diagnosed with OSA (reflecting under-detection), estimates suggest up to 30% actually have clinically relevant sleep apnea, and many of these also report insomnia symptoms. Across all age groups, HF patients with COMISA reported poorer quality of life and sleep quality than those with one sleep disorder, highlighting an additive burden on daily functioning.

Conclusions: The data support our hypothesis that COMISA has a greater clinical impact on heart failure than either insomnia or sleep apnea alone. Patients with HF and COMISA experienced more frequent cardiac events and hospitalizations, suggesting a synergistic deleterious effect of concurrent sleep fragmentation and sleep-disordered breathing on the failing heart.

Co-morbid Insomnia and Obstructive Sleep Apnea Augments Cardiac Autonomic Burden to Increase All-cause Mortality

H. Qin¹, T. Penzel², X. Zhang¹

¹The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China, ²Charité-Universitätsmedizin Berlin, Berlin, Germany

Introduction: Co-morbid insomnia and sleep apnea (COMISA) is associated with increased mortality. It remains unclear whether COMISA has cumulative deleterious impact on autonomic regulation to augment risk of deaths compared to insomnia alone and OSA alone. This study aimed to evaluate an association of heart rate variability (HRV) as a marker of autonomic burden to all-cause mortality in patients with COMISA.

Materials and methods: 5225 participants from the Sleep Heart Health Study were included. The participants underwent unattended polysomnography and completed sleep questionnaires on insomnia and daytime impairment from which the diagnosis of COMISA was determined. The diagnosis of COMISA required the criteria for both insomnia (difficulties initiating sleep, maintaining sleep, and/or early morning awakenings on 16-30 times/month and daytime impairment) and sleep apnea (an apnea-hypopnea index [AHI] ≥ 15 events/h) to be met. HRV measures were computed from a 5-min ECG segment extracted during wakefulness prior to sleep and sleep using time-domain and frequency-domain methods, detrended fluctuation analysis, entropy, symbolic dynamics, deceleration capacity (DC) and acceleration capacity (AC). Analysis of covariance controlling for relevant covariates (age, body-mass index, gender, race, smoking status, AHI and prevalent cardiovascular disease) was used to compare differences in HRV characteristics among control, insomnia, OSA, and COMISA groups. Multivariable Cox analysis and ROC were used to estimate the association between HRV and in COMISA subgroup. Multivariable-adjusted Cox proportional hazards analysis were conducted to estimate the associations between HRV metrics and all-cause mortality in patients with COMISA.

Results: Of the 5255 participants, 2697 (51.6%) were controls without insomnia or OSA, 170 (3.3%) had only insomnia, 2221 (42.5%) had only OSA, and 137 (2.6%) had COMISA. 42 deaths occurred in COMISA (30.6%). By comparisons of HRV metrics among these 4 groups, patients with COMISA were associated with elevated autonomic burdens, showing decreased parasympathetic function during wakefulness and sleep compared to controls. In the Multivariable Cox model, DC during wakefulness and sleep were significantly associated with all-cause mortality in COMISA (hazard ratio [HR] per 1-SD, 0.91; 95%CI, 0.84-0.99; $P=0.026$ and HR, 0.86; 95%CI, 0.77- 0.96, $P=0.007$, respectively). DC demonstrated favorable performance in identifying mortality risk in COMISA during wakefulness (the area under the curve, AUC, 0.78) and sleep (AUC, 0.76).

Conclusions: COMISA proposed HRV impairments to be related to the increased risk of all-cause mortality through decreased parasympathetic function during wakefulness. HRV can provide information on underlying pathogenic mechanisms of alterations in the autonomic cardiac modulation associated with all-cause mortality in COMISA.

Comparative Effectiveness of Digital CBT and MBSR for Insomnia in Cancer Survivors: Results from a Meta-Analysis

S. Lee¹, S. Choi¹, E.-S. Yu²

¹Duksung women's University, Psychology, Seoul, Korea, Republic of, ²The Cyber University of Korea, Counseling Psychology, Seoul, Korea, Republic of

Introduction: Insomnia is a prevalent complaint among cancer patients, with a significant impact on various aspects of their lives throughout the cancer continuum. The present study conducted a meta-analysis to evaluate the effectiveness of digital interventions in alleviating insomnia symptoms by intervention type: CBT vs. MBSR.

Materials and methods: Following PRISMA guidelines, a comprehensive search of the published literature from January 2009 and July 2023 was conducted across 10 major databases, including PubMed, EMBASE, Cochrane, Web of Science, PsycINFO, CINAHL, KoreaMed, MedRIC, KISS, and RISS. Eligible studies included adults (≥ 18 years) with cancer or cancer survivors who received digital psychological interventions and reported quantitative sleep-related outcomes before and after the intervention. Key outcomes included insomnia severity (ISI), overall sleep quality (PSQI), sleep onset latency (SOL), total sleep time (TST), and wake after sleep onset (WASO). Meta-analyses were conducted using a random-effects model, and effect sizes were reported as Hedges'g.

Results: A total of 17 studies were included in the meta-analysis. digital CBT demonstrated significant improvements across multiple outcomes: ISI (Hedges' g = -2.09, 95% CI [-3.63, -0.56]), sleep disturbance (g = -0.52, 95% CI [-0.72, -0.31]), total sleep time (TST) (g = 1.02, 95% CI [0.23, 1.82]), sleep onset latency (SOL) (g = -1.44, 95% CI [-2.69, -0.18]), and total PSQI score (g = -0.79, 95% CI [-1.51, -0.06]). In contrast, digital-based MBSR showed statistically significant improvement only in sleep disturbance (g = -0.33, 95% CI [-0.53, -0.13]), while other outcomes such as total PSQI score (g = -0.76, 95% CI [-1.56, 0.05]) did not reach statistical significance. Heterogeneity was higher among CBT studies ($I^2 = 81.1-96.7\%$) compared to MBSR ($I^2 = 0\%$).

Conclusions: Digital psychological interventions are effective in improving sleep problems among cancer patients. However, effectiveness varies by intervention type and sleep domain. Digital CBT showed robust effects across several sleep outcomes, while digital-based MBSR showed more limited benefits. These findings highlight the need to tailor digital interventions based on therapeutic mechanisms and targeted sleep problems.

Acknowledgments: This research was supported by a grant of the Korean Cancer Survivors Healthcare R&D Project through the National Cancer Center, funded by the Ministry of Health & Welfare, Republic of Korea (RS-2023-CC139638)

Consistency of Objective Results on Sleep Onset and Sleep Maintenance Parameters From Global Studies of Lemborexant

A. Lowe¹, N. Yamakawa², T. Takase², K. Nakai², D. Kumar³, N. Kubota², M. Moline³

¹University of Toronto, Toronto, Canada, ²Eisai Co., Ltd., Tokyo, Japan, ³Eisai Inc., Nutley, United States

Introduction: When selecting a hypnotic for patients, it is important to know whether there are differences in response based on age, sex, and/or race. For registration purposes and to increase patient diversity across the clinical development program for lemborexant (LEM), a dual orexin-receptor antagonist approved to treat adults with insomnia, 2 additional studies were conducted beyond the original Phase 3 studies that enrolled patients in North America, Europe, and Japan, but few from South Korea and none from China. Since studies have now completed in these latter countries, it is possible to compare results on polysomnography (PSG) from the 3 studies conducted globally with South Korea or China.

Materials and methods: Each study was 1-month, multiple-site, randomized, and placebo-controlled enrolling participants with insomnia disorder. Study E2006-G000-304 (Study 304) included females ≥ 55 years/males ≥ 65 years with confirmed sleep maintenance insomnia. Studies E2006-J086-311 (Study 311) and E2006-J082-204 (Study 204) enrolled adults ≥ 18 and 19–80 years, respectively, with confirmed sleep onset and/or maintenance insomnia. PSGs were obtained during the placebo run-in (baseline) and at end-of-treatment. Each study included LEM 10 mg (LEM10) and placebo. Study 304 also included zolpidem extended-release, and Studies 204 and 304 included LEM 5 mg (not discussed here). Change from baseline to Day 30 in latency-to-persistent-sleep (LPS), sleep efficiency (SE), and wake-after-sleep-onset (WASO) were calculated. Safety and pharmacokinetics were assessed.

Results: Results from the 3 PSG studies (204, 304, and 311) were compared using 95% confidence intervals (CIs). LEM10 led to larger changes from baseline in LPS, SE, and WASO compared to placebo. The CIs overlapped, demonstrating that the direction and magnitude of effect were similar. LEM pharmacokinetics from Studies 204 and 311 were comparable to Study 304. Based on the totality of LEM data from clinical trials, analyses show that oral clearance was not affected by race. In Studies 204 and 311, like global Study 304, overall incidence of LEM10 treatment-emergent adverse events was similar to placebo. In all studies, most TEAEs were mild/moderate.

Conclusions: These data support the view that LEM is an effective and well-tolerated treatment for patients with insomnia without influence by race/national origin.

Acknowledgments: We thank Kisaki Onishi for her contributions to this work. Medical writing assistance was provided by Lindsay Achzet, PhD, of Peloton Advantage, LLC, an OPEN Health company, and was funded by Eisai, Inc., and Eisai Co., Ltd.

Co-occurrence of Dysfunctional Cognitions about Sleep and Excessive Daytime Sleepiness as a Psycho-behavioral Characteristic of Comorbid Insomnia and Sleep Apnea

T. Utsumi¹, T. Yoshiike¹, A. Kawamura¹, K. Nagao¹, S. Okamura¹, M. Fushimi¹, K. Matsui², K. Kuriyama¹
¹National Center of Neurology and Psychiatry, Department of Sleep-Wake Disorders, National Institute of Mental Health, Kodaira, Japan, ²National Center of Neurology and Psychiatry, Department of Laboratory Medicine, National Center Hospital, Kodaira, Japan

Introduction: Chronic Insomnia Disorder (CID) and Obstructive Sleep Apnea (OSA) are both common sleep disorders that frequently co-occur as Comorbid Insomnia and Sleep Apnea (COMISA). COMISA has worse clinical symptoms and poorer treatment outcomes than either condition alone. Despite the clinical importance of COMISA, little is known about how psychological and behavioral characteristics are similar to or different from those of each condition. Dysfunctional cognitions about sleep and excessive daytime sleepiness are not necessarily central to the clinical presentation of CID and that of OSA, respectively. However, patients with COMISA could simultaneously exhibit amplified psycho-behavioral characteristics. This study examined whether the co-occurrence of dysfunctional cognitions about sleep and excessive daytime sleepiness differentiates COMISA from CID and OSA.

Materials and methods: We analyzed data from 346 patients in the NCNP database, which is part of a polysomnography databank for sleep disorders in Japan, comprising three distinct groups: CID alone (n = 42, median age: 43.5), OSA alone (n = 166, median age: 51.0), and COMISA (n = 75, median age: 61.0), who didn't have other sleep disorders. Participants were categorized into 4 groups based on combinations of high and low scores on the Dysfunctional Beliefs and Attitudes about Sleep Scale (DBAS) and Epworth Sleepiness Scale (ESS), with each measure dichotomized by a median split. We conducted two separate logistic regression analyses to examine the relationship between DBAS/ESS combinations and COMISA. One analysis compared COMISA to CID, and the other compared COMISA to OSA. The DBAS/ESS combinations served as the independent variables, and age and sex were included as the covariates.

Results: The high-DBAS/high-ESS groups were younger than the low-DBAS/low-ESS groups across all conditions (COMISA, CID, and OSA). Additionally, the conditions with sleep apnea (i.e., COMISA and OSA) had a higher proportion of males compared to CID. Analyzing logistic regression models adjusting for age and sex, significant associations emerged between the high-DBAS/high-ESS combination and COMISA in both comparative analyses: COMISA vs. CID (adjusted odds ratio [AOR] = 8.01; p = 0.001) and COMISA vs. OSA (AOR = 3.09; p = 0.008).

Conclusions: A concurrent worsening of dysfunctional cognitions about sleep and excessive daytime sleepiness may be a psycho-behavioral characteristic of patients with COMISA. These findings highlight

the need for comprehensive assessment and treatment approaches that address both cognitive and physiological aspects of COMISA.

Correlates between sleep architecture and sleep reactivity to stress in the context of cumulative adversities: Is REM sleep continuity a potential protective factor for sleep reactivity?

C.X. Chen¹, M. Zhou¹, W.I. Ao¹, R. Wang², S. Xie¹, J.W.Y. Chan¹, B. Huang¹, T.M.C. Lee^{3,4}, S.X. Li², Y.K. Wing^{1,5}, N.Y. Chan¹

¹The Chinese University of Hong Kong, Li Chiu Kong Family Sleep Assessment Unit, Department of Psychiatry, Sha Tin, Hong Kong, SAR of China, ²University of Hong Kong, Sleep Research Clinic and Laboratory, Department of Psychology, Hong Kong, Hong Kong, SAR of China, ³University of Hong Kong, The State Key Laboratory of Brain and Cognitive Sciences, Department of Psychology, Hong Kong, Hong Kong, SAR of China, ⁴University of Hong Kong, Laboratory of Neuropsychology and Human Neuroscience, Department of Psychology, Hong Kong, Hong Kong, SAR of China, ⁵The Chinese University of Hong Kong, Li Ka Shing Institute of Health Sciences, Faculty of Medicine, Sha Tin, Hong Kong, SAR of China

Introduction: Stress is a well-known risk factor for sleep problems, particularly insomnia. While life stressors may induce high sleep reactivity and precipitate insomnia in some vulnerable individuals, some others demonstrate resilience. Thus, it is of significant interest to understand the underlying mechanisms involved in low sleep reactivity against life stressors and adversities. This study aimed to examine the associations of sleep architecture with sleep reactivity in the context of cumulative life stressors in adults.

Materials and methods: All participants received clinical interview, completed questionnaires measuring demographic, sleep characteristics, childhood trauma, and life stressful events, and underwent one-night polysomnography (either ambulatory or in a laboratory setting). The sleep reactivity was measured by the Ford Insomnia Response to Stress Test (FIRST) questionnaire, and other sleep characteristics were measured by the Insomnia Severity Index (ISI) and Pre-sleep Arousal Scale (PSAS). Usage of medications, including hypnotics, antidepressants, NSAIDs, Beta-blockers, antihistamines, anticonvulsants, and melatonin were recorded. Childhood trauma including emotional and physical neglect and abuse, and sexual abuse were self-reported. Life stressful events were grouped into 5 categories: job-related stress, death of a loved one, enormous change in relationship, severe injury or chronic illness, and sexual related uncomfortable experiences or assault. We calculated the level of sleep reactivity versus that of cumulative adversities (life stressful events and childhood trauma) by the standardized residual value in the regression model. We further dichotomized into 2 groups by the split-median value (Low sleep reactivity despite cumulative adversities vs High sleep reactivity with cumulative adversities). The associations of sleep characteristics and sleep architectures with sleep reactivity residuals were further examined, with covariates including age, sex, PSG measures type (Ambulatory or Laboratory), and medications adjusted.

Results: A total of 354 participants (Mean age: 39.16 years; 62.7% female) were included. Among them, 178 participants were grouped into high sleep reactivity and 176 participants into low sleep reactivity, in the context of cumulative adversities. The group with low sleep reactivity upon cumulative adversities showed lower insomnia severity, lower pre-sleep arousal, higher sleep efficiency, less wake time after sleep onset, and less REM sleep transitions to Wake stage (All p values <0.05). The findings remained the same after adjustment of covariates, that participants with low sleep reactivity (despite cumulative adversities) had lower insomnia severity (OR: 0.91; 95%CI: 0.87-0.94), lower pre-sleep arousal (Somatic: OR: 0.88; 95%CI: 0.83-0.93; Cognitive: OR: 0.87; 95%CI: 0.84-0.91), better sleep efficiency (OR: 1.03; 95%CI: 1.00-1.05), less wake time after sleep onset (OR: 0.99; 95%CI: 0.98-0.99) and lower chance of REM sleep transitions to Wake stage (OR: 0.92; 95%CI: 0.86-0.99).

Conclusions: The persistence of low sleep reactivity despite cumulative life adversities is associated with higher sleep continuity, particularly REM sleep continuity. These suggest that maintaining sleep continuity with focus on REM sleep may be potential prevention and intervention target for stress-related sleep pathology.

Introduction: A subset of insomnia patients perceives their sleep as worse than what is objectively measured by polysomnography (PSG), a phenomenon known as sleep state misperception (SSM). In South Korea, the prevalence of SSM is estimated at 26.4%; yet its classification remains inconsistent. This study aimed to classify SSM subgroups by integrating PSG and self-reported indices, and we hypothesized that distinct SSM profiles may represent physiologically unique characteristics, particularly in cortical and autonomic activity during sleep.

Materials and methods: We retrospectively reviewed the medical records of adult patients (≥ 18 years) who underwent PSG at department of psychiatry of Seoul National University Hospital between May 2018 and August 2022. Participants with ≥ 5 on the Pittsburgh Sleep Quality Index were classified as insomnia patients ($n = 78$; 51.3% female; age = 40.3 ± 14.7), while those with scores < 5 as controls ($n = 34$; 82.4% females; age = 34.5 ± 12.1). Exclusion criteria included PSG-confirmed sleep disorders, major psychiatric disorders (e.g., schizophrenia), and severe medical conditions (e.g., cancer). SSM index was calculated and EEG/ECG power spectral analysis were performed. Latent class analysis (LCA) was conducted based on total sleep time (TST) misperception and anxiety severity. LASSO regression selected EEG and heart rate variability (HRV) features, followed by multinomial logistic regression to identify group-defining markers.

Results: LCA identified two insomnia subtypes: an SSM group ($n = 53$; 60.4% female; age = 42.9 ± 14.3) and a simple insomnia group (INS) ($n = 25$; 32.0% female; age = 34.9 ± 14.2). Compared to the INS group, the SSM group exhibited greater TST misperception (misperception index: -0.261 vs. 0.001 ; $t = 6.82$, $p < 0.001$) and higher anxiety and depression scores than both the INS and control groups (Beck Anxiety Inventory: 17.4 vs. 7.8 vs. 3.2 ; Beck Depression Inventory: 16.1 vs. 11.0 vs. 4.6 ; both $ps < 0.001$). Compared to controls, the SSM group showed decreased N3 sigma power in the right central region (coefficient = -87.5 , $z = -79.3$, $p < 0.001$), while the INS group showed a significant increase (coefficient = 92.9 , $z = 84.2$, $p < 0.001$). N2 beta power in the left frontal region also showed opposite patterns between the SSM and INS groups (SSM: coefficient = 80.4 , $z = 23.1$, INS: coefficient = -84.1 , $z = -24.2$, both $ps < 0.001$). Both groups exhibited reduced REM delta power in the left central region (SSM: coefficient = -44.1 , $z = -7.9$; INS: coefficient = -72.9 , $z = -13.1$, both $ps < 0.001$), reduced normalized high-frequency (HF) power of heart rate variability (HRV) during REM (SSM: coefficient = -35.3 , $z = -20.1$; INS: coefficient = -35.6 , $z = -20.2$, both $ps < 0.001$), and increased N1 sleep percentage (SSM: coefficient = 2.5 , $z = 7.9$; INS: coefficient = 2.3 , $z = 7.3$, both $ps < 0.001$).

Conclusions: Reduced sigma power and increased beta power during deep sleep may serve as a physiological marker of SSM.

Cost-utility of fully automated digital cognitive behavioral therapy for insomnia: Trial-based economic evaluation with 2 year follow up

Z. Khan¹, H. Kallestad², Ø. Vedaa³, B. Sivertsen³, K. Kidholm⁴, G. Morken², V. Halsteinli⁵

¹Norwegian University of Science and Technology, Public Health and Nursing, Trondheim, Norway,

²Norwegian University of Science and Technology, Trondheim, Norway, ³Norwegian Institute of Public Health, Bergen, Norway, ⁴Odense University Hospital, Odense, Denmark, ⁵St Olav Hospital, Trondheim, Norway

Introduction: Introduction: Insomnia is a common condition that affects approximately one-third of the general population. Cognitive behavioral therapy for insomnia (CBTi) is the recommended first-line treatment; however, a shortage of trained healthcare professionals limits access and increases wait times. Fully automated, digitally delivered CBTi (dCBTi) presents a promising alternative, but there is limited evidence on its cost-effectiveness, particularly over the long-term. This study aims to address this gap by conducting a trial-based economic evaluation of fully automated dCBTi compared to an active control group receiving online patient education.

Study design: Participants were recruited from the general population through advertisement in outpatient clinics and social media. They were assessed for eligibility using an automated questionnaire in the study's website. Eligible participants were randomized 1:1 to the intervention and control arms without stratification. A cost-utility analysis was conducted from a public health service perspective, with evaluations performed at 6 months and 24 months post-treatment. Post-treatment was defined as 9 weeks after randomization.

Materials and methods: Methods: Health utility index scores were obtained from the Short Form 12 at baseline, post-treatment, and at 6 and 24 months post-treatment, using UK preference weights for SF-6D. Quality-adjusted life years (QALYs) were calculated using the area under the curve method. Total costs included the program costs of treatment and health service utilization in terms of sleep medication, GP visits and mental health outpatient visits. Program costs for dCBTi and online patient education were derived from license fees paid during the study period. Resource utilization and costs were assessed based on patients' self-reported questionnaires. Unit costs were obtained from the Norwegian Medicines Agency's costing guidelines and published literature. All costs were adjusted to 2020 Norwegian kroner, and a 4% discount rate was applied to health service utilization costs at the 24-month follow-up.

Cost-utility was expressed in terms of the incremental cost-effectiveness ratio (ICER). Probabilistic sensitivity analyses were performed to explore uncertainty via non-parametric bootstrapping. Given the uncertainty around the dCBTi's market price, threshold analyses were conducted to explore the maximum price per patient.

Results: Results: Preliminary analysis indicated a significant improvement in health-related quality of life post-treatment, which was sustained at both the 6- and 24-month follow-ups. Mixed linear models showed a significant between-group difference in health utility index scores at post-treatment, though this difference reduced at 6 months and further narrowed at 24 months. Patients in the dCBTi group reported fewer GP visits and less sleep medication use compared to the control group.

Conclusions: Conclusion: Fully automated dCBTi may represent a cost-effective solution for increasing access to insomnia treatment in the general population, with potential long-term benefits in both health outcomes and resource utilization.

Data-driven subtypes of youth insomnia: A mixed-feature clustering analysis

Z. Chen¹, X. Li¹, R.N.Y. Chan², J.W.Y. Chan², J. Zhang^{2,3,4}, A.M. Li⁵, Y.K. Wing², C.A. Espie⁶, S.X. Li^{1,7}

Introduction: Insomnia is a heterogeneous sleep disorder and frequently co-occurs with depressive and other daytime symptoms. Insomnia is prevalent in adolescence and young adulthood, which represents a unique transitional period associated with various biological and psychosocial changes and challenges. Whilst previous research has explored different subtypes of insomnia, the findings were mainly limited to the adult population. The current study aimed to identify and characterize subtypes of insomnia in youth using a data-driven approach.

Materials and methods: This was a secondary analysis of the baseline data (N = 172) collected from two randomized controlled trials conducted in youths aged 12 to 24 years old with DSM-5 insomnia disorder. A series of demographic and clinical features, including age, gender, education, depression diagnosis, duration of insomnia, chronotype preference (as measured by the reduced Morningness-Eveningness Questionnaire, rMEQ), depressive and anxiety symptoms (as measured by Hospital Anxiety and Depression Scale, HADS-D/A), cognitive failures (as measured by Cognitive Failures Questionnaire, CFQ), fatigue (as measured Multidimensional Fatigue Inventory, MFI), and five actigraphy-based sleep parameters, were used as the feature set for clustering. Missing values ($\leq 35\%$) were imputed via missForest, then Gower distances were computed and Partitioning Around Medoids applied. The optimal cluster number ($k = 3$) was selected by majority vote across 23 NbClust indices and confirmed by bootstrap stability (Jaccard > 0.60). Insomnia severity (ISI) and subjective sleep efficiency based on prospective 7-day sleep diary were compared across the clusters using linear regression models adjusted for age and gender.

Results: Partitioning-Around-Medoids applied to the 15 standardized baseline variables produced three reproducible subtypes (Jaccard = 0.69, 0.75, 0.65) with average Silhouette widths of 0.283. There were 39 (23 %), 98 (57 %), and 35 (20 %) participants in Clusters 1-3, respectively. Cluster 1 was characterized with a Low-Distress-Burden profile with lower depression, anxiety, fatigue and cognitive failures, and slightly higher objectively-estimated TST and SE. Cluster 2 was characterized with a High-Distress-Fatigue profile, exhibiting the highest mood and fatigue related scores while objectively-estimated sleep parameters remained near average. Cluster 3 was characterized with a Young Evening-Chronotype profile, containing the youngest and more evening-typed participants, with more cognitive failures and fewer actigraphy-based awakenings. Regressed on above-identified cluster with adjusting for age and gender, cluster 2 (High-Distress/Fatigue subgroup) had significantly higher ISI ($p=0.004$) and lower subjective sleep efficiency based on sleep diary ($0=0.045$) than cluster 1 (Low-Distress-Burden subgroup) but there were no differences in these measure between cluster 1 and 3.

Conclusions: Three distinct insomnia subtypes were identified in youths using a novel data-driven approach. These clusters were mainly driven by mood, fatigue, circadian preference rather than objectively-estimated sleep parameters. Identification of different profiles of youth insomnia may help develop personalized intervention to target specific needs. Future studies should validate these subtypes in larger, more diverse samples and examine their biological markers, as well as treatment response of these subtypes.

Development of the Integrated Home Sleep Detection System Based on the Pathophysiology of Insomnia

T.-H. Lu¹, C.-Y. Lin², F.-Z. Shaw³, S.-F. Liang⁴

¹National Cheng Kung University Hospital, Psychiatry, Tainan, Taiwan, ²National Cheng Kung University Hospital, Otolaryngology and Sleep Medicine Center, Tainan, Taiwan, ³National Cheng Kung University, Psychology, Tainan, Taiwan, ⁴National Cheng Kung University, Computer Science and Information Engineering, Tainan, Taiwan

Introduction: The diagnostic criterions of insomnia are not based on pathophysiological etiologies, leading to high diagnostic instability and imprecise treatments of insomnia. The polysomnography has first-night effects, inconvenience and might impact original sleep quality. Wearable devices such as actigraphy are highly applied in insomniac disorder, but the correlation between different variables and sleep quality is controversial. These biological signals could stand for the physiology of sleep based on the three major physiopathologies of insomnia^[1]: dysregulation of the circadian system, homeostatic system, and arousal system. By using information engineering technology, we converted physiological signals into digital signals, and analyzed them into pathophysiological models for assisting clinicians in diagnostic evaluation.

Materials and methods: Self-developed wearable devices were used, including the eye-mask^[2] and actigraphy^[3]. The eye-mask was frontal EEG/EOG-based device, with high correlation coefficients between eye-mask and PSG. It was used for scoring sleep stage and EEG power spectrum before sleep. The actigraphy recorded circadian quotation(CQ), inter-daily stability(IS), intra-daily variability(IV), activity counts of the most active 10 hour period(M10) and of the least active 5 hour period(L5), midpoint daytime of M5 and L5(mM5, mL5) and relative amplitude(RA). The portable ANS test analyzed

heart-rate variability(HRV) included SDNN, RMSSD, LF/HF. The salivary melatonin were also collected. All these devices and examinations were applied at home as home sleep test(HST). The above variables contributed to the above three systems of sleep, showed as [Table 1](#).

The inclusion criteria of insomniac group was (1) Pittsburgh Sleep Quality Index>5 (2) DSM-5 defined insomniac disorder. Normal group were also enrolled by age-and-gender match participants from insomniac groups. All participants used the HST during their daily life as the following figure 2. The above biological signals were statistically analyzed by T-test between these groups.

Results: A total of 30 normal sleepers and 42 insomniac sleepers were enrolled. The average age 25.40 ± 5.65 year-old. Gender distribution showed 50% male and 50% female. In insomniac group, the average PSQI was 10.90 ± 2.95 and ISI was 13.05 ± 5.07 , indicating moderate insomniac severity. In circadian rhythm, mM10 was 2 hour earlier in the insomniac group, about 15:00. The melatonin onset was not detected before bedtime, possible due to night-time light exposure in naturalistic setting. Early rest time might cause misalignment with endogenous circadian rhythm. In homeostatic system, theta and delta wave power and stage III sleep were lower in insomniac group. Sleep pressure accumulated from mental and physical activity might be more specific with slow wave by EEG than activity counts by actigraphy. In arousal system, lower alpha wave power, higher beta wave and lower SDNN under stress state were noted in the insomniac group. The hyperarousal insomnia might be the over-sensitivity of stress reaction. These signals were translated to a visualized model as [figure 1](#) for proposing precise treatments by different pathophysiology.

Conclusions: This system could offer a poly-signal, more precise and personalized evaluation in the naturalistic setting for insomniac patients. By specifying the pathophysiology of insomnia, the precise interventions could be applied more efficiently. Furtherly, more sample size from community and elderly is needed to develop the norm.

Diagnostic stability of insomnia and obstructive sleep apnea in 8 years – implications for the prevalence and progression of COMISA

G.N. Pires¹, Y.M. Luciano¹, M.L. Andersen^{1,2}, S. Tufik²

¹Universidade Federal de São Paulo, São Paulo, Brazil, ²Instituto do Sono / Associação Fundo de Incentivo à Pesquisa, São Paulo, Brazil

Introduction: Co-morbid obstructive sleep apnea (OSA) and insomnia (known as COMISA) is associated with a worse prognosis when compared to each of its constituent disorders alone. Proper therapeutic and prevention approaches imply understanding the disease prevalence, incidence and progression over time. Previous studies have demonstrated that the prevalence of COMISA is 17.6% in the city of São Paulo, Brazil, with an incidence rate of 16.7% and a remission rate of 53.5% over a follow-up of eight years. Although the epidemiology of COMISA is increasingly understood, the contribution and diagnostic progression of each of its constituent disorders (OSA and insomnia) is not known.

Materials and methods: This study was based on the São Paulo Epidemiologic Sleep Study (EPISONO), a population-based study aimed at evaluating the prevalence of sleep disorders in São Paulo, Brazil. Data from EPISONO third edition (2007) and its follow up edition (2015) were considered for the analyses. All procedures were similar in both editions, and all participants underwent type-I polysomnography (PSG) and subjective sleep assessment through validated questionnaires. OSA severity was scored based on the apnea-hypopnea index (AHI) as ≥ 5 for mild, ≥ 15 for moderate, and ≥ 30 for severe cases. Insomnia was evaluated based on the Insomnia Severity Index (ISI) score as ≥ 8 for mild/subthreshold, ≥ 15 for moderate and ≥ 22 for severe insomnia. Diagnostic stability was considered as remaining with the same diagnostic status from baseline to follow-up, either considering the dichotomic diagnosis (yes or no), or the disease severity (no, mild, moderate, or severe).

Results: The final sample was composed of 585 individuals with valid AHI data and 690 individuals with valid ISI data for both editions. Regarding OSA, when all severity levels are considered, 307 (52.5%) participants remained stable, while 230 (39.32%) worsened and 48 (8.21%) improved OSA severity status. When only the dichotomous diagnosis is considered, 416 (71.11%) remained stable, while 142 (24.3%) worsened (OSA incident cases) and 27 (4.6%) improved (OSA remission cases). Regarding insomnia, when all symptom levels are considered, 384 (55.6%) participants remained stable, while 115 (16.7%) worsened and 191 (27.7%) improved. When only the dichotomous conditions are considered, 464 (67.2%) participants remained stable, while 88 (12.8%) worsened (insomnia symptoms onset) and 138 (20.0%) improved (insomnia symptoms remission).

Conclusions: Both insomnia and OSA are stable conditions in most cases, as more than half of the patients with either of these conditions remained with the same diagnostic statuses over a follow-up of eight years. However, when considered individuals who changed their diagnostic status, OSA follows a unidirectional progression, as most individuals evolve into more severe cases, while OSA remission is unlikely without treatment. Conversely, insomnia follows a bidirectional progression, as both increase and decrease in symptoms severity levels are observable. The more unstable progression of insomnia might contribute more to the incidence and remission of COMISA cases.

Acknowledgments: This study was funded by Associação Fundo de Incentivo à Pesquisa (AFIP), São Paulo, Brazil. ST and MLA received funding from *Conselho Nacional de Desenvolvimento Científico e Tecnológico* (CNPq). MLA received funding from FAPESP (2020/13467-8).

Differential Efficacy of Online Group BBTI on Fatigue and Sleep in Depressed Patients with Insomnia Symptoms Based on Sleep Reactivity: A Pilot Study

S. Hu¹, A. Zhang¹, L. Wang¹, X. Gao¹, H. Sun¹

¹Peking University Sixth Hospital, Beijing, China

Introduction: Fatigue and insomnia symptoms are highly prevalent in patients with depressive disorder, severely impeding their quality of life and treatment outcomes. Behavioral-Based Therapy for Insomnia (BBTI) has potential in enhancing sleep quality and alleviating depressive symptoms, which may also relieve the fatigue symptom. This study aims to investigate the differential efficacy of online group BBTI on fatigue and insomnia symptoms in depressed patients with insomnia symptoms, based on their sleep reactivity as measured by the Ford Insomnia Response to Stress Test (FIRST) score.

Materials and methods: Participants meeting the criteria of the Mini-International Neuropsychiatric Interview 6.0 for major depressive episode and with Insomnia Severity Index (ISI) ≥ 8 were randomized into two online groups: the BBTI group ($n=33$) and the sleep education group ($n=16$). After excluding four participants due to missing FIRST scores, 33 and 12 participants respectively remained in the intervention and control groups. Measures included subjective assessments (insomnia severity, sleep quality, fatigue, mood) and objective testing with polysomnography (PSG). PSG was conducted for two consecutive nights at baseline (using the second night data to exclude first-night effects) and post-intervention. At baseline, 45 participants were categorized into high sleep reactivity (SR) ($n=24$) and low SR ($n=21$) groups based on FIRST scores (>21). Clinical and sleep characteristics were compared between these groups. Twenty-nine participants (13 in high SR group; 16 in low SR group) completed all follow-ups in the BBTI group. Repeated-measures ANOVA was used to compare intervention effects between high SR and low SR groups across baseline, post-intervention, and 3- and 6-month follow-ups.

Results: Among the 45 patients with depressive episodes and insomnia symptoms, high SR was associated with increased subjective depressive symptoms (measured by the Beck Depression Inventory, BDI), reduced subjective positive affect (measured by the Positive and Negative Affect Schedule, PANAS), elevated subjective negative affect (measured by the PANAS), and higher objective sleep microarousal indices (all $p < 0.05$). The interaction between time and SR was statistically significant for the Fatigue Severity Scale (FSS; $p = 0.010$, partial $\eta^2 = 0.358$) and the microarousal index (MAI; $p = 0.003$, partial $\eta^2 = 0.446$). For FSS, high SR patients exhibited higher initial fatigue that decreased significantly post-intervention ($p < 0.05$), while low SR patients showed minimal change. For MAI, high SR patients had higher baseline microarousal indices that decreased significantly post-intervention ($p < 0.05$), whereas low SR patients showed less change. The interaction for subjective sleep onset latency (SSOL) approached significance ($p = 0.056$, partial $\eta^2 = 0.185$), with high SR patients showing a trend toward longer initial SSOL that improved over time, though changes were not statistically significant. Other subjective and objective sleep parameters did not show statistically significant interaction effects differences between the high and low SR groups.

Conclusions: Depressed patients with insomnia symptoms and high SR are characterized by higher negative affect, lower positive affect, more severe depressive symptoms, and increased objective sleep fragmentation. The online group BBTI intervention significantly reduced fatigue and microarousals in this subgroup, although these improvements did not reach statistical significance at later follow-up time points.

Digital CBTi improves insomnia and reduces sleeping pill use in Australian primary care patients: Preliminary analysis of a randomised controlled implementation trial

C. Reynolds^{1,2}, C. Richardson², A. Sweetman²

¹University of South Australia, Justice and Society, Adelaide, Australia, ²University of Western Australia, School of Psychological Science, Perth, Australia

Introduction: Insomnia is a prevalent and debilitating disorder in Australian primary care. Only 1% of patients access the recommended first-line treatment for insomnia, Cognitive Behavioural Therapy for Insomnia (CBTi). Most are instead managed with sleeping pills. Digital CBTi (dCBTi) programs may improve CBTi access and reduce sleeping pill dependence in primary care. However, most clinical trials of CBTi have been conducted in specialist settings that have excluded those using sleeping pills. More research in primary care is therefore required to investigate; 1) the effectiveness of dCBTi in the presence of sleeping pill use, and 2) the effect of dCBTi on reducing sleeping pill use in primary care.

Materials and methods: An Australia-wide primary care randomised controlled implementation trial investigated the effects of dCBTi versus digital sleep education (control), in patients with insomnia symptoms referred by general practitioners (GPs). Participants were randomised 1:1 to a self-guided 5-session interactive dCBTi program (Bedtime Window), or 5-weeks of digital sleep education (control). No deprescribing guidance was provided. Insomnia Severity (ISI) and sleeping pill use (any medicine used 'for sleep') were assessed via questionnaire at baseline, 8-weeks, 16-weeks, and 24-weeks. The control group accessed dCBTi after 8-weeks. Linear mixed models (LMM) with bonferroni corrections and Chi-square analyses were used to investigate; 1) the effect of baseline sleeping pill use (y/n) on changes in ISI between the dCBTi and control group, and 2) between-group differences in sleeping pill use/cessation over time.

Results: Participants included 346 adults with insomnia (68% female, M age = 55.6yrs [SD=15.5]). Baseline sleeping pill use did not differ between the dCBTi and control groups (61.8% vs 59.1%; $p=.61$), with a range of medications used, including benzodiazepines, melatonin, antidepressants and sedating-antihistamines. Treatment-response to dCBTi versus control did not significantly differ based on baseline sleeping pill use (interaction $p=.63$). Instead, a statistically significant group-by-time interaction indicated larger ISI improvement in the dCBTi group (M reduction=7.4 [95% CI:6.4-8.5]) than the control group (M reduction=1.9 [0.8-3.1], interaction $p<.001$), regardless of baseline sleeping pill use. ISI improvements in the dCBTi group were sustained at 24-weeks, and the control group experienced similar improvements from 8-weeks to 24-weeks (i.e., after accessing the dCBTi program). At 8 weeks, the CBTi group reported significantly lower sleeping pill use compared to the control group (34.6% vs 50.9%; $p=.009$), representing a 44% rate of sleeping pill cessation from baseline to 8-weeks. After the control group subsequently accessed the dCBTi program, rates of sleeping pill use were similar between groups (16-weeks: 32.3% vs 35.6%; 24-weeks: 30.3% vs 34.8%), indicating similar levels of cessation after accessing dCBTi.

Conclusions: Among a diverse sample of Australian general practice patients with insomnia symptoms, this digital CBTi program led to large, sustained improvements in insomnia severity regardless of the presence/absence of sleeping pill use before treatment. Compared to digital sleep education, dCBTi was associated with a 44% rate of sleeping pill cessation by post-treatment, sustained at 24-week follow-up. These findings support recommending this dCBTi program to primary care physicians and patients to improve insomnia and facilitate reduced dependence on sleeping pills in primary care.

Disentangling Co-morbid Insomnia and Obstructive Sleep Apnea (COMISA): Evaluating the additive diagnostic value of extended features in polysomnographic data

E.S. Schubert^{1,2}, B. Bruinsma², F. Smits², S. Mithani³, V. Mysliwiec⁴, K. Pruiksma⁴, E. Geuze², S. Young-McCaughan⁴, X. Li⁴, C. Straud⁴, M. Brock⁵, A. Peterson^{6,7,8}, f.t. Strong Star Consortium⁹

Service, San Antonio, United States, ⁸University of Texas, Department of Psychology, San Antonio, United States, ⁹University of Texas Health Science Center, San Antonio, United States

Introduction: Comorbid insomnia and sleep apnea (COMISA) is a highly prevalent and burdensome disorder, associated with an increased risk of mental health disorders and all-cause mortality. Disentangling COMISA from insomnia and obstructive sleep apnea (OSA) is critical for effective therapeutic intervention. However, overlapping symptoms and mixed findings regarding the clinical characteristics of COMISA – based on commonly used diagnostic approaches such as questionnaires and standard clinical polysomnography (PSG) – complicate its identification and classification. Extended PSG variables, including (neuro)physiological metrics extracted from EEG and ECG recordings, may offer additional insight.

Materials and methods: This study tested machine learning models using XGBoost to evaluate the discriminative value of four feature sets: questionnaire features, conventional PSG features, extended PSG features, and a combined multimodal set. Classification performance was assessed across three pairwise group comparisons: COMISA vs. insomnia, COMISA vs. OSA, and insomnia vs. OSA.

Results: COMISA and insomnia were accurately distinguished using conventional PSG features, whereas questionnaire features showed moderate discriminative value. For COMISA vs. OSA, conventional PSG features were not informative. Questionnaire features performed acceptably, but not good enough for clinical usability, confirming the challenge of distinguishing between COMISA and OSA. Across all comparisons, extended PSG variables did not enhance classification, either independently or in combination.

Conclusions: Extended PSG variables, despite being identified as promising biomarkers, did not show meaningful discriminative power between COMISA, insomnia, and OSA. This suggests that these diagnosis groups do not exhibit unique (neuro)physiological profiles during sleep that can aid diagnostic differentiation.

Does the increase or decrease in the patient's vigilance performance during sleep restriction reflect a build-up of sleep pressure that contributes to treatment success in chronic insomnia?

Z. Zhang¹, E. Gražys¹, R. Khatami¹

¹Clinic Barmelweid, Center for Sleep Medicine, Sleep Research, and Epileptology, Barmelweid, Switzerland

Introduction: Cognitive behavioral therapy for insomnia (CBT-I) is the first-line treatment for chronic insomnia disorder (CID) and includes sleep restriction therapy (SRT) as a core component. SRT aims to consolidate sleep by reducing wake time in bed and reinforcing the sleep-wake cycle. Previous home-based CBT-I studies have reported increased daytime sleepiness and impaired vigilance during SRT in CID, indicating the patients have similar response to SRT induced sleep pressure as healthy populations. However, these findings may be confounded by poor protocol adherence at home due to the lack of professional supervision. To address this, we investigated changes in daytime sleepiness and vigilance during a two-week, tightly controlled in-lab CBT-I program in patients with CID.

Materials and methods: We retrospectively analyzed clinical data from 56 patients with CID (mean age: 49.5 ± 14.9 years; 23 female) who completed a standardized two-week CBT-I in house program with the SRT (sleep window: 5-6 hours/night) as the core component at the Clinic Barmelweid, Switzerland. Daily Stanford Sleepiness Scale (SSS), subjective sleep quality (SQ) and psychomotor vigilance tests (PVTs) were performed between 3–4 p.m. . A linear mixed-effects model (LMM) with random slopes and intercepts was used to predict changes in vigilance quantified by the inverse of the mean reaction time ($1/RT$) of PVT across 10 subsequent working days, adjusting for age, sex, SQ and SSS. Changes in daily SSS scores and SQ were modeled similarly. To assess robustness of subject-specific slope of $1/RT$ over days, we performed a subject-level (cluster) bootstrap: in each of 500 replicates we sampled 90% of patients with replacement to refit the LMM. Patients were classified as positive-slope (>95% of bootstrap slopes >0), negative-slope (>95% of bootstrap slopes <0), or uncertain otherwise.

Results: SSS negatively ($p < 0.001$) while SQ tends to positively ($p = 0.07$) associate with $1/RT$ in all patients; however, $1/RT$ did not significantly change over the 10 days ($p = 0.39$). Similarly, SSS scores showed no significant change across days ($p = 0.14$), but negatively associated with SQ ($p < 0.001$). Overall, SQ significantly improved in our patients over the whole CBT-I ($p < 0.001$). Bootstrap analysis showed that 26 and 19 patients had negative and positive slopes of $1/RT$ over days, respectively.

There was no difference in age ($p=0.71$) or gender ($p=1$) between these two subgroups. Notably, the positive-slope group showed significantly improving vigilance ($p < 0.001$) while the negative-group had significantly declining vigilance ($p < 0.001$) when LMM was fit in the two subgroups separately. In both subgroups, the negative association between SSS and $1/RT$ remained (both $p < 0.001$). SQ positively associated with $1/RT$ in positive-slope group ($p=0.03$), not in the negative-slope group ($p=0.31$).

Conclusions: Contrary to prior home-based studies, our supervised, in-lab CBT-I protocol did not lead to consistent declines in vigilance or increases in sleepiness during SRT. Instead, a considerable proportion of patients showed an improvement in PVT performance, which was associated with reduced sleepiness and improved sleep quality. Improved PVT performance with concomitant reduction in subjective sleepiness could therefore be explained by an improved recovery effect of SRT-induced sleep consolidation.

Ecological momentary assessment as an outcome measure in insomnia clinical trials: Preliminary results

E. Wickwire¹, C. Pfaeffle¹, J. Zhou², C. Johnston¹, D. Buysse³, S. Chen¹, A. Verceles¹

¹University of Maryland School of Medicine, Baltimore, United States, ²University of Maryland, College Park, United States, ³University of Pittsburgh, Pittsburgh, United States

Introduction: Assessment of daytime insomnia symptoms has historically relied on clinical interview or retrospective questionnaires with varying recall periods. Ecological momentary assessment (EMA) is a data-rich approach to assessing participant experiences in real-time. Participants respond to queries multiple times per day in their own natural environments. The purpose of this study was to employ EMA methods as the primary outcome measure in a randomized clinical trial of insomnia medication among older adults. As an initial analytic step, we hypothesized that 1) prior night sleep is associated with next-day insomnia symptoms and 2) within-day mood is associated with same-night sleep.

Materials and methods: This was a double-blind, placebo-controlled randomized clinical trial employing a two-group parallel design among older adults with insomnia. All research procedures including medication administration were entirely remote. Interested volunteers were recruited via print, online, and other media in a tertiary academic medical center and completed diagnostic interview, validated questionnaires, and home sleep apnea testing. Eligible participants were then randomized 1:1 to suvorexant (SUV) or placebo (PBO) nightly for 16 days, including a two night at 10mg run-in period then 14 nights at 20mg (study dose). Throughout, participants subjective sleep diaries each morning and the Daytime Insomnia Symptom Scale (DISS) 4x/day (i.e., 64 survey administrations over 16 days) via a commercially available smart phone app. Finally, participants completed a post-treatment outcomes assessment. To test the hypothesis that prior night sleep is associated with next-day insomnia symptoms among older adults in an insomnia RCT, a series of mixed models (MM) were developed. Each model included a single prior-night sleep metric (e.g., total sleep time [TST, sleep onset latency [SOL], wake after sleep onset [WASO], sleep efficiency [SE] sleep quality [QUAL]) as the independent variable and a single DISS domain (e.g., Alert Cognition, Negative Mood, Positive Mood, and Fatigue/sleepiness) as the dependent variable, controlling for age and sex as covariates. To test the hypothesis that within-day mood predicts same-night sleep, a similar approach was used. To adjust for multiple testing, the Benjamini-Hochberg procedure for correcting false discovery rate (BH-FDR) was employed, with statistical significance set at 0.05.

Results: Forty older adults with insomnia participated (M age=67.9 years, SD=5.4; 90% women; 64.3% White, 30.9% Black, 2.4% American Indian, and 2.4% Asian race). No significant between-groups (SUV n=20, PBO n=20) differences were observed in demographic characteristics. Lagged MM analyses across the 16-day study period revealed that prior-night TST, WASO, SE and QUAL were significantly associated with all next-day insomnia symptoms. Within-day Positive Mood and Negative Mood both demonstrated significant associations with same-night sleep. Participants completed 93.3% of sleep diaries and EMA surveys. 86.5% of participants reported that they were “mostly satisfied” or “very much satisfied” with the remote study approach.

Conclusions: Among older adults with insomnia participating in an insomnia treatment clinical trial, the associations between prior-night sleep and daytime insomnia symptoms, as well as the associations between within-day mood and same-night sleep, were strong. These preliminary results support further evaluation of EMA as an outcome measure in insomnia treatment research.

Effectiveness of Nurse-Led Web-Based and Face-to-Face Brief Behavioral Therapy for Insomnia in Stroke Survivors: A Pilot Randomized Controlled Trial

F. Hasan¹, H.-Y. Chiu², C.J. Gordon³, D.J. Bartlett⁴

¹Faculty of Nursing, Chulalongkorn University, Bangkok, Thailand, ²School of Nursing, Taipei Medical University, Taipei, Taiwan, ³Department of Health Sciences, Macquarie University Faculty of Medicine and Health Sciences, Sydney, Australia, ⁴Faculty of Medicine and Health, The University of Sydney, New South Wales, Australia

Introduction: Insomnia is prevalent among stroke survivors and is associated with adverse outcomes such as increased fatigue, anxiety, and depression. Brief Behavioral Therapy for Insomnia (BBTI) is a structured, short-term intervention that has shown efficacy in managing insomnia. This study aimed to evaluate the effectiveness of nurse-led web-based and face-to-face BBTI compared to Sleep Hygiene Education (SHE) in reducing insomnia severity and associated symptoms in stroke survivors.

Materials and methods: An assessor-blinded, three-arm, parallel-group pilot randomized controlled trial was conducted in an outpatient clinic in Indonesia. Thirty stroke survivors experiencing insomnia were randomly assigned to one of three groups: web-based BBTI, face-to-face BBTI, or SHE. Each intervention comprised four sessions. Data were collected using paper-based questionnaires assessing insomnia severity, daytime sleepiness, anxiety, depression, and fatigue.

Results: All participants completed the study. Both web-based and face-to-face BBTI groups demonstrated significant improvements in insomnia severity, anxiety, depression, and fatigue compared to the SHE group. No significant changes were observed in daytime sleepiness across all groups. The effectiveness of web-based BBTI was comparable to that of face-to-face BBTI in alleviating insomnia and associated symptoms.

Conclusions: Nurse-led web-based BBTI is as effective as face-to-face BBTI in managing insomnia and related symptoms among stroke survivors. Given its accessibility and practicality, web-based BBTI offers a viable alternative for patients with limited access to in-person therapy. These findings support the integration of web-based BBTI into clinical practice for stroke survivors experiencing insomnia.

Acknowledgments: This presentation was supported by funding from Chulalongkorn University.

Effectiveness of Stepped-Care Chinese Herbal Medicine and Psychotherapy on Improving Sleep in Adults with Insomnia: A Stepped-Wedge Cluster Randomized Trial

D. Yu^{1,2}, H.T. Tang^{1,2}, S.Y. Chen^{1,2}, Y.L. Kwok^{1,2}, A. Yeung³, J. Yang², Z.X. Bian^{1,2,4,5}

¹Hong Kong Baptist University, Vincent V.C. Woo Chinese Medicine Clinical Research Institute, School of Chinese Medicine, Hong Kong, Hong Kong, SAR of China, ²Hong Kong Baptist University, School of Chinese Medicine, Hong Kong, Hong Kong, SAR of China, ³Harvard University, Depression Clinical and Research Program, Massachusetts General Hospital, Boston, United States, ⁴Hong Kong Baptist University, Centre for Chinese Herbal Medicine Drug Development Limited, Hong Kong, Hong Kong, SAR of China, ⁵The Chinese Medicine Hospital of Hong Kong, Hong Kong, Hong Kong, SAR of China

Introduction: Insomnia is one of the most common sleep disorders in adults, with global prevalence rates ranging between 2.3% and 25.5%. Cognitive behavioral therapy for insomnia (CBT-I) and pharmacotherapy are recognized as common treatments for managing insomnia. However, access to CBT-I is often limited, while low acceptance rate of pharmacotherapy is also a well-known limitation. Therefore, it is imperative to identify alternative treatments that are accessible, effective and acceptable.

Traditional Chinese medicine (TCM), including Chinese herbal medicine (CHM), has been proved to be effective for treating insomnia and is particularly popular in Eastern Asia. In Hong Kong (HK), 34.5% of insomnia patients choose TCM, making it the leading treatment option and reflecting strong cultural acceptance. However, most previous Chinese medicine studies on insomnia were well-controlled randomized trials, and real-world evaluations are lacking. This study aims to examine the effectiveness of stepped-care CHM and psychotherapy intervention in treating insomnia in adults in four clinical centers.

Materials and methods: (1) Study design

This stepped-wedge, cluster randomized trial recruited 366 adults with insomnia in HK between April and November 2024. The 18 geographic districts in HK are grouped into 4 clusters of 4 to 6 districts each, with randomization conducted at cluster level. The intervention was implemented sequentially in one cluster at a time based on a pre-generated random number, while the other clusters remained unexposed. After four steps, all clusters received the intervention. The study was approved by HK Baptist University Research Ethics Committee and prospectively registered with the Chinese Clinical Trial Registry (ChiCTR2400083685).

(2) Population

Adults with an insomnia severity index (ISI) score ≥ 14 .

(3) Stepped-care intervention

The intervention consists of two levels. In level 1, the CHM treatment was based on TCM syndrome differentiation, classifying participants into three subtypes: excess syndrome, treated with Jia Wei Xiao Yao powder; deficiency syndrome, treated with Gui Pi decoction; and excess-deficiency complex syndrome, addressed with Huang Lian E Jiao decoction and Jiao Tai bolus. This level lasted 6 weeks, with participants taking a 5-gram herbal formula twice daily. Those without sleep improvement (ISI score ≥ 14 after level 1 treatment) progressed to level 2, which involved an 8-week personalized CHM intervention and 8-session psychotherapy.

(4) Outcome

Outcome assessments were conducted at baseline and post-intervention. The primary outcome was ISI. The acceptance rate was operationalized as adherence rate by counting unconsumed sachets. Participants' self-management skills for handling insomnia and awareness of sleep health were also measured.

Results: All participants (age [SD]: 45.50 [13.08]; female: 282 [77.05%]) received the level 1 treatment, among whom, 49 (age [SD]: 47.61 [12.83]; female: 34 [69.39%]) progressed to the level 2 treatment. Only level 1 treatment significantly reduced insomnia severity (mean difference [95% CI]: -3.38 [-4.03 to -2.73]; $p < 0.0001$; level 2: -0.90 [-2.49 to 0.69]; $p = 0.26$). The adherence rate was high, at 84.8%. 98.4% of participants reported improved self-management skills for handling insomnia, while 97.3% expressed increased awareness of their sleep health.

Conclusions: The stepped-care CHM and psychotherapy is effective and acceptable in treating insomnia, empowering participants in self-managing insomnia and increasing awareness of sleep health.

Effect of combined treatment with transcranial direct current stimulation and repetitive transcranial magnetic stimulation compared to monotherapy for the treatment of chronic insomnia: a randomised, double-blind, parallel-group, controlled trial

Q. Zhou¹, Z. Liu¹, C. Yu¹, H. Yu¹, D. Zhou¹

¹Affiliated Kangning Hospital of Ningbo University, Ningbo, China

Introduction: Chronic insomnia increases the risk of various health problems and mental illness. Existing research suggests promise for both transcranial direct current stimulation (tDCS) and repetitive transcranial magnetic stimulation (rTMS) in treating chronic insomnia individually. However, the combined effects of tDCS and rTMS on this condition remain unclear. This study aimed to verify the efficacy and safety of tDCS combined with rTMS for the treatment of adult patients with chronic insomnia.

Materials and methods: This was a randomised double-blind parallel-group controlled study. Overall, 157 participants with chronic insomnia were randomly assigned to one of three neurotherapy regimens: tDCS + rTMS, sham tDCS + rTMS, or tDCS + sham rTMS. All groups received 20 treatment sessions over 4 consecutive weeks. The primary outcome was the change in patients' sleep as assessed by the Pittsburgh Sleep Quality Index (PSQI) at 2 weeks, 4 weeks, and 3 months of follow-up. The secondary outcome was the assessment of different dimensions of depression and anxiety in patients through the Hamilton Depression Scale (HAMD) and Hamilton Anxiety Scale (HAMA), as well as the occurrence of adverse events.

Results: Throughout the intervention and after the 3-month follow-up, the tDCS + rTMS group had significantly reduced total PSQI scores compared with the other two groups [tDCS + rTMS, 9.21 vs. sham tDCS + rTMS, 10.03; difference – 1.10; 95% confidence interval (CI), – 1.82 to – 0.38; $p = 0.003$; tDCS + rTMS, 9.21 vs. tDCS + sham rTMS, 10.76; difference – 2.14; 95% CI, – 2.90 to – 1.38; $p < 0.001$; sham tDCS + rTMS, 10.03 vs. tDCS + sham rTMS, 10.76; difference – 1.04; 95% CI, – 1.82 to – 0.26; $p = 0.010$], indicating improved overall sleep quality. Total HAMD and insomnia factor scores were significantly lower in the tDCS + rTMS group than in the other two groups after treatment ($p < 0.05$). Notably, no adverse events or serious adverse reactions were observed during the study period.

Conclusions: Combining tDCS with rTMS effectively relieved insomnia symptoms, achieving a significant therapeutic effect after 2-week of intervention, and demonstrating the persistence of treatment effects in later follow-up, emphasising the advantages of combination therapy in improving treatment stability and long-term benefits, reflecting the rapid and effective augmentation of combination therapy. This combined therapy may serve as a safe and effective treatment for adults with chronic insomnia.

Acknowledgments: The authors are grateful to all participants for their excellent cooperation.

Effect of daridorexant on wakefulness throughout the night and morning sleepiness in patients with insomnia disorder

Y. Dauvilliers¹, G. Zammit², P.-P. Luyet³, G. Braunstein³, O. Briasoulis³, A. Olivieri³

¹Centre Hospitalier Universitaire de Montpellier, Montpellier, France, ²Clinilabs Drug Development Corporation, New York City, United States, ³Idorsia Pharmaceuticals Ltd, Allschwil, Switzerland

Introduction: Reducing wakefulness throughout the night without residual effects the next morning are essential characteristics for drugs for chronic insomnia disorder. In Phase 3 trials, daridorexant, a dual orexin receptor antagonist, significantly reduced wake after sleep onset (WASO) with rates of daytime somnolence similar to placebo. We now examine in more detail the effect of daridorexant on wakefulness throughout the night and next-morning sleepiness.

Materials and methods: Data from 930 patients with insomnia disorder randomized to daridorexant 50 mg ($n=310$), 25 mg ($n=310$) or placebo ($n=310$) for 3 months were analyzed. Polysomnography-determined WASO by quarter of the night (QoN: Q1 to Q4) at Month (M)1 and M3 of treatment, and morning sleepiness upon awakening by a visual analogue scale (VAS; range 0-100; higher score indicates less sleepiness) were assessed (full analysis set).

Results: Decreases in WASO in Q2-4 of the night were numerically larger in both daridorexant dose groups versus placebo. Baseline WASO in Q1 was low in all groups and thus there were no visible changes in WASO in Q1. At M1, placebo reduced WASO evenly across QoN (Q2-4): Q2: -3.3 min, Q3: -3.7 min, Q4: -3.9 min. Daridorexant 25 mg reduced WASO by -6.2 min, -7.2 min and -7.6 min and daridorexant 50 mg reduced WASO by -8.7 min, -9.6 min, -11.3 min in Q2, Q3 and Q4, respectively. Results were similar at M3.

Mean baseline VAS morning sleepiness scores were 37-38 across groups. Scores increased (i.e. improved) from Day 1 of treatment in all groups and continued to improve as treatment duration increased, with treatment numerically ranked as daridorexant 50 mg > 25 mg > placebo. Mean weekly scores at Week 4 increased by 5.2, 8.8 and 10.2 with placebo, daridorexant 25 mg and 50 mg respectively, and at Week 12, scores increased by 11.6, 14.6 and 15.3 respectively (p values <0.05 for comparison of daridorexant 25 mg or 50 mg vs placebo at Weeks 4 and 12).

Conclusions: In patients with insomnia disorder, daridorexant reduces wakefulness throughout the entire night including Q4, while decreasing morning sleepiness upon awakening.

Effect of daridorexant on wakefulness throughout the night: Post-hoc analysis of a randomised, double-blind, active reference (zolpidem) study in patients with insomnia disorder

B. Steiniger-Brach¹, O. Briasoulis¹, A. Olivieri¹, S. Pain¹, L. Palagini², D. Kunz³, P.-A. Geoffroy⁴

¹Idorsia Pharmaceuticals Ltd, Allschwil, Switzerland, ²University of Pisa, Department of Neuroscience, Section of Psychiatry, Pisa, Italy, ³St. Hedwig-Krankenhaus, Clinic for Sleep & Chronomedicine, Berlin, Germany, ⁴Université de Paris, NeuroDiderot, Inserm, Paris, France

Introduction: Daridorexant, a dual orexin receptor antagonist [DORA] which works by selectively reducing the orexin-induced wake signalling, has been shown to induce a dose-dependent reduction in wake time after sleep onset [WASO] in patients with insomnia disorder (Dauvilliers et al. Ann Neurol 2020; 87 347–356). This exploratory analysis examined the efficacy of daridorexant in reducing the duration of awakenings in each quarter of the night, when compared to placebo and to the GABA-receptor agonist zolpidem, which induces sleep through widespread CNS sedation.

Materials and methods: This was a multi-centre, double-blind trial (NCT02839200), including adult (18–64y) patients with insomnia randomized (1:1:1:1:1) to placebo, daridorexant (5, 10, 25, or 50mg), or zolpidem (10mg) for 30 days. Polysomnography [PSG]-determined WASO was evaluated using descriptive statistics by quarter of the night (Q1–Q4) i.e. every 2 hours over 8 hours at Days 1 & 2, 15 & 16, and 28 & 29. Baseline was defined as the mean of the two PSG nights during the run-in period and Days 1 & 2 as the mean of the first two PSG treatment nights; Days 15 & 16 and 28 & 29 were defined similarly.

Results: Dose-dependent decreases in mean change from baseline in Q1–Q4 WASO were observed with daridorexant (5–50mg) at Days 1 & 2. Whereas the approved doses of daridorexant (25mg and 50mg) provided similar response to zolpidem 10mg in the first half of the night, mean reductions from baseline in WASO were numerically greater with daridorexant 50mg versus zolpidem 10mg during the second half of the night – with the difference most pronounced in the fourth quarter (mean WASO change from baseline Q3: –13.49 min versus –9.73 min; Q4: –17.51 min versus –7.81 min). Similar effects were seen at Days 15 & 16, and Days 28 & 29.

Conclusions: In patients with insomnia disorder, daridorexant reduces the duration of awakenings throughout the entire night, including the last two quarters.

Introduction: The objective of this study was to examine the efficacy of lemborexant (LEM) in patients with insomnia associated with depressive episodes.

Materials and methods: This was a multicenter, collaborative, prospective intervention study in patients with insomnia diagnosed with either major depression disorder (MDD) or bipolar disorder (BD) receiving stable treatment for the depressive episodes. Participants with a prior medication for insomnia were enrolled into either the MDD add-on or BD add-on cohort, and those without concomitant hypnotic medication were enrolled into either the MDD mono or BD mono cohort. The starting dose of LEM was 5 mg and could be titrated up and down. The primary endpoint was the change from baseline (BL) in the Insomnia Severity Index (ISI) at Week 4. The changes in both insomnia (ISI) and depressive symptoms (Hamilton Depression Rating Scale [HAMD-17] total scores and Young Mania Rating Scale [YMRS] total score [BD cohorts only]) during 12 weeks of LEM treatment were evaluated as secondary endpoints. This study was conducted with the approval of the certified ethical review board and with the participants' written informed consent.

Results: In total, 83 participants were enrolled, and 82 were included in the full analysis set (MDD add-on, n=29 participants; MDD mono, n=23; BD add-on, n=15; BD mono, n=15). The average age was 47.2 years, and 64.6% were women. For MDD add-on, MDD mono, BD add-on, and BD mono cohorts, the mean ISI total score at BL was 14.5, 13.2, 13.5, and 11.8, respectively, and the mean change from BL (95% confidence interval) after 4 weeks of treatment was –2.3 (–3.9, –0.7), –3.2 (–5.0, –1.3), –5.2 (–7.9, –2.5), and –4.5 (–6.3, –2.6), respectively. Improvements in insomnia were maintained up to 12 weeks in all cohorts. The mean score on the HAMD-17 at BL was 13.6, 12.6, 13.9, and 11.4,

respectively, and the mean change from BL (95% CI) after 12 weeks of treatment was -6.4 (-7.8, -4.9), -6.2 (-7.7, -4.6), -5.2 (-8.4, -2.1), and -5.4 (-7.2, -3.5), respectively. The mean score on the YMRS at BL was 1.1 and 2.3 for the BD add-on and BD mono cohorts, respectively, and the mean change from BL (95% CI) after 12 weeks of treatment was -0.7 (-1.9, 0.5) and -1.5 (-2.8, -0.2), respectively. The incidence of adverse events (AEs) was similar across cohorts (41.4%, 43.5%, 37.5%, and 33.3%, respectively). Most common treatment-emergent AEs (≥ 5 participants in total) were somnolence (MDD add-on, $n=4$ [13.8%]; MDD mono, $n=4$ [17.4%]; BD add-on, $n=4$ [25%]; BD mono, $n=0$) and nightmares ($n=2$ [6.9%]; $n=1$ [4.3%]; $n=2$ [12.5%]; $n=1$ [6.7%], respectively). All adverse events were mild to moderate and consistent with the known profile of LEM; no serious adverse events were observed. Three patients (3.6%) discontinued LEM due to AEs, all from the MDD add-on group.

Conclusions: The results of this study suggest the effectiveness of LEM for insomnia comorbid with depressive episodes.

Effect of Lemborexant on Subjective Sleep Parameters in Chinese Participants With Insomnia Disorder: Results From a Phase 3, Randomized Study in China

W.-F. Mi¹, L. Lu¹, D. Wen², L. Xu³, J. Pan⁴, P. Gu⁵, T. Takase¹⁰, M. Moline¹¹

¹Peking University Sixth Hospital, Beijing, China, ²First Hospital of Shanxi Medical University, Shanxi, China, ³The Second Affiliated Hospital of Nanchang University, Nanchang, China, ⁴The First Affiliated Hospital of Jinan University, Guangzhou, China, ⁵The First Hospital of Hebei Medical University, Shijiazhuang, China, ⁶Eisai Co., Ltd., Tokyo, Japan, ⁷Eisai Inc., Nutley, United States

Introduction: Approximately 16.8–30.8% of people in China experience symptoms of insomnia. This post hoc analysis investigated the efficacy and safety of lemborexant (LEM), a competitive dual orexin-receptor antagonist, on subjective sleep parameters compared with placebo (PBO) in participants with insomnia disorder in China.

Materials and methods: Study E2006-J086-311 (Study 311; NCT04549168), a phase 3, one-month, multicenter, randomized, double-blind, PBO-controlled, parallel group study, evaluated the efficacy and safety of LEM 10 mg (LEM10) in Chinese adults (≥ 18 years) who met the criteria for insomnia disorder per *Diagnostic and Statistical Manual of Mental Disorders*, Fifth Edition, and who had an insomnia severity score ≥ 15 . Participants were randomized (1:1) to receive LEM10 or PBO, which was taken immediately before bedtime. Participants completed a sleep diary within 1 hour of awakening each morning throughout the study. Subjective sleep onset latency (sSOL; min), wake after sleep onset (sWASO; min), and total sleep time (sTST; min) were evaluated using sleep diary data. Baseline means (7 nights during the approximately 7-day single-blind PBO run-in period) and least square mean (LSM) (standard error [SE]) changes from baseline for the first and last 7 nights of the treatment period were calculated for sWASO and sTST. sSOL data (log-transformed) are presented as median (quartile [Q1, Q3]) changes from baseline for the first and last 7 nights of the treatment period. Safety data were collected.

Results: The full analysis set comprised 193 participants (LEM10: 93; PBO: 100). Baseline mean (SD) values for LEM10 and PBO, respectively, were 93.13 (70.46) and 86.60 (45.39) for sSOL; 122.76 (84.72) and 116.32 (75.31) for sWASO; 308.69 (92.58) and 306.68 (82.69) for sTST. Decreases (improvements) from baseline in sSOL were larger and statistically significant with LEM10 versus PBO during the first 7 nights (median [Q1, Q3]: LEM10: -17.00 [-42.86, -2.14]; PBO: -11.86 [-25.00, 5.17]; $P=0.0010$) and the last 7 nights (LEM10: -29.29 [-57.14, -10.00]; PBO: -20.46 [-38.71, -3.43]; $P=0.0063$). Decreases (improvements) from baseline in sWASO were larger and statistically significant with LEM10 (LSM [SE]: -19.67 [7.75]) during the first 7 nights compared with PBO (-4.79 [6.90]; $P=0.0095$); during the last 7 nights, sWASO decreased from baseline with LEM10 (-30.04 [8.47]), but was not significantly different from PBO (-19.67 [7.63]; $P=0.1625$). Increases (improvements) from baseline in sTST were larger and statistically significant in the LEM10 group compared with PBO during the first 7 nights (LSM [SE]: LEM10: 34.93 [10.24]; PBO: 0.87 [9.09]; $P<0.0001$) and the last 7 nights (LEM10: 52.42 [11.44]; PBO: 29.78 [10.26]; $P=0.0300$). Treatment-emergent adverse events occurred in 30 (31.9%) and 21 (21.0%) participants in the LEM10 and PBO groups, respectively. LEM10 was well tolerated.

Conclusions: In this study, LEM consistently improved subjective sleep parameters (sSOL, sWASO, and sTST) compared with PBO in Chinese participants with insomnia. LEM was well tolerated and may be a potential treatment option for patients with insomnia in China.

Effect of Scalp Acupuncture on Neurological Deficits and Insomnia in Patients with Stroke

Y. Wang¹, S. Zhan¹

¹Xuanwu Hospital Capital Medical University, Department of Neurology, Beijing, China

Introduction: The scalp acupuncture is a treasure of traditional Chinese medicine treatment. This study was to observe the effect of scalp acupuncture on neurological deficits and insomnia in patients with stroke.

Materials and methods: A total of 40 patients with neurological deficits and insomnia disorders after stroke who were hospitalized in the Department of Neurology were enrolled prospectively from November 2021 to November 2022. According to whether or not scalp acupuncture (SA) treatment was performed, it was divided into a SA group (n = 23) and a control group (n = 17). The observation group received scalp acupuncture therapy in addition to conventional internal medicine treatment. The control group did not receive any acupuncture treatment and only received conventional internal medicine treatment. The NIH Stroke Scale (NIHSS), Modified Rankin Scale (mRS), Pittsburgh Sleep Quality Index (PSQI), and Insomnia Severity Index (ISI) were performed before and after treatment, and reassessed after 3 months and followed up for 6 months. Safety assessment was performed at beginning and at 4 weeks after the treatment.

Results: At 3 and 6 months after treatment, there were statistically significant differences in mRS improvement between the observation group and the control group ($P < 0.05$). After treatment and 3 months of follow-up, there was no significant difference in NIHSS between the two groups ($P > 0.05$), while there was a significant difference in NIHSS between the two groups after 6 months of follow-up ($P < 0.05$). After treatment, the insomnia symptoms of the two groups were improved ($P < 0.05$). After 3 to 6 months of follow-up, the PSQI and ISI scores of the observation group were lower than those of the control group ($P < 0.05$).

Conclusions: Scalp acupuncture has clinical therapeutic value and high safety in reshaping neurological function and improving insomnia symptoms after stroke.

Acknowledgments: The authors thank Prof. Zhaoyang Huang, and Jing Li for their excellent technical assistance, and would like to acknowledge all participants who completed the study.

Effects and Influencing Factors of the Different Components in Cognitive Behavioral Therapy for Insomnia

L. Meng¹, F. Meng¹, Z. Li¹

¹Beijing Anding Hospital affiliated with Capital Medical University, Beijing, China

Introduction: This study, combining the psychological characteristics of Chinese patients with insomnia, aims to verify the efficacy of CBT-I in Chinese insomnia patients and explore the different therapeutic components of CBT-I as well as the related factors affecting its efficacy, so as to provide a basis for the further localization and individualization of CBT-I.

Materials and methods: 120 insomnia patients were recruited from the outpatient department and randomly assigned to four groups: Cognitive Behavioral Therapy (CBT), Cognitive Therapy (CT), Behavioral Therapy (BT), and Treatment as Usual (TAU) (n=30/group). All groups received weekly interventions for 8 weeks. The Insomnia Severity Index (ISI), Beck Anxiety Inventory, and Multidimensional Fatigue Inventory (MFI-20) were used for evaluations at baseline, week 4, week 8, week 16, and week 24.

Results: (1) All four patient groups showed significant improvements in insomnia severity after eight weeks of treatment and at the end of 24 weeks of follow-up ($P < 0.05$). Compared to CT-I, CBT-I demonstrated a significantly greater short-term effect on sleep quality, but with no statistically significant difference relative to BT-I. Age and baseline insomnia severity were risk factors for

treatment efficacy, while being married was an independent protective factor. (2) All four groups showed a significant improvement in anxiety symptoms post-treatment ($P < 0.001$), with the CBT, BT, and TAU groups showing a faster improvement rate than the CT group. During follow-up, the therapeutic effects were maintained in the CBT, CT, and BT groups, while the BAI scores increased in the TAU group. At the end of treatment, all four groups showed significantly relieved fatigue symptoms ($P < 0.05$), without significant differences between them ($P > 0.05$).

Conclusions: The short-term improvement effect of CBT-I on sleep quality was similar to that of BT-I, but superior to that of CT-I, highlighting the cost-effectiveness of BT-I.

Effects of Cognitive Behavioral Therapy for Insomnia on Cortical Hyperarousal: A Multicenter Polysomnographic and Quantitative EEG Study

Introduction: Chronic Insomnia Disorder (ID) is a prevalent condition characterized by difficulty initiating or maintaining sleep, driven by a persistent state of physiological and cortical hyperarousal, the most widely accepted pathophysiological model. While Cognitive Behavioral Therapy for Insomnia (CBT-I) is established as the first-line treatment, most evidence of its efficacy is based on self-reported indices, leaving the impact on neurophysiological markers largely unexplored. Addressing this gap is essential for understanding the underlying mechanisms of CBT-I and refining precision-based treatment strategies. This multicenter study aimed to investigate the effect of CBT-I on sleep-related cortical hyperarousal, measured via the delta/beta ratio from quantitative EEG (qEEG) during NREM sleep. Secondary objectives included evaluating CBT-I's effects on sleep stability and examining differences in response across insomnia phenotypes (based on total sleep time).

Materials and methods: Ninety-eight individuals with chronic ID were recruited across five international sleep research centers. Participants completed a standardized 6-8 week CBT-I protocol administered by certified clinicians, incorporating behavioral, cognitive, and psychoeducational components. Pre- and post-treatment assessments included overnight polysomnography (PSG), one-week sleep diaries, and the Insomnia Severity Index (ISI). EEG data were processed using artifact rejection and automated sleep staging algorithms. Cortical hyperarousal was indexed by the delta/beta ratio, calculated from relative power in the delta (1–4 Hz) and beta (16–30 Hz) bands during NREM sleep (NREM1, NREM2, and NREM3). Sleep stability (Sstab) was derived from a transition probability matrix reflecting the likelihood of remaining in stable sleep stages (NREM2, NREM3, REM). Participants were classified as Insomnia with Short Sleep Duration (ISSD) or Normal Sleep Duration (INSDD) based on PSG-derived median TST (347.3 minutes).

Results: CBT-I significantly improved ISI scores and sleep parameters (sleep onset latency, wake after sleep onset, time in bed, sleep efficiency) in both self-reported and PSG macrostructural indices, with smaller effects in the latter. qEEG analyses demonstrated a significant increase in the delta/beta ratio following CBT-I (13.4 ± 4.9 to 14.6 ± 5.9 ; $F=10.05$, $p=0.002$, $\eta^2=0.09$), indicative of reduced cortical hyperarousal, with no differences across centers. Sstab also improved significantly post-treatment ($p=0.005$), yet was not correlated with changes in the delta/beta ratio, suggesting distinct physiological

processes. Phenotypic analysis revealed that ISSD patients exhibited significantly greater improvements in the delta/beta ratio compared to INSD individuals ($p=0.014$), despite comparable baseline insomnia severity.

Conclusions: These findings demonstrate that CBT-I not only improves self-reported and PSG-derived macrostructural sleep parameters but also induces measurable reductions in cortical hyperarousal, as evidenced by increased delta/beta ratios during NREM sleep. The lack of association with sleep stability improvements suggests that CBT-I may modulate multiple, partially independent physiological systems. Moreover, the enhanced response observed in ISSD patients underscores the importance of insomnia phenotyping in predicting treatment efficacy. qEEG biomarkers such as the delta/beta ratio may provide a valuable tool for tracking treatment-related neurophysiological changes and informing personalized interventions. This work supports the integration of EEG-based physiological measures alongside traditional outcomes to advance precision medicine approaches in insomnia care and to better elucidate the mechanisms of CBT-I.

Effects of cognitive behavior therapy for insomnia with adjunctive bright light therapy on sleep variability in youths with insomnia and eveningness: secondary analysis of a randomized controlled trial

Y. Pan¹, F.T.W. Cheung^{1,2}, N.Y. Chan³, J.W.Y. Chan³, J. Zhang^{3,4,5}, A.M. Li⁶, C.A. Espie², M. Gradisar^{7,8}, Y.-K. Wing^{3,9}, S.X. Li¹

Introduction: Insomnia is a common sleep complaint among youth, negatively impacting their physical and mental health. Youths with insomnia and evening chronotype, i.e., a circadian preference for later bedtime and rise time, tend to have more irregular sleep patterns, characterized by greater night-to-night sleep variability. Cognitive behavioral therapy for insomnia (CBT-I) and bright light therapy (BLT), a circadian-focused intervention, have been shown to improve sleep but their effects on reducing sleep variability in youths remained unclear. The present study aimed to explore the effects of CBT-I with adjunctive BLT on sleep variability in youths with insomnia and eveningness.

Materials and methods: This was a secondary analysis of a randomized controlled trial (ClinicalTrials.gov Ref No. NCT04256915). Youths aged 12-24 years with insomnia disorder and eveningness were recruited and randomized to one of the three arms: 1) six weeks of CBT-I with adjunctive BLT (CBTI+BLT); 2) six weeks of CBT-I with placebo BLT (CBTI-BLT); 3) waitlist control (WL). All participants completed a 7-day sleep diary with actigraphy monitoring and self-reported questionnaires at pre-treatment and post-treatment, with additional follow-ups at one-month and six-month for the two treatment groups. Subjective and objective sleep variabilities were calculated using root mean squared successive differences from the sleep diary and actigraphy data.

Results: A total of 159 participants (mean age: 20.10 s.d. 2.20 years, 55% female) were randomized into three arms (CBTI+BLT: $n = 54$, CBTI-BLT: $n = 53$, WL: $n = 52$). A significant Time (pre-treatment vs. post-treatment) $\times$ Group (CBTI+BLT vs CBTI-BLT vs WL) interaction was observed for self-reported variability in sleep onset latency (SOL) ($p = .035$). CBTI-BLT resulted in a significantly greater reduction in self-reported SOL variability at post-treatment compared to WL ($d = -0.71$, $p = .010$). However, there were no significant differences in sleep variability parameters between CBTI+BLT and WL. In addition, no significant group $\times$ time interactions were found for sleep variability parameters at one- and six-month follow-ups between CBTI+BLT and CBTI-BLT. Within-group analyses indicated that reductions in SOL variability in the CBTI-BLT group were maintained at one-month ($d = -0.74$, $p = .027$) and six-month ($d = -0.71$, $p = .020$) follow-ups compared to baseline. Neither the improvement of depressive

symptoms nor the change of circadian preference significantly mediated the effects of CBT-I on reduction of sleep variability.

Conclusions: The findings indicate that CBT-I significantly reduced variability in sleep onset latency, with effects maintained at one-month and six-month follow-ups. Future research should investigate the specific mechanisms underlying the effects of CBT-I on sleep variability.

Effects of DORA daridorexant in the long- term treatment of insomnia disorder: findings from a naturalistic two years follow up

L. Palagini¹, G. Alfi², G. Grenno², G. Aquino², G. Cerofolini¹, M. Gambini¹, M. Pioltino¹, D. Marazziti¹, A. Gemignani²

¹University of Pisa, Department of Neuroscience, Section of Psychiatry, Pisa, Italy, ²University of Pisa, Department of Surgical, Medical, Molecular, and Critical Area Pathology, Pisa, Italy

Introduction: Insomnia disorder is the most common sleep disorder and has a considerable effect on health, making its effective management crucial in clinical practice. Insomnia disorder is a chronic condition affecting more than 40% of individuals for over five years, often resulting in recurring episodes. Therefore, it is crucial to have pharmacological treatments effective for long term use. Daridorexant is the most recent Dual Orexin Receptor Antagonist (DORA) that has been endorsed by international guidelines for the long-term management of chronic insomnia. Emotional dysregulation, maladaptive beliefs regarding sleep, and cognitive as well as somatic pre-sleep arousal are regarded as core features of insomnia disorders, so we aimed to study the long term effect of daridorexant on these core symptomatology of chronic insomnia

Materials and methods: A study was conducted with consecutive outpatients diagnosed with Insomnia Disorder according to DSM-5-TR criteria (Sleep Condition Indicator SCI<16) attending the Insomnia Clinic at the University of Pisa, Italy. Patients received treatment with the novel DORA daridorexant starting from January 2023 to February 2025, in accordance with the guidelines for managing chronic insomnia. Data collected in the current study included a subsample of patients who were under treatment for at least 6 months and up to 2 years. Evaluations were performed at baseline (T0), 3 months (T1), 6 months (T2), 12 months (T3) 18 months and 24 months (T4 and T5). Demographic information and clinical assessments of insomnia severity (Insomnia Severity Index-ISI), pre-sleep arousal (Pre Sleep Arousal Scale-PSAS), emotional dysregulation (Difficulties in Emotion Regulation Scale-DERS), and dysfunctional beliefs about sleep (Dysfunctional Beliefs and Attitudes About Sleep Scale -DBAS) were computed and pharmacological treatments were taken into account. The sedative-hypnotics or sedative antidepressants that were previously prescribed for insomnia were decreased 25% of dosage each week through a cross-tapering program starting at T0, while introducing daridorexant at a dosage of 50 mg.

Results: The study included 60 patients (36 were females, mean age 53 ± 12.6 , insomnia duration 7.4 ± 3.2), who reached at least 6 months of treatment. Among them N°50 patients were under treatment for at least 12 months, N°40 for 18 months and N°25 for 24 months. Repeated measures of ANOVA analyses revealed a significant reduction in scores for the ISI, DERS, DBAS and PSAS across the first three months of treatment with F-values of 35.7, 45.75, 32.77 and 22.74 ($p < 0.001$) at T1. Predictive factors for insomnia symptom remission ($ISI < 8$) at T1 included sedative-hypnotic cross-tapering programs at T0 (OR: 3.00, $p = 0.049$), menopausal transition at T0 (OR: 2.11, $p = 0.039$), ISI severity at T0 (OR: 0.70, $p = 0.020$), DERS, DBAS and PSAS scores reduction at T1 (OR: 2.88, $p = 0.011$; OR: 1.70, $p = 0.039$; OR: 1.70, $p = 0.033$). Following a three-month treatment period, the scores for ISI, DERS, DBAS, and PSAS have shown stability over time, extending up to 24 months.

Conclusions: Preliminary research on the long term use of daridorexant in individuals with Insomnia Disorder suggest significant therapeutic potential for insomnia symptoms, while improving maladaptive beliefs about sleep, emotional regulation, and hyperarousal. It is emerging crucial for the long-term management of insomnia related to peri-menopause.

Effects of Music Presentation on Sleep Quality and Functional Connectivity in the Brain Estimated using EEG

H. Irimajiri¹, S. Otsuka^{2,3,4}, S. Nakagawa^{2,3,4,5}

¹Chiba university, Department of medical engineering, Graduate School of science and Engineering, Chiba, Japan, ²Chiba university, Center for Frontier Medical Engineering, Chiba, Japan, ³Chiba university, Graduate School of Engineering, Faculty of Engineering, Chiba, Japan, ⁴Chiba university, Department of medical engineering, Faculty of engineering, Chiba, Japan, ⁵Chiba University Hospital, Med-Tech Link Center, Chiba, Japan

Introduction: It is estimated that approximately 30% of the global population suffers from insomnia. Although sleeping pills remain the primary treatment, but they involve some problems including dependency and other side effects. Therefore, non-pharmacological approaches such as music therapy, known for its ease of implementation and absence of side effects, have been explored in recent years. *Classical and environmental music are commonly used* in such interventions, however, previous studies have reported inconsistent results regarding the effectiveness of music on sleep improvement. We hypothesize that these discrepancies stem from insufficient control of auditory impressions. To address this, in this study, we investigated the effects of method of music presentation (monaural and stereo), which significantly alter auditory impressions without changing the melody or tempo, on sleep quality. On the other hand, some recent studies have found that fMRI- or EEG-based functional connectivity of the brain in insomnia patients differs from that of healthy individuals. In this study, we also evaluated changes in functional connectivity induced by music presentation during sleep.

Materials and methods: 11 healthy adults (5 females), aged 21–25 years, participated in the experiments. The first movement of *Moonlight Sonata* was used as the auditory stimulus. The experiment was conducted in a soundproof room between 14:00 and 16:00. Three conditions were implemented: (1) silence, (2) monaural presentation, and (3) stereo presentation. Each subject experienced all three conditions once. Subjects were instructed to keep their bedtime on the day before the experiment and their waking time on the day of the experiment, and to refrain from consuming alcohol or caffeine, or engaging in strenuous exercise.

Sleep stage was assessed using EEG (32 channels) and EOG (2 channels), along with the OSA Sleep Inventory MA version (OSA-MA). Band-pass filters of 0.4–17 Hz and 0.1–17 Hz were applied to EEG and EOG signals. Functional connectivity of the brain was calculated from the coherence between EEG channels. Sleep stages were manually scored by the experimenter based on the filtered EEG data.

Results: No significant differences or trends were found among the three conditions in terms of sleep latency, total sleep time, slow wave sleep time, or OSA-MA scores. These results suggest that the method of music presentation had minimal influence on overall sleep quality.

In contrast, functional connectivity in δ and α bands in the silence decreased after sleep onset compared to wakefulness. Also, the decrease in functional connectivity in δ band was observed during wakefulness in the stereo presentation compared to the silence.

Conclusions: Sleep quality didn't change when the same piece of music was presented through different auditory presentation methods, suggesting that musical elements such as tempo and melody may have a stronger influence on sleep promotion.

On the other hand, decrease of functional connectivity in δ band indicates that sleep was promoted by the stereo music stimuli.

Efficacy and Adherence of a Two-Week Bedtime Routine Intervention via the Sleep Coaching App in Adults with Insomnia Symptoms

W. Shin¹, J.-I. Byun¹

¹Kyung Hee University Hospital at Gangdong, Neurology, Seoul, Korea, Republic of

Introduction: Sleep disorders are a rapidly escalating global health concern, profoundly impacting individual well-being, cognitive function, productivity, and economic stability. While Cognitive Behavioral Therapy for Insomnia (CBT-I) is the established first-line treatment, its widespread application is hindered by challenges related to cost, time consumption, and limited accessibility. This has spurred interest in digital health solutions, such as mobile applications, as a more accessible

alternative. This study evaluated "Kkuljam Doctor," a novel sleep coaching mobile application, specifically focusing on its "Bedtime Routine" feature, which integrates relaxation therapy—a core component of CBT-I to leverage effective relaxation techniques and the benefits of fixed bedtime schedules for improving insomnia. This study aimed to evaluate the efficacy and user adherence of a 2-week "Bedtime Routine" intervention, delivered via the Kkuljam Doctor app, in adults reporting recent declines in sleep satisfaction

Materials and methods: This prospective pre-post study enrolled 40 community-dwelling adults (mean age 36.5 ± 6.8 years; 37.5% male). Participants exhibited at least one insomnia symptom (difficulty initiating or maintaining sleep, early awakening, or unrefreshing sleep) and baseline Insomnia Severity Index (ISI) ≥ 5 and Pittsburgh Sleep Quality Index (PSQI-K) ≥ 5 . Participants engaged with the app's "Bedtime Routine" for 14 consecutive days. Sleep efficiency (primary outcome) and other sleep parameters were tracked using in-app sleep diaries and validated questionnaires (PSQI, ISI, ESS). Adherence was also evaluated.

Results: Significant improvements were observed across both objective and subjective sleep parameters after the 2-week intervention. From sleep diaries, TST significantly increased (360.2 ± 60.1 min to 417.1 ± 43.6 min, $p < 0.001$), while sleep latency (41.6 ± 22.1 min to 31.4 ± 19.5 min, $p = 0.016$) and WASO (19.9 ± 17.7 min to 12.8 ± 11.4 min, $p = 0.002$) significantly decreased. Consequently, sleep efficiency significantly improved ($85.2 \pm 7.7\%$ to $90.4 \pm 4.0\%$, $p < 0.001$). Subjective measures also showed marked improvement: PSQI global score (10.3 ± 2.2 to 5.9 ± 2.0 , $p < 0.001$), ISI (15.2 ± 4.3 to 8.3 ± 4.0 , $p < 0.001$), and ESS (11.7 ± 4.6 to 6.1 ± 3.5 , $p < 0.001$) all significantly decreased. All seven PSQI component scores demonstrated significant improvement ($p < 0.001$ for all). Mean adherence to the app was high at $82.8 \pm 9.9\%$; however, four participants (10%) with less than 70% adherence.

Conclusions: A 2-week intervention using the "Bedtime Routine" feature of the Kkuljam Doctor app significantly improved various objective and subjective sleep parameters in adults with mild to moderate insomnia symptoms, demonstrating high user adherence. It demonstrates the effectiveness of a digital app focused on relaxation techniques and fixed sleep schedules in improving sleep.

Efficacy and safety of daridorexant in patients with chronic insomnia disorder and comorbid nocturia

K. Lederer¹, S. Schoffner², J.-E. Batista Miranda³, R. Rowles⁴, A. Olivieri⁴, M. Meinel⁴

¹Advanced Sleep Research GmbH, Berlin, Germany, ²Accellacare Research of Cary, Cary, United States,

³Centro Médico Teknon, Barcelona, Spain, ⁴Idorsia Pharmaceuticals Ltd, Allschwil, Switzerland

Introduction: Chronic insomnia and nocturia are frequently associated, particularly in older adults. Both chronic insomnia and nocturnal voids ≥ 2 /night significantly impact sleep quality, daytime functioning and quality of life. This study evaluated the efficacy and safety of daridorexant in patients with insomnia and comorbid nocturia.

Materials and methods: This double-blind, placebo-controlled, two-way cross-over study randomised 60 patients aged ≥ 55 years with chronic insomnia (insomnia complaints ≥ 3 months; insomnia severity index [ISI] score ≥ 13) and self-reported nocturia (≥ 3 voids/night for ≥ 1 month) to 4-weeks nightly treatment of daridorexant 50 mg or placebo. This was followed by a 14–21-day washout period, after which patients received the alternate 4-week treatment. The primary endpoint was change from baseline to Week 4 in self-reported total sleep time (sTST). Other insomnia endpoints included change from baseline in ISI score (to Weeks 2, 4), sTST (to Weeks 1, 2, 3), depth of sleep (visual analogue scale, to Weeks 1, 2, 3, 4) and daytime functioning (Insomnia Daytime symptoms and Impacts Questionnaire [IDSIQ] total score, to Weeks 1, 2, 3, 4). Nocturia endpoints, evaluated using the Minze diary Pod, included change from baseline in number and time to first nocturnal void (Weeks 1, 4). Safety endpoints included adverse events (AEs) and AEs of special interest (AESI: falls, urinary incontinence).

Results: Daridorexant (vs. placebo) significantly increased mean sTST (56.6 vs. 35.7 mins; $p=0.002$) at Week 4; significant improvements were seen from Week 1 (first timepoint). Daridorexant (vs. placebo) significantly ($p<0.05$) decreased ISI scores (Weeks 2, 4) and significantly ($p<0.05$) improved depth of sleep (Weeks 1–4) and IDSIQ total score (Weeks 1, 3). Daridorexant (vs. placebo) reduced the number of nocturnal voids (Week 1: -1.5 vs. -1.0, $p<0.001$; Week 4: -1.6 vs. -1.3, $p=0.09$) and increased median time to first nocturnal void (difference to placebo, Week 1: +31 mins, $p=0.0027$; Week 4: +23 mins, $p=0.2026$). No serious AEs/AEs leading to discontinuation were reported in the study. No AESIs were reported during daridorexant administration.

Conclusions: In patients with insomnia and comorbid nocturia, daridorexant improves sleep, daytime functioning and nocturia symptoms, with no increased risk of falls or urinary incontinence.

Introduction: Insomnia is common, burdensome, and under-researched in women undergoing the menopausal transition. This is the first evaluation of the efficacy and safety of daridorexant (a novel insomnia treatment), specifically in an age group representative of the menopausal transition, enrolled in the phase 3 study NCT03545191.

Materials and methods: In this randomized, double-blind study, 930 patients with insomnia disorder received daridorexant 25 mg, 50 mg or placebo for 3 months. Subgroup analyses were performed among the 117 women aged 47-55 years (25 mg n=43; 50 mg n=35; placebo n=39). Efficacy endpoints included change from baseline in polysomnography-measured wake after sleep onset (WASO) and latency to persistent sleep (LPS), self-reported total sleep time (sTST) and insomnia-related daytime impairment (Insomnia Daytime Symptoms and Impacts Questionnaire [IDSIIQ]).

Results: At Month 3, daridorexant 50 mg vs placebo decreased WASO and LPS by a least-squares mean (LSM) of 13.8 min (95% CI -29.0, 1.4) and 14.7 min (-30.0, 0.6) respectively, increased sTST by a LSM of 21.8 min (-3.9, 47.4) and decreased (improved) IDSIIQ total score by an LSM of -4.1 (-14.4, 6.3). These results were generally consistent with those of the overall study population. The incidence of somnolence/fatigue was low in both daridorexant groups and comparable to placebo. Comparable improvements in morning sleepiness (visual analogue scale score) were observed across groups.

Conclusions: These post-hoc exploratory analyses suggest that daridorexant 50 mg improves sleep outcomes and daytime functioning and is well tolerated in women aged 47-55 years with insomnia disorder.

Acknowledgments: Funding: Idorsia Pharmaceuticals Ltd

Efficacy and Safety of Fazamorexant in Adults with Insomnia: A Phase 3 Randomized Controlled Trial of a Rapid-Onset, Short-Acting DORA

W. Zhu¹, J. Gu¹, X. Dong¹, F. Han¹

¹Division of Sleep Medicine, Peking University People's Hospital, Beijing, China

Introduction: Dual orexin receptor antagonists (DORAs) are effective medications for insomnia. However, one of the major side effects is excessive daytime sleepiness due to long $t_{1/2}$. Fazamorexant (FAZ; YZJ-1139) is a DORA characterized by rapid absorption (T_{max} : 0.63~1.25 hours) and short elimination half-life ($t_{1/2}$: 1.91-3.68 hours), potentially enabling fast sleep onset and minimal next-morning effects. A Phase 3 RCT was conducted to evaluate its efficacy and safety.

Materials and methods: In this multicenter, randomized, double-blind Phase 3 trial (NCT05525637), adults aged 18-64 with insomnia disorder were randomized (1:1:1) after a 2-week placebo run-in to receive placebo (n=344), FAZ 20 mg (n=344), or FAZ 40 mg (n=346) for 14 days. On Day 15, placebo patients were re-randomized to FAZ20 or FAZ40, continuing for 166 days, while FAZ groups maintained original doses. Efficacy was assessed using Least squares mean (LSM) change from baseline (CFB) and 95% confidence intervals (CIs), via a mixed-effects model for repeated measurements. Co-

primary endpoints were change from baseline to Day 14 in polysomnography-assessed sleep efficiency (SE) and diary-based subjective sleep efficiency (sSE). Durability was assessed at Day 180 via maintenance of improvements in subjective sleep onset latency (sTSO) and total sleep time (sTST).

Results: Both FAZ20 and FAZ40 significantly improved SE (FAZ20, +4.8% [3.3-6.3]; FAZ40, +5.0% [3.5-6.5]) and sSE (FAZ20, +3.3% [1.9-4.8]; FAZ40, +3.1% [1.7-4.5]) versus placebo at Day 14 (all $P < 0.0001$). FAZ20 and FAZ40 significantly outperformed placebo on all PSG measures, including latency to persistent sleep (LPS) and total sleep time (TST) at nights 2 and 14 ($P < 0.005$), and on subjective sleep onset latency (sTSO) and total sleep time (sTST) at days 7 and 14 ($P < 0.001$). Objective and subjective outcomes were concordant over 14 days. Notably, improvements were sustained at Day 180, with sTSO reduced by 52.9 min (FAZ20) and 40.7 min (FAZ40), and sTST increased by 109.7 min and 87.5 min, respectively (all vs baseline; $P < 0.0001$). Fazamorexant was well tolerated, with a low discontinuation rate due to adverse events (0.6%). Common treatment-related AEs ($\geq 2\%$) included hyperlipidemia, dizziness, Leukopenia. No rebound insomnia or withdrawal symptoms were observed upon discontinuation.

Conclusions: Fazamorexant significantly improves sleep onset and maintenance in adults with insomnia, with sustained efficacy over 6 months and a favorable safety profile. Its rapid-onset and short half-life profile make it an unique DORA for insomnia.

Acknowledgments: This study was supported by Yangtze River Pharmaceutical Group Haiyan Pharmaceutical Technology Co., Ltd. The authors gratefully acknowledge the YZJ-1139-3-01 Study Investigator Group for their contribution to this study.

Efficacy and Safety of FLORANBIDIN® in Patients with Chronic Insomnia: A Phase 2 Randomized, Double-Blind Clinical Trial

C. Aiewtrakoon¹, P. Jirakkakul², P. Pomruang³

¹Khon Kaen university, Medicine, Khon Kaen, Thailand, ²Khon Kaen university, Agricultural engineering, Khon Kaen, Thailand, ³Chulalongkorn university, Pharmaceutical science, Bangkok, Thailand

Introduction: Chronic insomnia is a significant health issue that impacts patients' overall well-being and quality of life. Current treatment options primarily include cognitive behavioral therapy for insomnia (CBT-I) and the use of sleeping medications, both of which may lead to adverse effects and long-term dependency. **FLORANBIDIN®** is a novel formulation containing **nano-emulsion cannabidiol (CBD-NE) combined with piperine**, designed to enhance the efficacy of CBD on the **endocannabinoid system (ECS)**. This formulation holds potential for improving sleep quality without severe adverse effects.

Materials and methods: This study is a **randomized, double-blind, placebo-controlled trial** conducted in **patients aged 18-60 years** diagnosed with **chronic insomnia** according to **ICSD-3 criteria**. Eligible participants must have an **Insomnia Severity Index (ISI) score of ≥ 15** and experience **insomnia at least three times per week for over three months**. Participants were randomly assigned into two groups: 1) **FLORANBIDIN® group:** Received **50 mg of FLORANBIDIN® before bedtime** 2) **Placebo group:** Received an **inactive placebo**. The treatment duration was **4 weeks**, and the efficacy was assessed using **Belun Ring, Polysomnography (PSG), ISI, Pittsburgh Sleep Quality Index (PSQI), and Epworth Sleepiness Scale (ESS)**. This study aims to evaluate: 1) The **efficacy of FLORANBIDIN®** in improving sleep quality in patients with chronic insomnia using sleep duration and efficiency as key indicators. 2) The **safety profile of FLORANBIDIN®**, including potential adverse effects. 3) The **impact of FLORANBIDIN®** on daytime sleepiness and overall quality of life in patients.

Results: The study results showed that the **FLORANBIDIN® group** demonstrated a **statistically significant reduction in ISI scores** compared to the placebo group ($p < 0.01$). **Total sleep time (TST)** increased by **17%** ($p < 0.05$), and **sleep efficiency (SE)** improved from **85% to 91%** ($p < 0.01$). Additionally, **sleep onset latency (SOL)** and **wake after sleep onset (WASO)** were significantly reduced in the **FLORANBIDIN® group** compared to the placebo group. No serious adverse events were reported among participants receiving FLORANBIDIN®.

Conclusions: **FLORANBIDIN®** demonstrated significant potential in **improving sleep quality in patients with chronic insomnia by increasing sleep duration, reducing sleep onset latency, and decreasing night-time awakenings** without altering sleep architecture.

Acknowledgments: The authors would like to express their sincere gratitude to all study participants for their valuable time and commitment to this clinical trial. Special thanks are extended to the research team, clinical staff, and coordinators at the participating hospitals and sleep research centers for their

dedicated support in patient care, data collection, and study monitoring.

We are particularly grateful to the technical staff involved in the operation and analysis of sleep data using Belun Ring and Polysomnography (PSG) equipment. Appreciation is also given to the laboratory teams for conducting the biochemical and safety assessments throughout the trial period.

This study was supported by **CHAKRA Group Co., Ltd.**, who provided the investigational product (FLORANBIDIN®) and technical assistance related to product formulation and quality assurance.

Finally, the authors acknowledge the contribution of our scientific advisors and ethical review boards whose guidance and oversight ensured that the study was conducted in compliance with Good Clinical Practice (GCP) and relevant ethical standards.

Efficacy and Safety of Lemborexant in South Korean Participants With Insomnia Disorder: Results From a Randomized Phase 2 Bridging Study

Y.W. Cho¹, Y. Pyo², K. Nakai³, T. Takase³, N. Kubota³, M. Moline⁴

¹Keimyung University School of Medicine, Daegu, Korea, Republic of, ²Eisai Korea Inc., Seoul, Korea, Republic of, ³Eisai Co., Ltd., Tokyo, Japan, ⁴Eisai Inc., Nutley, United States

Introduction: Insomnia disorder is characterized by difficulties falling asleep and/or staying asleep and is reported by approximately 23% of South Korean adults. The objective of the current study was to evaluate the efficacy and safety of lemborexant (LEM), a competitive dual orexin-receptor antagonist, compared with placebo (PBO) in Korean participants with insomnia disorder.

Materials and methods: Study E2006-J082-204 (Study 204; NCT05594589) was a 1-month, multicenter, double-blind, PBO-controlled, parallel-group study evaluating the efficacy and safety of LEM 5 mg (LEM5) or LEM 10 mg (LEM10) in Korean participants (aged 19–80 years) who met *Diagnostic and Statistical Manual of Mental Disorders*, Fifth Edition, criteria for insomnia disorder (sleep onset difficulties with or without complaints of sleep maintenance) with insomnia severity index (ISI) score ≥ 13 . Participants (target sample size, N=60) were randomized (1:2:2) to PBO, LEM5, or LEM10, respectively, and received study drug immediately before bedtime for 30 days. A minimum 28-day follow-up period occurred where participants received no study drug. Polysomnograms were conducted during an ~14-day single-blind PBO run-in (baseline) and after 1 month (Day 30). Analyses included changes from baseline in latency to persistent sleep (LPS; min, log-transformed), sleep efficiency (SE; %), and wake after sleep onset (WASO; min). Statistical significance was determined with an analysis of covariance model adjusted for baseline sleep parameter and treatment. Safety data were collected throughout the study.

Results: The full analysis set comprised 64 participants (PBO, n=13; LEM5, n=25; LEM10, n=26). Mean (SD) ages were 38.6 (13.33), 48.5 (15.84), and 43.2 (13.84) years for PBO, LEM5, and LEM10 groups, respectively. Most participants in the PBO (n=10, 76.9%) and LEM10 (n=17; 65.4%) groups were female; 12 (48.0%) participants were female in the LEM5 group. At Day 30, decreases (improvements) from baseline in LPS were larger and statistically significant with LEM5 versus PBO. With LEM10, LPS decreased from baseline, but was not statistically significant versus PBO. SE increased from baseline with LEM5 but was not statistically significant versus PBO; increases (improvements) from baseline in SE were larger and statistically significant with LEM10 versus PBO. Decreases (improvements) from baseline in WASO were larger and statistically significant with LEM5 and LEM10 versus PBO. LEM was well tolerated with no new safety signals compared with the known safety profile.

Conclusions: The efficacy and safety profile noted in this bridging study in Korean patients with insomnia disorder was consistent with previous global studies of LEM. These findings support the clinical applicability of LEM as a therapeutic option for insomnia management in clinical practice in South Korea.

Acknowledgments: The authors thank Kisaki Onishi for her contribution. Medical writing assistance was provided by Lindsay Achzet, PhD, of Peloton Advantage, LLC, an OPEN Health company, and was funded by Eisai Inc.

Efficacy and Safety of Yokukansan in Patients with Initial-Onset Insomnia: A Multicenter Prospective Observational Study

M. Ozone¹, Y. Hyodo¹, T. Ohsako², M. Ishitsuka³, R. Shin⁴, K. Uematsu⁵, S. Hirota⁶, E. Goto⁷, H. Hiejima¹

¹Kurume university school of medicine, Department of neuropsychiatry, Kurume city, Fukuoka prefecture, Japan, ²Tomo thyroid clinic, Kagoshima, Japan, ³Ishitsuka Neurology Clinic, Fukuoka, Japan, ⁴Shin Kampo mental Clinic, Kurume, Japan, ⁵Uematsu Mental Clinic, Chikugo, Japan, ⁶Hirota Clinic, Kurume, Japan, ⁷Shinwadou Goto Clinic, Fukuoka, Japan

Introduction: In recent years, there has been a shift toward melatonin receptor agonists and orexin receptor antagonists in the development of hypnotic drugs. This transition has been driven by concerns about adverse effects associated with GABA_A receptor agonists, such as residual sedation, cognitive dysfunction, and dependence.

In the treatment of insomnia, non-pharmacological approaches, including sleep hygiene education and cognitive behavioral therapy for insomnia are also emphasized as important.

Yokukansan (YKS) is a Kampo medicine (a Japanese traditional herbal remedy) that has been approved by the Japanese Ministry of Health, Labour and Welfare for the treatment of insomnia.

We conducted a prospective clinical study to evaluate the efficacy and safety of YKS in drug-naïve patients newly diagnosed with insomnia. This study was approved by the Kurume University Ethics Committee (No. 22237).

Materials and methods: The aim of this study was to investigate the efficacy and safety of YKS in patients presenting with insomnia, following the administration of sleep hygiene education.

This is a multicenter, prospective, single-arm, open-label study. Patients who presented to participating facilities with insomnia between May 1, 2023, and June 30, 2024, and provided informed consent were enrolled. Participants were instructed to watch an educational video on sleep hygiene and received YKS (TSUMURA & CO.) at doses ranging from 2.5 to 7.5 g/day for 4 weeks, with dosage adjustments permitted at the discretion of the attending physician.

The primary outcome was the change in score on the Japanese version of the Insomnia Severity Index (ISI-J). Secondary outcomes included the Pittsburgh Sleep Quality Index (PSQI), the Japanese version of the Patient Health Questionnaire-9 (PHQ-9), Visual Analogue Scale (VAS) scores for daytime functional impairments (e.g., sleepiness, fatigue, tension), the Patient Global Impression of Improvement (PGI-I), and the proportion of patients who wished to continue YKS treatment at the end of the study.

Statistical analyses were performed using the Wilcoxon signed-rank test. The study was funded by TSUMURA & CO.

Results: Of the 100 patients who consented to participate, 95 (mean age 42.7 ± 13.0 years; 58 females) were included in the final analysis. The primary outcome, ISI-J score, significantly decreased from baseline to week 4 (13.5 to 6.5; $p < 0.001$).

Significant improvements were also observed in secondary outcomes, including PSQI (8.7 to 8.1; $p = 0.033$), PHQ-9 (8.7 to 4.6; $p < 0.05$), and VAS scores for sleepiness, heaviness of the head, fatigue, lassitude, tension, sense of well-being, calmness, and dizziness. At the end of the study, 62.5% of patients expressed a desire to continue YKS treatment. No serious adverse events were reported during the observation period. Mild adverse events included dizziness (1%), drowsiness (1%), and urticaria (1%).

Conclusions: This study demonstrated that the combination of sleep hygiene education and YKS administration significantly improved insomnia severity to a level comparable with healthy individuals, without causing adverse events commonly associated with GABA_A receptor agonists.

Our findings suggest that the use of YKS in conjunction with video-based sleep hygiene instruction may serve as a safe and effective initial treatment option for insomnia.

Efficacy of a stepped care approach to deliver cognitive behavioural therapy for insomnia in the community: A pragmatic stepped-wedge cluster randomized controlled trial

R.N.Y. Chan¹, D.J.C. Yu², J.W.H. Sun¹, A.C.M. Fu¹, S. Chen¹, S.X. Li^{3,4}, J.W.Y. Chan¹, Y.K. Wing^{1,5}

¹The Chinese University of Hong Kong, Psychiatry, Hong Kong, Hong Kong, SAR of China, ²Hong Kong Baptist University, School of Chinese Medicine, Hong Kong, Hong Kong, SAR of China, ³The University of Hong Kong, Psychology, Hong Kong, Hong Kong, SAR of China, ⁴The University of Hong Kong, The State Key Laboratory of Brain and Cognitive Sciences, Hong Kong, Hong Kong, SAR of China, ⁵The Chinese University of Hong Kong, Li Ka Shing Institute of Health Sciences, Hong Kong, Hong Kong, SAR of China

Introduction: Insomnia affects up to 30% of the general population and is a significant global public health concern. While Cognitive Behavioral Therapy for Insomnia (CBT-I) is the first-line treatment, its accessibility remains limited. Digital CBT-I (dCBT-I) may enhance accessibility, but the evidence for its effectiveness in the real-world context is scarce. Given the high prevalence of insomnia, a stepped care approach is recommended to improve the accessibility of effective interventions. This study aims to evaluate the effectiveness of a stepped care model for delivering CBT-I in a community context.

Materials and methods: This pragmatic stepped-wedge cluster randomized trial was conducted across 18 districts in Hong Kong, with the intervention introduced sequentially over six months to all districts. The stepped care approach commenced with step 1 which was a dCBT-I with 4 self-paced modules, followed by step 2 with the guided support by trained sleep coaches from six non-governmental organizations, and the final step involved individual therapy with clinical psychologists. Participants aged 18-70 years old and with Insomnia Severity Index (ISI) score of ≥ 10 were included. Outcomes were assessed at post-intervention and at three-month follow-up. Linear mixed models with random effects for clusters and for participants nested within clusters is employed to evaluate the intervention effect across all timepoints.

Results: A total of 5,085 individuals registered in the digital platform (HKJC Sleep Well Project), of whom 3,513 initially met the inclusion criteria. Following the screening assessment, a total 1194 (mean age: 51.7yrs $\pm$ 15.5; female: 77.0%) enrolled the trial and 75% were retained in the service. In the stepped care model, about 59% continued to exhibit insomnia symptoms (ISI ≥ 10) after step 1, and 23.3% of them maintained moderate insomnia (ISI > 14) despite receiving step 2 guided support. Analysis of overall stepped care model suggested that intervention group reported a greater reduction in insomnia symptoms (adjusted difference: -2.36; 95% CI: -3.04 to -1.69, $p < 0.001$), depression (adjusted difference: -2.27; adjusted difference: -2.36 95% CI: -3.07 to -1.47, $p < 0.001$), anxiety (adjusted difference: -1.62; 95% CI: -2.41 to -0.83, $p < 0.001$), and improved quality of life (adjusted difference: 0.04; 95% CI: 0.01 to 0.07, $p = 0.009$) and overall general health (adjusted difference: 3.37; 95% CI: 0.48 to 3.27, $p = 0.022$) compared to control. These improvements were maintained at 3-month follow up ($P_s < 0.001$). In addition, insomnia remission defined as ISI < 8 (30.0% vs 9.9%, $p < 0.000$) and response rate defined as reduction of ISI ≥ 6 (38.6% vs 14.9%, $p < 0.001$) were significantly higher in intervention period compared to control.

Conclusions: This large-scale, district-wide stepped wedged and stepped care approach of insomnia intervention in the community demonstrated significant improvements in insomnia and mood outcomes, along with enhancements in quality of life and general health. The findings suggest substantial potential for population-level benefits of this model. Future research should focus on evaluating the long-term effects and cost-effectiveness of the stepped care approach.

Acknowledgments: This project is supported by The Hong Kong Jockey Club's Charity Trust Fund (Jockey Club Sleep Well Project).

Efficacy of Jasmine Aromatherapy Pillow on Sleep Quality in Insomnia Patients

J. Wanchaitanawong¹, K. Panjapornpon¹, N. Luekitinun¹, S. Pawaphutanon na mahasarakam¹, R. Singpeam¹, N. Chuenchomboon¹, T. Muengsrir¹, P. Pinthong¹

¹Central Chest Institute of Thailand, Sleep Disorders Center, Pulmonary Medicine Department, Muang Nonthaburi, Thailand

Introduction: Insomnia is a common symptom of sleep problems, and there are various interventions to treat it. However, there is increasing interest in non-pharmacologic interventions.

Materials and methods: A prospective crossover study was conducted between August 1, 2023, and January 31, 2024, at the Sleep Disorders Clinic, Central Chest Institute of Thailand. The study included subjects aged ≥ 18 years who self-reported insomnia for at least 3 nights/week over a minimum duration of 1 month. Participants used their regular pillows for one week to collect baseline data on PSQI, GAD7, PHQ9, ISI, ESS, along with recording a sleep log and wearing an actigraphy watch. Subsequently, they were provided with a straw pillow and a Jasmine aromatherapy pillow for an additional week of use. Data were collected using the same questionnaire after participants utilized each intervention for one week.

Results: Six female participants with a mean age of 52 $\pm$ 14.76 years were enrolled. Both the straw pillow (11.17 $\pm$ 2.14 vs 14.33 $\pm$ 4.03, $p=0.045$) and the Jasmine aromatherapy pillow (10.17 $\pm$ 2.64 vs 14.33 $\pm$ 4.03, $p=0.002$) significantly reduced PSQI scores compared to the baseline. The ISI significantly

decreased after using the Jasmine aromatherapy pillow compared to both the baseline (13.50 ± 3.94 vs 16.17 ± 3.25 , $p=0.047$) and the straw pillow (13.50 ± 3.94 vs 15.83 ± 3.43 , $p=0.017$). The data from sleep log and actigraphy did not show significant improvement of TIB, TST, SL, SE, WASO, and NNA.

Conclusions: Both the straw pillow and Jasmine aromatherapy pillow help to improve sleep quality. Notably, the Jasmine aromatherapy pillow also decreased insomnia symptoms.

Embodied AI coach for delivering CBT-I in virtual reality- a pilot feasibility study

R. Huang¹, Y. Liu¹, L. Xian¹, N.Y. Chan¹, S.X. Li^{2,3}, J.W.Y. Chan¹, Y.K. Wing^{1,4}, T.M.H. Li¹

¹Li Chiu Kong Family Sleep Assessment Unit, The Chinese University of Hong Kong, Department of Psychiatry, Hong Kong, China, ²The University of Hong Kong, Department of Psychology, Hong Kong, China, ³The State Key Laboratory of Brain and Cognitive Sciences, The University of Hong Kong, Hong Kong, China, ⁴Li Ka Shing Institute of Health Sciences, Faculty of Medicine, The Chinese University of Hong Kong, Hong Kong, China

Introduction: Recent AI advancements have shown promise in digitalizing psychotherapeutic interventions, including CBT-I, for more cost-effective and scalable interventions. However, most dCBT-I chatbots are limited by their provision of predefined responses in a text-based format. They lack embodied presence of AI (i.e. Embodied AI) for enhancing users' engagement. This also restricts AI's ability to perceive user behaviors and respond adaptively. This study aims to explore the feasibility of using Embodied AI coach for delivering CBT-I in virtual reality (VR).

Materials and methods:

Subjects

Inclusion criteria: 1) adults of Chinese ethnicity, 2) presence of insomnia, as indicated by a score of 8 or higher on the Insomnia Severity Index (ISI).

VR-Based CBT-I program

Embodied AI-Avatar coach

The virtual avatar was designed based on a typical therapist prototype, with a warm and approachable demeanor. Human-like animations (e.g., sitting, talking) and refined facial expressions, including lip synchronization and eye blinking, were integrated. Besides, the avatar made real-time adjustment of its position and eye gaze, as enabled by the movement tracking of the users. The avatar was powered by ChatGPT with an overarching prompt of character's backstory (e.g., roleplaying real-world therapists). A rule-based prompt structure (e.g., a CBT-I workflow) was imposed to determine which following sets of prompts should be utilized by ChatGPT, given users' current reply or question. Thus, a standardized conversation flow with personalized information was achieved. Moreover, the avatar had access to an external knowledge bank with CBT-I knowledge.

Content Design

The interventional content is based on our previous studies with 4 weekly CBT-I modules including (1) psychoeducation about insomnia and sleep restriction, (2) sleep hygiene and behavioral strategies, (3) cognitive restructuring and constructive worry strategies, and (4) stress management and relaxation training.

Procedure

Eligible participants were enrolled in a 4-week Chinese-speaking VR-based CBT-I program, with one module being delivered each week. Participants were asked to complete the ISI and user survey in the final session.

Results: In total, 7 participants (71% female; mean age: 27.14 yrs) were recruited and 6 of them completed the program. In the completer analysis, the results from the pre-intervention ($M=10.17$, $SD=1.94$) and post-intervention ($M=7$, $SD=2.97$) ISI scores indicated that the VR-based CBT-I program significantly reduced insomnia symptoms ($t(6)=-2.71$, $p=.04$), with an apparent large effect size ($d=1.26$). The user survey demonstrated a good level of satisfaction, with 67% of users showing moderate to strong intentions to continue using this virtual AI-Avatar coach to manage their sleep problems. Moreover, 67% of users felt that the utilization of embodied AI and virtual environments resulted in enhanced user experience and engagement.

Conclusions: The pilot data showed promising results with positive user feedback of utilizing Embodied AI Avatar coach to deliver CBT-I among individuals with insomnia. Further development to better leverage immersive technology and further formal comparative study with traditional dCBT-I intervention is needed.

Emotion dysregulation and insomnia: the mediating role of repetitive thought and REM arousal

S. Mombelli^{1,2}, E. Fasiello³, M.C. Di Perri⁴, F. Casoni³, M. Zucconi³, V. Castronovo³, L. Ferini-Strambi^{3,5}, A. Galbiati^{3,5}

¹Center for Advanced Research in Sleep Medicine, Research center of the Centre intégré universitaire de santé et de services sociaux du Nord de l'Île-de-Montréal, Montréal, Canada, ²Université de Montréal, Department of Psychiatry and Addictology, Montréal, Canada, ³Neurology-Sleep Disorders Center, IRCCS San Raffaele Scientific Institute, Department of Clinical Neurosciences, Milan, Italy, ⁴Sleep Medicine Center, Neurophysiopathology and Movement Disorders Unit, Department of Clinical and Experimental Medicine, University of Messina, AOU "G. Martino", Messina, Italy, ⁵Vita-Salute San Raffaele University, Faculty of Psychology, Milan, Italy

Introduction: Worry and rumination are forms of repetitive negative thinking closely associated with emotional dysregulation and are increasingly recognized as central contributors to the persistence of insomnia. Beyond their cognitive/emotional impact, these processes have also been linked to alterations in rapid eye movement (REM) sleep, a crucial stage for emotional regulation and memory consolidation, potentially leading to increased fragmentation and reduced efficiency. However, the mechanisms through which these factors interact remain insufficiently understood, limiting the development of targeted interventions for insomnia. This study aimed to examine the interplay between emotional dysregulation, worry, rumination, and REM sleep instability in individuals with insomnia disorder and healthy controls.

Materials and methods: Twenty-three patients with insomnia disorder and twenty-three matched healthy controls completed questionnaires assessing emotional dysregulation (DERS), rumination (RRS), worry (PSWQ), insomnia severity (ISI), depression (BDI), and anxiety (STAI). Only patients underwent overnight in-laboratory polysomnography. REM sleep instability was quantified using a REM arousal index, calculated as the number of arousals per hour of REM sleep. REM arousals were defined according to AASM criteria as abrupt shifts in EEG frequency lasting at least 3 seconds, following a minimum of 10 seconds of stable REM, and accompanied by a concurrent increase in submental EMG activity lasting at least 1 second. Group comparisons were conducted using Mann-Whitney U tests, and Spearman correlations were used to examine associations among emotional dysregulation, worry, rumination, insomnia severity, and depressive symptoms. Three mediation models were tested using maximum likelihood estimation with bootstrapped confidence intervals: (1) whether rumination and worry mediated the relationship between emotional dysregulation and impact of insomnia (ISI subscale); (2) whether these variables mediated the association between difficulties in distracting with emotions (DERS subscale) and depressive symptoms; (3) in the insomnia group only, whether rumination and REM arousal mediated the relationship between distracting with emotions and the impact of insomnia.

Results: Compared to healthy controls, insomnia patients showed higher scores of emotional dysregulations, worry, rumination, depressive symptoms, and anxiety (all $p < 0.001$). Emotional dysregulation was associated with both rumination ($r = 0.73$, $p < 0.001$) and worry ($r = 0.53$, $p < 0.001$), but only rumination mediated the relationship between emotional dysregulation and impact of insomnia ($p = 0.007$). Rumination, but not worry, also mediated the link between DERS subscale and depressive symptoms ($p = 0.005$). Furthermore, the DERS subscale was positively correlated with REM arousal index ($r = 0.53$, $p = 0.009$), and both rumination and REM instability mediated its link with insomnia severity ($p = 0.002$ and $p = 0.039$, respectively).

Conclusions: These findings highlight rumination as a key mechanism linking emotional dysregulation to both insomnia and depressive symptoms. REM sleep instability also emerged as a possible physiological marker of emotional dysregulation. Interventions targeting rumination and REM-related arousal may offer promising avenues for improving treatment outcomes in chronic insomnia.

Epigenetic Characterization of Insomnia with Short Sleep Duration through Salivary microRNA Profiling: Study Protocol

S. Perdigoto¹, M.G. Meira e Cruz², C.A. Noriega³, M.d.R.G. Soltero⁴, M.d.P. Herraes⁵

¹Universidad Europea Madrid, Orofacial Pain, Oral Pathology and Dental Sleep Medicine Research Group. Faculty of Biomedical Sciences, Madrid, Spain, ²Faculty of Medicine of the University of Lisbon, Sleep Unit, Cardiovascular Centre of the University of Lisbon, Lisbon, Portugal, ³Universidad Europea de Madrid, Department of Medicine, Faculty of Medicine, Health and Sports, Madrid, Spain, ⁴Universidad Europea de Madrid, Faculty of Biomedical and Health Sciences, Madrid, Spain, ⁵Universidad Europea de Madrid, Orofacial Pain, Oral Pathology and Dental Sleep Medicine Research Group. Department of Postgraduate Clinical Dentistry. Faculty of Biomedical Sciences, Madrid, Spain

Introduction: Insomnia with short sleep duration (ISSD) is a clinically significant phenotype associated with increased risk of cardiometabolic disease, cognitive impairment, and reduced treatment responsiveness. Identifying biological markers specific to ISSD may help differentiate pathophysiological pathways and improve personalized treatment strategies in complex sleep disorder presentations such as COMISA. Among the most promising molecular tools are microRNAs (miRNAs), small, non-coding RNA molecules that regulate gene expression post-transcriptionally and are increasingly recognized for their role in sleep regulation and cardiometabolic health. The investigation of salivary miRNAs as epigenetic markers for ISSD offers a non-invasive approach to understanding disease mechanisms and identifying potential therapeutic targets.

Materials and methods: This two-phase study will explore salivary miRNA profiles in ISSD:

Part 1 – Pilot Study: Forty participants will be enrolled and divided into two clinically homogeneous groups: 20 patients with ISSD and 20 with insomnia without objectively verified short sleep duration. Saliva (1–4 mL) will be collected using Presto™ cfDNA/cfRNA kits. High-throughput miRNA profiling will be performed using next-generation sequencing (NGS). Bioinformatics analysis will identify and quantify miRNAs, and functional annotation will be conducted using databases such as miRTarBase and TargetScan. Group comparisons and enrichment analyses (GO, KEGG) will help identify relevant biological pathways.

Part 2 – Validation Study: In a larger cohort, candidate miRNAs from Part 1 will be validated using quantitative real-time PCR (qPCR), enabling precise quantification. Additional confirmatory techniques such as in situ hybridization or Northern blotting may be applied for selected miRNAs.

Results: The study will generate a miRNA expression profile in ISSD, highlighting both known and novel salivary miRNAs. Identified miRNAs will be linked to target genes and biologically significant pathways, particularly those involved in metabolic and sleep-related processes. The qPCR-based validation will confirm the reproducibility and clinical relevance of the findings.

Conclusions: By characterizing miRNA expression in ISSD and validating their associations with gene targets and biological functions, this study aims to identify epigenetic biomarkers that can inform the diagnosis and treatment of insomnia phenotypes. Functional bioinformatics will support the discovery of pathways potentially linking ISSD to cardiometabolic vulnerability, ultimately contributing to precision sleep medicine.

Acknowledgments: This study is conducted in the context of the first author's doctoral thesis at Universidad Europea de Madrid.

Esketamine rapid antidepressant combined with dexmedetomidine sleep modulation for patients with depression and insomnia

M. Zuo¹

¹University of Chinese Academy of Sciences, Beijing, China

Introduction: Depression combined with insomnia is a complex bidirectional relationship that is more difficult to treat versus a single disorder, and there is a lack of effective treatments available. In this study, we carried out a novel way to simultaneously intervene in depression combined with insomnia: the novel antidepressant esketamine as well as the bionic sleep-inducing drug dexmedetomidine.

Materials and methods: A total of 105 patients with depression and insomnia were included in this observational and prospective study. fMRI scans were performed at baseline and 2 hours after treatment, and follow-up was conducted for 6 months to collect 17 items of the Hamilton Depression Scale (HAMD-17) and the Pittsburgh Sleep Quality Index (PSQI).

Results: We found that after 2 hours of treatment, there were significant changes in neuroimaging of the brain, with a consistent decline in spontaneous neural activity in the left amygdala, left hippocampus, left superior temporal gyrus, left anterior cingulate gyrus, and left accessory cingulate gyrus. The right dorsolateral superior frontal gyrus, middle frontal gyrus, infraorbital frontal gyrus, middle orbital frontal gyrus, and right caudate nucleus had increased the consistency of spontaneous nerve function. Moreover, the depression response rate was higher than that of conventional antidepressants and electroconvulsive therapy.

Conclusions: The results of this study support the efficacy and safety of esketamine combined with dexmedetomidine in the treatment of patients with depression and insomnia, and provide a new idea for clinical treatment.

Acknowledgments: Thanks to Shuangjie Cao MD. PhD., Kun Niu MD. PhD. from Institute for Innovation Diagnosis & Treatment in Anesthesiology, Shandong Second Medical University and Le Shi MD. PhD. from Peking University Sixth Hospital for their helpful suggestions.

Estimating the Prevalence of Insomnia Disorder in the Asia-Pacific Region Using Published Data

F. Sert Kuniyoshi¹, A. Benjafield², A. Malhotra³, L. Maurer⁴, C. Morin⁵, J. Martin⁶, J.-L. Pépin⁷, P. Cistulli⁸, E. Wickwire⁹

¹Resmed Scinece Center, San Diego, United States, ²Resmed Science Center, Sydney, Australia, ³University of California San Diego, La Jolla, United States, ⁴mementor DE GmbH, Leipzig, Germany, ⁵Université Laval, Quebec, Canada, ⁶VA Greater Los Angeles Healthcare System, Los Angeles, United States, ⁷Grenoble Alps University, Grenoble, France, ⁸Charles Perkins Centre, Faculty of Medicine and Health, University of Sydney, Sydney, Australia, ⁹University of Maryland, School of Medicine, Blatimore, United States

Introduction: Insomnia disorder is a major clinical issue due to its high prevalence and negative health and economic outcomes. However, epidemiological data on insomnia disorder remain limited, particularly in the Asia-Pacific (APAC) region, where most countries lack reliable prevalence estimates. This analysis aimed to estimate the prevalence of insomnia disorder in the APAC region using published data.

Materials and methods: We applied published, nation-specific prevalence estimates of insomnia disorder to current population data for all APAC countries. Inclusion criteria for prevalence estimates prioritized: 1) studies that reported prevalence stratified by both age and sex together; 2) studies that reported prevalence by age and sex separately, we used the age-based results; 3) studies that reported prevalence by sex but not age; 4) studies that reported only a single prevalence estimate. When multiple studies existed for a country, the most methodologically rigorous study was selected based on expert opinion. When no nation-specific data were unavailable, prevalence estimates were extrapolated from a large, well-conducted study (Leger et al, 2000). Population estimates were sourced from the United Nations World Population Prospects 2022.

Results: Of the 56 APAC countries defined by the United Nations, 8 (14%) had suitable prevalence data, highlighting the need for further regional insights. We estimated that approximately 502 million adults in the APAC region (16.3%) have insomnia disorder, including 291 million females (18.9%) and 211 million males (13.6%). The highest insomnia burden was observed in India (166 million), China (164 million), Indonesia (33 million), Pakistan (22 million) and Bangladesh (20 million).

Conclusions: This analysis highlights the substantial burden of insomnia disorder in Asia, with an estimated 502 million adults affected. Results underscore the need for improved targeted interventions to reduce the health and economic burden of insomnia in the APAC region.

Evaluating behavioral therapy as a stand-alone treatment for insomnia: the SLEEPwindow study

M. Angelillo¹, C.L. Schneider¹, K.D. Fehér¹, P. Henckaerts¹, T. Berger², C. Nissen¹, E. Hertenstein¹

¹University of Geneva, Psychiatry, Genève, Switzerland, ²University of Bern, Clinical psychology and psychotherapy, Bern, Switzerland

Introduction: Chronic insomnia, a disorder characterized by a complaint of reduced sleep quality or quantity and associated with daytime impairments, is linked to reduced quality of life and is highly prevalent. Cognitive Behavioral Therapy for Insomnia (CBT-I) is the first-line treatment, however, its implementation and accessibility remain limited. The key element of CBT-I is the behavioural component (i.e. bedtime restriction and stimulus control) and has demonstrated effectiveness on its own. This study examines whether the SLEEPwindow intervention, which focuses on the behavioural component only, is non-inferior to full CBT-I. By reducing treatment duration and complexity, SLEEPwindow supports implementation, accessibility, and overall improvement of chronic insomnia care.

Materials and methods: The SLEEPwindow study is a prospective non-inferiority trial comparing full CBT-I with the SLEEPwindow intervention (i.e. bedtime restriction and stimulus control). A total of 160 insomnia patients will be randomized into two groups: CBT-I and SLEEPwindow. CBT-I will consist of six 90-minute group sessions covering sleep education, bedtime restriction, stimulus control, cognitive therapy, and relaxation techniques. SLEEPwindow will be delivered in four 60-minute group sessions over six weeks and focuses on individualized sleep windows, adjustment of sleep schedules, and group discussions. The insomnia severity index as a primary outcome will be measured at baseline, six weeks (T1), three months (T2), and six months (T3). Secondary outcomes include sleep quality, health-related quality of life, treatment adherence, and satisfaction. In addition to the clinical trial, barriers and facilitators to implementation of CBT-I will be evaluated in qualitative interviews.

Results: Results will determine whether the SLEEPwindow intervention is non-inferior to full CBT-I in improving the clinical symptomatology of chronic insomnia.

Conclusions: If confirmed, the efficacy of the SLEEPwindow intervention could offer a shorter, more accessible, and cost-effective treatment for chronic insomnia, facilitating broader implementation in clinical practice. Future research should continue to explore treatment mechanisms and barriers to implementation.

Evaluating the Effectiveness of Cognitive Behavioral Therapy for Insomnia in School Settings: A Systematic Review and Meta-Analysis

C. Ewart¹, K. Egan², S. McCrory¹, M. Henderson³, L. Fleming¹

¹University of Strathclyde, Centre for Sleep Health, Department of Psychological Sciences and Health, Glasgow, United Kingdom, ²University of Strathclyde, Digital Health and Wellness Group, Department of Computing and Information Sciences, Glasgow, United Kingdom, ³University of Strathclyde, School of Social Work and Social Policy, Glasgow, United Kingdom

Introduction: Poor sleep among adolescents is a significant public health concern. Delivering Cognitive Behavioral Therapy for insomnia (CBT-I) in schools may be an effective way to reach adolescents with poor sleep. This systematic review and meta-analysis examined the effectiveness of school-based CBT-I for improving sleep quality and/or duration among adolescents with insomnia symptoms or disorder.

Materials and methods: A systematic search of studies between 2003-2025 was conducted in March 2025. Inclusion criteria were adolescents aged 10-19 years (population) with insomnia symptoms, school-based interventions using evidence-based CBT-I principles (intervention), randomized or non-randomized trials (comparator), and reported sleep quality and/or duration (outcome).

Results: Eight studies ($n = 323$; M age = 15.3 years; 62.57% female) from four countries were included. Meta-analysis of within sleep intervention condition groups ($n = 8$) found significant subjective improvements post-intervention: total sleep time (TST) increased by 23.87 minutes ($p < 0.001$), sleep onset latency (SOL) decreased by 8.34 minutes ($p < 0.01$), and sleep quality improved $g = 0.376$ ($p = 0.001$). Objective measures of TST increased by 20.91 minutes ($p = 0.100$), SOL decreased by 1.35 minutes ($p = 0.202$), and sleep efficiency rose by 0.50% ($p = 0.792$). Anxiety improved significantly $g = 0.373$ ($p < 0.01$), but depression did not $g = 0.806$ ($p = 0.196$).

Conclusions: While sleep improvements were only observed for subjective sleep outcomes, this review suggests that school-based CBT-I may be an effective avenue to address adolescent insomnia. Given the limited evidence, we identify key methodological and implementation considerations to guide practice.

Evaluation of the Cutoff Score Determination for the Quality of Life Scale for Insomnia

N. Ayabe^{1,2}, K. Mishima^{2,3}

¹Akita University, Department of Regional Studies and Humanities, Faculty of Education and Human Studies, Akita, Japan, ²National Center of Neurology and Psychiatry, Department of Sleep-Wake Disorders, National Institute of Mental Health, Kodaira, Japan, ³Akita University, Department of Neuropsychiatry, Graduate School of Medicine, Akita, Japan

Introduction: Insomnia is diagnosed based on nighttime sleep disturbances, such as difficulty falling asleep, frequent awakenings, and early morning awakenings, and associated daytime functional impairments. The authors developed the Quality of Life Scale for Insomnia (QOL-I) to assess quality of life (QOL) in individuals with insomnia and confirmed its reliability and validity (Ayabe et al., 2025). This study aimed to examine the clinical use of the QOL-I by determining a cut-off point for identifying individuals with reduced QOL.

Materials and methods: This study used the same dataset employed by Ayabe et al. (2025) in the development of the QOL-I. The insomnia and control groups comprised 93 (mean age; 54.16 ± 16.01 years, 35 men, 58 women) and 228 participants (mean age; 44.96 ± 15.66 years, 95 men, 133 women), respectively. The study was approved by the Ethics Committee of the National Center of Neurology and Psychiatry and the participating medical institutions.

Results: Receiver operating characteristic (ROC) analysis yielded an area under the ROC curve (AUC) of 0.804, indicating a good discriminative ability. Sensitivity and specificity were 0.785 and 0.675, respectively. The cutoff QOL-I score was 32.5. The positive and negative predictive values were 0.497 and 0.885, respectively.

Conclusions: The ROC analysis results suggest that the QOL-I is a clinically useful tool for screening for reduced QOL in patients with insomnia. A score < 32.5 may reflect a diminished QOL. However, considering their moderate positive predictive value, interpreting QOL-I scores may benefit from combining them with other indicators, such as insomnia severity. Furthermore, because QOL is inherently a continuous and multidimensional concept, the cutoff QOL-I score may be better understood as a reference point rather than a strict diagnostic threshold.

Excessive daytime sleepiness should be systematically assessed in individuals with insomnia: A population-based study employing a virtual agent-based digital tool

J. Coelho^{1,2}, F. Pécune¹, A. Chanteclair^{2,1}, E. De Sevin¹, E. D'Incau^{1,2}, P. Sagaspe², H. Alia¹, C. Morin³, J.-A. Micoulaud-Franchi^{1,2}, P. Philip^{1,2}

¹Bordeaux University, SANPSY, CNRS, UMR6033, Bordeaux, France, ²Bordeaux University Hospital, Sleep Medicine Unit, Bordeaux, France, ³Laval, Psychology, Quebec, Canada

Introduction: Insomnia and excessive daytime sleepiness often co-occur despite they involve distinct physiological mechanisms. The KANOPIÉE application collects sleep-related data over a 17-day period and offer a unique opportunity to gain a deeper understanding of this unexpected phenotype.

Materials and methods: We analyzed a digital cohort of 21,590 participants, which included screening for sleep and mental health disorders (e.g., obstructive sleep apnea syndrome, restless legs syndrome, and depression); and a three-wave assessment of insomnia and excessive daytime sleepiness; completion of a 17-day sleep diary (recording total sleep time, mid-sleep point, sleep regularity index, and sleep medication intake).

Results: At baseline, 10,114 (46.8%) participants reported insomnia complaints. Of these participants, 4,843 (47.9%) were categorized as 'sleepy insomniacs' (i.e., Epworth sleepiness scale ≥ 11 and Insomnia severity index ≥ 15). Half of this subgroup reported at least one comorbidity, with depression being the most frequent. After excluding participants with comorbidities, 3,239 (44.3%) remained in the 'sleepy insomniac' category. These individuals exhibited no significant differences in self-reported sleep behaviors, including total sleep time, but were more likely to have middle or late insomnia compared to those with insomnia without excessive daytime sleepiness.

Conclusions: Excessive daytime sleepiness is highly prevalent among individuals with insomnia. Although comorbidities, particularly depression, accounted for the co-occurrence in approximately half

of our sample, a significant proportion of participants without comorbidities also demonstrated this unexpected phenotype. The lack of clear sleep debt in 'sleepy insomniacs' and the associations with specific insomnia subtypes underscores the need for further investigation.

Acknowledgments: We thank all institutions and professionals involved in developing the application (University of Bordeaux and especially Emeric Labbé) and in its dissemination (University of Bordeaux, Mutuelle Nationale des Hospitaliers MNH®, Fédération Hospitalière de France FHF).

Exploring pregnant women's perspectives in developing a WeChat-delivered cognitive behavioral therapy for insomnia: a qualitative study

X. Shang^{1,2}, T.T. Luk^{1,3}, A.Y.K. Lai⁴, M.P. Wang¹

¹ The University of Hong Kong, School of Nursing, LKS Faculty of Medicine, Hong Kong, Hong Kong, SAR of China, ²Yangzhou University, School of Nursing School of Public Health, Yangzhou, China, ³National University of Singapore, Alice Lee Centre for Nursing Studies, Yong Loo Lin School of Medicine, Singapore, Singapore, ⁴Hong Kong Metropolitan University, School of Nursing and Health Studies, Hong Kong, Hong Kong, SAR of China

Introduction: WeChat, the most popular mobile instant messaging app, offers a highly accessible but untested platform for delivering tailored CBT-I program to pregnant women. To inform its content and design, we conducted a formative study to explore the perceptions of Chinese pregnant women on a WeChat-delivered CBT-I program.

Materials and methods: A descriptive qualitative design was used. Focus groups and individual interviews with semi-structured questions were conducted via a video conferencing platform with 29 Chinese pregnant women with insomnia symptoms (Insomnia Severity Index score > 7) during December 2023 to March 2024. Data were analyzed using content analysis.

Results: Three themes and 10 subthemes were identified: (1) Appreciating sleep intervention for pregnancy insomnia; (2) Suggestions for intervention contents; (3) Recommendations on the format of WeChat articles. Participants appreciated the intervention's focus on pregnancy insomnia as it is often overlooked by healthcare providers despite its significant impact on their well-being. Participants also recognized its potential to address previously neglected insomnia challenges. Participants indicated a willingness to engage with the program, although they raised concerns about an excessive focus on sleep-related issues. Suggestions for content improvement included using clear and plain language, incorporating scientific explanations to reinforce credibility, combining generalized content with personalized insomnia solutions, and including information relevant to the perinatal period. Participants also emphasized the need for family involvement to support them in managing insomnia. Regarding the format of WeChat articles, participants highlighted form is secondary to content helpfulness, while many suggested using engaging titles and visuals. Additionally, some participants preferred short-form videos delivered via short video platforms over WeChat--delivered methods.

Conclusions: WeChat for delivering CBT-I for reducing insomnia symptoms was well received by the Chinese pregnant women and the identified main features may facilitate the design for future intervention studies.

Acknowledgments: The authors acknowledge all participants in this study for their dedication and time.

Exploring Subgroup Differences in Response to Digital Cognitive Behavioral Therapy for Insomnia in Preventing Major Depressive Disorder among At-Risk Youth

Introduction: Previous study has shown that digital (app-based) cognitive behavioral therapy for insomnia (dCBT-I) can reduce the future risk of developing major depressive disorder (MDD) by more than 40% in youth with insomnia disorder and subclinical depression, yet it remains unclear who will achieve the optimal outcomes. The current study aimed to identify different subgroups of at-risk youth who would respond differentially to the dCBT-I intervention.

Materials and methods: This was a secondary analysis of a randomized, parallel group-controlled trial in Chinese youth (aged 15-25 years) with insomnia disorder and subclinical depressive symptoms. A total of 708 participants were randomly assigned to 6-week dCBT-I or 6-week app-based health education (HE). Assessments were conducted at baseline, post-intervention, 6- and 12-month follow-ups. Baseline sleep- and mood related variables were used to determine different subgroups by latent class analysis (LCA).

Results: Three insomnia subgroups were identified through LCA: 1) moderate insomnia with mild depressive and anxiety symptoms (40.3%), 2) moderate insomnia with stronger dysfunctional sleep beliefs, moderate depressive symptoms and mild anxiety symptoms (43.2%), and 3) moderate insomnia with more intense suicidal ideation, moderate depressive symptoms and mild anxiety symptoms (16.5%). The risk of developing MDD over the 12-month follow-up was significantly reduced for youth receiving the dCBT-I in subgroups 2 (14.7% versus 26.6%; hazard ratio [HR] 0.57 [95% CI 0.34 to 0.96]; $P = 0.03$) and 3 (14.8% versus 30.4%; HR 0.44 [95% CI 0.20 to 0.99]; $P = 0.047$) compared with the controls. Higher remission rates of insomnia disorder were observed in youth who received intervention in subgroups 1 (dCBT-I versus HE, 57.0% versus 29.0%; RR 1.97 [95% CI 1.47 to 2.64]; $P < 0.001$) and 2 (52.6% versus 25.2%; RR 2.08 [95% CI 1.53 to 2.84]; $P < 0.001$) at post-intervention, with intervention benefits sustained in both subgroups for at least 6 months.

Conclusions: Youth with insomnia disorder and subclinical depression can be categorized into different subgroups based on their sleep and mental health profiles, which were associated with distinct response patterns to dCBT-I indicated for depression prevention. These findings highlight the importance of further phenotyping at-risk youth to promote the development of personalized prevention for youth depression.

Acknowledgments: This study was funded by the National Natural Science Foundation of China (no. 81761128036) and The Chinese University of Hong Kong Postdoctoral Fellowship.

Exploring the associations between data-driven insomnia disorder combined with mild anxiety or/and depressive symptoms and the efficacy of Cognitive-Behavioral Therapy for insomnia

D. Lyu¹, R. Qian¹, F. Ge¹, Y. Wang¹, H. Wang¹, Y. Zhao¹, H. Han¹, R. Liu¹, Y. Liu¹, Y. Chen¹, C. Ji¹, X. Luo¹, T. Zhang¹, Y. Leng², J. Zhang¹, Z. Xiao¹, C. Yuan¹

¹Shanghai Mental Health Center, Department of Sleep Disorders, Shanghai, China, ²University of California, San Francisco, Department of Psychiatry and Behavioral Sciences, San Francisco, United States

Introduction: The endophenotype of insomnia disorder is complex and the treatment is not targeted. The data-driven typing method might provide some bases for precise treatment. The present study was based on a post hoc analysis, aiming to explore the association between subtypes of insomnia disorder and the efficacy of cognitive-behavioral therapy for insomnia (CBT-I).

Materials and methods: The present study was conducted on data of 118 patients with chronic insomnia disorder combined mild anxiety or/and depressive symptoms, who had completed an 8-week randomized controlled trial of CBT-I vs CBT-I plus (CBT-I combined with modules targeting anxiety and depressive symptoms). The silhouette coefficient determined the optimal number of clusters, and a K-means clustering analysis was performed. T-tests were conducted to assess baseline differences at

eight weeks, and the changes in self-reported total sleep time (sTST), Pittsburgh Sleep Quality Index (PSQI), Hamilton Depression Rating Scale (HRSD-17), and Hamilton Anxiety Rating Scale (HAMA) scores in order to explore the impact of subtypes and treatment approaches (CBT-I and CBT-I plus) on insomnia and emotional symptoms.

Results: The analysis revealed no significant demographic differences between the two clusters. Subtype 2 was characterized by significantly poorer baseline sleep quality (PSQI: 16.59 vs 12.74, $t = -9.90$, $p < 0.01$), higher depressive (HRSD: 18.47 vs 13.21, $t = -8.37$, $p < 0.01$), and anxiety levels (HAMA: 17.47 vs 13.46, $t = -6.23$, $p < 0.01$), and shorter sTST (4.67 vs 6.09 h, $t = 8.31$, $p < 0.01$) compared to Subtype 1. Post-treatment analyses showed significant improvements in both subtypes, with Subtype 2 experiencing a larger increase in sleep duration (csTST: 0.58 vs 1.77 h, $t = -7.18$, $p < 0.01$) and more pronounced improvements in sleep quality (cPSQI: 6.92 vs 8.88, $t = -3.57$, $p < 0.001$), depression (cHRSD: 8.07 vs 10.59, $t = -2.71$, $p = 0.008$), and anxiety (cHAMA: 9.28 vs 11.22, $t = -2.56$, $p = 0.012$). Despite these improvements, Subtype 1 maintained significantly better outcomes in sleep quality (PSQI: 5.81 vs 7.71, $p < 0.01$), depression (HRSD: 5.14 vs 7.89, $p < 0.01$), and anxiety (HAMA: 4.18 vs 6.25, $p < 0.01$) at 8 weeks. No significant differences in baseline characteristics were found between treatment groups within subtypes, indicating homogeneity. Within Cluster 1, CBT-I plus was more effective in reducing depressive symptoms (cHRSD: $t = -2.48$, $p = 0.016$), whereas CBT-I was superior in enhancing sTST in Cluster 2 ($t = 2.01$, $p = 0.049$), with no significant differences in other measures.

Conclusions: The study underscores the heterogeneity within ID subtypes and the differential response of sleep quality and depressive symptoms to CBT-I and CBT-I plus, highlighting the importance of personalized treatment strategies based on insomnia subtypes.

Acknowledgments: This study was supported by Shanghai Mental Health Center (2021-YJ12, 2021-QH-05).

Gender Differences and the Role of Mood in Sleep Misperception: Evidence from Healthy Young Adults

T.-Y. Deng¹, Y.-C. Huang^{1,2}, Y.-J. Wang¹, H.-L. Lin¹, C.-M. Yang^{1,2}

¹National Cheng-Chi University, Department of Psychology, Taipei, Taiwan, ²The Research Center for Mind, Brain, and Learning, National Cheng-Chi University, Taipei, Taiwan

Introduction: The discrepancy between subjective and objective measurements of sleep is referred to as sleep misperception. Previous studies have shown that women tend to have objectively better sleep than men (e.g., longer total sleep time), yet report more sleep complaints. Meanwhile, research on sleep misperception among patients with depression has found that a higher percentage of females fell into the underestimation group compared to the overestimation group, and that individuals with higher depression scores were more likely to overestimate wake after sleep onset. Since depression and anxiety are more prevalent among women, we hypothesized that these symptoms might mediate gender differences in sleep misperception.

Materials and methods:

This study aimed to investigate whether there are gender differences in sleep misperception among healthy individuals without sleep complaints, and to examine the potential mediating roles of anxiety and depression. A total of 33 healthy sleepers (48% male; mean age = 24.0 years, range 20–37) without diagnosed mental or medical disorders participated in the study. Participants wore a wrist actigraphy for objective sleep measurement and kept sleep diaries for subjective measurement across seven consecutive days. Sleep variables collected included sleep onset latency (SOL), total sleep time (TST), wake after sleep onset (WASO), and sleep efficiency (SE). Depression and anxiety symptoms were assessed using the Beck Depression Inventory-II (BDI-II) and Beck Anxiety Inventory (BAI), respectively. The indices of sleep misperception used were: (1) subjective values minus objective values; (2) the discrepancy between subjective and objective values divided by the objective values; and (3) subjective values divided by objective values.

Results: ANCOVA analyses comparing sleep misperception between genders, controlling for age, showed no significant differences across any of these indices. Additionally, Pearson's correlations between depression and anxiety scores and sleep misperception indices were not significant. This lack

of association between gender, mood, and sleep misperception indicates that the originally hypothesized mediating model was not supported.

Conclusions:

Overall, our results did not demonstrate a gender effect on sleep misperception, nor did they support a mediating role for depression and anxiety symptoms in the relationship between gender and sleep misperception. These findings differ from previous studies that showed gender and mood-related influences on sleep misperception. One possible explanation is that our sample was relatively young and healthy compared to samples in earlier studies, and sleep misperception may develop after prolonged exposure to sleep or mood pathology, which was not present here. Additionally, our small sample size may have limited the findings. Future research with larger samples and/or longitudinal designs is warranted to further clarify the associations among gender, mood, and sleep misperception.

Gender Differences in the Impact of Pre-Sleep Hyperarousal on Insomnia and OSA Risk in Individuals with PTSD Symptoms

N. Mumenah^{1,2,3}, I. Hartescu¹, D.J Morris^{4,5}, J.B. Barker¹

¹Loughborough University, School of Sport, Exercise and Health Sciences, Loughborough, United Kingdom, ²Department of Respiratory Therapy, College of Applied Medical Sciences, King Saud bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia, ³King Abdullah International Medical Research Centre, Riyadh, Saudi Arabia, ⁴The Centre for Developmental and Complex Trauma, St. Andrews healthcare, Northampton, United Kingdom, ⁵University of Buckingham, Medicine and Life Sciences, Buckingham, United Kingdom

Introduction: Hyperarousal is a core feature of posttraumatic stress disorder (PTSD) and presents differently across genders. Women are more prone to internalised distress, such as anxiety and dysphoria, while men are more likely to externalise symptoms through anger and irritability. These differences may shape how PTSD contributes to sleep disorders. Somatic hyperarousal—marked by physical tension and heightened physiological responses—may be more common in men and increase the risk of obstructive sleep apnoea (OSA). In contrast, cognitive hyperarousal, characterised by mental overactivity and worry, may be more prevalent in women and contribute to insomnia. Understanding these gender-based patterns may support more targeted, gender-sensitive interventions.

Materials and methods: We analysed 270 UK adults from the general population with clinically significant PTSD symptoms (PCL-17; DSM-5 criteria) who completed validated questionnaires. Pre-sleep hyperarousal was assessed using the Pre-Sleep Arousal Scale (PSAS) and categorised into low and high cognitive and somatic hyperarousal groups. Insomnia severity was measured with the Insomnia Severity Index (ISI), with scores ≥ 15 indicating clinical insomnia. OSA risk was assessed using the STOP-BANG questionnaire and classified as low risk (<3) or intermediate/high risk (≥ 3). Gender-stratified logistic regressions examined whether cognitive and somatic hyperarousal predicted insomnia and OSA risk, restricted to participants meeting PTSD criteria.

Results: Among PTSD-symptomatic participants (N = 270; 21.5% males, 78.5% females), high somatic pre-sleep arousal was highly prevalent, with 97.0% (n = 262) classified as high and only 3.0% (n = 8) as low. A significantly higher proportion of females (98.6%) than males (91.4%) reported high somatic hyperarousal, while males were more likely to report low somatic hyperarousal (8.6% vs. 1.4%), ($\chi^2(1) = 8.224$, $P = 0.004$, $ES = 0.175$). Cognitive hyperarousal was more evenly distributed: 64.4% (n = 174) were classified as low and 35.6% (n = 96) as high, with no significant gender difference ($P = 0.847$). Among males, high somatic hyperarousal significantly predicted insomnia ($B = 1.613$, $P = 0.042$, $OR = 5.02$), while cognitive hyperarousal did not ($P = 0.776$). Among females, neither somatic ($P = 0.411$) nor cognitive hyperarousal ($P = 0.827$) predicted insomnia. For OSA risk, neither somatic nor cognitive hyperarousal significantly predicted risk among males, though high cognitive hyperarousal showed a non-significant trend ($OR = 1.48$, $P = 0.600$). Among females, high cognitive hyperarousal was inversely associated with OSA risk ($OR = 0.62$, $P = 0.118$), but not significantly; somatic hyperarousal was not predictive ($P = 0.919$).

Conclusions: Males with PTSD symptoms, high somatic hyperarousal is a significant predictor of clinical insomnia. No hyperarousal subtype significantly predicted OSA risk in either gender. These findings

support a gender-specific model of sleep disturbance in PTSD, suggesting that somatic arousal plays a key role in insomnia for males. Targeting somatic symptoms in behavioural treatments may enhance outcomes for PTSD-symptomatic males. Further research should validate these findings in larger, diverse populations and incorporate physiological sleep data.

Gender differences, psychological factors, and sleep parameters in paradoxical insomnia and non-paradoxical insomnia

M. Wang¹, F. Han¹, F. Xiao¹, W. Zhu¹, H. Wang¹, Z. Feng¹

¹Peking University People's Hospital, Division of Sleep Medicine, Beijing, China

Introduction: Paradoxical insomnia is characterized by a discrepancy between subjective sleep perception and objective sleep measurements. Despite growing research interest, the underlying mechanisms of paradoxical insomnia remain poorly understood. This study aimed to investigate gender differences and identify key clinical, self-reported, and objective sleep characteristics that distinguish paradoxical insomnia from non-paradoxical insomnia.

Materials and methods: A total of 862 participants were analyzed. Data on demographics, clinical characteristics, biochemical parameters, depression, anxiety and polysomnographic (PSG) were collected. Gender differences were assessed, and the relationship between self-reported and objective sleep measures was examined. Logistic regression analysis was conducted to identify factors associated with paradoxical insomnia.

Results: Paradoxical insomnia was present in 30.51% of the study population. Logistic regression identified older age (OR = 1.019, $p = 0.004$), gender (OR = 0.643, $p = 0.007$), lower Insomnia Severity Index (ISI) scores (OR = 0.947, $p = 0.032$), and heightened somatic symptoms from the Hamilton Depression Rating Scale (HAMD) (OR = 1.374, $p = 0.010$) as independent predictors of paradoxical insomnia. No significant differences in biochemical parameters were observed between groups. Gender analysis revealed that females with paradoxical insomnia were older and had higher ISI scores than males, while males had higher BMI in both non-paradoxical insomnia and paradoxical insomnia groups.

Conclusions: Paradoxical insomnia is prevalent among individuals with insomnia, with gender and psychological factors, such as somatic symptoms of depression, playing key roles. Further research is needed to explore the underlying mechanisms and inform targeted interventions.

Group-based and digital cognitive behavioural therapy for insomnia in adolescents with insomnia: Interim analysis of a three-arm, assessor-blinded, parallel randomised controlled trial

H.F. Sit¹, R.N.Y. Chan², J.W.Y. Chan², J. Zhang^{2,3,4}, L. Albert Martin⁵, Y.K. Wing², C.A. Espie⁶, S.X. Li^{1,7}

¹The University of Hong Kong, Sleep Research Clinic & Laboratory, Department of Psychology, Hong Kong, Hong Kong, SAR of China, ²The Chinese University of Hong Kong, Li Chiu Kong Family Sleep Assessment Unit, Department of Psychiatry, Faculty of Medicine, Hong Kong, Hong Kong, SAR of China, ³The Affiliated Brain Hospital of Guangzhou Medical University, Center for Sleep and Circadian Medicine, Guangzhou, China, ⁴Guangzhou Medical University, Key Laboratory of Neurogenetics and Channelopathies of Guangdong Province and the Ministry of Education of China, Guangzhou, China, ⁵The Chinese University of Hong Kong, Faculty of Medicine, Hong Kong, Hong Kong, SAR of China, ⁶University of Oxford, Nuffield Department of Clinical Neurosciences and Sleep and Circadian Neuroscience Institute, Oxford, United Kingdom, ⁷The University of Hong Kong, The State Key Laboratory of Brain and Cognitive Sciences, Hong Kong, Hong Kong, SAR of China

Introduction: Insomnia is common in adolescents. While cognitive behavioural therapy for insomnia (CBT-I) is a well-established interventional approach in adults, its effects on insomnia and associated symptoms in adolescents remain unclear. Additionally, leveraging technology to deliver interventions is an innovative approach to address the needs of the population. The present study examined the effects of group-based CBT-I (gCBT-I) and digitally delivered CBT-I (dCBT-I) on insomnia severity, mood

symptoms, and other sleep- and health-related outcomes in adolescents with insomnia, compared to a waitlist control.

Materials and methods: An assessor-blind, parallel, randomised controlled trial was conducted in adolescents aged 12-20 years diagnosed with DSM-5 insomnia disorder. Eligible participants were randomly allocated to one of the three conditions, namely gCBT-I (6 weekly sessions, n=53), dCBT-I delivered via mobile application (6 self-paced modules with modest weekly text-based support), or waitlist (WL, n=54). Assessments were completed at baseline and post-treatment for the three conditions, and additionally at 6-month after intervention for the two active treatment groups. The primary outcome included insomnia symptoms as measured by the Insomnia Severity Index (ISI). Secondary outcomes included sleep parameters measured by sleep diary and actigraphy, and the measures of mood symptoms and other sleep- and health-related outcomes. Linear mixed models were utilised to examine treatment effects following the intention-to-treat principle.

Results: A total of 159 participants (Age: 18.14 ± 1.77 years, Female: 66.06%) were recruited. Primary outcome analysis showed that, as compared to WL, gCBT-I led to significantly greater improvements in insomnia symptoms at post-treatment. Remission rates for insomnia (as defined by ISI score <9) were 54.8%, 34.7%, and 25.9% for gCBT-I, dCBT-I, and WL, respectively ($p < 0.05$). Self-rated treatment response rates (reduction in ISI ≥ 6) were 47.6%, 40.8%, and 22.2% for gCBT-I, dCBT-I, and WL, respectively. Clinician-rated treatment response rates (CGI-I ≤ 2) were 35.7%, 38.8%, and 11.1% for gCBT-I, dCBT-I, and WL, respectively. The improvement in insomnia symptoms in both gCBT-I and dCBT-I was maintained at 6-month after treatment. As compared to WL, gCBT-I also led to greater improvements at post-treatment in sleep quality, anxiety symptoms, sleep-related dysfunctional beliefs, sleep schedule and timing, arousal-related behaviours, and daytime sleepiness. Meanwhile, dCBT-I resulted in significantly greater improvements at post-treatment in sleep quality, sleep-related dysfunctional beliefs, and self-reported sleep onset latency.

Conclusions: Both gCBT-I and dCBT-I show promise in improving sleep in adolescents with insomnia, but group CBT-I may be superior in addressing insomnia-related factors and associated symptoms. Digitally delivered CBT-I presents a viable alternative that enhances the accessibility of effective strategies for managing adolescent insomnia.

Group delivered sleep restriction therapy for insomnia patients in primary care: Preliminary results from a randomized controlled trial

C. Bini^{1,2}, M. Jansson-Fröjmark^{3,4}, K. Årestedt^{5,6}, J. Bäckström^{7,8,9}, C. Sandlund^{1,2}

¹Karolinska Institutet, Department of Neurobiology, Care Sciences and Society, Huddinge, Sweden, ²Region Stockholm, Academic Primary Health Care Centre, Stockholm, Sweden, ³Karolinska Institutet, Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden, ⁴Region Stockholm, Stockholm Health Care Services, Stockholm, Sweden, ⁵Linnaeus University, Faculty of Health and Life Sciences, Växjö, Sweden, ⁶Region Kalmar, Department of Research, Kalmar, Sweden, ⁷Uppsala University, Department of Medical Sciences, Clinical Psychiatry, Uppsala, Sweden, ⁸Luleå University of Technology, Luleå, Sweden, Department of Health, Education and Technology, Luleå, Sweden, ⁹Marie Cederschiöld University, Department of Health Care Sciences, Stockholm, Sweden

Introduction: Cognitive-behavioral therapy for insomnia (CBT-I) is the recommended treatment, with sleep restriction therapy (SRT) as one of its most effective components. Despite guidelines, sleep medication remains the most common treatment, likely due to prescribing habits and a shortage of CBT-I providers. This randomized controlled trial aimed to evaluate the effectiveness of nurse-led group sleep restriction therapy (G-SRT) compared to standard care in primary care settings.

Materials and methods: Between 2021 and 2025, 104 patients were recruited for the study, with follow-up data collection ongoing until 2027. This abstract presents preliminary results for the primary outcome—Insomnia Severity Index (ISI)— at baseline, at 3-month follow-up, and at 6-months follow-up for the first 78 patients. Eligible patients were aged 18+ with DSM-5 diagnosed insomnia and were recruited by specially trained G-SRT nurses from six primary care centers in Stockholm, Sweden. Nurses received 1.5 days of training in insomnia assessment and G-SRT delivery. Recruitment took place during routine visits, and patients meeting inclusion criteria were invited to participate. After providing informed consent, participants were block-randomized (in groups of four) into one of two

arms. The G-SRT intervention included four group sessions: the first three weekly, and a fourth session four weeks later. The initial session covered sleep education, SRT introduction, and medication reduction planning. Subsequent sessions focused on group discussions, barrier identification, sleep window calculations, and forward planning. Control participants received standard care, consisting of a sleep hygiene brochure. Analyses were conducted using linear mixed models performed in a stepwise manner. The first step examined changes from baseline to 3-months follow-up, while the second step analyzed changes from 3-month to 6-month follow-up. The study is prospectively registered at Clinical Trials (NCT04975776).

Results: Preliminary analyses included 78 participants, 61 women (78%) and 17 men (22%), aged 20 to 90 years, with a mean age of 57.5 years. Relative to the control, G-SRT was significantly superior in reducing ISI scores from baseline to 3-month follow up ($F=4.27$, $p=.046$). The between-group effect size at 3-month follow up was large ($d=0.93$) in favor of SRT. From baseline to 3-month follow-up, ISI scores were reduced by 8.3 points in the G-SRT group and by 3.2 points in the control group. There was no significant group difference between 3-month to 6-month follow-up ($F=0.19$, $p=.892$). The between-group effect size at follow-up was small ($d=0.37$) in favor of SRT.

Conclusions: Patients presenting with sleep disturbances who were assessed by trained SRT nurses and subsequently treated with G-SRT for insomnia showed clinically significant improvements at post treatment. These findings are consistent with previous studies, although a sustained clinical effect at the 6-month follow-up could not be confirmed. However, these findings will require further analysis, including adjustments for covariates and withdrawal, once the complete dataset has been collected. Therefore, no definitive conclusions can be drawn at this stage.

Guided internet-based cognitive behavioral therapy for insomnia in people suffering from insomnia and psychological distress: results of a randomized controlled trial

Introduction: Insomnia and mental health disorders frequently co-occur. Up to 70% of individuals with mental disorders experience sleep complaints, which worsen psychiatric symptoms and undermine treatment outcomes. Insomnia is also a major risk factor mental disorders and can worsen existing symptoms, impede recovery, and increase the chance of relapse. Although cognitive behavioral therapy for insomnia (CBT-I) is the recommended first-line treatment, even when other disorders are present, it's still rarely available in routine care. To advance adoption of treatment of insomnia in care settings, this study addressed three key research gaps by (1) evaluating efficacy in individuals with insomnia co-occurring with symptoms of anxiety- trauma, and/or borderline personality disorder; 2) assessing transdiagnostic effects on both negative and positive mental health indicators; and (3) conducting a process evaluation to optimize the intervention and inform future implementation strategies.

Materials and methods: A total of 157 participants (72% female; mean age = 54.1 years, SD = 13.8) with co-occurring insomnia and psychological distress yet not currently in (or awaiting) mental health treatment, were randomized to receive either therapist-guided iCBT-I (i-Sleep: 5–8-week intervention) or a sleep diary control (control). The primary outcome was the Insomnia Severity Index (ISI); secondary outcomes included symptom severity across dimensions of anxiety- trauma, and/or borderline, sleep diary parameters, positive mental health (PMH), protective lifestyle behaviors (PLB) and wellbeing. Assessments occurred at baseline (week 0), post-treatment (week 8), and follow-up (8 months). Linear mixed-effects models evaluated time x iCBT-I interactions. A concurrent mixed-methods process

evaluation, guided by the RE-AIM framework, collected quantitative satisfaction ratings and qualitative feedback from i-Sleep participants and 15 i-Sleep therapists (mean experience 0.8 ± 1.1 years).

Results:

Compared to controls, the iCBT-I group showed significantly greater reductions in insomnia severity at post-test ($d = 0.97, p < 0.01$) and at 8-month follow-up ($d = 1.03, p < 0.01$). No significant between-group differences were observed in the dimensions of anxiety- trauma, and/or borderline personality disorder, at post-treatment or follow-up. Positive mental health indicators showed small effects in favor of the iCBT-I group compared to controls, with significant improvements in protective lifestyle behaviors at post-treatment ($d = 0.30, p < 0.01$), and in positive mental health at 8-month follow-up ($d = 0.38, p = 0.01$). Intervention satisfaction averaged 7.30 (SD = 1.40), with 88.40 % of participants indicating they would recommend i-Sleep. Satisfaction with therapist guidance averaged 7.90 (SD = 1.70), although preferences for guidance format and frequency varied.

Conclusions: Therapist guided iCBT-I (i-Sleep) effectively reduces insomnia symptoms up to six months in individuals with insomnia and co-occurring psychological distress. Universal implementation could offer significant benefits, while adaptable content and flexible guidance may better meet individual needs. Together these findings underscore the need for widespread integration of iCBT-I into routine mental healthcare.

Gut microbiota regulate insomnia-like behaviors via gut-brain metabolic axis

Z. Wang¹, Y. Han², L. Lu¹

¹Peking University Sixth Hospital, Beijing, China, ²National Institute on Drug Dependence and Beijing Key Laboratory of Drug Dependence, Beijing, China

Introduction: Sleep is a complex physiological process and is a critical determinant of physical and mental health. Over the past decade, significant progress has been made in understanding the neural mechanisms of sleep and awakening. However, the initiation and maintenance of the sleep-wake behavior is regulated not only by the central system but is also affected by signals from peripheral tissues. Growing evidence shows that the microbiota-gut-brain axis contributes to the regulation of sleep and may play a critical role in the etiology and pathogenesis of sleep. This study aims to investigate the role of gut microbiota in sleep-wake regulation and its gut microbe-brain axis mechanisms.

Materials and methods: The automatic sleep-wake recording system was used to record the electroencephalogram-electromyogram signal of specified pathogen free and germ free animals. Subsequently, metabolomics was used to screen gut microbiota metabolites that can participate in regulating sleep-wake behavior. Fiber photometry combined with EEG-EMG recording were used to record the calcium activity of orexin neurons to explore their activity during sleep-wake cycle after tributyrin administration. Electrophysiological patch clamp was used to explore electrophysiological properties of orexin neurons in the lateral hypothalamic area after tributyrin administration. We employed shotgun metagenomics and metabolomics to assess characteristics of gut microbiota metabolic changes in individuals with insomnia and healthy controls. Fecal microbiota transplantation technology was used to explore whether intestinal microbial disturbance can induce sleep disorders.

Results: The absence of gut microbiota can lead to alteration in sleep-wake architecture. After short-term sleep deprivation, the metabolites of hypothalamus and fecal contents of SPF and GF mice were screened. Further *in vivo* experiments showed that tributyrin, a precursor of butyric acid, could promote sleep in mice. Fiber optic recording combined with EEG-EMG monitoring showed that tributyrin promoted sleep by inhibiting orexin neuron activity in lateral hypothalamus. Compared with healthy controls, the α diversity of gut microbiota in insomnia patients decreased, and the abundance of butyrate-producing bacteria decreased significantly. The fecal microbiota transplantation experiment found that colonization of mice with gut microbiota from human donors with insomnia is sufficient to induce insomnia-like behaviors. The butyrate level in the serum of insomnia-like recipient mice was significantly reduced, accompanied by an increase in the activity of orexinergic neurons in the lateral hypothalamus. Finally, our results demonstrate that oral administration of butyrate delays onset of insomnia-like behaviors.

Conclusions: Here, we sought to define functional contributions by the gut-brain signaling molecule to sleep behaviors. We initially found changes in sleep-wake architecture and sleep homeostasis in GF mice. Subsequently, we identified butyrate as a metabolite derived from gut microbiota that promoted sleep by inhibiting orexin neuronal activity in the lateral hypothalamus. The gut microbiota of insomnia patients can lead to the occurrence of insomnia-like phenotypes, and butyrate supplementation can improve the insomnia-like phenotypes of insomnia-like recipient mice. The above results show that under normal circumstances, the body's gut microbiota metabolizes butyrate and participates in the regulation of sleep behavior. In the case of intestinal microbial disturbance, butyrate produced by gut microbiota metabolism is reduced, causing abnormal sleep-wake behavior.

How Attentional System Shapes Sleep Response to Stress: A Comparative Study of Individuals With and Without Insomnia Symptoms

F. Berra¹, F. Bolengo¹, F. Siclari², L. Ferini-Strambi^{3,1}, A. Galbiati^{1,3}

¹Vita-Salute San Raffaele University, Psychology, Milan, Italy, ²The Netherlands Institute for Neuroscience, Amsterdam, Netherlands, ³IRCCS San Raffaele Scientific Institute, Clinical Neurosciences, Neurology - Sleep Disorder Center, Milan, Italy

Introduction: A thorough understanding of the cognitive mechanisms involved in the development and maintenance of Insomnia Disorder (ID) is essential for shaping targeted and effective clinical interventions. According to Espie's Attention-Intention-Effort model, increased attention to sleep-related cues, together with excessive intention and effort to sleep, can disrupt the natural sleep process, fostering ID. Despite its theoretical importance, the role of attention in the development of ID remains unclear. Given that stress exposure is a well-established trigger for ID, the present study examines the role of attentional performance in shaping sleep response to stress in healthy individuals with and without ID symptoms.

Materials and methods: A total of 20 healthy participants (mean age: 26.25 ± 3.60 years; M/F: 7/13) were enrolled and divided into two groups based on the clinical cut-off of the Sleep Condition Indicator (SCI ≤ 16): 10 participants with ID symptoms, and 10 without. All participants completed a two-week Sleep Diary, which they were instructed to fill out within 10 minutes of awakening. The diary collected subjective reports of the previous night's sleep (i.e., sleep latency [SL], total sleep time [TST], number of awakenings [NAWK], etc.). After the first seven days of diary recording, participants' attentional performances were evaluated using the Attention Network Task (ANT), a widely recognized tool for assessing the three fundamental domains of attention: alerting, orienting, and executive control. Finally, in the late afternoon participants were exposed to a stress-inducing video, based on the Trauma Film Paradigm, previously validated to induce sleep-disturbances.

Results: Independent-sample t-tests indicated that SL ($p=.001$), NAWK ($p=.037$), restorative score ($p=.005$), wake after sleep onset ($p=0.003$), both calculated and estimated TST ($p=.021$; $p=.027$) and SE% ($p<.001$) were significantly worse in the ID symptom group at baseline. Additionally, paired-sample t-tests revealed a significant increase in SL ($p=.026$) and NAWK ($p=.029$), along with a significant decrease in both estimated and calculated TST ($p=.016$; $p=.016$) and SE% ($p=.004$) following stress exposure in both groups. No group differences emerged in attentional performance.

Generalized Linear Mixed Models showed that executive control performance significantly moderated the effects of group and time on SL ($\beta=.202$; $p=.021$), TST ($\beta=-.555$; $p=.033$), and NAWK ($\beta=.267$; $p=.042$), with poorer executive control (slower reaction time) associated with longer SL, higher NAWK, and shorter TST specifically in the ID symptom group. Additionally, attentional orienting performance significantly moderated SE% ($\beta=-0.174$; $p=.015$), with worse orienting scores predicting lower SE% across groups. Attentional orienting also significantly moderated the three-way interaction between group, time, and calculated TST ($\beta=-1.798$; $p=.024$), with reduced TST observed in individuals with poorer orienting performance, especially within the ID symptom group.

Conclusions: Our results highlight the complex interplay between cognitive functioning and sleep system reactivity to stress. Specifically, attentional systems, in particular executive control and orienting, appear to influence sleep responses following stress exposure, with distinct patterns observed in individuals with ID symptoms. The results suggest that cognitive factors may contribute to individual differences in sleep vulnerability, supporting the importance of incorporating attentional and cognitive assessments in the understanding and potential treatment of ID.

How Does Rumination Impact the Relation Between Insomnia and Depression Symptoms?

V. Floyd¹, H. Dickens¹, E. Leen-Feldner¹, I. Vargas²

¹University of Arkansas, Department of Psychological Science, Fayetteville, United States, ²University of Notre Dame, Department of Psychology, South Bend, United States

Introduction: Results from prior research have shown insomnia symptoms can be individual predictors for the development of depressive disorders. Studies cited by the National Institute of Health report that between 75%-90% of individuals with depression endorse insomnia symptoms. However, there is still much to explore about the mechanisms that drive this relationship. One common factor that insomnia and depression share is rumination. Rumination is often conceptualized as repetitive thinking of negative emotions or distress and their causes and effects. Despite this commonality, few studies have examined whether rumination moderates the association between insomnia and depression. Understanding the interaction between insomnia and rumination is essential for informing effective preventative and intervention measures. The aim of this study, therefore, was to quantify the impact of insomnia symptom severity and trait level rumination on depression symptom outcomes. Specifically, we assessed whether rumination moderated the effect of insomnia on depression.

Materials and methods: Data was collected through an online survey using the Qualtrics platform. Participants included 560 University of Arkansas undergraduate students ($M_{age}=19.1$, 68% Women, 80% White). Depression was measured using the depressive symptoms and anhedonic depression subscales of the Mood and Anxiety Questionnaire (MASQ-90). Rumination was measured using the Ruminative Response Scale (RRS-22) and insomnia symptom severity was measured using the Insomnia Severity Index (ISI). All analyses controlled for the effects of race and gender.

Results: Linear regression analyses revealed that rumination was positively associated with depression symptoms ($B = 0.51$, $t(544) = 22.56$, $p < .001$) as was insomnia symptoms ($B = 0.30$, $t(544) = 5.19$, $p < .001$). Analyses also showed a significant two-way interaction between rumination and insomnia symptoms ($B = 0.0092$, $t(544) = 2.69$, $p = 0.007$) suggesting that the association between insomnia and depression intensified with greater rumination tendencies. Analyses also showed that rumination ($B = 0.43$, $t(544) = 10.7$, $p < .001$) and insomnia symptoms ($B = 0.58$, $t(544) = 5.66$, $p < .001$) were positively associated with anhedonic depression symptoms. However, the interaction between insomnia and rumination on anhedonic depression was not significant ($B = -0.006$, $t(544) = -0.93$, $p = 0.35$). The results of this study did not show a significant effect of race or gender on depression outcomes.

Conclusions: These results indicate that rumination and insomnia act as individual predictors of depression. However, students who are experiencing sleep disturbances are more likely to endorse depressive symptoms if they have greater ruminative tendencies. The difference in interaction outcomes may suggest that rumination and insomnia work together to amplify global depressive symptoms whereas anhedonic depressive symptoms may be moderated by different psychological factors.

Identifying Major Life Stressors that Precipitate Incident Insomnia Disorder

M.B. Jennings¹, D.A. Kalmbach¹, H. Afaneh¹, P. Cheng¹, C.L. Drake¹

¹Henry Ford Health, Sleep Research Center, Detroit, United States

Introduction: Insomnia disorder is a chronic condition affecting approximately 12.4% of adults globally, marked by persistent difficulty falling and/or staying asleep that leads to significant daytime impairment. Major life stressors—such as the death of a loved one or the onset of chronic illness—are often associated with adverse health outcomes and may trigger the development of insomnia. However, less is known about how specific stressors, or their cumulative impact, influence the onset and prevalence of insomnia over time. This study examined a large cohort of healthy adults over the course of one year to investigate the prospective effect of major life events on insomnia incidence.

Materials and methods: 2,892 US adults with no history of insomnia or depression were assessed at baseline then again a year later. Life stressors were assessed using the Revised Social Readjustment Rating Scale (SRRS-R), which asks participants to indicate whether they experienced any of 52 distinct

major life events, categorized into four domains: Interpersonal, Work, Home, and Network stressors. Insomnia diagnoses at 1-year follow-up were based on DSM-5 criteria. Both insomnia diagnoses and major life stressors were dichotomized (Yes/No). Initial bivariate associations between insomnia and each stress exposure were examined using chi-square tests of independence. Stressors significantly associated with insomnia in bivariate analyses ($p < .05$) were then entered into a multivariate logistic regression model to evaluate their unique contributions to predicting insomnia diagnoses.

Results: Among 2,892 US adults, the one-year incidence rate for DSM-5 insomnia disorder was 9.1%. Bivariate analyses identified 20 of the 52 assessed life stressors were significantly associated with insomnia incidence. Each of the four broad categories of stressors was associated with an elevated relative risk (RR) of developing insomnia disorder compared to those not reporting the stressor: Interpersonal (RR=1.9–4.2; Insomnia incidence: 16.9–24.7%), Work (RR=1.6–2.7; Insomnia incidence: 13.6–24.2%), Home (RR=1.9–3.7; Insomnia incidence: 8.2–37.5%), and Network (RR=1.4–2.8; Insomnia incidence: 12.0–25.0%). In the multivariate logistic regression model, several specific stressors remained independently associated with increased risk for insomnia. The most robust predictors included: death of a spouse (Odds Ratio [OR]=4.4, $p=.013$), major injury or illness to self (OR=2.5, $p<.001$), separation or reconciliation with a partner (OR=2.5, $p=.001$), financial problems (OR=2.0, $p<.001$), and efforts to address personal addiction (OR=2.3, $p=.010$).

Conclusions: Major life stressors, particularly those involving interpersonal loss, personal health crises, and financial or relational instability, predicted 1-year incidence of DSM-5 insomnia disorder. These findings highlight the importance of assessing major life events in both research and clinical contexts, as certain stressors place individuals at markedly higher risk for developing insomnia. Targeted screening and early intervention strategies may help mitigate sleep disturbance in those facing major life stress.

Acknowledgments: This study was funded by the National Institute of Mental Health (R01MH082785, PI: Drake).

Impact of a stepwise pharmacologic intervention on moderate-to-severe chronic insomnia: a German observational study

T. Toncar¹, A. Schüssel¹, J. Boer¹, M. Glos¹, L. Rosenblum¹, I. Fietze^{1,2}

¹Charité - Universitätsmedizin Berlin, Interdisciplinary Center of Sleep Medicine, Berlin, Germany,

²Southwest Medical University Affiliated Zigong Hospital, Luzhou, China

Introduction: Chronic insomnia is a highly prevalent disorder that affects quality of life a lot. However, there are only a few data and guidelines concerning outcome on long-time pharmacologic treatment. Our study evaluated the effect of a stepwise therapy scheme on self-reported sleep quality and the severity of the disease.

Materials and methods: Patients with moderate-to-severe insomnia where cognitive behavioral therapy was ineffective were asked for participation in the study and received a stepwise pharmacologic intervention, starting with L-tryptophan, melatonin, or agomelatine (S1 medication). The medication was applied for four weeks. If this led to an improvement the patients continued with the treatment (S1 responders) and if not (S1 non-responders) psychotropic drugs (S2 medication), hypnotics (S3 medication), or combination therapies were given instead. Standardized questionnaires of severity of the disease (ISI) and on sleep quality (PSQI) were applied after 6 and 9 months of study participation.

Results: Out of $n=116$ patients included in the study, $n=104$ started with S1-medication (90%) and $n=55$ were S1 responders after 4 weeks of therapy. After 6 months $n=26$ patients (22%) were still using S1 medication and a reduction of ISI (19.7 to 14.6) and of PSQI (13.2 to 11.5) were observed in this group. After 9 months $n=16$ patients (14%) further continued with S1 medication and in this subgroup a reduction of ISI (19.6 to 13.4) as well as PSQI (13.4 to 11.1) was observed for this time period. In the group of S1 non-responders, $n=16$ patients were taking psychotropic substances and $n=28$ hypnotics after 6 months of therapy. By month 9, $n=17$ patients were on psychotropic drugs and $n=25$ on hypnotics. In all groups ISI as well as PSQI values were improved.

Conclusions: A stepwise therapeutic approach should be used for patients with moderate-to-severe insomnia. Even if only 14% remained on S1 substances after 9 months, the quality of sleep and the severity of insomnia improved significantly – independently of the initial severity of the disorder.

Impact of insomnia symptoms on the clinical outcomes among patients with major depressive disorder and eveningness – results from a randomized controlled trial

J.W.Y. Chan¹, S.P. Lam¹, N.Y. Chan¹, S.X. Li², Y.K. Wing¹

¹The Chinese University of Hong Kong, Department of Psychiatry, Hong Kong, Hong Kong, SAR of China, ²The University of Hong Kong, Department of Psychology, Hong Kong, Hong Kong, SAR of China

Introduction: Insomnia is prevalent in major depressive disorder (MDD) and is associated with poor outcomes, including non-remission, relapse, and suicide risk. Eveningness, a circadian preference for later timings of activity and sleep, is also linked to worse depressive symptoms and outcomes. Insomnia and eveningness often co-occur, yet little is understood about their combined impact on clinical outcomes. This study hypothesized that patients with concurrent insomnia and eveningness (CI) exhibit more severe clinical symptoms, greater sleep disturbances, and poorer responses to circadian-based treatments.

Materials and methods: This is a secondary analysis of a randomized controlled trial included 93 MDD patients with eveningness (defined by Morningness-Eveningness Questionnaire, MEQ score of <42) randomized to either 5-week bright light therapy (BLT) or dim red light placebo (DRL), both prescribed with gradual advancing timing over the 5 weeks. Sleep was prospectively assessed using sleep diary and actigraphy. Primary outcomes included depressive symptoms (17-item Hamilton Depression Scale, 17-HDS), and secondary measures included insomnia remission rates (Insomnia Severity Index, ISI ≤ 7), self-report depressive and anxiety symptoms (Hospital Anxiety Depression Scale, HADS), fatigue (Chadler Fatigue Scale, CFS), and quality of life (Short-Form 36 Health Survey, SF36), measured at the end of five-week treatment. Longitudinal changes of the sleep and clinical parameters were analysed by within-group one-way repeated measures ANOVA.

Results: Ninety-one participants were included in the analysis (mean age $\pm$ SD, 46.5 ± 11.8 years old, Female 80%). Concurrent insomnia was defined as ISI ≥ 15 at baseline and was present in 62 (68%) participants. Comparing participants with concurrent insomnia (CI) and those without insomnia (NI), there were no differences in age, gender, MEQ scores and the type of treatment received. The CI group had a higher 17-HDS, HADS, CFS, and a lower SF-36 score. Baseline sleep diary showed that both CI and NI groups fell asleep late ($01:47 \pm 01:43$ vs $02:22 \pm 01:40$, $p=0.13$) but the CI group had an earlier wake time ($09:07 \pm 02:11$ vs $10:40 \pm 02:09$, $p=0.003$), and a shorter sleep duration ($08:16 \pm 01:27$ vs $07:22 \pm 01:36$, $p=0.01$), compared to the NI group. Upon interventions, both groups showed advancement in rise time and improvement in sleep efficiency after treatment as reflected by sleep diary. Analysis on the actigraphy data showed a significant advance in sleep offset (post-treatment vs baseline: $09:47 \pm 01:48$ vs $10:09 \pm 01:59$, $p=0.035$) and shortened sleep duration in the CI group (post-treatment vs baseline: $06:35 \pm 00:55$ vs $06:59 \pm 01:27$, $p=0.01$) after treatment. Only 4% of CI group achieved insomnia remission by week 5, despite significant improvement of both MEQ and 17-HDS within each group.

Conclusions: Depressed patients with eveningness and concurrent insomnia represent a high-risk MDD subtype with more severe clinical symptoms. Upon intervention, they had earlier wake time but shortened sleep duration. Majority of these patients could not achieve remission of insomnia after 5 weeks of chronobiological treatment. Concurrent management of insomnia and eveningness is critical to improving outcomes.

Acknowledgments: This study is supported by the Health and Medical Research Fund, The Food and Health Bureau, The Government of Hong Kong Special Administrative Region (Ref 12131131).

Impaired alertness in those physicians with depressive condition and insomnia

H. Wada¹, M. Basner², M. Cordoza³, T. Tanigawa¹

¹Juntendo University, Tokyo, Japan, ²University of Pennsylvania, Perelman School of Medicine, Philadelphia, United States, ³Vanderbilt University School of Nursing, Nashville, United States

Introduction: We previously showed that response speed and lapses derived from psychomotor vigilance test (PVT) were associated with burnout and depression [1]. While insomnia is linked to both vigilance deficits and depressive symptoms, its role in modulating the relationship between PVT performance and depression remains unclear.

Materials and methods: This study was a part of the National Survey for The Work Style Reform of Long Working Physicians. Based on our prior study [1], we analyzed data from 1,221 physicians who completed the PVT. Depressive condition and insomnia were defined as their CES-D ≥ 20 and Athens Insomnia Scale (AIS) ≥ 6 , respectively. The participants were separated into 4 groups, those having both depressive condition and insomnia (DI group), exclusively depressive condition (D group, exclusively insomnia (I group) and neither of them (control, C group). PVT metrics of response speed, lapse and LRM were compared among the four groups, using Kruskal Wallis Test, followed by post-hoc Dunn Test. All the statistical analyses were conducted using STATA16 (Stata Corp LLC, College Station, TX). Statistical significance was defined as p value was <0.05 .

Results: Mean [SD] PVT Lapse was 3.8 [9.1] in DI group, 3.2 [7.1] in D group, 1.5 [3.3] in I group and 1.3 [2.3] in the control group, and those in DI and D group were significantly lower than that in control group (both $p < 0.01$). This suggest that alertness is impaired in those who suffered from both depressive condition and insomnia. It is observed in parallel that response speed and PVT-LRM in DI and D groups were significantly impaired compared to control group.

Conclusions: We previously found that depressive condition and reduced alertness were associated [1]. The present study further demonstrates that those who suffered from depressive condition and insomnia were more likely to show significant reduced alertness, as assessed by PVT. The present study will help us not only grasp underlying cause of health deteriorations among long-working physicians but also make an effective intervention.

Improved Sleep Quality and Reduction in Sleep Medication Use with Multimodal Non-Invasive Neuromodulation in Chronic Primary Insomnia: A Case Report

P. Prawirohario¹, A. Fakhri², V. Martalia², A. Gabrielle³, S. Alya⁴

¹University of Indonesia, Department of Neurology, DKI Jakarta, Indonesia, ²University of Indonesia, DKI Jakarta, Indonesia, ³University of Hang Tuah, Surabaya, Indonesia, ⁴Sebelas Maret University, Surakarta, Indonesia

Introduction:

Background: Chronic primary insomnia is a common and challenging condition, particularly among older adults. Pharmacological management, while frequently used, often leads to tolerance, dependence, and undesirable side effects. As a result, there is growing interest in non-pharmacological interventions, such as neuromodulation and brainwave entrainment, to address persistent insomnia symptoms and reduce reliance on hypnotic medications.

Materials and methods:

Case Illustration: A 68-year-old woman with chronic sleep-onset insomnia, previously managed with polypharmacy (clonazepam, quetiapine, mirtazapine, alprazolam, fluoxetine), experienced relapse with daytime sleepiness, anxiety, and cognitive impairment. Polysomnography showed abnormal architecture (0% REM, 1% N3, 98.9% N2) despite 88.4% sleep efficiency. She underwent daily non-invasive interventions: tDCS (0.5 mA, Fp1-Fp2), 2 Hz delta audio entrainment, and head/neck/shoulder acupressure. Within two weeks, she discontinued clonazepam and reported faster sleep onset, reduced anxiety, and improved alertness.

Results: Discussion: This case demonstrates how multimodal non-invasive neuromodulation may effectively treat chronic primary insomnia by simultaneously targeting its key pathophysiological components. Transcranial direct current stimulation (tDCS) applied to the prefrontal cortex likely modulated cortical hyperexcitability, rebalancing the dysfunctional sleep-wake regulation characteristic of insomnia. The delta wave audio specifically addressed age-related slow-wave sleep deficits by promoting neural synchronization to sleep-inducing delta frequencies (0.5-4 Hz). Concurrent acupressure therapy contributed by reducing muscle tension in the head and neck region, thereby decreasing somatic arousal that often perpetuates sleep difficulties. The combination produced

synergistic effects: tDCS normalized central nervous system hyperarousal, delta stimulation enhanced endogenous sleep rhythms, and acupuncture alleviated peripheral tension. Notably, this approach facilitated rapid benzodiazepine discontinuation while improving both subjective sleep quality and daytime functioning, suggesting particular utility for elderly patients with medication-resistant insomnia and abnormal sleep architecture. These findings support further investigation of combined neuromodulation strategies as potential alternatives to pharmacotherapy in chronic insomnia management.

Conclusions:

Conclusion: These findings highlight the potential of non-pharmacological approaches in managing refractory insomnia, particularly in elderly patients at risk for medication side effects. Further research is needed to confirm these benefits in larger and more diverse patient populations.

Insomnia as a result of severe traumatic brain injuries in young female patients

N. Syrmos¹

¹Aristotle University, Thessaloniki, Greece

Introduction: Aim of this study was to present cases of insomnia after traumatic brain injuries in young female patients(<40 years old)

Materials and methods: 10 cases are presented.10 young male patients. Range of age 18-40 years old.

Results: Some common symptoms were: Difficulty sleeping in 4 patients (40%),sleep fragmentation or interrupted and broken sleep pattern in 2 patients (20%) ,waking up during the wee hours of the night and unable to go back to sleep in 4 patients (40%).All of them received :Cognitive behavioral therapy (CBT),Natural sleep-inducing remedies, Pharmacotherapy and continue Neurological, Psychological and Psychiatric Support.Good results in 9 patients (90%) and moderate in 1 (10%).

Conclusions: Multidisciplinary approach is essential to achieve optimal results for our patients.

Insomnia as a result of severe traumatic head and neck injuries in young male patients

N. Syrmos¹

¹Aristotle University, Thessaloniki, Greece

Introduction: Aim of this study was to present cases of insomnia after severe traumatic head and neck injuries in young male patients(<30 years old).

Materials and methods: 10 cases are presented.10 young male patients. Range of age 18-30 years old.

Results: Some common symptoms were: Difficulty sleeping in 4 patients (40%),sleep fragmentation or interrupted and broken sleep pattern in 3 patients (30%) ,waking up during the wee hours of the night and unable to go back to sleep in 3 patients (30%).All of them received :Cognitive behavioral therapy (CBT),Natural sleep-inducing remedies, Pharmacotherapy and continue Neurological, Psychological and Psychiatric Support.

Conclusions: Good results in 8 patients (80%) and moderate in 2 (20%).Multidisciplinary approach is essential to achieve optimal results for our patients.

INSOMNIA AND ASSOCIATED FACTORS SIXTH-YEAR MEDICAL STUDENTS AT HO CHI MINH CITY UNIVERSITY OF MEDICINE AND PHARMACY

T. Nguyen¹, L. Tran²

¹university of medicine and pharmacy Ho Chi Minh city, Family medicine center, Ho chi Minh, Vietnam,

²university of medicine and pharmacy Ho Chi Minh city, Ho chi Minh, Vietnam

Introduction: Insomnia is a common sleep disorder that affects both physical and mental health, increasing the risk of dementia, hypertension, and diabetes. Approximately 10% of adults suffer from chronic insomnia, and 20% experience transient insomnia. This rate is higher among students,

particularly medical students, due to the pressures of studies, exams, and long hours of clinical practice. Sixth-year medical students face stress from graduation exams and internships, making them susceptible to sleep disorders. This study aims to assess the prevalence of insomnia and related factors among sixth-year students at the University of Medicine and Pharmacy, Ho Chi Minh City.

Materials and methods: Objectives:

To determine the prevalence of insomnia and to explore its associations with academic stress, sleep habits, and electronic device use among sixth-year medical students.

Methods:

This cross-sectional, descriptive-analytic study was conducted among 191 sixth-year medical students at the University of Medicine and Pharmacy at Ho Chi Minh City between January and May 2024. Data collected included demographic characteristics, academic performance (GPA), perceived academic pressure, and sleep-related behaviors. Insomnia severity was assessed using the Insomnia Severity Index (ISI).

Results: Approximately 90% of participants were 24 years old, with an age range from 23 to 27. The majority were male (62.9%), of Kinh ethnicity (90.1%), and reported no chronic illnesses (87.4%). Insomnia symptoms were reported by more than 60% of students, with 42.9% classified as mild, 15.7% moderate, and 4.2% severe.

Students who frequently experienced exam stress had a 1.27 times higher prevalence of insomnia (PR = 1.27; 95% CI: 1.12–1.45; $p < 0.001$). Those with frequent fears of academic failure had a 1.14 times higher prevalence (PR = 1.14; 95% CI: 1.04–1.26; $p = 0.007$), and those who felt peer pressure had a 1.18 times higher prevalence of insomnia (PR = 1.18; 95% CI: 1.07–1.31; $p = 0.001$).

Sleep behaviors also demonstrated significant associations. Students who used electronic devices before sleep had a 2.06 times higher prevalence of insomnia compared to those who did not (PR = 2.06; 95% CI: 0.99–4.30; $p = 0.010$). Moreover, each additional day of staying up past midnight increased the risk of insomnia by 9% (PR = 1.09; 95% CI: 1.03–1.15; $p = 0.001$), indicating a relationship between late-night sleep patterns and insomnia.

Conclusions: Insomnia is highly prevalent among senior medical students and is significantly associated with academic stress, late-night sleeping habits, and pre-sleep electronic device use. Interventions to reduce academic pressure and improve sleep hygiene are urgently needed to enhance students' sleep quality and overall well-being.

Insomnia and Cardiometabolic Risk: Uncovering a Silent Driver of Chronic Disease

J. Kim¹, A. Jain², A. Khullar³, N. Parast⁴

¹Vineyard Medical Clinic & University of Calgary, Calgary, Canada, ²TLC Diabetes and Endocrinology & University of British Columbia, Vancouver, Canada, ³University of Alberta, Psychiatry, Edmonton, Canada, ⁴University of Ottawa Heart Institute, Ottawa, Canada

Introduction: Insomnia, a prevalent sleep disorder marked by difficulty initiating or maintaining sleep, is increasingly recognized as a critical yet underappreciated contributor to chronic disease. Affecting nearly one-third of adults globally, insomnia has been linked to a cascade of physiological disruptions that elevate the risk for cardiometabolic conditions. These include type 2 diabetes, cardiovascular disease, chronic kidney disease, and metabolic dysfunction-associated steatotic liver disease (MASLD). Despite its high prevalence and modifiability, insomnia remains insufficiently addressed in preventive health strategies.

Materials and methods: Objective:

This narrative review synthesizes current evidence on the relationship between insomnia and cardiometabolic health, with a focus on type 2 diabetes. It aims to equip healthcare professionals with practical insights for identifying and managing insomnia as a strategy to mitigate chronic disease risk.

Methods:

A multidisciplinary team conducted a comprehensive review of recent literature exploring the biological mechanisms linking insomnia to cardiometabolic dysfunction. Key areas of investigation included autonomic nervous system activity, hormonal imbalances, and systemic inflammation.

Results: Insomnia is associated with heightened sympathetic nervous system activity, dysregulation of the hypothalamic-pituitary-adrenal axis, and increased inflammatory markers. These changes contribute to impaired glucose metabolism, insulin resistance, and elevated risk for type 2 diabetes.

Additionally, insomnia is linked to obesity, MASLD, and cardiovascular conditions such as hypertension, myocardial infarction, and heart failure.

Conclusions: Insomnia is a modifiable risk factor with profound implications for cardiometabolic health. Integrating sleep assessment and management into routine care could significantly reduce the burden of chronic diseases. Healthcare providers should prioritize early detection and evidence-based interventions for insomnia to improve long-term health outcomes.

Insomnia in Dementia Patients

J.H. Lee¹, S.-H. Hwang²

¹National Health Insurance Service Ilsan Hospital, Neurology, Goyang, Korea, Republic of, ²Hallym University College of Medicine, Neurology, Seoul, Korea, Republic of

Introduction: Many dementia patients complain insomnia and depressive mood, and hypnotics and antidepressants are being prescribed. As prevalence of dementia is increasing, insomnia and depressive mood are becoming more important.

Materials and methods: We reviewed medical records of the patients who visited outpatients clinic of NHIS Ilsan Hospital Dementia Center during 2024.

Results: Total 716 patients are included; Subjective Memory Impairment(SMI) : 143 patients(20%), non-amnesic Mild Cognitive Impairment(MCI): single domain 70 (10%), multiple domain 34 (5%), amnesic MCI: single domain 74 (10%), multiple domain 159 (22%), Early onset Alzheimer's disease (AD): 9 (1%), AD 121 (17%), Vascular dementia: 62 (9%), Mixed dementia 44 (6%).

Hypnotics and antidepressants are prescribed as follows; SMI : hypnotics 14 patients (10%), antidepressants 27 (19%), non-amnesic MCI: single domain hypnotics 9 (13%), antidepressants 12 (17%), multiple domain hypnotics 4 (12%), antidepressants 6 (18%), amnesic MCI: single domain hypnotics 10 (14%), antidepressants 16 (22%), multiple domain hypnotics 22 (14%), antidepressants 24 (15%), Early onset Alzheimer's disease (AD): hypnotics 1 (11%), antidepressants 2 (22%), AD: hypnotics 10 (8%), antidepressants 36 (30%), Vascular dementia: hypnotics 8 (13%), antidepressants 20 (32%), Mixed dementia: hypnotics 4 (9%), antidepressants 17 (39%)

Conclusions: Among the outpatients of Dementia Center, MCI and SMI are majorities and the number of MCI patients are almost half. Depression are more prevalent in AD and Vascular dementia than MCI and SMI, and about 22% of patients are being prescribed by antidepressants and 11% by hypnotics.

Insomnia in the Modern World: Challenges and Interventions

D. Nayak¹, K. Verma²

¹SMS Medical College and Hospital Jaipur, India, Jaipur, India, ²Sleep-Cognition and Psychology Experimental Laboratory, Indian Institute of Technology Indore, School of HSS, Indore, India

Introduction: Insomnia is one of the most prevalent sleep problems in modern society and has a large association with negative physical and mental health outcomes. Insomnia (inability to fall or remain asleep) is widely associated with daily deficits such as fatigue, irritability, and reduced cognitive performance. Increased stress, sedentary lifestyles, and excessive use of screens and digital devices are some of the factors contributing to the rise in this condition today. The worldwide shift to remote working has contributed to already disrupted sleep patterns, and now insomnia has become a major public health concern as more people find these boundaries between work and home life have disappeared.

Materials and methods: This point of view reviews the evidence behind a multidisciplinary treatment of insomnia and the integration of cognitive psychology, neuroscience, and new technology. The methodology involves:

1. **Literature Synthesis:** An extensive review of prior intervention studies, such as cognitive behavioural therapy for insomnia (CBT-I), pharmacological approaches, and lifestyle-focused interventions, to consider their gaps and merits.

2. **Technology Evaluations:** Evaluation of the available digital health technological advancements such as mobile applications, wearable sleep detectors, and neurostimulation techniques, etc., to determine their potential efficacy in insomnia management and access improvement.
3. **Development of the framework:** we propose a conceptual framework for the delivery of personalised and scalable insomnia treatment approaches that combine evidence-based interventions and innovative technologies.

Results: CBT-I is the gold standard treatment for insomnia with short- and long-term benefits that are robust, but its accessibility is limited due to the requirement for trained specialists. Rigorous pharmacological treatments give rapid relief but entail risks of dependency and side effects. Relaxation and meditation techniques are promising but rarely adopted consistently. Digital interventions, including CBT-I programs, wearables, or smart devices, can effectively mitigate treatment barriers by providing remote, personalised, and real-time solutions and by enhancing adherence to sleep hygiene. Novel treatments such as neurostimulation, biofeedback, and light therapy hold significant promise in targeting the pathophysiology of insomnia; however, further investigation is needed to evaluate their long-term efficacy and practical integration into routine care. This integrative perspective might support better data as well as scalable access to different treatment modalities in a sustainable way by developing an evidence-based framework that can easily support multidisciplinary cooperation in the provision of digital health solutions and will guide future research about insomnia management.

Conclusions: Given the increasing prevalence of insomnia and its public health implications, innovative approaches are needed to address this issue. Traditional therapies can present significant barriers to treatment, and these barriers can be overcome through the use of digital health solutions, which have greatly advanced in the form of wearable technology and neuroscience-based interventions. But applying those successful strategies will necessitate a collaborative solution that integrates cognitive psychology, technology, and health care.

Insomnia Severity Patterns Predict Overdose and Return to Drug Use in Individuals with Stimulant Use Disorder

T. Pareek¹, A. Hoadley¹, S. Hailu¹, J. West¹, A. Huhn¹

¹Johns Hopkins University, Department of Psychiatry and Behavioral Sciences, Baltimore, United States

Introduction: Insomnia is a common symptom reported among individuals with stimulant use disorders and has been associated with poor treatment outcomes. However, there is limited understanding of how insomnia symptoms might impact return to stimulant use and/or non-fatal overdose following treatment. Therefore, the goal of the present study was to characterize patterns of insomnia severity during treatment and to evaluate their relationship with post-treatment relapse and non-fatal overdose.

Materials and methods: Participants (n = 742) entering addiction treatment with primary cocaine, methamphetamine, or prescription stimulant use and ≥ 3 insomnia assessments were included. The Insomnia Severity Index (ISI) was administered weekly for the first four weeks of treatment and monthly following treatment. Repeated measures latent class analysis (RMLCA) was used to identify insomnia trajectories. Logistic regression models were used to assess the associations between insomnia class (e.g., Class 1) and return to drug or alcohol use as well as non-fatal overdose.

Results: Four insomnia trajectory classes (i.e., Classes 1-4) were identified. Here, Class 1-4 represented Low-Stable (36.5%), Moderate-Decreasing (32.6%), Initially Severe-Improving (24.0%) and Severe-Persistent (6.9%), respectively. Compared to Class 1, individuals in Class 3 had significantly greater odds of reporting a non-fatal overdose (OR = 5.45, 95% CI: 2.43–12.22, $p < .0001$), followed by Class 4 (OR = 3.49, 95% CI: 1.85–6.58, $p = .0001$). Additionally, odds of non-fatal overdose were significantly greater in Class 3 (OR = 2.43, 95% CI: 1.34–4.27, $p = .0035$) and Class 4 (OR = 3.80, 95% CI: 1.59–9.06, $p = .0008$) when compared to Class 2. Similarly, odds of return to drug use were significantly increased in Class 2 (OR = 2.08, 95% CI: 1.45–2.99, $p = .0001$), Class 3 (OR = 2.53, 95% CI: 1.69–3.81, $p < .0001$) and Class 4 (OR = 5.03, 95% CI: 2.28–11.10, $p = .0001$), relative to Class 1. Odds were also greater in Class 4 compared to Class 2 (OR = 2.42, 95% CI: 1.08–5.44, $p = .0313$).

Conclusions: These results indicate that patterns of insomnia severity during stimulant use disorder treatment were associated with both relapse and non-fatal overdose. Risk was highest among those with persistent or initially elevated insomnia symptoms, suggesting that these patterns may reflect underlying vulnerability. The current findings underscore the importance of sleep health during

addiction treatment and suggest that sleep medicine consultations are appropriate to improve both sleep and addiction-related outcomes.

Intensive Sleep Retraining and Total Sleep Deprivation for Treating Chronic Insomnia: A Randomised Controlled Trial

J. Le Bouthillier¹, H. Ivers¹, C. M. Morin¹

¹Université Laval, École de psychologie, Québec, Canada

Introduction: This study aimed to: (1) compare the efficacy of intensive sleep retraining (ISR) and total sleep deprivation (TSD) against a no-treatment control condition for treating chronic insomnia, (2) examine two potential mechanisms: the resolution of conditioned insomnia and the increase in homeostatic sleep drive produced by sleep deprivation, and (3) compare recovery sleep over a 2-week period after undergoing ISR and TSD.

Materials and methods: Thirty-four unmedicated adults with chronic sleep onset insomnia (with or without sleep maintenance difficulties) were randomized to ISR, TSD or a control condition. The ISR condition consisted of a 38.5-hour period of sleep deprivation, the last 21 hours of which included 42 sleep onset trials; the TSD condition consisted of an equivalent 38.5-hour sleep deprivation period without any sleep onset trials, and the control condition consisted of one night of habitual sleep in the laboratory. Participants completed several measures including the Insomnia Severity Index (ISI) and daily sleep diaries at pre-treatment, post-treatment, and at 1, 2, and 3 months after treatment.

Results: Significant decreases in insomnia severity were observed from pre-to post-treatment in both ISR and TSD, but not in the control condition. A significant reduction in sleep onset latency was observed during the same period for the ISR condition, but not for the TSD or control conditions, with no clinically meaningful change in anxiety or depressive symptoms. Significant decreases in fatigue were also observed for both ISR and TSD conditions during the same period. These results were generally significant at 3 months after treatment. Mixed model analyses on night-to-night data revealed significant increases in total sleep time from baseline to night 1 post-treatment recovery in ISR, TSD and control conditions. The magnitude of sleep duration increase was significantly higher in the treatment conditions (3 to 4 times higher) compared to the control condition. At night 2 post-treatment, total sleep time remained significantly improved for ISR, but not in the TSD or control conditions. Beginning at night 3 up to night 14 post-treatment, no notable changes were observed in any of the conditions.

Conclusions: Sleep improvements produced by ISR, and to a lesser extent by TSD, suggest that both the resolution of conditioned insomnia and the increase in homeostatic sleep drive represent important mechanisms responsible for the efficacy of ISR. Sleep recovery following ISR and TSD was characterized by significant sleep improvements on the first night post-treatment, followed by a rapid decline on the second night. The rebound effect was less pronounced for ISR than TSD condition, with similar reported sleep quality, suggesting that ISR may offer better therapeutic potential.

Acknowledgments: This research was supported by a grant from the Canadian Institutes of Health Research (#148410).

Interoception Abnormalities in Frontal Neural Circuits during N1 in Insomnia Disorder

Y. Tong¹, Y. Guo¹, Y. Zhou¹, P. Yao², Y. Shao¹, Y. Li³, G. Zou^{4,5}, L. Wang¹, S. Lou¹, S. Hu¹, Y. Dong⁶, J.-H. Gao^{4,5,7}, Q. Zou^{4,5}, H. Sun¹

¹Peking University, Institute of Mental Health, Beijing, China, ²Inner Mongolia Medical University, College of Basic Medicine, Hohhot, China, ³Capital Medical University, Department of Neuropsychiatry, Beijing, China, ⁴Peking University, Institute of Heavy Ion Physics, Beijing, China, ⁵Peking University, Academy for Advanced Interdisciplinary Studies, Beijing, China, ⁶National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore, ⁷Peking University, McGovern Institute for Brain Research, Beijing, China

Introduction: Insomnia Disorder (ID) is characterized by sensory hypersensitivity during wakefulness and sleep. Previous studies have shown that people with insomnia have an inappropriate adaptation of their brain responses to the ever-present heartbeat during the evening wakeful rest. Interoceptive

sensitivity can be assessed quantitatively by measuring the cerebral cortical response to one's own heartbeat (heartbeat-evoked potential, HEP). Here, we investigated whether interoceptive sensitivity, as indicated by the amplitude of one's own HEP, differs between people with ID and healthy controls (HC) during different stages of wakefulness and sleep.

Materials and methods: Thirty-nine patients with ID (meeting the diagnostic criteria of DSM-5) and sixty-two HC (meeting the criteria of normal sleepers) were recruited. HEP was obtained from 64-channel electroencephalogram (EEG), which recorded the brain electrical activities during wakefulness and sleep cycles. A registered polysomnographic technologist categorized the EEG data into wake, nonrapid eye movement sleep, and rapid eye movement (REM) sleep based on the American Academy of Sleep Medicine criteria. Significance of group differences in HEP amplitude and its topographical distribution over the scalp were assessed using cluster-based permutation tests.

Results: During wakefulness, patients with ID had a larger amplitude EEG component than HC at frontal electrodes 50-70 ms before the R-wave peak ($P_{FDR}=0.045$). During stage 1 of nonrapid eye movement sleep (N1), patients with ID had a larger amplitude late HEP component than HC at frontal electrodes 404-482 ms after the R-wave peak ($P_{FDR}=0.049$). During stage 2 of nonrapid eye movement sleep (N2), patients with ID had a larger amplitude EEG component than HC at frontal electrodes 54-64 ms before the R-wave peak ($P_{FDR}=0.048$), and patients with ID had a larger amplitude late HEP component than HC at frontal electrodes 406-424 ms after the R-wave peak ($P_{FDR}=0.048$). During stage 3 of nonrapid eye movement sleep (N3), patients with ID had a larger amplitude EEG component than HC at frontal electrodes 72-90 ms before the R-wave peak ($P_{FDR}=0.047$), patients with ID also had a larger amplitude HEP component than HC at frontal electrodes 12-18 ms after the R-wave peak ($P_{FDR}=0.047$). Source localization suggested increased neural activity time-locked to heartbeats in patients with ID mainly in inferior frontal cortices/medial frontal cortices ($P_{FDR}=0.010$) in the beta band during N1. It should be noted that no statistical analysis was performed due to the lack of data in the REM stage.

Conclusions: Significant differences in interoception were found between patients with ID and HC during wakefulness and each stage of nonrapid eye movement sleep. These findings suggest that abnormalities in the frontal neural circuits during N1 involved in interoception may play a crucial role in the pathophysiology of ID. Future research with more comprehensive data, especially in the REM stage, is warranted further to elucidate the full picture of interoception differences in ID.

Interpreting Adverse Events of Somnolence With Lemborexant in Clinical Trials

M. Moline¹, C.J. Reaume¹, D. Kumar¹, K. Pinner², J. Swainson³

¹Eisai Inc., Nutley, United States, ²Eisai, Ltd., Hatfield, United Kingdom, ³University of Alberta, Edmonton, AB, Canada

Introduction: Assessments of treatment-emergent adverse events (TEAEs) are routinely conducted in clinical trials and are frequently compared among drugs in the same class and between classes. In the case of hypnotics, the TEAE of somnolence (TEAE-S) is often a focus since residual sleepiness can lead to functional impairment. In assessing the potential impact of TEAE-S, however, parameters other than incidence should be considered. Other important parameters including severity and timing of TEAE-S relative to the initiation of treatment and impact on early morning/daytime function are important for informing clinical use. In addition, study design elements can impact TEAE-S rates. Analyses of TEAE-S from 2 large phase 3 studies of lemborexant (LEM), a dual orexin-receptor antagonist approved in many countries to treat adults with insomnia, provide data to support use in real-world settings.

Materials and methods: Study E2006-G000-304 (NCT02783729) and Study E2006-G000-303 (NCT02952820) evaluated efficacy and safety across 1 and 12 months, respectively, of LEM 5mg (LEM5), LEM 10mg (LEM10), and placebo (PBO) in adults with insomnia disorder. In addition to the incidence/severity of TEAE-S, a Kaplan-Meier analysis was conducted using pooled safety data from the 2 studies. To assess the potential for important morning residual sleepiness, a highway-driving study (Study E2006-E044-106; NCT02583451) was conducted in 48 healthy participants (age range: 23–78 years; 50% ≥65 years) following single and multiple doses of approved doses, LEM5 and LEM10, compared with PBO and active control, zopiclone (7.5mg).

Results: In the pooled dataset, TEAE-S was the most common TEAE, with a dose-related increase in incidence. The overall incidence of TEAE-S was low. LEM5 consistently showed approximately 5%–6% higher incidence than PBO, and LEM10 consistently showed 7%–8% higher incidence than PBO. The

majority of TEAE-S was mild in severity. Few participants discontinued from the phase 3 studies due to somnolence (PBO: 0.6%; LEM5: 1.1%; LEM10: 2.3%). Importantly, the onset of most TEAE-S was within the first few days of LEM administration. Kaplan-Meier analysis revealed that the probability of having a first incidence of TEAE-S was greatest during the first 2 weeks of treatment, with much lower probability later in the treatment period. In Study E2006-E044-106, there were no statistical differences in the standard deviation of lateral position between LEM5, LEM10, and PBO, supporting a lack of driving impairment.

Conclusions: While the incidence of somnolence was greater with LEM10 than with LEM5, it should be noted that the phase 3 studies were of fixed design, meaning that participants could not down-titrate if they were experiencing TEAEs. The probability of somnolence in this fixed-dose setting diminished after the first 2 weeks of administration. Further, patients are advised to initiate treatment with LEM5, suggesting that somnolence rates in clinical practice could be different than in the clinical trial for that dose group. Additionally, LEM10 was not associated with driving impairment, suggesting TEAE-S does not equate with impairment. Thus, there are many considerations in interpreting TEAE-S between and among hypnotic drug classes.

Acknowledgments: Medical writing assistance: Peloton Advantage, LLC, an OPEN Health company, and funded by Eisai Inc. and Eisai Co., Ltd.

Iron metabolism status in three types of sleep disorders (OSA, chronic insomnia, RLS without insomnia)

A. Kalinkin¹

¹Moscow State University, University Clinic, Sleep medicine centre, Moscow, Russian Federation

Introduction: The peculiarities of iron metabolism play a key role in the development of many diseases and are also associated with sleep disorders. Currently, the state of iron metabolism is considered mainly in the aspect of the pathogenesis and treatment of RLS, while with other sleep disorders, its meaning remains unclear.

Materials and methods: The study included 185 patients who were divided into three groups based on their clinical symptoms (OSA, chronic insomnia (Chrlns), RLS without insomnia (RLSwoi)). PSG study (Embla N7000) was performed in all patients. A biochemical blood test was also performed to assess the level of ferritin, serum iron, transferrin, UIBC, transferrin saturation and CRP. Pts with ferritin > 400 mcg/l and pts with CRP > 5,0 mg/l were excluded from the analysis. Finally, data from 134 patients were used for statistical analysis (female 72, male 62). Median age was 46 (Q1–Q3: 36.00–58.00), median BMI was 24.82 (Q1–Q3: 22.41–28.73). The comparison of three or more groups regarding quantitative variables with normal distribution was performed using one-way analysis of variance (ANOVA). Post-hoc comparisons were conducted using Tukey's test under the assumption of equal variances. Comparisons of three or more groups on a quantitative variable whose distribution differed from normal were made using the Kruskal-Wallis test and Dunn's test with Holm correction as a post-hoc method. Differences were considered statistically significant at $p < 0.05$. A key characteristic of our study design was that none of the groups had any coexisting sleep disorders.

Results: Ferritin levels were statistically significantly higher in OSA pts (Me 117.1 $\mu\text{g/L}$, Q1–Q3: 70.22 – 178.00) vs. Chrlns (Me 59.59 mcg/L, Q1–Q3: 38.73 – 94.30, $p < 0.001$) and RLSwoi (Me 54.00 mcg/L, Q1–Q3: 34.65 – 80.00, $p = 0.008$). There was no statistically significantly difference for ferritin between Chrlns and RLSwoi groups. Transferrin levels were statistically significantly higher in OSA pts (Me 2.76 g/L, Q1–Q3: 2.54 – 2.90) vs. Chrlns (Me 2.61 g/L, Q1–Q3: 2.29 – 2.80, $p = 0.009$) but not vs. RLSwoi (Me 2.35 g/L, Q1–Q3: 2.30 – 2.80, $p > 0.05$). When comparing of serum iron, UIBC, transferrin saturation depending on type of sleep disorders there were no statistically significant differences ($p = 0.328$, $p = 0.115$, $p = 0.151$ respectively). The main indices characterizing sleep breathing disorders have demonstrated the following results: AHI OSA (Me 22.80, Q1–Q3: 13.80 – 61.95), AHI Chrlns (Me 3.10, Q1–Q3: 0.83 – 7.40, $p_{\text{OSA-Chrlns}} < 0.001$), AHI RLSwoi (Me 3.80, Q1–Q3: 2.10 – 4.10, $p_{\text{OSA-RLSwoi}} < 0.001$); $\text{SpO}_{2 \leq 90\%}$, (%) OSA (Me 6.00, Q1–Q3: 0.25 – 27.50), $\text{SpO}_{2 \leq 90\%}$, (%) Chrlns (Me 0.00, Q1–Q3: 0.00 – 0.10, $p_{\text{OSA-Chrlns}} < 0.001$), $\text{SpO}_{2 \leq 90\%}$, (%) RLSwoi (Me 0.00, Q1–Q3: 0.00 – 0.00, $p_{\text{OSA-RLSwoi}} < 0.001$). There was no statistically significantly difference for age between the groups ($p = 0.734$), but there was statistically significantly difference for BMI with higher level for OSA group ($p < 0.001$).

Conclusions: Patients with chronic insomnia may require to be checked for iron deficiency. Not only RLS, but also chronic insomnia may be associated with iron deficiency. We assume the existence of iron deficiency chronic insomnia phenotype.

Is Sedentary Time Resistant to the Efficacy of Behavioral Sleep Interventions? A Secondary Analysis of a Randomized Controlled Trial

L. Fang¹, S. Zheng¹, S. Du², Y. Zhao², S. Li², B. Zhang²

¹Leqin Fang, Department Of Psychiatry, Sleep Medicine Center, Nanfang Hospital, Guangzhou, China,

²Bin Zhang, Department of psychiatry, Sleep Medicine Center, Guangzhou, China

Introduction: Behavioral sleep interventions (BSIs), including digital cognitive behavioral therapy for insomnia (dCBTI) and digital sleep hygiene education (dSHE), are proved to be effective for insomnia. However, it remains unclear the relationship between sedentary time (ST) and efficacy of BSIs.

Materials and methods: This secondary analysis included 178 adults diagnosed with acute insomnia, randomly assigned to 4 weeks of dCBTI or dSHE. Follow-up assessments at 1 to 3, and 3 to 6 months captured ISI>7, ESS>10, TST≤6h, and SE<80% events via questionnaire and accelerometer. Kaplan-Meier estimates, and Cox regression models and restricted cubic spline analyses (RCS) were employed to evaluate the association of ST and adverse sleep outcome. To address immortal time bias, landmark analysis was performed. Interactions between ST and adverse sleep outcome were investigated in subgroup analyses.

Results: Because both the dCBTI and dSHE groups illustrated comparable improvements for insomnia at follow up, with no significant group-by-time interaction, we pooled them as BSIs for joint analysis. In unadjusted Cox models, high ST was associated with an increased risk of TST≤6 h (HR 1.59; 95% CI 1.01–2.50), but not with ISI>7, ESS>10, or SE<80%. In fully adjusted landmark analyses, high ST predicted higher risk of ISI>7 events within 3 months post-BSIs (HR 2.46; 95% CI 1.37–4.43) and higher risk of TST≤6 h beyond 3 months post-BSIs (HR 2.76; 95% CI 1.30–5.90). The RCS regression analyses demonstrated a positive nonlinear association between ST and the incidence of TST≤6 h in the insomnia population (P for overall < 0.01, P for nonlinear <0.01), with a potential threshold of 701 min/day. Furthermore, subgroup analysis indicated that there was a significant interaction between the subgroups of age<35 years and the high ST, which caused a higher risk event ratios of TST≤6 h (HR, 2.93; 95% CI, 1.44 to 5.97; P for interaction<0.05).

Conclusions: ST significantly impedes early subjective sleep improvements after BSIs, while it specifically increase the risk of shorter sleep duration in the long term. Incorporating interventions to reduce daytime sitting into BSIs may enhance the efficacy of insomnia treatment.

Acknowledgments: The authors declare that they do not have any conflicts of interest related to this manuscript.

“It’s just normal” experiences of insomnia symptoms among Chinese pregnant women: a qualitative study

X. Shang^{1,2}, T.T. Luk^{1,3}, A.Y.K. Lai⁴, M.P. Wang¹

¹ The University of Hong Kong, School of Nursing, LKS Faculty of Medicine, Hong Kong, Hong Kong, SAR of China, ²Yangzhou University, School of Nursing School of Public Health, Yangzhou, China,

³National University of Singapore, Alice Lee Centre for Nursing Studies, Yong Loo Lin School of Medicine, Singapore, Singapore, ⁴Hong Kong Metropolitan University, School of Nursing and Health Studies, Hong Kong, Hong Kong, SAR of China

Introduction: Insomnia is prevalent among pregnant women and associated with various adverse health outcomes, such as gestational hypertension, perinatal depression, increased suicidal risk, miscarriage, preterm birth, and low infant birth weight. Existing studies have focused on using the quantitative method to investigate the factors associated with insomnia in pregnant women, but they did not capture the experiences of pregnant women with insomnia, which hinders the development of tailored interventions from the perspective of these women. This study explored the experiences of insomnia symptoms among Chinese pregnant women, including their perceptions, the impacts of insomnia on their daily lives, and coping strategies.

Materials and methods: Data were collected through individual interviews and focus groups with 29 pregnant women experiencing insomnia symptoms across all trimesters, from two tertiary hospitals in Yangzhou, China. The interviews were conducted online using a video conferencing platform and analyzed using content analysis.

Results: Four themes were identified from the data: manifestations of insomnia, perceived impacts of insomnia, coping strategies, and perceptions of insomnia in pregnancy. The manifestations of insomnia had impaired daily functioning, somatic complaints and noticeable changes in appearance, and psychological distress. Coping strategies included sleep habit adjustments, multifaceted social support, and alleviating pregnancy discomforts. Informants expressed a normalization of insomnia as a common experience during pregnancy, a belief in self-regulation, and skepticism regarding the effectiveness of medical consultations.

Conclusions: This study provides insights into the multifaceted nature of insomnia experiences among Chinese pregnant women, emphasizing the need for tailored, evidence-based interventions that address misconceptions about insomnia and promote effective coping strategies for managing insomnia symptoms during pregnancy.

Acknowledgments: The authors acknowledge all participants in this study for their dedication and time.

Locus Coeruleus-Cingulate Cortex Hyperconnectivity during N2 Sleep: A Functional Pathway to Depression in Insomnia Disorder

P. Lu¹, Y. Guo¹, Y. Shao¹, J. Chen¹, X. Gao¹, Y. Zhou¹, Y. Zhang¹, Y. Tong¹, G. Zou^{2,3}, Y. Li⁴, P. Yao⁵, Y. Dong⁶, J. Gao^{2,3,7}, Q. Zou^{2,3}, H. Sun¹

Introduction: Insomnia disorder (ID) frequently coexists with substantial psychiatric comorbidity, particularly anxiety and depression. The locus coeruleus (LC), a pontine nucleus within the ascending reticular activating system, plays a crucial role in sleep-wake regulation and emotional processing. However, the neurobiological mechanisms underlying the association between ID and emotional dysregulation remain incompletely understood. This study investigated LC-based whole-brain functional connectivity patterns across different sleep stages and their associations with subjective sleep quality and emotional symptoms in patients with ID.

Materials and methods: Simultaneous electroencephalography and functional magnetic resonance imaging (EEG-fMRI) data were acquired from 37 patients with ID and 30 well-matched healthy controls (HC) during their nocturnal sleep. Using a probabilistic template, the LC region was defined as the seed for whole-brain connectivity analyses. Group-by-stage interactions in LC-based functional connectivity were assessed using a linear mixed-effects model. Associations between functional connectivity patterns and Pittsburgh Sleep Quality Index (PSQI), Self-Rating Depression Scale (SDS), and Self-Rating Anxiety Scale (SAS) were evaluated using Spearman's rank correlations.

Results: Significant group-by-stage interactions were observed in multiple brain regions, including the cingulate cortex, right insular cortex, left temporal cortex and left insular cortex. Post-hoc analyses revealed that patients with ID exhibited significantly enhanced LC-cingulate cortex functional connectivity during N2 sleep compared to healthy controls ($p = 0.024$, Bonferroni-corrected). Within the total sample, N2-specific LC-cingulate cortex connectivity strength demonstrated significant positive correlations with both SDS scores ($r = 0.337$, $p = 0.018$, Bonferroni-corrected) and PSQI scores ($r = 0.401$, $p = 0.003$, Bonferroni-corrected).

Conclusions: The observed alterations in LC-cingulate cortex functional connectivity during N2 sleep suggest a distinct neural circuit that may underlie the dysregulation of emotional processing in ID,

providing a potential neurobiological substrate for the well-documented association between sleep disruption and emotional symptoms.

Longitudinal associations between couple relationship quality and insomnia symptoms among Chinese couples: A cross-lagged panel design

X.X. Wang¹, J.J. Liu¹

¹Peking University, School of Nursing, Beijing, China

Introduction: Insomnia is a highly prevalent sleep disorder linked to elevated risks of various physical and mental health conditions. Recent evidence from our team suggests that couple relationship quality plays a critical role in sleep health. Although substantial research supports the association between couple relationship quality and sleep quality, few studies have focused specifically on insomnia. To date, only three cross-sectional studies have indicated that higher couple relationship quality is associated with less severe insomnia symptoms. However, the longitudinal directionality of this association remains unclear. This study aimed to investigate the bidirectional relationship between couple relationship quality and insomnia over time among Chinese couples.

Materials and methods: A total of 247 Chinese adults (median age = 30 years [IQR = 7]; 72.1% women) in committed relationships were recruited via social media to participate in a two-wave longitudinal survey conducted over six months. Relationship quality was measured using the Locke-Wallace Marital Adjustment Test, and insomnia severity was assessed with the Insomnia Severity Index. Cross-lagged panel models were used to examine the temporal associations between overall relationship quality (and specific relational dimensions) and insomnia severity. Multiple regression analyses were performed to assess whether changes in relationship quality predicted changes in insomnia severity.

Results: Higher overall relationship quality at baseline significantly predicted lower insomnia severity at 6-month follow-up ($\beta = -0.141$, 95% CI = -0.231 to -0.052 , $p = 0.010$), with the effect being significant among females ($\beta = -0.139$, 95% CI = -0.244 to -0.035 , $p = 0.028$) but not males. Among specific relational dimensions, greater contentment and communication ($\beta = -0.132$, 95% CI = -0.208 to -0.055 , $p = 0.005$), as well as shared philosophy ($\beta = -0.167$, 95% CI = -0.253 to -0.082 , $p = 0.001$), at baseline predicted lower insomnia severity at follow-up. Baseline insomnia severity did not significantly predict subsequent changes in either overall couple relationship quality or its specific dimensions. Regression analyses further indicated that improvements in overall relationship quality ($\beta = -0.181$, SE = 0.013, $p = 0.004$), as well as in contentment and communication ($\beta = -0.177$, SE = 0.017, $p = 0.007$), significantly predicted alleviation of insomnia, independent of depression, anxiety, and age.

Conclusions: Couple relationship quality appears to be a significant longitudinal predictor of insomnia severity. Interventions that enhance overall relationship quality—particularly contentment and communication, and shared philosophy—may help mitigate future insomnia risk. These findings underscore the importance of integrating relational factors into the assessment and treatment of insomnia.

Long-term real-life experience with daridorexant in patients with chronic insomnia

Y. Winter¹, D. Apel², J. Kuhn³

¹Saarland University Medical Center, Department of Neurology, Homburg, Germany, ²Johannes Gutenberg-University, Department of Neurology, Mainz, Germany, ³University Hospital Cologne/ Germany and Alexianer Hospital Cologne, Department of Psychiatry and Psychotherapy, Cologne, Germany

Introduction: Daridorexant is the new dual orexin-receptor antagonist approved in Europe, USA and Canada for the treatment of chronic insomnia. Its clinical efficacy and safety was showed in randomized controlled studies. However, the long-term real-world data including health-related quality of life is still not available. We performed an prospective observational study to investigate one-year outcome of daridorexant treatment and its influence on the health-related quality of life (HrQoL) in patients with chronic insomnia.

Materials and methods: Patients with chronic insomnia diagnosed according to DSM V criteria were participants of this study. The clinical and HrQoL evaluation was performed prior to begin the therapy

with daridorexant (baseline) in the standard dosis of 50qd and after 3, 6 and 12 months. The following sleep parameters were measured: wake after sleep onset (WASO), latency to persistent sleep (LPS), total sleep time (TST) and subjective total sleep time (sTST). HrQoL was assessed using EuroQoL5D (EQ5D Index and EQVAS: visual analogue scale).

Results: 102 patients aged 52.8 ± 9.4 years (56.9% females) participated in our study. The baseline values of sleep parameters showed a continuous and constant improvement during the study period: WASO at baseline 93.8 ± 10.3 min vs 62.1 ± 9.9 min after 12 months ($p < 0.01$), LPS at baseline 62.8 ± 9.3 min vs 33.5 ± 8.7 min after 12 months ($p < 0.01$), TST at baseline 321.0 ± 20.5 min vs 403.6 ± 21.4 min after 12 months ($p < 0.01$), sTST at baseline 310.1 ± 23.7 min vs 388.2 ± 24.0 min after 12 months ($p < 0.01$). The EQ5D Index and EQVAS were reduced by approximately 23% in comparison to general German population. The baseline EQ5D Index value (0.60 ± 0.13) improved by 22% (0.73 ± 0.17) after 12 months of daridorexant treatment baseline (0.61 ± 0.8). Similar increase of HrQoL was observed on EQVAS (61.3 ± 12.6 at baseline versus 74.5 ± 17.4 , $p < 0.01$).

Conclusions: We provide the real-world data showing sustained improvement of sleep parameters and HrQoL in patients treated with daridorexant for chronic insomnia.

Long-Term Risk of Dementia in middle-age and older adults with Sleep Disorders: Evidence from 20 Years of Nationwide Taiwanese Data

C.-C. Hsieh^{1,2}, Y.-C. Chen^{2,3}

¹Zouying Armed Forces General Hospital, Surgery, Kaohsiung, Taiwan, ²National Sun Yat-sen University, Institute of Medical Science and Technology, Kaohsiung, Taiwan, ³National Sun Yat-sen University, School of Medicine, College of Medicine, Kaohsiung, Taiwan

Introduction: A growing body of research has identified an association between various sleep disorders and increased dementia risk; however, the extent to which specific types of sleep disorders differentially contribute to dementia onset remains unclear. This research aimed to utilize comprehensive population-representative data to understand the risk of dementia in patients with sleep disturbances, and to compare the effects and risk factors of different types of sleep disorders on the risk of dementia.

Materials and methods: A retrospective study contained adults ≥ 40 years of age who enrolled in National Health Insurance Research Database (NHIRD) from 2000 to 2020. The subjects are: 1) patients with sleep disorders encompassed insomnia, sleep-related breathing disorders (SBDs), and restless leg syndrome (RLS) as their primary or secondary diagnosis according to the International Classification of Diseases; 2) aged 40 years or older; 3) with at least ten years of observable data in the health database. The incidence rate of all-cause dementia, Alzheimer's disease (AD), vascular dementia (VD) per 1,000 person-years will be observed. Cox proportional hazards model will focus on risk factors associated with dementia.

Results: Among the 236,837 participants, the majority were classified as having insomnia ($n = 233,529$), followed by those with sleep-related breathing disorders (SBDs; $n = 2,367$) and restless legs syndrome (RLS; $n = 1,209$). The overall incidence of all-cause dementia among subjects with sleep disorders was 7.83 per 1,000 person-years (PYs), with incidences of AD and VD reported at 1.31 and 1.11, respectively. Kaplan–Meier survival analysis revealed significantly lower dementia-free survival among participants with RLS (log-rank $p < .0001$). Participants with RLS exhibited the highest incidence of dementia (15.55/1,000 PYs) and demonstrated significantly elevated risks of all-cause dementia (adjusted hazard ratio [aHR], 1.96; 95% confidence interval [CI], 1.73–2.21), AD (aHR, 4.73; 95% CI, 4.57–4.90), and VD (aHR, 4.73; 95% CI, 4.57–4.90) compared to those with insomnia. Additional risk factors included advanced age, female sex, depression, alcohol abuse, and a high comorbidity burden.

Conclusions: RLS confers the highest risk of all-cause and subtype-specific dementia compared with insomnia and SBDs. Advanced age, female sex, depression, alcohol abuse, and a high comorbidity burden further compound this risk, underscoring the need for targeted screening and management strategies in these vulnerable populations.

Acknowledgments: sleep disorders, insomnia, sleep-related breathing disorder (SBDs), restless leg syndrome (RLS), Alzheimer's disease (AD), vascular dementia (VD), National Health Insurance Research Database (NHIRD)

Managing Insomnia in an Adult Female with ADHD and Sedative Abuse: A Case Report on the Combined Use of Lemborexant, Agomelatine, and Methylphenidate

H. Christian¹, D.A. Purnama²

¹Atma Jaya Catholic University of Indonesia, Psychiatry, Jakarta, Indonesia, ²Krida Wacana Christian University, Psychiatry, Jakarta, Indonesia

Introduction: Insomnia is a frequent and impairing comorbidity in adults with Attention-Deficit/Hyperactivity Disorder (ADHD), often exacerbated by the core symptoms of hyperarousal, emotional dysregulation, and stimulant treatment. The situation becomes more challenging when insomnia coexists with past sedative misuse, such as benzodiazepine abuse, which limits therapeutic options.

Pharmacological management of insomnia in such patients must balance the need for ADHD symptom control with strategies that restore circadian stability and improve sleep quality—without inducing dependence or next-day sedation.

Materials and methods: A 38-year-old woman, an art performer and mother of two, presented with persistent insomnia and difficulty falling and staying asleep. She had a longstanding diagnosis of adult ADHD and a history of alprazolam abuse. There was also past cannabis use, although not active at the time of consultation.

The patient had previously tried lemborexant 5 mg (an orexin receptor antagonist) with minimal benefit. After structured discontinuation of alprazolam, a combined regimen was initiated: lemborexant was titrated to 10 mg, agomelatine 25 mg was added for circadian regulation, and methylphenidate was reintroduced for ADHD symptom control. Sleep hygiene education and routine stabilization were also implemented.

Results: After two month of therapy, the patient experienced substantial improvement in sleep quality under the combination therapy. The Pittsburgh Sleep Quality Index (PSQI) score improved significantly, with subjective reports of easier sleep initiation, fewer nocturnal awakenings, and more restorative sleep.

Importantly, ADHD symptoms—such as mental restlessness, distractibility, and emotional lability—were better controlled with methylphenidate, leading to improved daytime functioning. This, in turn, reduced bedtime hyperarousal and mental rumination, indirectly supporting improved sleep onset. The synergistic effects of agomelatine and lemborexant appeared to counterbalance stimulant-induced arousal without inducing sedative side effects or tolerance.

This case illustrates that effective treatment of insomnia in adult ADHD patients with a history of substance misuse may require a strategic pharmacologic combination. Rather than avoiding stimulants, judicious use alongside sleep-promoting agents may yield superior outcomes when carefully titrated and monitored.

Conclusions: Managing insomnia in adults with ADHD and prior sedative abuse is clinically challenging. However, this case demonstrates that a thoughtfully designed regimen—combining lemborexant, agomelatine, and methylphenidate—can lead to meaningful improvement in both sleep and daytime functioning. The key lies in targeting complementary neurobiological mechanisms: orexin inhibition for arousal, melatonergic support for circadian rhythm, and dopaminergic enhancement for executive dysfunction.

This case supports the idea that stimulant use could be considered in patient with insomnia and have ADHD comorbidity. Further exploration of such integrative approaches is warranted.

Mechanistic Insights into Cognitive Behavioral Therapy for Adolescents with Comorbid Insomnia and Anxiety: Mediation Analysis in a Randomized Controlled Trial

X. Li¹, N.Y.R. Chan², J.W.Y. Chan², J. Zhang^{3,4}, C.K.-s. Shea², A.M. Li⁵, R. Manber⁶, A.M. Gregory⁷, Y.K. Wing^{2,8}, S.X. Li⁹

Faculty of Medicine, The Chinese University of Hong Kong, Hong Kong, China, ⁶Department of Psychiatry and Behavioral Sciences, Stanford University, Stanford, United States, ⁷Department of Psychology, Royal Holloway University of London, London, United Kingdom, ⁸Li Ka Shing Institute of Health Sciences, Faculty of Medicine, The Chinese University of Hong Kong, Shatin, Hong Kong, China, ⁹The University of Hong Kong, Hong Kong, China

Introduction: Insomnia and anxiety are highly prevalent and frequently co-occurring in adolescents. Their comorbidity can exacerbate each condition and lead to significant psychosocial and functional impairments. Cognitive behavioral therapy for insomnia (CBT-I) and cognitive behavioral therapy for anxiety (CBT-A) have demonstrated efficacy in reducing insomnia and anxiety symptoms, respectively. However, the mechanisms underlying their effects on comorbid anxiety symptoms and insomnia disorder remain unclear. This study aimed to explore whether improvement in insomnia / anxiety would mediate anxiety / insomnia reduction.

Materials and methods: This was a secondary analysis of a three-arm randomized controlled trial conducted in adolescents with comorbid insomnia and anxiety. Participants were aged 12-20 years had DSM-5 insomnia disorder with a score of ≥ 9 on the Insomnia Severity Index (ISI) and presented with increased anxiety symptoms (Spence Children's Anxiety Scale (SCAS) scores of > 37 for females and > 32 for males). A total of 135 participants (mean age: 18.31 ± 1.61 years; 76% female) were recruited randomly assigned to one of three groups: eight weekly sessions of group-based CBT-I ($n=47$), eight weekly sessions of group-based CBT-A ($n=45$), or a waitlist control group (WL, $n=43$). All participants were assessed at baseline and post-treatment for their insomnia severity (via ISI) and anxiety symptoms (via the Hospital Anxiety and Depression Scale—Anxiety subscale, HADS-A).

Results: There was a significant group $\times$ time interaction effect on insomnia severity ($F(2, 119.84) = 10.95, p < 0.001$) and anxiety symptom severity ($F(2, 108.93) = 3.59, p = 0.031$). Compared to the WL, both CBT-I and CBT-A led to significant reductions in insomnia (CBT-I: $d = -2.06$; CBT-A: $d = -1.14$; WL: $d = -0.55$) and anxiety symptoms (CBT-I: $d = -0.86$; CBT-A: $d = -0.33$; WL: $d = -0.3$). Mediation analysis showed that, within the CBT-I group, improvements in anxiety was fully mediated by reductions in insomnia severity, with an indirect effect of -1.9 ($SE = 0.8, 95\% CI: -3.6$ to -0.36). However, reductions in anxiety did not significantly mediate improvements in insomnia within the CBT-I group. No significant mediating effects were found for either improving insomnia through changing anxiety or reducing anxiety through improving insomnia within the CBT-A group.

Conclusions: The findings suggest that improvements in insomnia symptoms following CBT-I may mediate the improvement of anxiety in adolescents with comorbid insomnia and anxiety. This underscores the transdiagnostic implications of targeting insomnia to alleviate anxiety symptoms in young people. Future research should investigate the underlying neurobiological and behavioral mechanisms and explore sequencing CBT-I and CBT-A protocols to optimize treatment effects.

Melatonin Prolonged-Release may improve insomnia and depression in epilepsy patients

D.W. Kwack¹, D.W. Kim¹

¹Konkuk University Medical Center, Neurology, Seoul, Korea, Republic of

Introduction: Insomnia is one of the most common sleep problems in general population and is highly prevalent among patients with epilepsy. Despite the well-documented effects of melatonin on insomnia and potential anticonvulsive effect, there only limited information on the effect of melatonin in epilepsy patients with the comorbid insomnia. We performed this pilot study to evaluate the effect and safety of prolonged release (PR) formulation of melatonin in epilepsy patients with insomnia.

Materials and methods: We prospectively enrolled 34 adult patients with epilepsy from March 2024 to February 2025. We collected and compared the Insomnia Severity Index (ISI) and the Korean version of the Neurological Disorders of Depression Inventory for Epilepsy (K-NDDI-E) before and after melatonin PR intake, and analyzed the results using the Wilcoxon signed-rank test.

Results: A total of 34 patients (13 males, mean age 55.3 ± 11.1 years) were included in the analysis. 31 patients were classified as having focal-onset seizures and 3 patients were classified as having generalized-onset seizures. A significant improvement, as measured by the ISI, from 16.0 ± 4.4 to 12.2 ± 5.2 after 12 weeks of melatonin PR ($p = 0.041$). In addition, a significant improvement in depression,

as measured by the K-NDDI-E, from 11.3 ± 4.2 to 9.8 ± 3.2 after 12 weeks of melatonin PR ($p = 0.001$). None of the patients discontinued melatonin PR due to seizure aggravation during the study.

Conclusions: Our study shows that melatonin PR was effective in improving sleep quality in epilepsy patients with insomnia and was also effective in improving depression. This finding suggests that melatonin PR may be a potential treatment option for epilepsy patients with both insomnia and depression.

Mindfulness-imbued insomnia therapy enhances antidepressant outcomes for pregnant women with insomnia and depression: A comparative effectiveness randomized controlled trial of CBTI and PUMAS

D. Kalmbach¹, H. Afaneh², P. Cheng², A. Reffi², M. Jennings², M. Hirata², D. Pitts¹, J.C. Ong³, D.M. Fresco⁴, L. Swanson⁴, L. O'Brien⁴, C. Drake²

¹Henry Ford Health, Novi, United States, ²Henry Ford Health, Sleep Research, Novi, United States,

³Rush University Medical Center, Chicago, United States, ⁴University Of Michigan, Ann Arbor, United States

Introduction: Insomnia affects half of pregnant women and significantly heightens the risk for comorbid depression. Among pregnant women with insomnia, nearly half also experience depression, compounding challenges to quality of life, mother-infant bonding, and perinatal health outcomes. Identifying effective treatments for co-occurring insomnia and depression during pregnancy remains a critical priority. Cognitive-behavioral therapy for insomnia (CBTI) improves sleep quality but has limited impact on depressive symptoms—an effect attributed to persistent cognitive arousal (e.g., worry and rumination). Addressing cognitive arousal may enhance depression outcomes for pregnant women with insomnia. Emerging evidence suggests that mindfulness-based interventions substantially reduce cognitive arousal during pregnancy. This randomized controlled trial (RCT) evaluated the comparative effectiveness of CBTI versus Perinatal Understanding of Mindful Awareness for Sleep (PUMAS), which integrates mindfulness and behavioral sleep strategies, targeting insomnia, depression, and cognitive arousal.

Materials and methods: A single-site, two-arm RCT of N=100 pregnant women with DSM-5 insomnia disorder and comorbid depression were randomized to CBTI or PUMAS. All treatment was delivered via six weekly telemedicine video sessions. Clinical symptoms were assessed a week before treatment, weekly throughout therapy, then one week after treatment. Clinical outcomes included the insomnia severity index (ISI), Edinburgh postnatal depression scale (EPDS), and two nocturnal cognitive arousal measures: (1) general nocturnal cognitive arousal via the pre-sleep arousal scale's cognitive factor (PSASC) and (2) perinatal-focused nocturnal rumination via the perinatal rumination scale at night (PRS-Night). Linear mixed models (LMM) using an intent-to-treat (ITT) approach were used to test treatment effects across repeated measures by evaluating Treatment X Time interactions. Covariates included time, age, gestational week, race, and session attendance. Insomnia remission was operationalized as posttreatment ISI scores of ≤ 7 , and depression remission was operationalized as $EPDS < 10$.

Results: Over 90% of patients completed ≥ 4 sessions, indicating high engagement. LMM analyses revealed that both CBTI and PUMAS resulted in insomnia severity reductions but overall, did not differ from one another ($b = -.14$, $p = .142$). However, insomnia remission rates were significantly higher for PUMAS as compared to CBTI (78.0% vs 50.0% remission, $\chi^2 = 8.51$, $p = .004$). Regarding depression, LMM analyses showed that PUMAS produced greater reductions in EPDS scores as compared to CBTI ($b = -.31$, $p < .001$), which also corresponded to higher depression remission rates for the PUMAS group (82.0% vs 58.0% remission, $\chi^2 = 6.86$, $p = .009$). Regarding cognitive arousal, LMM analyses showed that, relative to CBTI, PUMAS produced greater reductions in PSASC ($b = -.34$, $p = .009$) and PRS-Night scores ($b = -.44$, $p = .007$). Mediation analysis using PRODCLIN revealed that PUMAS-linked reductions in perinatal depression were mediated by decreases in nocturnal cognitive arousal, highlighting its role as a key mechanism of therapeutic change.

Conclusions: CBTI and PUMAS are effective for prenatal insomnia, whereas PUMAS was superior to CBTI for alleviating depression. Mechanistic findings suggest that reducing general and perinatal-focused rumination at night enhances PUMAS antidepressant effects. Our findings support triaging pregnant women with insomnia and comorbid depression to PUMAS over CBTI, whereas prenatal insomnia patients without depression may benefit similarly from either cognitive-behavioral or mindfulness-based therapies.

Acknowledgments: This study was funded by the National Institute of Mental Health (R34MH130562, PI: Kalmbach).

Multimodal assessment of sleep-wake perception in insomnia disorder

C.L. Schneider^{1,2}, K.D. Fehér^{1,2}, E. Hertenstein^{1,2}, F. Hügli², M. Wunderlin³, M.A. Züst³, C. Mikutta⁴, A.R. Adamantidis⁵, T. Berger⁶, D. Riemann⁷, B. Feige⁷, C. Nissen^{1,2,8}

¹University of Geneva, Department of Psychiatry, Geneva, Switzerland, ²University of Bern, University Hospital of Psychiatry and Psychotherapy, Bern, Switzerland, ³University of Bern, University Hospital of Old Age Psychiatry and Psychotherapy, Bern, Switzerland, ⁴Privatklinik Meiringen, Meiringen, Switzerland, ⁵University of Bern, Department of Neurology, Bern, Switzerland, ⁶University of Bern, Department of Clinical Psychology and Psychotherapy, Bern, Switzerland, ⁷University of Freiburg Medical Center, Department of Psychiatry and Psychotherapy, Freiburg, Germany, ⁸Geneva University Hospitals (HUG), Department of Psychiatry, Geneva, Switzerland

Introduction: Insomnia disorder is a prevalent health problem. The primary diagnostic criterion is a subjective complaint about reduced quantity or quality of sleep, which is often not observed in objective sleep measurements.

Materials and methods: Thirty patients with insomnia disorder (20 female, 8 male, 2 divers, 39±15 years) and 30 healthy controls (21 female, 9 male, 36±13 years) reported on their sleep-wake perception from up to 12 awakenings performed from consolidated NREM sleep.

Results: We show that patients with insomnia disorder, characterized by substantial subjective sleep complaints, did not differ on objective measures of sleep continuity, sleep architecture, spectral power, spectral slope, and phase-amplitude coupling of slow oscillatory and spindle activity. Perception of wakefulness following 559 serial awakenings from NREM sleep was frequent in both patients (59.7±33.5%) and controls (47.9±32.5%), with no significant group difference ($p = 0.223$; Cohen's $d = 0.32$, small effect size). High frequency spectral power, as an index of cortical arousal prior to awakening, but not standard measures of sleep, predicted the perception of wakefulness across groups, possibly related to physiological wake-like activity during sleep.

Conclusions: Our results support the notion that sleep-wake regulatory systems and direct sleep-wake perception are often intact in patients with insomnia disorder. These results propose empirical support for cognitive behavioral therapy for insomnia as the first-line treatment.

Music Intervention for Insomnia: Does Liking the Music Matter?

A. Partmann¹, B. Rasch¹, K.V. Jespersen²

¹University of Fribourg, Cognitive Biopsychology and Methods, Fribourg, Switzerland, ²Aarhus University, Department of Clinical Medicine, Center for Music in the Brain, Aarhus, Denmark

Introduction: Insomnia is highly prevalent in today's society and music interventions have been shown to be effective for individuals with this condition. However, there are considerable inconsistencies between studies regarding size and certainty of the effects, and the contributing mechanisms have not yet been tested empirically. In music interventions for other purposes, such as pain and relaxation, the extent to which participants like the music has been identified as an important influence. Therefore, we hypothesised that higher ratings of liking the intervention music would be associated with greater improvement in insomnia symptoms following the intervention period.

Materials and methods: We pooled data from three randomised controlled trials investigating music as a treatment for poor sleep. In all studies, participants in the music group listened to the intervention music at bedtime each night for at least three weeks and completed the Insomnia Severity Index (ISI) at baseline and post-treatment. Music liking was rated post-treatment on a 5-point scale. While Studies 1 and 2 only involved individuals fulfilling the criteria for insomnia disorder (DSM-V), Study 3 included pregnant women with a complaint of poor sleep. We used a linear mixed-effects model to predict ISI improvement based on Time (post-treatment vs. baseline), Liking, and Study, with random intercepts for participants.

Results: In the pooled sample ($n = 69$), we observed a trend for the interaction between Time and Liking ($p = .07$), suggesting that participants who liked the music more experienced greater

improvement in ISI scores. Study was identified as a meaningful control variable. Due to the differing sample in Study 3, we conducted a subsample analysis including only Studies 1 and 2 ($n = 40$). In this subsample analysis, the Time $\times$ Liking interaction was significant ($p = .016$).

Conclusions: Our findings suggest that the degree to which subjects liked the intervention music influenced its effectiveness in improving insomnia symptoms, especially in clinically diagnosed individuals. Limitations include low variance in the liking ratings, as well as one subject exerting a strong influence on the model fit. Excluding this individual weakened significance levels, but the effects remained directionally stable. Our results highlight the potential benefits of allowing participants to select their most-liked music in clinical interventions for sleep and contribute to the ongoing debate about subject- vs. experimenter-chosen intervention music.

Neural basis of emotion dysregulation in insomnia disorder: A task-based fMRI study

W. Zhao¹, Z. Xu², F. Xin³, L. Tang¹, X. Lei^{4,5}, C. Li¹

¹Sleep Medicine Center, Chongqing Traditional Chinese Medicine Hospital, Chongqing, China,

²Department of Psychiatry and Psychotherapy, Medical Center - University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, Germany, ³School of Psychology, Shenzhen University, Shenzhen, Guangdong, China, ⁴Sleep and Neuroimaging Center, Faculty of Psychology, Southwest University, Chongqing, China, ⁵Key Laboratory of Cognition and Personality (Southwest University), Ministry of Education, Chongqing, China

Introduction: Insomnia disorder (ID) is one of the most prevalent sleep disorders, affecting approximately 10% of the adult population. Beyond its hallmark nighttime difficulties with initiating or maintaining sleep, insomnia is increasingly recognized for its adverse consequences on daytime functioning, particularly in cognitive and emotional domains. Among these, deficits in emotion regulation have been consistently reported, implicating alterations in both behavioral and neurobiological systems. However, the neural mechanisms underlying the emotional dysregulation in ID remain poorly understood. Functional neuroimaging approaches offer critical insights into the brain circuitry involved in emotional regulation in this population.

Materials and methods: To investigate the neural correlates of emotion regulation in ID, we employed task-based functional magnetic resonance imaging (fMRI) in a sample of 19 patients diagnosed with insomnia disorder and 28 age- and sex-matched normal sleepers (NS). All participants completed standardized self-report measures assessing insomnia severity, anxiety, and depressive symptoms. During fMRI acquisition, participants performed an explicit emotion regulation task comprising three conditions: passive viewing of neutral pictures, passive viewing of negative pictures, and cognitive reappraisal of negative pictures. For each trial, participants were instructed either to observe the picture naturally or to reinterpret its meaning in a way that reduced its emotional impact, followed by a self-report of their current negative feelings. Brain activation patterns were analyzed using whole-brain approaches, focusing on areas previously implicated in emotion regulation.

Results: Behavioral performance data confirmed that all participants reported higher negative affect in response to negative pictures compared to neutral ones. Individuals with ID reported significantly greater negative responses during the reappraisal condition than NS controls, suggesting the impaired capacity to downregulate negative affect. Neuroimaging findings revealed that, relative to passive viewing of negative stimuli, the ID group exhibited significantly reduced activation during reappraisal in the sub-gyral region of the temporal lobe, the inferior frontal gyrus (IFG), and the right para-hippocampal gyrus compared to NS. These areas are known to support top-down cognitive control and contextual modulation of emotional responses.

Conclusions: Our findings provide convergent behavioral and neurobiological evidence for impaired emotion regulation in individuals with insomnia disorder. Specifically, hypoactivation in prefrontal and temporal-limbic regions during cognitive reappraisal suggests disrupted neural mechanisms underlying emotional processing. These results highlight the importance of targeting emotion regulation processes in the treatment of insomnia and indicate potential neural targets for intervention.

Novel Approach for Biologically-Guided Therapeutics in Insomnia

Y. Yan^{1,2}, T. Campelo^{2,1}, M. Aime³, N. Calcini^{4,2,1}, T. Rusterholz^{2,1}, A. Adamantidis^{2,1}, C. Gutierrez Herrera^{2,1}

¹University of Bern, Bern, Department for Biomedical Research, Bern, Switzerland, ²Centre for Experimental Neurology, Inselspital University Hospital Bern, University of Bern, Bern, Switzerland, Department of Neurology, Bern, Switzerland, ³Université Lyon, Centre de Recherche en Neurosciences de Lyon, INSERM U1028 - CNRS UMR5292, Lyon, France, ⁴University of Maastricht, Faculty of Science and Engineering, Maastricht Centre for Systems Biology, Maastricht, Netherlands

Introduction: Sleep is a fundamental biological process whose disruption is implicated in neurodegenerative and psychiatric disorders. Despite the global burden of insomnia—12.5% of the population worldwide—current pharmacological treatments remain limited by suboptimal efficacy and adverse effects such as dependence and cognitive impairment. This therapeutic gap stems partly from a lack of mechanistic understanding of how brain activity is regulated across sleep stages and neural organizational levels. Defining sleep-related neural signatures—from single-cell to population dynamics—is expected to support the development of more precise, biologically-guided treatments. Importantly, current hypnotics, including benzodiazepines (e.g., diazepam) and non-benzodiazepine Z-drugs (e.g., zolpidem), differentially modulate GABAergic circuits, offering an opportunity to understand sleep control at a mechanistic level.

Materials and methods: To investigate the pharmacology of diazepam (a benzodiazepine) and zolpidem (a Z-drug) on sleep-dependent brain dynamics, we used 1) in vivo whole-cell patch-clamp recordings to measure subthreshold membrane potentials of layer 2/3 pyramidal neurons in the prefrontal of head-restrained mice across wakefulness, NREM, and REM sleep; 2) longitudinal single-cell calcium imaging in freely behaving mice to track the activity of genetically-defined neuronal populations from the hypothalamus and neocortex. Pharmacological interventions included systemic administration of diazepam (a benzodiazepine) and zolpidem (a Z-drug), along with local NMDAR antagonists to probe excitatory and inhibitory mechanisms underlying sleep regulation.

Results: At the single-cell level, we found that Diazepam reduced the depolarization of cortical neurons in the prefrontal cortex, possibly by enhancing GABAergic inhibition via parvalbumin (PV+) interneurons during NREM sleep. In contrast, Zolpidem, selectively acting at $\alpha 1$ -containing GABA-A receptors, induced a similar decreased of neuronal excitability in the prefrontal cortex, although with less impact on interneuron-driven inhibition, reflecting distinct circuit-level mechanisms. Interestingly, subthreshold depolarization was reduced during REM sleep as compared to NREM sleep and wake states, while the opposite was found in retrosplenial neurons, suggesting a region-specific modulation of excitability across sleep states.

At the population level, hypothalamic neurons displayed overlapping, state-dependent activity patterns rather than strict state selectivity. These distributions were stable across time, with minimal disruption by sleep deprivation. However, both Diazepam and Zolpidem modulated activity biases—Diazepam shifted cellular activity toward NREM sleep, while Zolpidem promoted rapid NREM initiation associated with a distinct neuronal activity signature, suggesting different pharmacodynamic mechanisms.

Conclusions: Our study reveals that despite a common GABA-A receptor pathway, Diazepam and Zolpidem influence sleep through divergent receptor selectivity and network recruitment. These findings emphasize a novel biologically driven approach for pre-clinical drug development based on single cell and network biomarkers relevant to the underlying neural dynamics of EEG signatures of sleep. Long-term perspectives include the development of predictive tools to improve drug development and personalized treatment of insomnia and other sleep disorders.

Nurse-Led, App-Based Sleep Behavioral Treatment for Insomnia Among Survivors of Traumatic Brain Injury: A Randomized Controlled Trial

H.-Y. Chiu¹, C.-J. Lin¹

¹Taipei Medical University, School of Nursing, Taipei, Taiwan

Introduction: Insomnia is a common issue among individuals with traumatic brain injury (TBI), yet effective treatment options remain limited for this population. This study evaluated the effects of a nurse-led, app-based **Sleep Behavioral Treatment for Insomnia (SBTi)** in individuals with TBI.

Materials and methods: A parallel, three-arm randomized controlled trial was conducted between August 2022 and January 2025. Patients diagnosed with TBI for at least three months and experiencing insomnia symptoms for more than one month were recruited and randomly assigned to one of three groups: a 4-week face-to-face SBTi, an app-based SBTi, or a sleep hygiene control group. Sleep outcomes were assessed using the Insomnia Severity Index (ISI), sleep diary, and actigraphy. Measurements were taken at baseline (T0) and weekly at T1 (week 1), T2 (week 2), T3 (week 3), and T4 (week 4) of the treatment. Generalized Estimating Equation (GEE) models were used for data analysis.

Results: A total of 80 patients (mean age: 45.9 years) were included and randomly assigned to the face-to-face SBTi (n = 27), app-based SBTi (n = 27), or sleep hygiene control group (n = 26). Compared to the sleep hygiene group, both the face-to-face and app-based SBTi groups showed significantly lower ISI scores at T3 and T4 ($p < 0.05$). The face-to-face SBTi group had significantly shorter subjective and objective wake after sleep onset (WASO) at T4, while the app-based SBTi group showed shorter WASO at T1, T2, and T3 ($p < 0.05$). For both subjective and objective sleep efficiency (SE), significant improvements were observed in the face-to-face and app-based SBTi groups at T3 and T4 compared to baseline in the sleep hygiene group ($p < 0.05$).

Conclusions: Both face-to-face and app-based SBTi demonstrated significant improvements in sleep outcomes, supporting their effectiveness in managing insomnia in individuals with TBI.

One-month follow-up results of Patient-Reported Outcomes for LEMborexant treatment in Chinese patients with insomnia (PROEM): a multicenter, prospective, real-world observational study

X. Li^{#1}, S. Zheng^{#2}, W. Jian³, Y. Tang⁴, Y. Lin⁵, F. Jia^{*1}, B. Zhang^{*2}

¹Guangdong Mental Health Center, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China, ²Nanfang Hospital, Southern Medical University, Guangzhou, China, ³Guangzhou United Family Hospital, Guangzhou, China, ⁴Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China, ⁵Clifford Hospital, Guangzhou, China

Introduction: Lemborexant (LEM) is a novel dual orexin receptor antagonist approved to treat adults with insomnia in the United States, Canada, Japan and some other countries. This first prospective study to assess LEM treatment for patients with insomnia in routine clinical practice in China was conducted under the "Hong Kong and Macao Medicine and Equipment Connect" policy. Recently, LEM has been approved to treat adult with insomnia in China.

Materials and methods: This 12-week, multicenter, prospective, real-world observational study (NCT06225947) enrolled 205 adult patients with insomnia who visited 1 of the 5 participating hospitals in Guangzhou, China from February 2024. All patients were treated with LEM as per routine clinical practice. The purpose of this interim report is to describe the efficacy and safety after 4 weeks treatment of LEM. The primary endpoint was the remitter rate after 4 weeks of treatment (the percentage of patients with a post-treatment Insomnia Severity Index [ISI] score of < 8). The responder rate (the percentage of patients whose ISI score decreased ≥ 6 points from baseline), mean changes in the ISI, Patient Health Questionnaire-9 (PHQ-9) and General Anxiety Disorder-7 (GAD-7) scores from baseline were also determined. Treatment-emergent adverse events (TEAEs) were recorded.

Results: Through April 14, 2025, 167 patients had been taking LEM for ≥ 4 weeks, and 38 patients had withdrawn from the study. The full analysis set (FAS) included 200 patients, and the safety set included 205 patients. The FAS population had a mean age of 46.08 ± 14.56 years and 124 (62.0%) patients were female. Their mean duration of insomnia was 7.55 ± 8.66 years and mean baseline ISI score was 17.44 ± 4.45 . Ninety-one (45.5%) patients had comorbid anxiety (GAD-7 score ≥ 5) and 132 (66.0%) patients had comorbid depression (PHQ-9 score ≥ 5). Seventy-five (37.5%) and 44 (22.0%) patients had been taking benzodiazepine or non-benzodiazepine hypnotics, respectively. Forty-two (21.0%), 33 (16.5%) and 125 (62.5%) patients received LEM as initial monotherapy, switched to LEM, or added LEM to their existing hypnotic therapy, respectively. The remitter rate after 4 weeks of treatment was 30.5% (61/200), and the responder rates after 1, 2 and 4 weeks of treatment were 36.0% (72/200), 56.5% (100/177) and 60.4% (96/159), respectively. Patients who took LEM as initial monotherapy had a higher remitter rate (50.0% [21/42]) than those who switched to LEM (27.3% [9/33]) and those who

took it as add-on therapy (24.8% [31/125]) after 4 weeks of treatment. The mean ISI, PHQ-9 and GAD-7 scores all decreased significantly from baseline after 4 weeks of treatment (-7.17 ± 5.83 , $P < 0.001$; -2.63 ± 4.04 , $P < 0.001$; and -1.77 ± 3.80 , $P < 0.001$, respectively). Thirty-three (16.1%) patients reported treatment-related TEAEs, all of which were mild or moderate. Eight (3.9%) patients withdrew from the study due to TEAEs. The most common TEAEs were somnolence (11 [5.4%]) and dizziness (10 [4.9%]).

Conclusions: This first prospective study of LEM treatment in China demonstrated that LEM treatment was effective, safe and tolerable in treating Chinese adult patients with insomnia. LEM treatment also improved the patients' mood.

Pathophysiological subtypes of paediatric insomnia based on familiar and clinical features

V. Mammarella¹, M. Breda¹, D. Polese², R. Ferri³, O. Bruni⁴

¹Sapienza University of Rome, Department of Psychology, Rome, Italy, ²Sapienza, Neuroscience, Rome, Italy, ³Oasi Research Institute, Neurology, Troina, Italy, ⁴Sapienza University of Rome, Department of Social and Developmental Psychology, Rome, Italy

Introduction: Pediatric insomnia is a multifaceted combination of biological, circadian, neurodevelopmental, and environmental variables. Recent studies have underscored the significance of genetic factors in childhood insomnia, elucidating how not only familial predisposition to insomnia plays a pivotal role, but also predisposition to other medical conditions (e.g., atopy, anemia, iron deficiency, psychiatric disorders, etc.). Various pathophysiological subtypes have been proposed based on clinical presentations of insomnia, reflecting specific sleep issues, pediatric disorders, and familial history. This study aims to delineate distinct clusters of clinical and familial features to ascertain whether specific familial predispositions are more commonly associated with particular pediatric insomnia phenotypes.

Materials and methods: We conducted a retrospective review of 424 medical records of children with insomnia admitted to the Child Neuropsychiatry Unit, Sant'Andrea Hospital, Rome, from January 2015 to October 2022. Demographic data, clinical features of insomnia, and medical and familial sleep histories were collected. Hierarchical and non-hierarchical cluster analyses were performed to identify the most representative model and to assess the stability and reproducibility of the clusters.

Results: Three reproducible and stable groups were identified, demonstrating significant differences ($p < 0.001$) in the frequency of various clinical and familial features. The first cluster ($n=144$) comprised children with insomnia onset post-weaning (10.4%) and medical histories of atopy (17.4%) or gastroesophageal reflux (12.5%). The second cluster ($n=119$) included children experiencing prolonged awakenings (29.4%), night terrors (24.4%), or sleepwalking (3.4%). The third cluster ($n=161$) consisted of children exhibiting restless sleep characterized by hyperactivity (63.4%) or symptoms of restless leg syndrome (RLS) (11.2%), with 51.6% experiencing delayed sleep onset and nocturnal awakenings. Regarding familial history, the first cluster had a high prevalence of allergies (87.5%), while the third cluster showed a predisposition to RLS (30.4%) and iron deficiency (75.2%).

Conclusions: Our findings support the existence of distinct pathophysiological subtypes within pediatric insomnia. We hypothesize that these insomnia subtypes may involve dysregulation of neurotransmitter systems implicated in sleep regulation, such as histamine, serotonin, and dopamine. Identification of these distinct phenotypes through meticulous medical and familial history-taking may inform personalized treatment strategies for pediatric insomnia, potentially revolutionizing current approaches to managing children's sleep disorders.

Acknowledgments: I thank Prof. Oliviero Bruni for his invaluable guidance and support throughout this project. I am also grateful to my beloved colleague, Maria Breda, for her collaboration and support.

Patient and Clinician Perspectives on Treating Perimenopausal Sleep Problems

K. Sharkey^{1,2}, S. Redline^{3,4,5}, K. Baron⁶, C. Drake^{7,8}, C. Singer^{9,10}, B. McCullough¹¹, S. Bertisch^{3,4}

¹The Warren Alpert Medical School of Brown University, Providence, United States, ²Rhode Island Hospital, Providence, United States, ³Harvard Medical School, Boston, United States, ⁴Brigham and Women's Hospital, Boston, United States, ⁵Harvard T.H. Chan School of Public Health, Boston, United States, ⁶University of Utah, Salt Lake City, United States, ⁷Henry Ford Health, Detroit, United States,

⁸Michigan State University, East Lansing, United States, ⁹University of Maine, Orono, United States, ¹⁰Northern Light Acadia Hospital, Bangor, United States, ¹¹ACIRAH Health, Inc., Chicago, United States

Introduction: Up to 60% of females experience transient perimenopausal sleep difficulties, and an estimated 30% develop chronic insomnia around the time of menopause. Patients seeking treatment for vasomotor symptoms report that improving sleep is their top priority when selecting among treatment choices. From the clinician's perspective, insomnia is one of the leading reasons for initiating therapy for menopausal symptoms. To inform an upcoming randomized clinical trial (RCT) comparing treatments for menopause-associated insomnia, we surveyed clinicians who treat midlife patients and individuals with current or past menopausal sleep difficulties about their treatment experiences and preferences.

Materials and methods: In April-May 2024, we used e-mails to colleagues and public social media posts to circulate two IRB-approved Qualtrics survey initiations: one geared toward clinicians (20 items) and the other aimed at individuals who may have experienced perimenopausal insomnia (17 items). Participants were not compensated, but the investigators donated \$1US to one of three participant-selected charities for each completed survey.

Results: Of those who initiated a survey, completion rates were 77.2% for clinicians (n=61 of 79) and 70.2% for perimenopausal individuals (n=92 of 131). Most clinicians were physicians (75%), and 56% specialized in internal medicine or family medicine; 92% identified as women, and 25% identified as historically underrepresented in medicine. Most perimenopausal persons identified as women, and one identified as gender non-conforming; 16% reported a racial/ethnic minority identity; 48% were perimenopausal, and 42% were postmenopausal. Perimenopausal insomnia was rated as a "moderate-to-severe problem" by 88.7% of perimenopausal people and 98.3% of clinicians. *Sleep hygiene*, *melatonin*, and *hormone replacement therapy* were the most common treatments used by those with perimenopausal insomnia, but only 18.6% reported that their symptoms were treated "fairly well-to-very well." Perimenopausal people identified the most important treatment goals as *not waking up at night*, *falling back to sleep quickly*, *feeling refreshed upon waking*, and *clearer thinking*. At least half of clinicians reported using the following treatment modalities with their patients: *sleep hygiene* (95%), *trazodone* (68%), *melatonin* (63%), *cognitive-behavioral therapy for insomnia* (62%), and *antidepressants such as venlafaxine* (51%). In terms of efficacy, clinicians ranked *sleep hygiene*, *hormone replacement therapy*, and *cognitive-behavioral therapy for insomnia* as the "treatments that work the best." With respect to our upcoming RCT for perimenopausal insomnia treatment, 75.3% of perimenopausal people reported they would be "somewhat-to-very likely" to participate, and 98% of clinicians reported that they would be "somewhat-to-very likely" to refer their patients. Among potential participants and clinicians, opposition to pharmacologic treatment was the main reason for lack of interest in the RCT.

Conclusions: In this convenience sample, perimenopausal insomnia was rated as an important problem by patients and clinicians. Most perimenopausal people reported experiencing insufficient treatment of their insomnia symptoms and identified the need to address sleep maintenance and daytime functioning as the top treatment targets. Sleep hygiene was the most common therapy used in both groups. Although hormone replacement therapy was identified as one of the most effective treatments by clinicians and potential patients, clinicians were more likely to prescribe medications that were ranked as less effective.

Performance of an Asian-modified STOP-BANG for Obstructive Sleep Apnea Screening in Patients with Insomnia

L. Eng¹, R.J. Liu², S.H. Wong¹, V.K.H. Wong¹

¹Singapore General Hospital, Singapore, Singapore, ²National Healthcare Group Psychiatry Residency Programme, Singapore, Singapore

Introduction: Identifying obstructive sleep apnea (OSA) in patients presenting primarily with insomnia is challenging, as these individuals may not report classical OSA symptoms and often describe fatigue rather than excessive daytime sleepiness. OSA prevalence is higher in this population, and there is a bidirectional relationship between OSA and insomnia. The STOP-BANG questionnaire, a validated screening tool that assesses snoring, tiredness, observed apneas, high blood pressure, BMI, age, neck circumference, and gender, is widely used in general and Western OSA populations. In Asian populations, unique craniofacial features and lower BMI thresholds may increase OSA risk at lower BMI

than in Western cohorts, prompting modified STOP-BANG cut-offs. However, evaluation of the STOP-BANG in an Asian insomnia clinic population remains limited. This study assessed whether an Asian-modified BMI cut-off improves STOP-BANG performance for OSA screening in this context.

Materials and methods: We retrospectively reviewed all diagnostic polysomnograms (PSGs) ordered by the Department of Psychiatry from January 1, 2015 to December 31, 2019 for adults referred for insomnia. STOP-BANG scores were retrospectively determined using standardized intake questionnaires and clinical records, applying two BMI cut-offs: ≥ 35 kg/m² (original) and ≥ 30 kg/m² (Asian-modified); all other criteria were unchanged. A score of ≥ 3 indicated high risk. OSA severity was classified using AASM 2013 criteria (3% desaturation/arousal), with primary analysis focused on detecting moderate-to-severe OSA (AHI ≥ 15).

Results: A total of 116 patients were included, with 84% Chinese, 4% Malay, 3% Indian, and 7% of other ethnicities; 59% were male. Of these, 39 (34%) had moderate-to-severe OSA. With a STOP-BANG score ≥ 3 , the original model (BMI ≥ 35) achieved a sensitivity of 89.7% (95% CI: 77.8-96.7), NPV 91.1% (CI: 80.5-97.2) and specificity of 53.2% (95% CI: 42.1-64.1) for moderate-to-severe OSA. The Asian-modified model (BMI ≥ 30) increased sensitivity to 94.9% (95% CI: 85.0-99.1) and NPV to 95.1% (95% CI: 85.7-99.2), while specificity was slightly lower at 50.6% (95% CI: 39.6-61.7). AUC was 0.741 (original) and 0.755 (Asian-modified).

Conclusions: STOP-BANG performed moderately well as a screening tool for moderate-to-severe OSA in Asian insomnia clinic patients. Adopting an Asian-specific BMI cut-off (≥ 30 kg/m²) increased sensitivity and NPV but at the cost of lower specificity, resulting in more false positives and potentially unnecessary PSG referrals. Given the relatively high prevalence of moderate/severe OSA in this population, routine use of STOP-BANG may facilitate case detection, but a negative result does not fully exclude OSA, especially in patients with atypical presentations. Limitations include the retrospective design, modest sample size, and predominantly Chinese cohort. STOP-BANG with an Asian-specific BMI cut-off may serve as a practical first-line screening tool for case-finding in insomnia clinics, although confirmatory testing remains warranted for high-risk patients. Future studies should validate these findings in broader Asian populations.

Acknowledgments: The authors would like to thank Ms Song Pei Rong for her assistance with data retrieval.

Predicting Insomnia Symptoms Among Youth Using Multimodal Ecological Momentary Assessment

K.Y. Chan¹, Y. Liu¹, L. Xian¹, Y. Wang¹, P.S. Lo¹, C.C.W. Cheng¹, S.X. Li^{2,3}, N.Y. Chan¹, J.W.Y. Chan¹, Y.K. Wing^{1,4}, T.M.H. Li¹

¹The Chinese University of Hong Kong, Li Chiu Kong Family Sleep Assessment Unit, Department of Psychiatry, Hong Kong, Hong Kong, SAR of China, ²The University of Hong Kong, Department of Psychology, Hong Kong, Hong Kong, SAR of China, ³The University of Hong Kong, Hong Kong, The State Key Laboratory of Brain and Cognitive Sciences, Hong Kong, Hong Kong, SAR of China, ⁴The Chinese University of Hong Kong, Li Ka Shing Institute of Health Sciences, Faculty of Medicine, Hong Kong, Hong Kong, SAR of China

Introduction: Insomnia is common among youth and often co-occurs with depression. Ecological momentary assessment (EMA), widely used for depression monitoring, may also offer a scalable, real-time method for identifying insomnia symptoms. This study explores the feasibility of using linguistic and acoustic features from a speech-based EMA to predict insomnia symptoms in youth.

Materials and methods: This is part of an ongoing study on depression detection using EMA, which recruited 328 Chinese youth aged 18-24 years from the community in Hong Kong. Structured Clinical Interview for DSM-5 (SCID-CV) was administered to assess lifetime diagnoses based on the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5). Results indicated that 23% of participants met criteria for a history of depression, while 17% of anxiety disorder(s). Of these, 300 participants completed a 7-day EMA, which included twice-daily voice recordings via Telegram, with a minimum compliance rate of 70% required for inclusion in the analysis. Acoustic features were extracted using Praat and openSMILE while transcripts were analysed by using the Linguistic Inquiry and Word Count (LIWC) tool. Insomnia symptoms were assessed by the Structured Interview Guide for the Hamilton Depression Rating Scale with Atypical Depression Supplement, with scoring ≥ 1 classified as having insomnia symptoms. Machine learning models were developed using linguistic, acoustic, and combined feature sets.

Results: Among the 300 participants, 203 (mean age=20.66, SD=2.00, 74% female, 17% with lifetime history of depression) did not have insomnia symptoms while 97 (mean age=20.74, SD=2.09, 79% female, 38% with lifetime depression) had insomnia symptoms in the past week. No significant differences in age or gender were observed, but lifetime history of depression was significantly associated with having insomnia symptoms ($p<.01$). Logistic regression adjusting for sex, age, and lifetime depression diagnosis revealed significant associations between insomnia symptoms and both linguistic and acoustic features. Increased use of impersonal pronouns (OR=1.83, 95% CI: 1.22-2.75, $p<.01$), and sad-related words (OR=1.72, 95% CI: 1.13-2.61, $p=.01$) were significantly associated with having insomnia symptoms. Shorter and more uniform speech pauses are associated with a higher likelihood of having insomnia symptoms (mean pause duration: OR=0.19, 95% CI: 0.05-0.76, $p=.02$; mean pause variability OR=0.09, 95% CI: 0.01-0.69, $p=.02$). Among eight common machine learning algorithms tested, random forest using LIWC features performed the best (AUC=0.61, F1=0.61).

Conclusions: This study demonstrates that linguistic and acoustic features captured through an EMA can reveal potential markers of insomnia symptoms in youth. Linguistic features such as impersonal pronouns and sad-related words, along with acoustic markers like shorter and less varied speech pauses, were significantly associated with having insomnia symptoms. These findings suggest that subtle changes in language and speech patterns may reflect underlying sleep disturbances, potentially linked to emotional dysregulation, cognitive dysfunction and fatigue. Extracting insomnia-related signals from non-sleep-targeted voice data highlights the potential of EMA for broader symptom detection. Future studies should incorporate sleep-specific EMA items, longitudinal follow-ups, and subgroup analyses to enhance prediction.

Prediction of treatment outcome on digital cognitive behavioural therapy for insomnia using machine learning and usage data

L. Xian¹, C.C.W. Cheng¹, Y. Liu¹, K.Y. Chan¹, R. Huang¹, N.Y. Chan¹, S.X. Li^{2,3}, J.W.Y. Chan¹, Y.K. Wing^{1,4}, T.M.H. Li¹

¹Li Chiu Kong Family Sleep Assessment Unit, Department of Psychiatry, The Chinese University of Hong Kong, Hong Kong, China, ²Department of Psychiatry, The Chinese University of Hong Kong, Hong Kong, China, ³The State Key Laboratory of Brain and Cognitive Sciences, The University of Hong Kong, Hong Kong, China, ⁴Li Ka Shing Institute of Health Sciences, Faculty of Medicine, The Chinese University of Hong Kong, Hong Kong, China

Introduction: Digital cognitive behavioural therapy for insomnia (dCBT-I) is recognized as an accessible and scalable intervention for treating insomnia. However, its effectiveness depends on patient adherence. Machine learning (ML) holds potential for outcome prediction, as it is designed to optimize predictive accuracy. Unlike classical statistical methods, which aim to describe relationships between variables based on predefined assumptions, ML can capture complex, nonlinear, and individualized patterns in data. This study employs ML techniques to evaluate the accuracy of ML models in predicting remission after intervention.

Materials and methods: The study recruited 35 participants aged 18-25 years (Mean ISI Score $\pm$ SD:19.3 $\pm$ 2.97;60% Female) to use a 28-day dCBT-I app. They met the DSM-IV-TR criteria for insomnia disorder, with an Insomnia Severity Index (ISI) score of 15 or higher. Those were excluded if they had a history of sleep disorders (other than insomnia), mental disorders (other than depression and anxiety), intellectual disabilities, severe suicidality, current pharmacological treatment or structured psychotherapy, or had recently engaged in shift work or trans-meridian travel.

During the intervention, participants provided daily sleep diaries, and their usage data was automatically tracked. App usage features, including daily usage durations (e.g., time spent on an app page), usage patterns (e.g., mean and maximum daily usage), time spent on each page (e.g., latest review time on a given day), and noncontinuous use of the app (e.g., number of days between two discrete usage) were recorded.

The state-of-the-art ML algorithms were used to predict whether participants achieved a post-intervention ISI score below 8, indicating remission of insomnia. We applied five-fold cross-validation and grid search for hyperparameter tuning, used the Synthetic Minority Over-sampling Technique

(SMOTE) to address class imbalance, and evaluated model performance using the Receiver Operating Characteristic–Area Under the Curve (AUC). Statistical significance between models was assessed using the DeLong test. SHapley Additive exPlanations (SHAP) was used to identify the important factors contributing to the models' predictions.

Results: In the study, 9% of participants (n=3) dropped out, while 91% (n=32) completed the 28-day dCBT-I app. In the completer analysis, 81% of participants experienced reduced ISI score (Mean Pre ISI Score $\pm$ SD:19.41 $\pm$ 3.15, Mean Post ISI Score $\pm$ SD:11.94 $\pm$ 5.65, Cohen's d=1.69, p<.001). Across all predictive models, XGBoost achieved the highest performance to predict remission (AUC=0.88, F1=0.86; p<.001), significantly outperforming other models (p<.05). Furthermore, Feature Importance analysis revealed that noncontinuous use of the app was the most predictive factors for remission after intervention across all models. Those remitted from insomnia (<8) (Mean days $\pm$ SD:4.75 $\pm$ 6.85) had a shorter gap in noncontinuous use of the app compared with other participants (Mean days $\pm$ SD:7.08 $\pm$ 3.80, p=.02).

Conclusions: Our findings indicate that ML models with users' engagement and adherence data of dCBT-I can accurately predict treatment outcome. In addition, noncontinuous use of the app emerged as the most important factor influencing model performance in predicting remission of insomnia, highlighting the importance of fostering sustained participation and adherence in digital interventions.

Predictors of Adherence to Digital CBT for Insomnia (dCBT-I) and Its Impact on Treatment Efficacy: A Large-Scale Real-World Analysis

X. Kong¹

¹anhui medical university, Hang Zhou, China

Introduction: While digital Cognitive Behavioral Therapy for Insomnia (dCBT-I) is a first-line treatment, variable adherence limits its real-world effectiveness. This study aimed to identify key determinants of dCBT-I adherence and quantify its prognostic value on clinical outcomes in a large patient cohort.

Materials and methods: We conducted a retrospective analysis of 3420 adults with DSM-5 insomnia treated with a dCBT-I mobile application between January 2017 and June 2024. Adherence was quantified using a novel, weighted scoring system based on engagement with core modules (sleep restriction, stimulus control, cognitive restructuring). Baseline demographic and clinical data, including the Pittsburgh Sleep Quality Index (PSQI), GAD-7, and PHQ-9, were collected. Multivariate logistic regression was used to identify independent predictors of high versus low adherence. Treatment response was defined as a $\geq 50\%$ reduction in the total PSQI score at an 8-week follow-up. Receiver Operating Characteristic (ROC) analysis was performed to evaluate the predictive power of the adherence score for achieving a positive treatment response.

Results: Multivariate logistic regression revealed that higher adherence was independently predicted by **older age** (≥ 40 vs. < 40 years; OR=2.85, 95% CI: 1.52-5.34, p=0.001), **higher education level** (College vs. Primary; OR=3.10, 95% CI: 1.61-5.96, p<0.001), **lower baseline anxiety** (per point on GAD-7; OR=0.88, 95% CI: 0.81-0.95, p=0.002), and **greater baseline insomnia severity** (per point on PSQI; OR=1.21, 95% CI: 1.05-1.40, p=0.008). The high-adherence group demonstrated a significantly greater mean reduction in PSQI scores at 8 weeks compared to the low-adherence group (**-8.5 $\pm$ 2.1 vs. -3.2 $\pm$ 1.8; p < .001**). The adherence score robustly predicted treatment response, with an Area Under the Curve (AUC) of **0.81** (95% CI: 0.75-0.87), a sensitivity of 78%, and a specificity of 75% at an optimal cut-off.

Conclusions: Adherence to dCBT-I is a powerful mediator of treatment success and is influenced by a distinct profile of demographic and clinical factors. Our findings suggest that an engagement-based adherence score can serve as a strong prognostic tool. This underscores the necessity of developing personalized, adaptive dCBT-I interventions that provide targeted support to at-risk populations (e.g., younger, less educated, highly anxious patients) to maximize engagement and improve clinical outcomes in real-world settings.

Acknowledgments: The authors gratefully acknowledge the funding support from the Zhejiang Provincial Department of Science and Technology (2025C01103) and the Zhejiang Province's 'Pioneer' and 'Leader' Science and Technology Support Projects (2024C04024). We also extend our sincere

gratitude to all the patients for their participation and to the dedicated clinical staff at the Hangzhou Seventh People's Hospital for their invaluable support in conducting this research.

Preliminary observations on insomnia phenotypes based on daily electroencephalography sleep monitoring in the natural sleeping environment

A. Khan^{1,2}, K. Dion^{1,2}, D. Smith^{1,2}, K. Fonseca¹, D. Keough³, A. Douglass^{2,3}, E. Lee^{1,3}, C.E. Carney⁴, T. Dang-Vu⁵, C. Morin⁶, R. Robillard^{1,2}

¹University of Ottawa Institute of Mental Health Research at The Royal, Ottawa, Canada, ²University of Ottawa, Ottawa, Canada, ³Royal Ottawa Mental Health Center, Ottawa, Canada, ⁴Ryerson University, Toronto, Canada, ⁵Concordia University, Montreal, Canada, ⁶Laval University, Quebec City, Canada

Introduction: The most commonly used classification of insomnia phenotypes focuses on the distinction between objectively defined short (<6h) and normal/near-normal (≥6h) sleep duration in the presence of subjective sleep complaints. Despite the common night-to-night variability in insomnia symptoms, objective sleep measurement is often restricted to a single recording in artificial laboratory environments. Using one week of EEG monitoring in the natural sleeping environment, this study assessed: i) the temporal stability of insomnia phenotypes, ii) the relation between EEG and sleep diary estimates of sleep duration; and iii) factors linked to larger gaps between EEG-based and subjective estimates.

Materials and methods: Thirty-three adults (36.1±11.6 y.o.; 81.8% female) with insomnia disorder and depression symptoms underwent up to 7 days of home-based sleep monitoring with a portable EEG monitor (Muse-S, InteraXon) for objective measurement and the consensus sleep diary to document subjective perceptions. Sleep EEG was scored with a validated automated algorithm. To track intra- and inter-individual variability in phenotypes, each individual EEG recording was classified in short (<6h) versus normal/near-normal (≥6h) sleep duration.

Results: Preliminary results suggest that 29% of participants had unstable insomnia phenotypes across the week of EEG monitoring, having at least a quarter of the nights with sleep duration above 6 hours and at least a quarter of the nights below 6 hours. Conversely, 18% had more stable short sleep phenotype and 53% had more stable normal/near-normal phenotypes. Subjective sleep durations based on diaries ranged between values that were 6 hours shorter than objective EEG-based measures to 12 hours longer than EEG-based measures, with a distribution that was moderately positively skewed. Over one third of participants had a mixed profile, with some nights for which diary-based sleep duration was shorter than EEG-based sleep duration and other nights where diary-based sleep durations were longer than EEG-based values. Lower estimation of subjective sleep duration relative to EEG-based measures was associated with more frequent EEG-based awakenings ($r=-.27$, $p=.044$), higher amounts of N2 sleep ($r=-.30$, $p=.024$), and lower percentage of N3 sleep ($r=.29$, $p=.028$).

Conclusions: These preliminary observations highlight the potential fluidity of insomnia phenotypes for a considerable proportion of individuals with insomnia. This raises questions about defining phenotypes based on a single night or averages that may obscure intra-individual variability. Objective measures are needed to identify this phenotype and this study confirms that subjective estimates are not helpful in predicting this phenotype as they differ from objective estimations in either direction, i.e., underestimation, overestimation, or both, and are unstable across time. However, in individuals with shallower sleep, there is a tendency towards lower subjective sleep duration estimations relative to EEG-based measures. Further work in larger insomnia samples and quantified EEG analyses is required to assess the daily sleep EEG signature of insomnia phenotypes. These preliminary observations raise concerns about relying on a single night of EEG recording to characterise insomnia phenotypes and call for more research to determine the minimal number of recordings for reliable phenotyping.

Psychological Aspects of Sleep Disorders – Insomnia and Maladaptive Cognitions: Results of the Multicenter Study “How Does Russia Sleep? (SleepStudyRu)”

M. Shchevliagina¹, E. Yakupov¹, R. Abdulina², I. Abitov², I. Kalimullina², N. Sumina³, I. Mitrofanov⁴, I. Raginene⁵, K. Magomedova⁶, A. Shershneva⁷, O. Savolkova⁸, T. Vlasova⁹, A. Ilyina¹⁰, R. Abdullina¹¹

Introduction: Insomnia is a prevalent sleep disorder with significant impacts on quality of life and mental health ([Porcheret K. et al., 2024](#)). Recent studies highlight the role of cognitive factors, such as rumination, reflection, and perfectionism, in the development and maintenance of insomnia ([N.K. Tang et al., 2023](#)). Additionally, anxiety and depression often accompany insomnia and may impact cognitive factors.

Materials and methods: A cross-sectional study was conducted within the multicenter project "How Russia Sleeps," involving 723 volunteers aged 18 to 65. Validated Russian-language scales were used: Insomnia Severity Index (ISI), Ruminative Responses Scale (RRS), Multidimensional Perfectionism Scale (MPS), Beck's Anxiety Inventory (BAI), Beck's Depression Inventory (BDI).

Results: Psychological Profile Characteristics of Individuals with Sleep Disorders

Findings:

- The Insomnia Severity Index (ISI) showed a significant positive correlation with level of depressive rumination ($p \leq 0.01$). A tendency toward repetitive, negatively toned thoughts focused on depressive symptoms was associated with more pronounced sleep disturbances. This aligns with the understanding of rumination as a potential risk factor for the chronicity of insomnia.
- A similarly strong positive correlation was identified between ISI scores and distressing thoughts ($p \leq 0.01$). The presence of cyclical, passive reflections on failures was linked to greater severity of insomnia symptoms.
- A significant positive correlation was also found between ISI scores and levels of reflection ($p \leq 0.01$). This suggests that even relatively constructive, goal-directed thinking related to problem-solving may be associated with difficulties in initiating and maintaining sleep.
- A significant positive correlation was observed between ISI scores and anxiety levels as measured by the Beck Anxiety Inventory ($p \leq 0.01$). Higher anxiety scores were associated with more severe sleep disturbances. This supports the contemporary psychophysiological model of insomnia, which considers anxious experiences as contributing factors to insomnia.
- ISI scores also demonstrated statistically significant positive correlations with various forms of perfectionism:
 - Self-oriented perfectionism ($p \leq 0.01$)
 - Other-oriented perfectionism ($p \leq 0.01$)
 - Socially prescribed perfectionism ($p \leq 0.01$)

Conclusions: Insomnia is significantly associated with cognitive and emotional factors, particularly rumination, distressing thoughts, reflection, anxiety, and depression.

Various forms of perfectionism (self-oriented, other-oriented, socially prescribed) showed significant positive correlations with the severity of insomnia symptoms, indicating a potential role of perfectionistic attitudes in the development and maintenance of sleep disturbances.

These findings underscore the importance of considering cognitive processes in the development of therapeutic interventions for individuals with insomnia, particularly within the framework of cognitive-behavioral therapy (CBT), including addressing rumination, anxious thoughts, and perfectionistic attitudes.

Real-world data on the abuse potential of medications for the treatment of insomnia

P. Saskin¹, W.V. McCall², D. Neubauer³, A. Crucitti⁴, P.P. Luyet⁵, R. Jaziri⁶, C. Vaillant⁵

¹Idorsia Pharmaceuticals US, Inc, Medical Affairs, Radnor, United States, ²Medical College of Georgia at Augusta University, Psychiatry and Health Behavior, Augusta, United States, ³Johns Hopkins University School of Medicine, Psychiatry and Behavioral Sciences, Baltimore, United States, ⁴Idorsia

Pharmaceuticals Ltd, Global Drug Safety, Allschwil, Switzerland, ⁵Idorsia Pharmaceuticals Ltd, Allschwil, Switzerland, ⁶Viatrix, Allschwil, Switzerland

Introduction: Insomnia disorder is a chronic medical condition that is estimated to affect 12% of adults. Although CBTi is recognized as an important first line therapy it can be challenging to access and implement, resulting in problems with compliance. As a result many individuals with insomnia disorder receive medication treatment, often for prolonged periods of time. The potential for abuse of hypnotics can prevent patients from accessing necessary medications to effectively treat insomnia as a chronic condition. This study examined the real-world abuse potential of approved and off-label medications used for the treatment of insomnia, employing data from the FDA Adverse Event Reporting System (FAERS) database.

Materials and methods: Data from 1 January 2014 to 31 March 2024 were retrieved from the FAERS database. We compared the occurrence of unsolicited reported drug abuse events defined via Standardized Medical Dictionary for Regulatory Activities (MedDRA) Queries SMQ). Drugs of interest included Schedule IV drugs (benzodiazepines, Z-drugs, dual orexin receptor antagonists [DORAs]) and non-scheduled drugs (trazodone, doxepin, ramelteon). Trazodone was selected for comparison as it is one of the most widely prescribed medications for insomnia in the US, despite it not being approved for this condition. Relevant reported adverse events denoting drug abuse were identified if they contained an event with any preferred terms (PTs) from the SMQ categories: drug abuse, dependence, and withdrawal (MedDRA v26.1), with a modified SMQ applied to exclude cases with PTs associated with overdose or suicidal behaviors. Only PT's with a frequency threshold > 1% in any drug group are reported. Trazodone and zolpidem were used as reference drugs for disproportionality as they are the most widely prescribed drugs for insomnia in the US. Reporting odds ratios (ROR) and proportional reporting ratios (PRR) were used as disproportionality measures.

Results: Rates of adverse event cases of abuse, dependence, and withdrawal retrieved were highest for benzodiazepines approved for any indication (27.7%), followed by benzodiazepines approved for insomnia (23.0%), trazodone (22.7%), doxepin (22.3%), Z-drugs (15.3%), ramelteon (8.0%), and DORAs (2.6%). DORAs were associated with a low ROR value relative to Z-drugs (ROR = 0.150; 95% CI [0.131, 0.171]), and to trazodone (ROR = 0.092; 95% CI [0.081, 0.105]). Similar results were obtained using the PRR to measure disproportionality.

Conclusions: This study identified significantly fewer reported cases of abuse, misuse, overdose, dependence and withdrawal for DORAs compared with drugs typically prescribed long term for insomnia treatment. This included benzodiazepines (both indicated for and used off label) as well as z-drugs. The DORA class had significantly lower odds of reporting for adverse events denoting drug abuse when compared with both the scheduled drug zolpidem and the non-scheduled drug trazodone. This suggests that categorization of DORAs as Schedule IV drugs may overstate their abuse potential.

Acknowledgments: The study was funded by Idorsia Pharmaceuticals Ltd. Thanks to Antonio Olivieri MD, Guy Braunstein MD PhD, and Martine Clozel MD for their thoughtful reviews and insights.

Real-World Treatment Patterns of Sleep Medications in the United States Veterans Affairs Health System

K. Brandao-Viruet¹, Y. Wang^{2,3}, J. Reisman^{4,5,6}, S. Zhao^{4,5}, B. Mittler⁷, D. Berlowitz⁴, P. Morin⁸, A.A. Tahami Monfared^{9,10}, M. Moline⁹, Q. Zhang⁹, W. Xia^{4,6,8}

¹Tufts Medical Center, Boston, United States, ²Research Service, VA Bedford Healthcare System, Bedford, United States, ³Wentworth Institute of Technology, Boston, United States, ⁴University of Massachusetts Lowell, Lowell, United States, ⁵Bedford VA Medical Center, Bedford, United States, ⁶Bedford VA Healthcare System, Bedford, United States, ⁷South Texas VA Healthcare System, San Antonio, United States, ⁸Boston University Chobanian and Avedisian School of Medicine, Boston, United States, ⁹Eisai Inc., Nutley, United States, ¹⁰McGill University, Montreal, Canada

Introduction: This study evaluated treatment patterns for select sleep medications in the Veterans Affairs Health System (VAHS) and the Centers for Medicare and Medicaid Services (CMS).

Materials and methods: We identified all patients aged ≥50 years with select sleep medication prescriptions in the merged VAHS and CMS databases (2020–2022). This age threshold was chosen to capture older adults who are more likely to experience chronic insomnia and may have greater exposure to polypharmacy. Clinical Practice Guidelines for pharmacological treatment of insomnia

define nonbenzodiazepines such as z-drugs as first-line. Other treatments may include the melatonin receptor agonist (ramelteon) or sedating antidepressants (trazodone, off label). The FDA has also approved three dual orexin receptor antagonists (DORAs), suvorexant, lemborexant, and daridorexant. These newer agents target the sleep-wake cycle differently by inhibiting the binding of orexin neuropeptides to their receptors, thereby reducing wakefulness. Frequency distributions of the select sleep drugs were examined. Data were descriptively analyzed to characterize prescription frequency, concurrent medication use, and changes over time. Patients were followed longitudinally within the 3-year window to assess treatment continuity and medication switches.

Results: Among Veterans using VA outpatient services (N=6,761,233), we identified 906,519 patients with ≥ 1 sleep drug prescribed during the 2020-2022 study period. Patients had a mean (SD) age of 65.2 (13.1) years at first prescription; 9.4% were women, 17.8% were Black/African American vs 71.1% White, and 6.7% were Hispanic vs 87.5% non-Hispanic. Overall, an estimated 2.6% were prescribed zolpidem, 0.7% temazepam, 0.28% eszopiclone, 0.12% ramelteon, 0.6% zaleplon, 0.5% suvorexant, 0.4% triazolam, 0.006 lemborexant, 0.005% estazolam, and 0.0001% daridorexant. Use of sedative antidepressants was prevalent (trazodone 10.4%; doxepin 0.9%). Over the 3-year period, most patients (89%) used a single sleep medication and 9.6% used 2 drugs. Melatonin supplements were prescribed in 46.2% of patients in conjunction with the other sleep medications.

Conclusions: The Z-drug zolpidem was the most commonly prescribed medication indicated for insomnia. Sedative antidepressants were also frequently utilized, likely due to their affordability and the lack of widely accepted, cost-effective alternatives for managing insomnia. This reliance on off-label agents such as trazodone suggests a potential gap between clinical guidelines and real-world practice, possibly reflecting formulary constraints, prescriber familiarity, or patient comorbidities. Lemborexant and daridorexant, more recently approved for insomnia, were prescribed less frequently and have not yet become mainstream frontline treatments. However, their novel dual orexin receptor antagonist mechanism provides a viable alternative therapeutic option for new users seeking effective insomnia management. Future research should examine whether newer agents gain broader adoption over time as prescribing trends respond to effectiveness, cost, and evolving treatment guidelines.

Relation Between Individual and Neighborhood-Level Lifetime Stressor Exposure and Insomnia Symptoms

H. Dickens¹, V. Floyd¹, I. Vargas²

¹University of Arkansas, Department of Psychological Science, Fayetteville, United States, ²Notre Dame University, South Bend, United States

Introduction: Introduction:

Insomnia is a prevalent disorder, impacting around 10% of adults worldwide. The link between insomnia and acute stressor exposure has been well-documented. However, less is known about the role that lifetime stressor exposure plays in the development and course of insomnia. Lifetime stressor exposure has been shown to contribute to the dysregulation of neuroendocrine, physiological, and psychological processes that directly impact sleep. Evidence on the impact of lifetime stressor exposure has focused primarily on individual-level stressors such as stressful life events. Less is known about the role that neighborhood-level stressors play in stress-related pathology, including insomnia. The current study aimed to investigate the association between both individual (self-reported life events) and neighborhood-level (objective markers of neighborhood deprivation) lifetime stressor exposure and insomnia symptoms.

Materials and methods: Data was collected from 143 participants (57% women, 38% White, 34% Latinx/Hispanic, 27% Black/African American, mean age = 19.83) from a university and surrounding community in the Mid-Southern region of the United States. Participants were asked to rate their insomnia symptoms using the Insomnia Severity Index (ISI) and individual-level stressor exposure using the Stress and Adversity Inventory (STRAIN). Total scores for ISI and total stressor count from the

STRAIN were used. Participants were also asked to provide a lifetime residential history which was linked the Area Deprivation Index (ADI) to create a composite score of neighborhood-level stressor exposure. A multiple linear regression was conducted with race, gender, and household income entered as covariates.

Results: Unadjusted analyses revealed a small, but significant effect of individual-level lifetime stressor exposure (total stressor count via STRAIN) on ISI scores ($b = 0.16$, $t(5,128) = -2.77$, $p < .05$). No significant effect of lifetime neighborhood-level stressor exposure on ISI was found. The main effect of individual-level stressor exposure remained significant in the adjusted analyses ($b = 0.16$, $t(5,120) = 3.06$, $p < .05$), even after controlling for race, gender, and household income.

Conclusions: Findings from the current study suggest that individual-level lifetime stressor exposure (e.g. stressful life events), but not neighborhood-level stressor exposure, is associated with the development and maintenance of insomnia. Future work would benefit from employing longitudinal designs to disentangle the mechanisms (e.g. stress-induced hyperarousal) by which this occurs to identify potential targets for prevention or early intervention.

Research Progress on the Role of Ferroptosis in Insomnia with Depression

王¹

¹Weihai Third Hospital, Department of Sleep Medicine, Weihai, China

Introduction: Insomnia is a prevalent sleep disorder that not only impairs daily functioning but also significantly increases the risk of developing depression. Depression is a common chronic mental illness. Insomnia and depression often coexist as comorbidities. The commonly used antidepressant drugs have slow onset and are prone to relapse, so exploring new antidepressant targets and methods is a necessary process to address the current status of depression treatment. Iron death is a novel form of cell death discovered in recent years, and numerous studies have shown that iron death plays an important role in neurological and psychiatric disorders. Recent studies have also shown that ferroptosis may play an important role in the pathogenesis and treatment of insomnia with depression. This review analyzes and summarizes the role of ferroptosis in the pathogenesis and treatment of insomnia with depression, aiming to provide new ideas and possible targets for the treatment of insomnia with depression.

Materials and methods: This is a review article. The materials mainly come from numerous existing research studies on ferroptosis, insomnia, and depression. The methods involve a comprehensive analysis and summary of relevant literature to explore the role of ferroptosis in insomnia with depression.

Results: Inhibiting tsRNA - 3029b reduces neuronal ferroptosis in CUMS - model mice, improving depressive - like behaviors, indicating epigenetics' role in depression. Ferroptosis is involved in the antidepressant effects of resveratrol, melatonin, and ECT with etomidate. Resveratrol and melatonin improve depression by inhibiting ferroptosis, and etomidate may enhance ECT's effect by protecting neurons from ferroptosis.

Conclusions: Ferroptosis plays an important role in many neurological and psychiatric disorders, including schizophrenia, insomnia, Alzheimer's disease, Parkinson's disease, autism, epilepsy, and cerebral infarction. The impact of ferroptosis on neural plasticity and inflammation is crucial in the pathogenesis and treatment of insomnia with depression. Ferroptosis - related genes and pathways may serve as new therapeutic targets for depression.

Acknowledgments: The author(s) would like to acknowledge the contributions of all researchers whose work was cited in this review. Also, the support from the Sleep Medicine Department, Weihai Third Hospital is gratefully acknowledged.

Resolving subjective emotional distress overnight: sleep diary data from a randomized controlled trial on Cognitive Behavioral Therapy for insomnia

R. Bongers^{1,2}, S. Ikelaar¹, A. van Keeken¹, S. van Trigt^{3,4}, J. Leerssen¹, A. Hoogendoorn^{3,4}, N. Batelaan^{3,4,5}, J. Lancee⁶, E. van Someren^{1,2,3,7}, J. Reesen^{2,1}

¹Netherlands Institute for Neuroscience, Royal Netherlands Academy of Arts and Sciences, Department of Sleep and Cognition, Amsterdam, Netherlands, ²Center for Neurogenomics and

Cognitive Research, Amsterdam Neuroscience, Vrije Universiteit University Amsterdam, Department of Integrative Neurophysiology, Amsterdam, Netherlands, ³Amsterdam UMC location Vrije Universiteit Amsterdam, Department of Psychiatry, Amsterdam, Netherlands, ⁴Amsterdam Public Health, Mental Health program, Amsterdam, Netherlands, ⁵GGZ inGeest Mental Health Care, Amsterdam, Netherlands, ⁶University of Amsterdam, Department of Clinical Psychology, Amsterdam, Netherlands, ⁷Amsterdam Neuroscience, Mood Anxiety Psychosis Stress Sleep, Amsterdam, Netherlands

Introduction: The phrase "sleep on it" reflects a common experience: distress often feels less intense after a good night's sleep. Unfortunately, many people—especially those with mental disorders—struggle with poor sleep. 70% of individuals with mental disorders experience sleep complaints, which worsen symptoms and hinder treatment outcomes. REM sleep is believed to facilitate the overnight resolution of daily distress—but only if it is uninterrupted. Insomnia, characterized by fragmented REM sleep, may impair this process, preventing the natural overnight reduction of negative emotions. Cognitive Behavioral Therapy for Insomnia (CBT-I) is the first-line treatment for insomnia and has shown to improve both sleep and comorbid mental complaints such as depression and posttraumatic stress disorder. This Randomized Controlled Trial examines the effect of online guided iCBT-I (iSleep) on the overnight resolution of emotional distress in people with clinically relevant insomnia and anxiety complaints. By improving sleep, we expect participants that have received iCBT-I to: 1) experience less negative feelings in general; 2) experience more decrease in negative feelings overnight.

Materials and methods: Participants ($n = 149$, 106 females, $M_{age} = 54$) were randomized in either CBT-I group ($n = 76$) or active control (sleep diary only). At baseline, post-treatment, and 6-months follow-up, participants completed the Consensus Sleep Diary for one week, from which several sleep metrics were derived. In addition, to monitor overnight changes in mood, they filled out their level of depressed, anxious, and tense mood every evening and morning, on a 5-point Likert scale. Sleep quality rating (Likert 1-5) and WASO was used as a proxy for uninterrupted REM sleep. Data was analyzed using random intercept mixed linear models, with morning mood ratings as outcomes, and evening mood ratings as predictors to model the overnight mood change.

Results: In general, iCBT-I improved depressive and tense feelings at 6-months follow-up. Moreover, at 6-months follow-up, we found a significant effect of iCBT-I on the overnight resolution of depressive feelings (interaction effects of iCBT-I x timepoint: $b = -0.26$, $p = 0.046$), but not for anxiety and tenseness. Interestingly, this iCBT-I effect was stronger after more depressed evenings (significant interaction of evening depressive feelings x iCBT-I x timepoint T2: $b = 0.32$, $p = 0.005$). Analyses separating within- vs. between subject effects showed that this is solely a within-subject effect, indicating that iCBT-I has a stronger effect on the more depressed evenings within a person. Across groups, the overnight resolution of all negative feelings was highly dependent on sleep quality ($b = -0.22$ to -0.12 , all $p < 0.001$) and WASO ($b = 0.001$ to 0.002 , all $p < 0.012$).

Conclusions: This suggests that iCBT-I improves the overnight resolution of depressive feelings in individuals with insomnia and anxiety complaints, especially after evenings when they felt most depressed. Moreover, only during nights of experienced good sleep quality, negative emotions can dissolve. Both findings highlight the fundamental role of sleep on emotional processing, and the importance of treating insomnia for good mental wellbeing.

Trial registration: International Clinical Trial Registry Platform (NL9776). Registered on 2021-10-07.

Restless Minds in Restless Nights: Insomnia and Mental Health in Medical Residents with ADHD

J.P. Azenha¹, J. Domingos¹, M. Cândido¹

¹Unidade Local de Saúde de Lisboa Ocidental, Psiquiatria e Saúde Mental, Lisbon, Portugal

Introduction: Insomnia is a prevalent and impairing symptom among medical professionals, particularly during specialty training. Its potential impact on functioning and well-being may be particularly high in individuals with comorbid ADHD. This study aims to explore the prevalence of insomnia in this population and its association with psychiatric comorbidities, ADHD symptoms, stimulant use, and training-related variables.

Materials and methods: We conducted a cross-sectional, anonymous online survey targeting medical residents in Portugal. The survey assessed sociodemographic data, presence of insomnia, psychiatric comorbidities, ADHD symptoms (6-item frequency-based scale), and stimulant use. Statistical analyses

included chi-square and Mann-Whitney U tests to examine associations between insomnia and key clinical and training variables.

Results: Out of 191 complete responses, 20 participants (10.5%) reported a diagnosis of insomnia. Insomnia was significantly associated with the presence of other psychiatric comorbidities ($p < 0.0001$), particularly anxiety ($p = 0.0016$) and depression ($p = 0.0022$). Although no specific rare comorbidity (e.g., bipolar disorder, OCD, autism spectrum disorder) showed significant associations individually, participants with insomnia had a markedly higher total burden of psychiatric diagnoses (median = 3 vs. 0; $p < 0.000000001$). No association was found between insomnia and total ADHD symptom scores or stimulant use. However, stimulant use was significantly associated with increased nocturnal restlessness ($p < 0.001$), a possible subclinical sleep-related manifestation. A non-significant trend was observed between insomnia and more advanced years of residency ($p = 0.090$).

Conclusions: Insomnia in medical residents is strongly associated with psychiatric comorbidity burden, particularly anxiety and depression. While not directly related to ADHD symptoms or stimulant use, restlessness in stimulant users may reflect subtle sleep disruption. These findings suggest insomnia as a clinical marker of psychological vulnerability in this population, with potential implications for mental health screening and support strategies during specialty training.

Rumination and Pre-sleep Arousal: The mediation role of attentional styles in adults with insomnia disorders

T.H.A. Su¹, C.X. Chen¹, M. Zhou¹, W.I. Ao¹, S.X. Li^{2,3}, J.W.Y. Chan¹, Y.K. Wing^{1,4}, N.Y. Chan¹

¹Li Chiu Kong Family Sleep Assessment Unit, The Chinese University of Hong Kong, Department of Psychiatry, Hong Kong, Hong Kong, SAR of China, ²Sleep Research Clinic and Laboratory, The University of Hong Kong, Department of Psychology, Hong Kong, Hong Kong, SAR of China, ³The State Key Laboratory of Brain and Cognitive Sciences, The University of Hong Kong, Hong Kong, Hong Kong, SAR of China, ⁴Li Ka Shing Institute of Health Sciences, Faculty of Medicine, The Chinese University of Hong Kong, Hong Kong, Hong Kong, SAR of China

Introduction: Rumination, as a cognitive activity, is a well-recognised risk factor of insomnia by triggering arousal and attention bias towards sleep-related threats. Previous studies suggested that individuals who ruminate at a higher level tend to have higher level of arousal before sleep and longer sleep-onset latency. Besides, both negative and positive information can induce arousal state and may impact sleep. However, there is limited evidence exploring how attentional styles for positive or negative information influence the association between rumination and arousal. The current study aims to investigate the potential mediating role of cognitive tendency focusing on positive or negative information between rumination and pre-sleep arousal.

Materials and methods: This was a cross-sectional study of the Hong Kong community-based sleep project. A total of 218 adults (mean age: 45.72 yrs $\pm$ 14.93; females: 76.6%) who met the DSM-V diagnostic criteria for insomnia disorder completed a battery of questionnaires including Pre-Sleep Arousal Scale (PSAS), Ruminative Response Scale (RRS) and Attention to Positive and Negative Information Scale (APNIS) for assessing hyperarousal before sleep, tendency to ruminate and cognitive tendency of focusing on positive (API) or negative information (ANI), respectively. Linear regression analysis was used to evaluate the association between rumination, attentional bias and pre-sleep arousal. Mediation analysis was performed to evaluate the influence of API/ANI on the association between rumination and pre-sleep arousal. Potential confounders included age, gender, education level and mental disorders were included as covariates in the analyses.

Results: The results indicated that women ($M=22.51$, $SD=6.11$) had a higher level of pre-sleep cognitive arousal than men ($M=20.47$, $SD=5.36$), $t(216)=2.13$, $p=0.03$. Regression analysis indicated that a greater tendency to engage in rumination and ANI was associated with both pre-sleep cognitive arousal (rumination: $B=0.27$, $SE=0.03$, 95% $CI=0.21-0.33$, $p<0.001$; ANI: $B=0.42$, $SE=0.07$, 95% $CI=0.29-0.55$, $p<0.001$) and somatic arousal (rumination: $B=0.23$, $SE=0.03$, 95% $CI=0.18-0.29$, $p<0.001$; ANI: $B=0.27$, $SE=0.06$, 95% $CI=0.15-0.38$, $p<0.001$). Rumination was positively associated with ANI ($B=0.25$, $SE=0.03$, 95% $CI=0.19-0.31$, $p<0.001$). Mediation analysis indicated that ANI partially mediated the association between rumination and pre-sleep cognitive arousal. The indirect effect from rumination to pre-sleep cognitive arousal through ANI was significant ($B=0.05$, $SE=0.02$, 95% $CI=0.02-0.10$), as well as the direct effect of rumination on pre-sleep cognitive arousal ($B=0.22$, $SE=0.04$, 95% $CI=0.14-0.29$, $p<0.001$), indicating that the relationship between rumination and pre-sleep cognitive arousal is

partially mediated by ANI. However, the indirect effect from rumination to pre-sleep somatic arousal through ANI was not significant. While for API, it did not play a role in the association between rumination and pre-sleep cognitive/somatic arousal.

Conclusions: The current findings revealed that a greater tendency to engage in rumination and predisposition to negative information could be risk factors that trigger cognitive arousal before sleep among people with insomnia. This suggests that interventions targeting reducing rumination and biased attention towards negative information could potentially help to reduce cognitive arousal and improve overall sleep quality.

Safety and Efficacy of Lemborexant in Indian Adult Patients with Insomnia: A Phase 4, Prospective, Multicenter, Real-World Study

G.P. Rao¹, M. Tripathi², S. Pangaonkar³, A. Yeole⁴, A. Rohtagi⁵, T. Mathew⁶, N. Shah⁷, B. Patil⁴, D. Dighe⁸

¹Asha Hospital, Hyderabad, India, ²Department of Neurology, All India Institute of Medical Sciences, New Delhi, India, ³Central Institute of Behavioral Sciences, Nagpur, India, ⁴Chopda Medicare & Research Centre Pvt. Ltd, Magnum Heart Institute, Nashik, India, ⁵Gangaram Hospital, New Delhi, India, ⁶Professor of Neurology, St. John's Medical College Hospital, Bangalore, India, ⁷Head of Department of Psychiatry, Lokmanya Tilak Municipal General Hospital and Lokmanya Tilak Municipal Medical College, Mumbai, India, ⁸Eisai Pharmaceuticals India Pvt Ltd, Mumbai, India

Introduction: Insomnia is characterized by difficulties with onset, and/or maintenance of sleep, and early morning awakening, causing impairment of daily activities. Lemborexant (LEM), a dual orexin receptor antagonist, is approved in several countries, including the US and India, for the treatment of adult patients with insomnia. This post-marketing surveillance study evaluated the safety, tolerability, and efficacy of LEM in Indian patients.

Materials and methods: Adults aged between 18-65 years with a clinical diagnosis of insomnia were enrolled in the study and treated with LEM 5 or 10 mg as per the investigator's discretion. The study consisted of a screening period and a 6-month treatment period. The primary endpoint included assessment of safety in terms of the incidence of treatment-emergent adverse events (TEAEs) and discontinuations due to TEAEs. Efficacy was assessed using the Patient Global Impression – Insomnia (PGI-I) questionnaire. The data were summarized descriptively using SAS® Enterprise Guide® 7.1.

Results: In total, 110 patients were enrolled in this study. The mean ($\pm$ SD) age of patients was 45.27 $\pm$ 11.04 years, and most patients (56.3%) were males. The patients were treated with a dose of LEM 5 mg (n=106) or LEM 10 mg (n=4), and 103 patients received ≥ 1 dose of study drug. Overall, 39 (37.86%) patients experienced ≥ 1 TEAE, including 38 patients in the LEM 5 mg cohort and 1 patient in the LEM 10 mg cohort without any serious TEAEs. Among these, 13 (12.62%) patients reported TEAEs related to the study drug, including 12 patients in the LEM 5 mg and 1 patient in the LEM 10 mg cohort. The most frequently occurring TEAEs were headache (9 [8.74%]), somnolence (8 [7.77%]), pyrexia (6 [5.83%]), dizziness (5 [4.85%]), head discomfort, and cough (4 [3.88%], for each). Most TEAEs were of mild (27 [26.21%]) intensity, followed by moderate (10 [9.71%]) intensity, and only 2 (1.94%) patients reported severe TEAEs. A dose-dependent increase in the percentage of patients was observed, reporting "positive medication effect" at the end of 1 month (56.31%, 58/103 patients; LEM 5 mg group: 55/99 patients and LEM 10 mg group: 3/4 patients), 3 months (68.93%, 71/103 patients; LEM 5 mg group: 67/99 patients and LEM 10 mg group: 4/4 patients) and 6 months (72.82%, 75/103 patients; LEM 5 mg group: 71/99 patients and LEM 10 mg group: 3/4 patients) of treatment. A similar trend was observed for patients who reported that the study medication decreased time to fall asleep at the end of 1 month (59.22%, 61/103), 3 months (73.79%, 76/103), and 6 months (77.67%, 80/103) of the treatment. LEM increased total sleep time in 66.02% (68/103), 72.82% (75/103), and 79.1% (82/103) of patients at the end of 1 month, 3 months, and 6 months of treatment, respectively. Around 84.5% of patients mentioned that the strength of LEM prescribed was appropriate.

Conclusions: The current study provides real-world safety, tolerability, and efficacy data, showing that LEM treatment effectively addresses both sleep onset and sleep maintenance difficulties.

Sleep and cardiovascular parameters in women with different insomnia phenotypes: a cross-sectional study from EPISONO

I. Ishikura¹, J. Vallim¹, H. Hachul¹, S. Tufik¹, M.L. Andersen¹

¹Federal University of São Paulo, Psychobiology, Sao Paulo, Brazil

Introduction: Insomnia is twice as prevalent in women as in men. The repercussions of insomnia in women might be intensified by menopause, when female sexual hormones are low. It is well known that the cardiovascular risk in women is increased after menopause becoming similar to that observed in men; however, few studies have comprised the different phenotypes of insomnia in women before and after menopause. **Aims:** Investigate the sleep parameters of the polysomnography and cardiovascular factors in women with different phenotypes of insomnia in a Brazilian cohort.

Materials and methods: A total of 236 women (44.4±14.3 years, 37% on menopause) of the São Paulo Epidemiologic Sleep Study (EPISONO) 4th edition conducted in 2018 from São Paulo city, Brazil, were included in this study. They responded to an institutional women questionnaire to acquire information about menstrual cycle and menopause symptoms. The DSM-V was used to distribute participants with insomnia, according to the criteria of difficulty to initiate or maintain sleep, or wake up too early, accompanied by repercussions in daily routine. Full night polysomnography was used to obtain the total sleep duration (TSD) and other sleep parameters of the participants. Participants with insomnia were then distributed in 2 groups: insomnia with short sleep duration (when TSD was <6 hours - ISSD) and insomnia with normal sleep duration (when TSD was >6 hours - INSD). Women without insomnia were distributed in 2 groups: with TSD >6 hours (control) and with TSD <6 hours (sleep restricted). Sleep and cardiovascular parameters (total cholesterol and fractions, homocysteine, blood pressure) were evaluated for each group, controlling for age, body mass index and menopausal status.

Results: Our findings demonstrated that sleep efficiency was significantly lower in ISSD group compared to all the other groups. Sleep latency was significantly increased in ISSD compared to INSD and the control with TSD>6h groups. REM sleep was statistically decreased in ISSD and sleep restricted groups compared to control. Systolic and diastolic blood pressures were higher in ISSD and sleep restricted groups compared to INSD. Participants on menopause presented worse results compared to premenopausal condition in wake after sleep onset, sleep efficiency, wake duration, homocysteine levels, and total cholesterol and fractions.

Conclusions: Alterations in sleep efficiency were associated with insomnia, whereas sleep restriction with or without insomnia was related to REM sleep and higher blood pressure. Cardiovascular parameters were negatively associated with menopause, confirming the protective effect of female sexual hormones on cardiovascular risk.

Sleep and Subsequent Mental Disorders in Young Adults: A National Prospective Diagnostic Study

M. Hysing¹, A.G. Harvey², B. Sivertsen³

¹University of Bergen, Department of Psychosocial Science, Bergen, Norway, ²University of California, Berkeley, California, United States, ³Norwegian Institute of Public Health, Department of Health Promotion, Bergen, Norway

Introduction: Sleep disturbances are common among young adults and may represent a key risk factor for developing mental disorders. While prior research has established links between insomnia and depression, most studies have relied on screening tools, lacked diagnostic precision, or failed to distinguish among types of anxiety disorders. This study prospectively examined the associations between insomnia, sleep characteristics, and DSM-5 mental disorders over one year in a large national student cohort.

Materials and methods: This prospective cohort study linked data from the 2022 wave of the Students' Health and Wellbeing Study (SHoT) with follow-up diagnostic assessments using the Composite

International Diagnostic Interview (CIDI 5.0) in 2023. Participants were full-time Norwegian students aged 18–35 ($N = 53,362$), of whom 10,460 completed at least one CIDI diagnostic module. Sleep parameters in 2022 included insomnia (operationalized using DSM-5 criteria), sleep duration, sleep onset latency (SOL), and wake after sleep onset (WASO). Mental disorders assessed in 2023 included major depressive episode (MDE), generalized anxiety disorder (GAD), panic disorder, agoraphobia, specific phobia, and social anxiety disorder. Multivariable log-binomial regression models estimated relative risks (RR), adjusting for age, sex, baseline mental health (HSCL-25), delayed sleep-wake phase disorder (DSWPD), hypnotic medication use, and somatic illness.

Results:

Students with insomnia in 2022 had significantly increased risk of MDE ($RR = 3.50$; 95% CI: 3.18–3.84) and GAD ($RR = 2.82$; 95% CI: 2.55–3.12) in 2023. Elevated risks were also observed for panic disorder ($RR = 2.66$), agoraphobia ($RR = 2.61$), social anxiety disorder ($RR = 2.23$), and specific phobia ($RR = 1.88$). Short sleep duration showed a reversed J-shaped association with mental health: students sleeping <5 hours had the highest risk for MDE ($RR = 3.28$) and GAD ($RR = 2.85$), with elevated risks also observed for 5–6 and 6–7 hour sleepers. Long sleep duration (>9 hours) was also linked to increased risk, though to a lesser extent. Longer sleep onset latency and greater WASO showed robust, graded associations with subsequent mental disorders. For example, students with $SOL \geq 120$ minutes had a 5.66-fold increased risk of MDE compared to those with $SOL < 15$ minutes. Similar dose-response patterns were seen for GAD, panic disorder, and social anxiety disorder. After adjusting for baseline symptoms and covariates, these associations remained significant, though attenuated, indicating the independent predictive value of poor sleep on future mental health.

Conclusions: This study provides strong prospective evidence that sleep disturbances—including insomnia, short or long sleep duration, long SOL, and increased WASO—predict a range of DSM-5 mental disorders in young adults. The findings underscore the importance of early detection and intervention for sleep problems to prevent the development of depression and anxiety. Sleep should be prioritized in student mental health strategies as both a transdiagnostic risk factor and a potential intervention target.

Sleep Architecture and Neurocognitive Performance in Insomnia Comorbid Obstructive Sleep Apnea Patients

Y. Wei¹, C.X. Chen¹, M. Zhou¹, W.I. Ao¹, J.W.Y. Chan¹, Y.K. Wing^{1,2}, N.Y. Chan¹

¹Li Chiu Kong Family Sleep Assessment Unit, Department of Psychiatry, The Chinese University of Hong Kong, Shatin, Hong Kong, SAR of China, ²Li Ka Shing Institute of Health Sciences, Faculty of Medicine, The Chinese University of Hong Kong, Shatin, Hong Kong, SAR of China

Introduction: Insomnia and obstructive sleep apnea (OSA) are the two most prevalent sleep disorders. Approximately 30% of individuals with insomnia also meet the diagnostic criteria for OSA, forming a comorbid condition known as Comorbid Insomnia and Sleep Apnea (COMISA). This co-occurrence could lead to elevated risk of disrupted nocturnal sleep, impaired daytime and cognitive function compared to the individual condition. However, few have examined the negative consequences of COMISA using objective cognitive measures. This study aimed to examine the differences in sleep architecture and neurocognitive functions between COMISA and insomnia-only patients, and to investigate whether COMISA is associated with greater sleep and cognitive impairment.

Materials and methods: Participants who met DSM-V criteria for chronic insomnia were included in this study. All participants underwent one night of home-based polysomnography (PSG) and performed a battery of neurocognitive tests including Psychomotor Vigilance Task (PVT), Balloon Analogue Risk Task (BART), Go/No-Go, and N-back tasks (0-, 1-, and 2-back) to assess vigilance, impulse control, and working memory, respectively. OSA was defined as an apnea-hypopnea index (AHI) ≥ 15 events/hour. Daytime sleepiness and fatigue were assessed using the Epworth Sleepiness Scale and the Multidimensional Fatigue Inventory. Group comparisons between COMISA and insomnia-only participants were conducted using independent t-tests or Mann-Whitney U tests, wherever appropriate. Mean reaction time for the PVT, Go/No-Go, and N-back were further analyzed using generalized linear models with a gamma distribution and log link, adjusting for age, gender, and BMI.

Results: A total of 147 adults (mean age: 46.2 ± 14.81 years, males: 21.77%) were recruited in Hong Kong. Thirty participants were classified as COMISA and 117 as Insomnia-only. Compared to the insomnia-only group, COMISA participants were older, had higher BMI, were more likely to be male, and reported significantly greater daytime sleepiness (12.30 ± 3.99 vs. 10.15 ± 4.49 ; $P = 0.018$) but not daytime fatigue. PSG-derived data revealed that the COMISA group had significantly higher oxygen desaturation index, total arousal count, and REM arousal index ($P < 0.005$), but no differences in total sleep time, sleep onset latency, sleep efficiency, or wake after sleep onset. For the neurocognitive performance, COMISA participants exhibited slower reaction time on the PVT (459.02 ± 163.95 vs. 397.64 ± 95.32 ms; $P = 0.047$), Go/No-Go (522.52 ± 74.67 vs. 473.35 ± 71.56 ms; $P = 0.001$), and N-back (570.84 ± 65.46 vs. 528.56 ± 83.85 ms; $P = 0.004$) tasks, with no group differences in error rates. After adjusting for age, gender, and BMI, COMISA participants showed longer mean reaction time on both the 1-back ($B = 0.077$, 95% CI: 0.015–0.139; $P = 0.016$) and 2-back ($B = 0.083$, 95% CI: 0.016–0.150; $P = 0.015$) conditions.

Conclusions: Individuals with COMISA reported greater daytime sleepiness but not higher levels of fatigue compared to those with insomnia alone. Although there was no difference in sleep architecture, COMISA exhibited impairments in vigilance and attention, particularly under higher cognitive load. These findings highlight the need for targeted screening and cognitive monitoring in this high-risk subgroup.

Sleep Architecture and REM Sleep Without Atonia in Post-COVID-19 Insomnia

A. Ibrahim¹, M. Cesari¹, Q. Tang¹, M.A. Süzgün¹, E. Brandauer¹, E. Holzknecht¹, A. Wachter¹, V. Anselmi¹, A. Heidebreder², A. Stefani¹, B. Högl¹

¹Medical University of Innsbruck, Neurology, Innsbruck, Austria, ²Johannes Kepler University Linz, Neurology, Linz, Austria

Introduction: Insomnia associated with COVID-19 infection is a common complaint in long-COVID. Studies to date have predominantly examined post-COVID-19 sleep disturbances with questionnaires. We aimed to investigate whether there are distinctive polysomnographic findings in post-COVID-19 insomnia compared to non-COVID-related chronic insomnia.

Materials and methods: We included 150 patients with chronic insomnia, stratified into three groups: post-COVID-19 insomnia, chronic insomnia during the pandemic without a history of COVID-19 infection, and pre-pandemic chronic insomnia. All patients underwent one-night video polysomnography (v-PSG). The sleep architecture, respiratory variables and REM sleep without atonia (RWA) were compared across the groups.

Results: Classical polysomnographic variables showed no significant differences across groups with regard to total sleep time, sleep efficiency, sleep stage percentages, and the apnea-hypopnea index. Post-COVID-19 insomnia patients had significantly increased RWA at both the chin and the flexor digitorum superficialis (FDS) ($p = 0.020$ for both), and higher nocturnal heart rates ($p = 0.046$). Sleep-bout analysis indicated shorter sustained N3-sleep periods ($p = 0.001$) and longer onset to stable REM-sleep ($p = 0.016$) in the post-COVID-19 insomnia group. Although sleep transitions did not withstand multiple comparison corrections, they revealed a trend towards decreased N3-sleep continuity and increased probabilities of transitioning to lighter stages (N3→N3: unadjusted- $p = 0.012$; REM→N1: unadjusted- $p = 0.027$) in the post-COVID-19 insomnia.

Conclusions: Classical PSG profile of post-COVID-19 insomnia does not differ from non-COVID-related chronic insomnia. However, subtle differences in RWA and sleep integrity suggest that post-COVID-19 insomnia is driven not merely by pandemic-related stress factors but by additional physiological alterations linked to viral CNS involvement.

Sleep Diary Entry Time can be a Predictive Marker for Digital CBT-I outcome: Post-hoc Analysis from Two Digital CBT-I Trials

Y. Lee¹, E. Lee²

¹WELT corp, Clinical, Seoul, Korea, Republic of, ²Yonsei University College of Medicine, Department of Psychiatry and the Institute of Behavioral Science in Medicine, Seoul, Korea, Republic of

Introduction: Digital Cognitive Behavioral Therapy for Insomnia (dCBT-I) have the potential for personalized and tailored therapy. WELT-IP is an dCBT-I designed to improve insomnia symptoms remotely through mobile application. Data such as sleep diary entry time, recommended time-in-bed (r-TIB) compliance, and lesson compliance are collected to create database for future algorithms. These data could be predictive markers used to tailor personalized user experience (UX), especially on the first week of usage.

Materials and methods: Eligible participants were adults (19-65) with a primary diagnosis of chronic insomnia (DSM-5). Major assessments such as Insomnia Severity Index (ISI) were performed at baseline and post-treatment (7-weeks). Daily sleep diary was collected using a participant-recorded electronic diary via WELT-IP for at least 7 weeks. The post-hoc analysis of two pivotal trials (n=120) was performed using the initial seven sleep diaries. Sleep diary entry time was recorded at the minute level, and the average time of [entry time - time out of bed] was calculated for the initial seven sleep diaries.

Results: A total of 55 (full analysis data set of WELT-IP group) participant data was included in the analysis. Multivariate regression was used to analyze the strength of the relationship between the predictor and response. The improvement of ISI was used as response. Diary entry time had correlation of 0.41 (R² value) with $p < 0.0001$. As the patient enters the sleep diary 0.08 seconds earlier, endpoint ISI decreased by 1 unit ($p < 0.0001$).

Conclusions: This analysis shows some new insights into potential predictive markers of dCBT-I based on user's data input patterns and compliance. First week's sleep diary entry time can be a predictive marker for dCBT-I outcome. Specifically, the more the participant showed willingness in completing sleep diary right after awakening, the higher the correlation for increase in ISI. This can be utilized in designing patient experience in the first few weeks of app which could induce increased patient outcome.

Sleep features and cognitive arousal in relation to insomnia and depression among adolescents – A case-control study

H.F. Sit¹, Y.L. Wong¹, R. Wang¹, X. Li¹, J.W.Y. Chan², K.S.C. Shea², R.N.Y. Chan², Y.K. Wing², S.X. Li^{1,3}

¹The University of Hong Kong, Sleep Research Clinic & Laboratory, Department of Psychology, Hong Kong, Hong Kong, SAR of China, ²The Chinese University of Hong Kong, Li Chiu Kong Family Sleep Assessment Unit, Department of Psychiatry, Faculty of Medicine, Hong Kong, Hong Kong, SAR of China, ³The University of Hong Kong, The State Key Laboratory of Brain and Cognitive Sciences, Hong Kong, Hong Kong, SAR of China

Introduction: Insomnia and depression often coexist and are both common in adolescents. Previous studies have primarily examined sleep characteristics and pathophysiology separately for insomnia and depression in the adult population. Evidence has shown an association of cognitive hyperarousal with insomnia and depression, respectively. However, little is known about sleep alterations and underlying mechanisms in insomnia and depression, as well as their comorbidity among adolescents. The current study examined sleep characteristics and cognitive arousal in relation to insomnia and depression in adolescents.

Materials and methods: A total of 117 adolescents (mean age: 17.3 years, SD = 2.0, 55.0% female), including 29 adolescents with comorbid insomnia and depression (CO), 28 with insomnia alone (ID), 28 with depression alone (DD), and 32 healthy controls (HC) were recruited. DSM-5 criteria were used to determine depression and insomnia. All participants underwent a clinical interview to ascertain their eligibility and completed self-report questionnaires to assess insomnia, depression, depressive rumination as measured by the Ruminative Response Scale (RRS), sleep-focused rumination as measured by the Daytime Insomnia Symptom Response Scale (DISRS), pre-sleep somatic and cognitive arousal, as measured by the Pre-sleep Arousal Scale, 7-day wrist actigraphy and Sleep Diary, and a two-night laboratory-based polysomnographic assessment, with the first night serving as the adaptation night.

Results: Compared to HC, CO and DD showed higher levels of depressive rumination, sleep-focused rumination, and pre-sleep somatic and cognitive arousal, and ID only showed higher levels of sleep-focused rumination, and pre-sleep somatic and cognitive arousal. Compared to the ID group, those in the CO group showed elevated levels of depressive and sleep-focused rumination and pre-sleep

cognitive and somatic arousal. Additionally, DD group showed a higher level of depressive rumination than ID group, and a lower level of pre-sleep cognitive arousal than the CO group. In terms of subjective sleep parameters as measured by sleep diary, DD group reported shorter total sleep time (TST) than HC group, while ID group reported longer sleep onset latency (SOL) than HC and those with DD. Similarly, CO group reported longer SOL than HC and DD. In terms of objective sleep parameters measured by actigraphy, adolescents with ID exhibited longer SOL than those with DD. For objective sleep parameters measured by polysomnography, participants with DD exhibited shorter SOL than healthy controls. There were no significant differences in other macro-sleep features and REM-related variables across groups.

Conclusions: Insomnia is manifested with prolonged subjective and objective SOL and elevated sleep-focused rumination, while depression is associated with shorter subjective TST with elevated depressive rumination, and the comorbidity of insomnia and depression is linked to prolonged subjective SOL with elevated pre-sleep arousal and rumination. Tailored intervention strategies that address these factors may improve treatment outcomes for the respective groups.

Sleep psychoeducation strategies for patients with chronic migraine and sleep quality complaints

A. Zanatta¹, D.d.G. Andreis², M.L.F. Rodrigues², I.J.M. Marchioro³, P.A. Kowacs⁴

¹Clinica Hospital-Federal University of Paraná, Internal Medicine, Curitiba, Brazil, ²Federal University of Paraná, Internal Medicine, Curitiba, Brazil, ³Clinical Hospital- Federal University of Paraná, Internal Medicine, Curitiba, Brazil, ⁴Clinical Hospital-Federal University of Paraná, Internal Medicine, Curitiba, Brazil

Introduction: Chronic migraine is a prevalent and debilitating condition, significantly associated with sleep disorders, particularly insomnia. Given the importance of the topic and the increasing use of non-pharmacological approaches in treating insomnia, this study aimed to evaluate the impact of sleep psychoeducation measures on the clinical aspects of migraine in chronic migraine sufferers with sleep quality complaints.

Materials and methods: Patients from the headache outpatient clinic of the Neurology Service at CHC-UFPR were screened using a standardized questionnaire developed by the service. The intervention group included 68 chronic migraine sufferers with sleep disturbance complaints, who answered the following questionnaires: Pittsburgh Sleep Quality Index (PSQI), Epworth Sleepiness Scale (ESS), and Insomnia Severity Index (ISI). A detailed history of sleep-related habits was taken, and sleep psychoeducation guidelines were provided, supported by an informative booklet with key recommendations, where specific guidelines for each patient were noted. The control group consisted of 32 chronic migraine patients with no complaints of sleep disorders. In a third phase, two to three months after the intervention, the scales and questionnaires were reapplied, and data from medical records were collected to assess changes in the intensity and frequency of migraine and sleep quality.

Results: showed that in the control group, there was no statistically significant variation in the frequency and intensity of headaches. However, in the intervention group, there was a statistically significant reduction in both the intensity and frequency of pain. Regarding clinical characteristics of sleep disturbance, the intervention group showed a statistically significant reduction in the PSQI (from an average of 13.7 to 11.7) and the ISI (from 18.5 to 13.4), but there was no statistically significant variation in the ESS.

Conclusions: Sleep psychoeducation, supported by an informative booklet, led to positive results not only in sleep but also in the reduction of the intensity and frequency of headaches in chronic migraine sufferers.

Sleep-Related Symptoms and Fatigue in Children with Long-Covid: Analyses of the RECOVER Longitudinal Cohort Study

A. Chung¹, S. Basu¹, R. Gross², M. Stockwell³, J. Lu¹, A. Salisbury⁴, K. Tantisira⁵, R. Bhattacharjee⁶

¹NYU Grossman School of Medicine, New York, United States, ²University of Illinois Chicago, Chicago, United States, ³Columbia University, New York, United States, ⁴Virginia Commonwealth University, Richmond, United States, ⁵University of California San Diego, San Diego, United States, ⁶University of California San Diego, San Diego, United States

Introduction: Sleep disturbance is highly prevalent in individuals diagnosed with post acute sequelae after SARS-CoV-2 COVID19 (PASC) or long COVID (LC). The NIH-funded RECOVER-pediatric cohort longitudinally follows children and adolescents who have and have not been infected with SARS-CoV-2 including identifying those with probable LC. Participants ages 0-25 years have been enrolled from >100 sites across the country. In this sub-analysis, we seek to answer the following research questions: What is the precise phenotype of sleep disturbance in children with LC? and what individual characteristics predict LC-related sleep disturbance?

Materials and methods: In RECOVER, parents reported sleep-related symptoms among children and adolescents at enrollment. Measures included: composite sleep duration, trouble sleeping, nightmares, feeling sleepy and feeling tired. Logistic regression models were conducted to examine insomnia (e.g. trouble falling or staying asleep), hypersomnia (e.g. daytime tiredness), mixed type (insomnia and hypersomnia) and sleep duration based on status (uninfected, LC probable, LC unspecified). Analyses were stratified by age group (middle childhood, adolescent). Models were adjusted for sex, race, rural, and medically underserved. Healthy vs. unhealthy sleep was defined based on children who met the recommended hours of sleep by age.

Results: The study sample was nearly evenly split in gender across all age groups, and about half of the sample was white. Approximately one-third of the sample was medically underserved. Compared to uninfected, participants with probable LC had higher odds of insomnia and hypersomnia across both age groups compared to the uninfected groups, with significant differences in mixed sleep among adolescents only. Fully adjusted logistic regression models demonstrate higher odds of insomnia in middle childhood (aOR 31.4 (95%CI 9.49- 125) and adolescents (aOR 28.6 (95%CI 18.8- 44.1) among LC-probable compared to the uninfected reference group; and hypersomnia 31.5 aOR (8.09 to 172) in middle childhood and 33.5 aOR (21.9 to 51.6) adolescence among PASC probable compared to the uninfected reference group, respectively. Mixed sleep type reported 32.6 aOR (20.3 to 53.1) among PASC probable compared to the uninfected reference group. An interaction of sex with PASC on insomnia, and an interaction of race on sleep duration with PASC in adolescents only, were also reported. An interaction with sex trended with mixed sleep disorder in adolescents as well (p=0.07).

Conclusions: We have identified important sleep phenotypes for children and adolescence demonstrating clear sleep disturbance in those with probable LC. Future research will examine sleep phenotypes among infancy and early childhood, as well as socio-demographic predictors of sleep problems and PASC across the life course.

Sleep-wake state discrepancy is more pronounced in individuals with insomnia than those with obstructive sleep apnoea (OSA)

D.-B. Bensen-Boakes^{1,2}, G. Micic², D.P. Nguyen², L. Lack^{1,2}, R. Adams², A. Reynolds², J. Paterson¹, N. Lovato²

¹Flinders University, College of Education, Psychology, and Social Work, Bedford Park, Australia,

²Flinders Health and Medical Research Institute: Sleep Health (formerly Adelaide Institute for Sleep Health), Bedford Park, Australia

Introduction: Sleep-wake state discrepancy (SWSD) is the difference between self-reported and polysomnography-derived sleep parameter values. Individuals experiencing insomnia often report less total sleep time (TST) and greater sleep onset latency (SOL) than what is measured by polysomnography, which can contribute to greater SWSD. To better understand the clinical presentation and management of this phenomenon, it would be beneficial to understand sleep disorder specific presentations of SWSD. This study examines whether sleep-wake state discrepancy presents differently between individuals with insomnia versus obstructive sleep apnoea (OSA).

Materials and methods: Data presented is from an ongoing study in a clinical setting. All participants (N = 79) completed diagnostic in-laboratory (Level 1) or ambulatory polysomnography (Level 2) sleep studies and next-morning self-report sleep diaries. SWSD was calculated for SOL, wake after sleep onset (WASO), and TST by subtracting polysomnography-derived values from sleep diary-derived

values. We had two groups: insomnia-alone with no significant OSA (determined by Apnoea-Hypopnoea Index (AHI) <15h/h, and Insomnia Severity Index (ISI) >15), and OSA-alone (determined by AHI > 15h/h, and ISI <15). Forty-eight participants (age M = 49, SD = 18, 56.3% female, 43.7% male) had insomnia, and thirty-one had moderate to severe sleep apnoea without insomnia (age M = 53, SD = 13, 29% female, 71% male). SWSD scores are presented as: (Median minutes (Inter Quartile Range)). Kruskal-Wallis H-test assessed between group differences.

Results: For SOL, the group with insomnia-alone (13mins(44)) reported greater SWSD compared to the group with OSA-alone (-1.5mins(38)); ($X^2(1) = 6.712$, $p .01$), mean rank scores: 45.38 (insomnia-alone), 31.68 (OSA-alone). For WASO, the group with OSA-alone (-49mins(79)) reported greater SWSD compared to the group with insomnia-alone (-5mins(49)); ($X^2(1) = 10.28$, $p .001$), mean rank scores: 46.65 (insomnia-alone), 29.71 (OSA-alone). For TST, there was a significant difference in SWSD between the groups, though in opposite directions: insomnia-alone (-21mins(78)), OSA-alone (51mins(94)); ($X^2(1) = 15.256$, $p <.001$), mean rank scores: 31.9 (Insomnia-group), 52.55 (OSA-group).

Conclusions: Individuals with insomnia self-reported worse SWSD for SOL and TST compared to polysomnography, whereas individuals with OSA self-reported better sleep for WASO and TST than polysomnography. This suggests that SWSD profiles are likely to differ across sleep disorders. Therefore, it is recommended that focusing on SWSD in individuals with insomnia may be more fruitful than when working with individuals with OSA-alone. Future investigations should explore specific treatment considerations regarding SWSD in co-occurring insomnia and significant OSA, and sex differences should be considered.

Acknowledgments: Our colleagues and peers at The Flinders Health and Medical Research Institute: Sleep Health (formerly Adelaide Institute for Sleep Health), all participants, clinicians, physicians, and technicians involved in the assessment and/or treatment process.

Sober sleep? Cognitive behavioral therapy for insomnia across the spectrum of alcohol use disorder

C. Türkmen¹, C.L. Schneider², W. Viechtbauer³, I. Bolstad⁴, S. Chakravorty⁵, M.B. Miller⁶, H. Kallestad¹, G.W. Angenete⁷, A.F. Johann^{8,9}, B. Feige⁸, K. Spiegelhalder⁸, D. Riemann⁸, Ø. Vedaa¹⁰, S. Pallesen¹¹, E. Hertenstein²

¹St. Olavs Hospital, Clinics of Mental Healthcare, Department of Research and Development, Trondheim, Norway, ²University of Geneva, Department of Psychiatry, Geneva, Switzerland, ³Maastricht University, Department of Psychiatry and Neuropsychology, Maastricht, Netherlands, ⁴University of Inland Norway, Faculty of Social and Health Sciences, Elverum, Norway, ⁵University of Pennsylvania, Department of Psychiatry, Philadelphia, United States, ⁶University of Missouri, Department of Psychiatry and Psychological Sciences, Columbia, United States, ⁷Norwegian University of Science and Technology, Department of Mental Health, Trondheim, Norway, ⁸University of Freiburg, Department of Psychiatry and Psychotherapy, Freiburg, Germany, ⁹University of Freiburg, Institute of Medical Psychology and Medical Sociology, Faculty of Medicine, Freiburg, Germany, ¹⁰Norwegian Institute of Public Health, Department of Health Promotion, Bergen, Norway, ¹¹University of Bergen, Department of Psychosocial Science, Bergen, Norway

Introduction: Comorbid insomnia is a common challenge among individuals with alcohol use disorder (AUD), increasing the risk of relapse and undermining treatment success. While cognitive behavioral therapy for insomnia (CBT-I) is the first-line treatment for chronic insomnia, its effectiveness within the context of AUD has not been well characterized. The aim of this meta-analysis was to quantify the effects of CBT-I on insomnia severity and alcohol-related outcomes in samples ranging from heavy-drinking individuals to those with severe AUD.

Materials and methods: A systematic search was conducted in MEDLINE, Cochrane Library, PsycINFO, and ClinicalTrials.gov for randomized controlled trials (RCTs) published from 1980 through February 2024. RCTs comparing CBT-I to control conditions among adults (≥ 18 years) with heavy drinking or AUD and comorbid insomnia were included. Two reviewers independently extracted data and assessed risk of bias using the Risk of Bias 2 tool. The primary outcome was insomnia severity, measured using the Insomnia Severity Index (ISI). Secondary outcomes included alcohol craving, alcohol-related psychosocial problems, and the number of heavy-drinking and abstinent days. All outcomes were evaluated at post-treatment and follow-ups. Multilevel meta-analyses were conducted to estimate mean differences for all outcomes, except for heavy-drinking and abstinent days, which were analyzed using incidence rate ratios.

Results: Eight RCTs involving 426 adults (68.78 % men) were included. Compared with control conditions, CBT-I resulted in a significant reduction in insomnia severity post-treatment [estimated ISI reduction = -5.51, 95% CI (-7.13 to -3.90)], with improvements maintained at 1-to-3-month [7 studies; estimate = -4.39, 95% CI (-6.08 to -2.70)] and 6-month follow-up [4 studies; estimate = -4.55, 95% CI (-6.77 to -2.33)]. No significant differences emerged for alcohol-related outcomes, which were inconsistently reported across studies. The included trials were judged as having low or moderate overall risk of bias for all outcomes.

Conclusions: CBT-I is effective in reducing insomnia severity in heavy-drinking and AUD samples, with sustained beneficial effects following treatment. These findings support its wide implementation in AUD prevention and treatment settings.

Social isolation and risk of insomnia: A cohort and Mendelian randomization study

Q. Wu¹, Y. Nie¹, Y. Chen², S. Guo¹, J. Zhang¹, Y. Liang¹

¹The Affiliated Brain Hospital, Guangzhou Medical University, Center for Sleep and Circadian Medicine, Guangzhou, China, ²The University of British Columbia, Department of Psychology, Vancouver, Canada

Introduction: Social isolation (SI) has been linked to various mental and behavioral disorders, including depression, anxiety, and schizophrenia. However, the causal relationship between SI and insomnia remains unclear. This study aimed to examine both the observational and genetic causal associations between SI and the risk of insomnia.

Materials and methods: This study utilized data from the UK Biobank, a large prospective cohort comprising over 500,000 participants aged 40–70 years, recruited between 2006 and 2010. SI was defined based on three components: number of household members, frequency of contact with others, and engagement in social activities. The primary outcome was incident insomnia, identified through hospitalization records and death registries in the UK Biobank. Cox proportional hazards models were used to assess associations between SI and incident insomnia. Additionally, bidirectional causal associations between genetic liability to SI and insomnia were examined using two-sample Mendelian randomization (MR). Genetic instruments were derived from the UK Biobank, and insomnia GWAS summary statistics were obtained from the European Bioinformatics Institute (EBI) and the FinnGen consortium (Round 12). Meta-analyses and sensitivity tests (MR-Egger, MR-PRESSO, and Cochran's Q) were conducted to validate causal estimates.

Results: Among the 489,741 participants (mean age 56.5±8.1 years; 54.5% female), 559 incident cases of insomnia were documented during a median follow-up of 12.7 years. SI was significantly associated with an increased risk of insomnia (HR = 1.56, 95% CI: 1.27-1.91). Each component of SI was also significantly associated with insomnia: living alone (HR = 1.36, 95% CI: 1.12-1.64), little contact with family/friends (HR = 1.25, 95% CI: 1.02-1.51), and fewer leisure/social activities (HR = 1.21, 95% CI: 1.01-1.44). These associations remained significant after adjusting for demographic, socioeconomic, and lifestyle factors. MR meta-analyses revealed no causal effect of overall SI on insomnia (OR = 0.73, 95% CI: 0.21-2.58), but identified potential causal effects of little contact with family/friends (OR = 1.14, 95% CI: 1.01-1.28) and fewer leisure/social activities (OR = 1.38, 95% CI: 1.03-1.85). Living alone showed no evidence of a causal association (OR = 1.00, 95% CI: 0.71-1.40). Bidirectional MR analyses found no evidence of a causal effect of insomnia on SI or its components. All sensitivity analyses supported the robustness of these findings.

Conclusions: Social isolation is a significant risk factor for insomnia. Among its components, little contact with family or friends and limited participation in leisure or social activities may be causal risk factors. These findings highlight the importance of promoting social engagement—particularly maintaining interpersonal connections and active participation in social life—as a potential strategy to prevent insomnia and improve sleep health.

Acknowledgments: This research used data from the UK Biobank (Application 58082) and GWAS consortia (EBI and FinnGen). We thank all UK Biobank participants and staff, as well as the researchers from EBI and FinnGen for making their GWAS data publicly available.

Student Sleep Across the Pandemic: Longitudinal Trends in Sleep Behavior and Sleep Problems Before, During, and After COVID-19 (2010–2023)

B. Sivertsen¹, A.G. Harvey², S. Pallesen³, Ø. Vedaa¹, M. Hysing³

¹Norwegian Institute of Public Health, Department of Health Promotion, Bergen, Norway, ²University of California, Berkeley, California, United States, ³University of Bergen, Department of Psychosocial Science, Bergen, Norway

Introduction: Sleep problems—including insomnia and difficulties initiating and maintaining sleep (DIMS)—are increasingly reported among university students. While the short-term sleep effects of the COVID-19 pandemic are well described, long-term trends in sleep problems and behaviors across the pre-, peri-, and post-pandemic periods remain insufficiently studied in this vulnerable population.

Materials and methods:

We used data from the Students' Health and Wellbeing Study (SHoT), a national survey conducted in 2010, 2014, 2018, 2021, 2022, and 2023 among full-time Norwegian students (N ≈ 200,000). DIMS was assessed in all waves using one item from the Hopkins Symptom Checklist-25 (HSCL-25) asking about difficulty falling or staying asleep over the past two weeks. Responses ranged from "Not at all" to "Extremely," with DIMS defined as reporting "Quite a bit" or "Extremely." In 2018, 2021, and 2022, additional self-reported sleep measures were collected: weekday bedtime, risetime, sleep onset latency (SOL), wake after sleep onset (WASO), and time in bed (TIB). Sleep duration was defined as TIB minus SOL and WASO. Sleep efficiency was calculated as (sleep duration ÷ TIB) × 100. DSM-5 insomnia disorder was operationalized using three criteria: (1) difficulties initiating, maintaining, or early morning awakening ≥3 nights/week; (2) daytime fatigue ≥3 days/week; and (3) sleep problems lasting ≥3 months. Analyses were stratified by sex and year, with 95% confidence intervals.

Results:

DIMS prevalence increased consistently from 2010 through 2023, with the highest levels observed in the most recent wave. Among women, it increased from 23.8% in 2010 to 32.4% in 2018, reached 34.1% in 2021, remained elevated at 32.8% in 2022, and climbed further to 38.3% in 2023—the highest level recorded. Among men, prevalence rose from 20.3% in 2010 to 26.2% in 2018, peaked at 32.4% in 2021, declined slightly to 28.4% in 2022, and increased again to 32.2% in 2023. DSM-5 insomnia symptoms followed a similar trend, rising from 2018 to 2021, with only partial improvement observed in 2022. From 2018 to 2021, sleep onset latency (SOL) increased from 50 to 59 minutes in women and from 43 to 54 minutes in men, followed by a modest decline in 2022 (51 and 46 minutes, respectively). WASO also rose across the period. Sleep efficiency decreased from 86.9% (2018) to 85.4% (2021) in women and from 88.6% to 86.7% in men, with slight improvement in 2022 (86.2% in women; 87.5% in men). Despite an increase in time in bed during the pandemic, mean sleep duration remained stable: 7h25 (2018), 7h32 (2021), and 7h27 (2022) in women; 7h24 across all years in men. Bedtime and risetime were delayed in 2021 and partially reverted toward pre-pandemic patterns in 2022.

Conclusions: Sleep problems and insomnia symptoms have increased markedly among university students since 2010, with pronounced peaks during the COVID-19 pandemic. While some indicators improved post-pandemic, 2023 DIMS levels were the highest recorded. These trends highlight the ongoing need for longitudinal sleep monitoring and targeted interventions to address persistent sleep challenges in student populations.

Study on the change of autonomic nerve function and insomnia disorder comorbid with diabetes mellitus

L. Cai¹, L. Zhu², Z. Wang¹

¹The first hospital of Jilin University, Changchun, China, ²Changchun Chaoyang District People's Hospital, Changchun, China

Introduction: This study aimed to assess changes in autonomic nervous function in patients with insomnia disorder comorbid with diabetes mellitus, explore its underlying pathological mechanisms, and provide a basis for the clinical diagnosis and treatment of these patients.

Materials and methods: A total of 120 participants were enrolled in this study and assigned to four groups: a comorbid insomnia and diabetes mellitus group, an insomnia disorder group, a diabetes mellitus group, and a healthy control group, with 30 participants in each group. Autonomic nervous function was assessed using heart rate variability (HRV) and the SCOPA-AUT scale, while sleep status was evaluated using the Insomnia Severity Index (ISI), Pittsburgh Sleep Quality Index (PSQI), Patient Health Questionnaire-9 (PHQ-9), Hospital Anxiety and Depression Scale (HADS), and sleep diaries. Additionally, postprandial blood glucose, glycated hemoglobin (HbA1c), and both fasting and postprandial islet function indicators were recorded. These metabolic parameters were subsequently included in the comprehensive analysis of intergroup differences in autonomic nervous function.

Results: The SCOPA-AUT scores for gastrointestinal, urinary, cardiovascular, and pupil regulation systems were significantly higher in the insomnia and diabetes comorbidity group compared to the insomnia disorder group, the diabetes group, and the normal control group ($P < 0.05$). However, no significant differences were found in the thermoregulatory and sexual functioning systems ($p > 0.05$). Analysis of HRV time-domain indices revealed that the mean heart rate (MeanHR) was significantly higher in the insomnia and diabetes comorbidity group compared to the insomnia group ($p < 0.05$). Analysis of HRV frequency-domain indices showed that the insomnia and diabetes comorbidity group had significantly increased low-frequency (LF) power and LF/HF ratio, along with decreased high-frequency (HF) power, compared to the other groups (all $p < 0.05$). Univariate linear regression analysis revealed that sex, duration of insomnia, fasting blood glucose, HbA1c, SCOPA-AUT score, and PSQI score were positively associated with sympathetic nervous activity, while gender and PSQI score were significantly associated with parasympathetic nervous activity.

Conclusions: Patients with comorbid insomnia and diabetes mellitus show significant autonomic dysfunction, marked by increased sympathetic activity and reduced parasympathetic activity. A possible synergistic interaction between sleep disturbances and diabetes-related metabolic abnormalities may contribute to the onset of autonomic dysregulation.

Subtyping and Prognosis of Insomnia Disorder Based on Clinical, Psychological, and Sleep EEG Features

D. Lyu¹, Y. Wang¹, C. Ji¹, J. Zhang¹, R. Qian¹, Y. Liu¹, T. Zhang¹, Y. Leng², Z. Xiao¹, C. Yuan¹

¹Shanghai Mental Health Center, Department of Sleep Disorders, Shanghai, China, ²University of California, San Francisco, Department of Psychiatry and Behavioral Sciences, San Francisco, United States

Introduction: Insomnia disorder (ID) is a clinically heterogeneous condition, limiting the effectiveness of standardized interventions. This study applied data-driven approaches to identify ID subtypes based on clinical, psychological, and sleep EEG features, and to assess their distinct profiles and treatment outcomes.

Materials and methods: Subjects aged 18–65 years, meeting DSM-5 criteria for ID without other sleep disorders, were included. Comprehensive clinical and psychological evaluations and polysomnographic (PSG) monitoring were conducted to collect clinical, psychological, and sleep EEG features. Clinical features included the Pittsburgh Sleep Quality Index (PSQI), Hamilton Depression Rating Scale (HAMD), Hamilton Anxiety Rating Scale, and Multidimensional Fatigue Inventory (MFI); psychological characteristics included the Pre-Sleep Arousal Scale (PSAS), Dysfunctional Beliefs and Attitudes about Sleep Scale (DBAS), Sleep Hygiene Index (SHI), Perceived Stress Scale (PSS), among others; sleep EEG features encompassed sleep structure and continuity, spectral power, and sleep spindle measures. Equivalent doses of benzodiazepine receptor agonists (BzRA) and antidepressants were recorded. PSQI and HAMD scores at 8 weeks post-treatment were used as outcome measures.

Feature selection was performed using a normalized correlation matrix, followed by dimensionality reduction via Uniform Manifold Approximation and Projection (UMAP). K-means clustering was employed based on optimal parameters based on silhouette coefficients and neighborhood preservation. Analysis of variance (ANOVA) and Kruskal-Wallis tests were utilized to compare subtype differences in characteristics and clinical outcomes, with significance set at two-tailed $P < 0.05$.

Results: A total of 220 participants completed baseline assessments. Feature selection yielded 7 clinical features, 9 psychological characteristics, and 57 EEG metrics. Three distinct subtypes emerged from UMAP dimensionality reduction and K-means clustering:

Subtype 1, labeled "Deep Sleep Deficient Insomnia" (28.2%), had significantly older participants

($F=4.78$, $p=0.009$), highest depression severity ($F=11.19$, $p<0.001$), shortest duration of N3 slow-wave sleep ($F=6.27$, $p=0.002$), and higher NREM β -band total power ($H=24.40$, $p<0.001$). This subtype received the highest equivalent dosage of BzRA ($F=14.74$, $p<0.001$) and showed significantly poorer improvement in PSQI scores at 8 weeks compared to other subtypes, as well as significantly worse HAMD outcomes compared to subtype 3 ($F=8.47$, $p<0.001$).

Subtype 2, "Stress Related Insomnia" (32.3%), displayed notable clinical anxiety ($F=4.00$, $p=0.020$) and fatigue ($F=9.24$, $p<0.001$), along with the highest insomnia vulnerability ($F=4.30$, $p=0.015$), pre-sleep arousal ($F=14.62$, $p<0.001$), rumination ($F=7.40$, $p=0.001$), and sleep hygiene issues ($F=10.91$, $p<0.001$). EEG analysis revealed reduced δ -band total power compared to other subtypes ($H=12.63$, $p=0.002$). This subtype received moderate BzRA dosages and demonstrated better overall improvement in PSQI scores at 8 weeks than subtype 1.

Subtype 3, "Spindle Deficient Insomnia" (39.5%), presented mild insomnia severity ($F=5.63$, $p=0.004$), lowest perceived stress ($F=14.18$, $p<0.001$), increased micro-arousals ($F=3.532$, $p=0.031$), and reduced spindle activity ($H=66.55$, $p<0.001$). Subtype 3 patients received the lowest equivalent dosages of BzRA and antidepressants, achieving the best overall outcomes in both PSQI and HAMD at 8 weeks.

Conclusions: This study identified three data-driven subtypes of insomnia with distinct EEG and clinical profiles, which were predictive of treatment response. These findings highlight the potential of personalized, subtypes-based management strategies for insomnia disorder.

Acknowledgments: This study was supported by Shanghai Mental Health Center (2021-YJ12, 2021-QH-05).

Temporal Subtypes and Characteristics of Insomnia Treatment Responses

Y. Zhang¹

¹The Fourth Clinical Medical College of Zhejiang Chinese Medical University, Hangzhou, China

Introduction: This study aims to identify specific characteristics that can predict the treatment efficacy and onset time in patients with insomnia.

Materials and methods: A retrospective study was conducted on patients who visited the Sleep Disorders Clinic between January 1, 2016, and October 19, 2024 and underwent digital CBT-I. Data on demographic characteristics, Pittsburgh Sleep Quality Index (PSQI), Generalized Anxiety Disorder Scale (GAD-7), Patient Health Questionnaire (PHQ-9), Somatic Symptom Questionnaire (PHQ-15), Epworth Sleepiness Scale (ESS), and Eysenck Personality Questionnaire (EPQ) were collected. The PSQI score reduction rate was used as an indicator of treatment efficacy, where a reduction rate of more than 25% was generally considered effective. Since patients in this study underwent multiple assessments and exhibited varying degrees of treatment response, the average reduction rate was ultimately used to determine treatment effectiveness within this time dimension. Based on the time dimension, patients ($N=834$) were categorized into two groups: the early-response group (≤ 8 weeks) and the late-response group (> 8 weeks or non-responsive).

Results: The demographic characteristics and scale data of 834 patients indicated no significant differences between the two groups in terms of gender ($P=0.491$), family history of insomnia ($P=0.167$), and ESS score ($P=0.949$). However, significant differences were observed between the two groups in age ($P=0.005$), education level ($P<0.001$), duration of insomnia ($P<0.001$), GAD-7 score ($P=0.031$), PHQ-9 score ($P=0.044$), and neuroticism personality trait ($P=0.039$). The late-response group had a higher mean age, a lower education level, and a longer duration of insomnia than the early-response group. Additionally, the late-response group exhibited lower GAD-7, PHQ-9, and neuroticism personality trait scores compared to the early-response group. Multivariate logistic regression analysis indicated that higher education level (college or above), higher PHQ-9 and PHQ-15 scores, and a neuroticism personality trait were significant predictors of better treatment response and earlier onset of efficacy in insomnia patients. A longer duration of insomnia was identified as a risk factor for poor treatment response and delayed onset of efficacy.

Conclusions: Insomnia patients with higher education levels (college or above), higher PHQ-9 and PHQ-15 scores, and a neuroticism personality trait tend to have better treatment outcomes and an earlier onset of efficacy. Longer duration of insomnia, tend to experience poorer treatment outcomes and a delayed response to treatment.

The 2024 Canadian Recommendations for Chronic Insomnia Management: A Practical, Evidence-Based Consensus

A. Khullar¹, R. Robillard², A. Desautels^{3,4}, M.S.B. Mak^{5,6}, T.T. Dang-Vu^{7,8}, W. Chow⁹, J. Habert⁵, S. Lessard², L. Alima¹⁰, N.T. Ayas¹¹, J. MacFarlane⁵, T. Kendzerska^{2,12}, E.K. Lee¹³, C.E. Carney¹⁴, C.M. Morin¹⁵

¹University of Alberta, Edmonton, Canada, ²University of Ottawa, Ottawa, Canada, ³Hôpital du Sacré-Coeur de Montréal, Montreal, Canada, ⁴Université de Montréal, Montreal, Canada, ⁵University of Toronto, Toronto, Canada, ⁶Centre for Addiction & Mental Health, Toronto, Canada, ⁷Concordia University, Montreal, Canada, ⁸Institut Universitaire de Gériatrie de Montréal, Montreal, Canada, ⁹Private Practice, Victoria, Canada, ¹⁰Private Practice, Edmonton, Canada, ¹¹University of British Columbia, Vancouver, Canada, ¹²Ottawa Hospital Research Institute, Ottawa, Canada, ¹³Royal Ottawa Mental Health Centre, Ottawa, Canada, ¹⁴Toronto Metropolitan University, Toronto, Canada, ¹⁵Université Laval, Quebec City, Canada

Introduction: Chronic insomnia is a serious disorder that usually follows a persistent course and should be managed as a long-term condition. While some individuals may experience periods of improvement or remission, the long-term impact on mental, physical, and occupational health is significant and should not be underestimated. The 2024 Canadian consensus recommendations for chronic insomnia were developed to assist healthcare providers, especially in primary care, with evidence-based recommendation for diagnosis and long-term management.

Materials and methods: The guidelines were established by 16 Canadian experts in sleep medicine representing family physicians, neurologists, psychiatrists, psychologists, pharmacists, and clinical researchers. The Delphi process, a common methodology to reach consensus on complex problems, was used to refine and arrive at a set of evidence-based recommendations and address practical needs.

Results: Among the recommendations that reached consensus, the experts agreed that:

- Chronic insomnia is highly prevalent, approximately affecting 1 in 7 Canadians
- Healthcare providers should proactively screen for chronic insomnia by routinely asking simple sleep-related questions about difficulties falling or staying asleep and functioning during daytime.
- Insomnia should be assessed and treated independently, even when comorbid with other sleep, mental, or physical health conditions.
- Comorbidities may potentiate insomnia's effects on physical and mental health.
- Tools such as ISI, PHQ-9, GAD-7, and STOP-Bang can help assess the nature and severity of insomnia and comorbidities.
- Sleep hygiene education alone is an insufficient treatment.
- Cognitive-behavioural therapy for insomnia (CBT-I) is the first-line treatment and can sometimes be combined with pharmacotherapy. CBT-I can be used in multiple modalities (virtual, self-help, face-to-face, group), although the efficacy varies across modalities.
- Dual Orexin Receptor Antagonists (DORAs) may have benefits that outweigh their risks for long-term use. Their side effect profile may be more favourable compared to BZRA agents, and other commonly prescribed pharmacotherapies.
- Ability of benzodiazepines and Z-drugs to improve sleep short term has been confirmed but are associated with potentially concerning adverse effects, e.g., daytime drowsiness, falls risk, motor vehicle accidents, addiction/abuse risk, rebound insomnia.
- Off-label and over the counter medications used in treating insomnia have unclear or hazardous safety and efficacy profiles that may outweigh their benefits.
- Outside of specialized subpopulations, there is a lack of evidence on the use of melatonin and long-term effect of cannabinoids for chronic insomnia.
- Key educational needs range from raising awareness of current treatment options to better understanding the balance of risk and benefits.

Conclusions: These guidelines for the management of chronic insomnia offer a pathway to more effective, evidence-based care. However, real-world implementation of the recommendations, particularly those related to novel therapies, will require a granular understanding of the evidence distinguishing the different classes of medication and identifying the most suitable treatment within

each class. This underscores the need to educate on the impact of insomnia and how to apply safe and effective evidence-based therapies to clinical practice for the benefit of patients living with insomnia.

The Association between Sleep Vulnerability and Autonomic Response to Nocturnal Arousals

S.W. Lu¹, Y.C. Li¹, L. Ting¹, C.M. Yang^{1,2}

¹National Chengchi University, Psychology, Taipei, Taiwan, ²The Research Center for Mind, Brain, and Learning, National Chengchi University, Taipei, Taiwan

Introduction: Sleep vulnerability is an individual trait reflecting the tendency to experience sleep disturbances under stress. It's assessed via self-report using the Ford Insomnia Response to Stress Test (FIRST), which measures the likelihood of sleep disruption in response to everyday stressors. Higher FIRST scores consistently predict development of insomnia disorder. Although prior research links high sleep vulnerability to heightened physiological arousal, dynamic processes underlying autonomic nervous system (ANS) responses, especially recovery following nocturnal arousals, remain poorly understood. This study aimed to investigate how high versus low sleep vulnerability individuals differ in ANS reactivity and recovery patterns following experimentally induced arousals during nocturnal sleep, assessing their potential as physiological markers of insomnia risk.

Materials and methods: Forty healthy adults ($M = 24.1 \pm 3.1$ years) were recruited based on FIRST pre-screening, including a high vulnerability group (HV, $n = 19$; 10 females; $FIRST \geq 23$) and a low group (LV, $n = 21$; 12 females; $FIRST \leq 18$). During overnight polysomnography, auditory stimuli (1-second 1000 Hz pure tones) were presented via speakers during sleep in ascending intensity sequences (40–90 dB, 13-second intervals). Each stimulus sequence began when at least 10 seconds of stable EEG activity were presented and were terminated if EEG-defined arousal occurred. ANS reactivity was indexed by peak heart rate (HR) following arousal onset, while recovery reflected the efficiency of HR return to baseline. Baseline HR was calculated as the average of 2–12 heartbeats prior to cortical arousal. ANS reactivity was also quantified by the area under curve (AUC) from baseline to peak HR. Higher values indicated stronger reactivity. ANS recovery was assessed as the AUC across the 30 beats after the HR peak, divided by peak amplitude; larger values indicated slower recovery and poorer autonomic regulation.

Results:

During NREM sleep, the HV group exhibited significantly higher HR peak responses compared to the LV group ($t(38) = 0.858, p = .005$), while no group differences were observed during REM sleep or when all stages combined. In contrast, AUC-based reactivity showed no differences across NREM, REM, or combined sleep stages.

ANS recovery was significantly slower in the HV group when combining all stages ($t(38) = 2.351, p = .024$), while no group differences were observed during REM or NREM sleep.

Conclusions: Our findings suggest that ANS recovery, rather than reactivity, may better represent a physiological marker of sleep vulnerability. The discrepancy between peak HR and AUC-based ANS reactivity may reflect differences in arousal-to-peak latency, with the LV group showing a slower, more gradual HR rise that yields comparable AUC values to the HV group's sharper, faster responses. In contrast, the slower recovery process in the HV group likely reflects reduced parasympathetic modulation, impairing the ability to return to physiological homeostasis following arousal. These findings underscore the importance of recovery dynamics in understanding sleep vulnerability and support the potential utility of targeting ANS recovery for early detection and intervention of insomnia disorder. Future research is needed for understanding ANS reactivity mechanism.

The associations between short-term changes in suicidal ideation and sleep disturbances in youth

R.W.L. So¹, K.Y. Chan¹, C.C.W. Cheng¹, Y. Wang¹, P.S. Lo¹, N.Y. Chan¹, S.X. Li^{2,3}, J.W.Y. Chan¹, Y.K. Wing^{1,4}, T.M.H. Li¹

¹The Chinese University of Hong Kong, Li Chiu Kong Family Sleep Assessment Unit, Department of Psychiatry, Hong Kong, Hong Kong, SAR of China, ²The University of Hong Kong, Department of Psychology, Hong Kong, Hong Kong, SAR of China, ³The University of Hong Kong, The State Key Laboratory of Brain and Cognitive Sciences, Hong Kong, Hong Kong, SAR of China, ⁴The Chinese University of Hong Kong, Li Ka Shing Institute of Health Sciences, Hong Kong, Hong Kong, SAR of China

Introduction: Sleep disturbances are recognized as transdiagnostic symptoms that significantly increase the risk for mental disorders and suicide. Despite the emergence of sleep-related issues during adolescence and early adulthood, there is a paucity of studies examining the sleep-suicide association in youth. Given the importance of early detection, this study examines the associations between short-term changes in suicidal ideation (SI) and sleep disturbances in youth.

Materials and methods: This is part of an ongoing study on examining depression symptomatology in youth, which recruited Chinese individuals aged 18-24 years using convenient sampling, excluding those with neuropsychiatric disorders (other than depression and anxiety). At baseline, participants underwent a structured interview to assess SI and the presence of sleep disturbances, including difficulties falling asleep (DIS), difficulties maintaining asleep (DMS), and early morning awakening (EMA), based on the Structured Interview Guide for the Hamilton Depression Rating Scale (HDRS). Participants also completed the Depression Anxiety Stress Scales-21 (DASS-21) to measure depression, anxiety, and stress levels. A week later, participants' SI was reassessed using HDRS interviews. The participants were classified into four groups, namely non-SI group (no SI at baseline and follow-up), SI remitted group (having SI at baseline but not at follow-up), incident SI group (no SI at baseline but having SI at follow-up), and persistent SI group (having SI at baseline and follow-up). Multiple logistic regression models were used to analyze the relationship between SI groups (outcomes) and sleep disturbances (predictor), adjusting for age, gender, and baseline levels of SI, depression, anxiety, and stress.

Results: The study included 328 individuals while 300 completed the study (mean age 20.68 years, SD 2.02; 76% female). Of these, 92 individuals (31%) exhibited at least one symptom, with 21% (n=63) experiencing DIS, 14% (n=41) having DMS, and 9% (n=28) showing EMA. In the completer analysis, there were 255 (85%) in the non-SI group, 15 (5%) in the SI remitted group, 16 (5%) in the incident SI group, and 14 (5%) in the persistent SI group. There were no significant differences observed in age and gender among the groups. Baseline sleep disturbances (OR= 4.79, 95% CI=1.50 to 16.93, p=.01) and depression severity (OR=1.18, 95% CI=1.08 to 1.30, p<.001) significantly predicted incident SI after one week. Baseline SI (OR=5.77, 95% CI=2.49 to 15.60, p<.001) increased the risk for persistent SI. Baseline anxiety severity (OR=0.86, 95% CI=0.75 to 0.98, p=.03) was negatively associated with SI remission. Baseline stress severity showed no significant links to short-term changes in SI.

Conclusions: This study identifies sleep disturbances as a significant predictor of incident SI in youths, alongside depressive symptoms. These results highlight the importance of focusing on sleep issues and depressive symptoms when developing strategies for suicide detection and prevention.

The Contributions of Biological Sex to Sleep Microarchitecture: A Systematic Review and Meta-Analysis of Biological Sex Differences in Sleep Spindles and Slow Wave Activity in Adults With and Without Insomnia

N.A. Walsh^{1,2}, E.-M. Phillips^{1,3}, A. Páez^{1,4,5}, N.E. Cross^{1,6}, T.T. Dang-Vu^{1,2,4,3}, A.A. Perrault^{1,7}

²Concordia University, Department of Psychology, Montreal, Canada, ³University of Montreal, Department of Neurosciences, Montreal, Canada, ⁴Concordia University, Department of Health, Kinesiology & Applied Physiology, Montreal, Canada, ⁵University of Oxford, Nuffield Department for Primary Care Health Sciences, Oxford, United Kingdom, ⁶University of Sydney, School of Psychology, Sydney, Australia, ⁷Woolcock Institute of Medical Research and Macquarie University, Sleep and Circadian Group, Sydney, Australia

Introduction: Insomnia Disorder (ID) is the most prevalent sleep disorder in adults, particularly amongst females (1.5x more likely than males). In fact, insomnia symptoms may manifest more frequently during key reproductive life events marked by hormonal and physical changes (e.g., puberty, pregnancy, perimenopause). However, much less is known regarding sex disparities within sleep biomarkers associated with sleep quality, such as sleep spindle activity (SSA; spindle events and sigma-band spectral power) and slow wave activity (SWA; slow oscillations [SO], slow waves [SW], and delta-band spectral power). This systematic review and meta-analysis aimed to synthesize research on the impact of biological sex (female, male) and sleep condition (ID, healthy sleep [HS]) on SSA and SWA.

Materials and methods: A systematic search was undertaken on PubMed, Embase, Scopus, and PsycInfo from database inception to December 2022, using Medical Subject Headings (MeSH) terms and keywords associated with SSA, SWA, HS, and ID. We included published peer-reviewed studies involving both males and females over 18 years old. Eligible studies examined sex-based differences in SSA and SWA via event detection and/or spectral analysis. A meta-analysis was conducted using a random-effects model to pool effect sizes. Heterogeneity was assessed using the I^2 statistic. Risk of bias was evaluated using the Newcastle-Ottawa Scale. This study is registered on PROSPERO (CRD 42022355969).

Results: Of the 247 included articles, only 17% (41 articles) reported results on sex-based analyses (31 HS, 2 with ID, 8 HS+ID). Only 13 of the 31 HS articles (42%; N=668) had sufficient statistical data for meta-analysis, and none of the ID or HS+ID articles did.

In healthy sleep, evidence from the systematic review and meta-analysis indicated that, compared to males, females showed higher sigma power (5 studies, n=365, SMD=-0.29, 95% CI=[-0.50, -0.08], $I^2=0\%$), spindle density (2 studies, n=190, SMD=-0.65, 95% CI=[-1.95, 0.66], $I^2=85\%$), and delta power (6 studies, n=407, SMD=-0.50, 95% CI=[-0.70, -0.30], $I^2=0\%$). Sex differences were less consistent when considering ID alone, or when comparing ID with HS, likely due to the scarcity of studies examining group-by-sex interactions, and findings being highly dependent on method, age, and analysis type.

Conclusions: To our knowledge, this is the first systematic review and meta-analysis to examine the effects of biological sex on SSA and SWA in adults with and without insomnia, assessed with quantitative EEG measures (e.g., event-based detection, spectral analysis). Our review also highlights critical gaps in current sleep research. Sex-based differences in SSA and SWA characteristics are infrequently and inconsistently examined in sleep research, despite known hormonal influences on brain oscillations and sex differences in sleep quality. It also underscores inconsistencies in samples and the methodology used to study brain oscillations, including ID criteria, sample analysis (e.g., age stratification, use of hormonal treatment in covariate, balance in sex distribution), and brain oscillations detection methods. Further research that includes sex as a primary outcome, while considering relevant nuances, is imperative to clarify whether true sex-based differences exist in insomnia-related oscillatory activity, and to inform more precise, inclusive interventions addressing health disparities in ID.

The effectiveness of self-help cognitive behavioural therapy for insomnia in adults: a systematic review and meta-analysis

Y. Huang¹, C. Yang¹, J.Y.Y. Kwok¹, P.H. Chau¹

¹the University of Hong Kong, School of Nursing, Hong Kong SAR, China

Introduction: Uptake of cognitive behavioural therapy for insomnia (CBT-I) as a first-line treatment for chronic insomnia is limited due to a shortage of trained therapists, access barriers, and economic burden. Self-help CBT-I appears to be a viable alternative due to its promising scalability, accessibility, and affordability. To date, the effectiveness of self-help CBT-I on insomnia severity among adults with insomnia symptoms has not been extensively explored. This meta-analysis aims to evaluate the overall effectiveness of self-help CBT-I on insomnia severity and to identify potential characteristics associated with greater estimated treatment effects.

Materials and methods: We systematically searched PubMed, Embase, PsycINFO, CINAHL Plus, Web of Science, the Cochrane Library Core, and two Chinese databases (China National Knowledge Infrastructure [CNKI] and Wanfang Data) for articles published up to 4 April 2025. Randomized controlled trials (RCTs) comparing self-help CBT-I with a control condition were included if they involved adults with insomnia symptoms and reported insomnia severity as an outcome. Two independent reviewers screened the search records and extracted data from eligible RCTs. Hedges' g

was pooled using a random-effects model, with post-intervention insomnia severity as the primary outcome. Subgroup analyses and meta-regressions were performed to identify characteristics potentially associated with enhanced treatment efficacy. The Cochrane Risk of Bias 2.0 tool was used to assess study quality. This meta-analysis followed Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines and was pre-registered on PROSPERO (registration number: CRD420251009153).

Results: A total of 33 RCTs (37 intervention vs. control comparisons) involving 6,187 participants (mean age range: 27.3–71.8 years), conducted in upper-middle- or high-income countries, were included. Self-help CBT-I interventions were mainly delivered via mobile apps or web platforms, with varying levels of support ranging from none to guided assistance. Compared with control conditions, self-help CBT-I demonstrated large effect sizes in reducing insomnia severity at post-intervention ($g = -0.97$, 95% CI: -1.19 to -0.75; $I^2 = 93.09\%$), moderate to large effects at 1–5 months post-intervention ($g = -0.67$, 95% CI: -0.83 to -0.51; $I^2 = 70.20\%$), and at 6–12 months post-intervention ($g = -0.78$, 95% CI: -1.03 to -0.52; $I^2 = 82.24\%$). Larger effect sizes were observed in trials that included relapse prevention components or were delivered via web platforms. No significant differences were found based on adaptation of CBT-I content, level of support, or provision of incentives. Of the included studies, 6 were rated as having a high risk of bias, 13 as having some concerns, and 14 as having a low risk of bias.

Conclusions: Compared with control conditions, self-help CBT-I demonstrated effectiveness in managing adult insomnia, regardless of the level of support or delivery format. Further rigorous research is warranted to evaluate the effectiveness of self-help CBT-I in low-income countries.

The effect of a tailored digital cognitive behavioural therapy for insomnia in people with co-morbid insomnia and sleep apnoea (COMISA): A pilot randomised controlled trial

A. Sweetman^{1,2,3}, C. Richardson², A. Smith⁴, C. Reynolds^{1,2}

¹Flinders University, Adelaide, Australia, ²University of Western Australia, Perth, Australia, ³Bond University, Gold Coast, Australia, ⁴NA, consumer representative, Adelaide, Australia

Introduction: Co-morbid insomnia and sleep apnoea (COMISA) is a prevalent and debilitating condition. Cognitive behavioural therapy for insomnia (CBTi) is an effective but largely inaccessible treatment in patients with COMISA. Self-guided digital CBTi programs may be one method to increase CBTi accessibility in people with COMISA. However, existing digital CBTi programs have largely been developed and tested in people with insomnia alone, and may not be as effective, appropriate, or safe in people with COMISA. We therefore aimed to develop and test a self-guided interactive digital CBTi program tailored for COMISA and insomnia-alone.

Materials and methods: An Australia-wide online pilot randomised controlled trial was conducted to investigate the effect of an interactive digital CBTi program, versus digital sleep education (control), on symptoms of insomnia, depression, anxiety, sleepiness, fatigue, and maladaptive beliefs about sleep in people with COMISA. Online questionnaires were administered at baseline, 8-weeks, 16-weeks and 24-weeks. The control group accessed the program after the 8-week follow up. Intent-to-treat mixed models and complete-case Fisher's exact analyses were used.

Results: Participants were 30 adults with COMISA (Age M [sd] = 61.0 [10.3], 60% female, BMI = 33.5 [6.5]). Compared to control, CBTi was associated with lower insomnia (M [95%CI] difference = 8.3 [5.0–11.6], $p < .001$, $d = 2.88$), depression (3.7 [1.0–6.5], $p = .008$, $d = 1.66$), anxiety (2.9 [0.9–4.9], $p = .005$, $d = 0.62$), sleepiness (2.7 [0.8–4.5], $p = .007$, $d = 0.71$), and maladaptive beliefs about sleep (13.9 [5.7–22.2], $p = .001$, $d = 1.16$), but not fatigue (1.9 [-1.2–4.9], $p = .229$, $d = 0.68$) at 8-week follow-up, controlling for baseline scores. The tailored CBTi group experienced greater rates of insomnia remission ($ISI < 8$; 42%, vs 0%, $p = .012$), and improvement (ISI reduction ≥ 6 ; 75% vs 14%; $p = .004$) by 8-weeks. Improvements in the tailored CBTi group were sustained by 24-weeks.

Conclusions: This digital CBTi program led to large and sustained improvements in insomnia, depression, anxiety, sleepiness, and maladaptive beliefs about sleep in people with COMISA. Larger trials are required to definitively understand the effectiveness of this program in diverse samples of people with COMISA, and "downstream" impacts of this program on acceptance and use of treatments for sleep apnoea.

Acknowledgments: We would like to acknowledge and thank all participants that took part in this clinical trial. We also thank members of the Sleep Health Foundation, Sleep Disorders Australia,

Flinders University media, and other Media organisations that assisted with study promotion. We acknowledge Aboriginal and Torres Strait Islander People as the traditional custodians of the lands on which this study was conducted. In particular, the work was carried out on the lands of the Peramangk, Kurna and Whadjuk Noongar People.

The Effect of Body Grounding on Sleep Quality of Cancer Inpatients, and the Relations between Body Voltage, Bedroom EMF and Sleep Quality: a Blinded Randomized Controlled Study

C.-H. Tu¹, S.-C. Hsu¹, C.H. Hsieh²

¹New Taipei Municipal Tucheng Hospital, Department of Psychiatry, New Taipei, Taiwan, ²Chang Gung Memorial Hospital (Linkou Branch), Oncology, Taoyuan, Taiwan

Introduction: The prevalence of sleep difficulties or insomnia is high in cancer patients. Compared with healthy people, it is common for cancer patients to have a long sleep onset, short sleep duration, and poor sleep efficiency. Many studies have found that the higher the body voltage, the lower the vagal tone, suggesting that the high and low body voltage values have physiological significance and clinical importance, and grounding is an intervention that has been proven to reduce body voltage.

Materials and methods: We implemented body grounding therapy during the sleep period of cancer patients in two different environments: hospitalization (two nights) and after discharge (more than one week) through a randomized, controlled group experimental design. The Pittsburgh Sleep Quality Inventory (PSQI), Hospital Anxiety and Depression Scale (HADS), Stress and Somatic Symptom Scale (DSSS), Sleep Assessment Questionnaire (SEQ), and Sleepiness Scale (KSS) were used to evaluate the differences between the subjects before and after receiving the grounding therapy. In addition, the bed body voltage (BV) values before and during bed grounding in hospital and at home were obtained, and finally statistical analysis was performed using statistical methods such as paired sample T test.

Results: There were 14 people enrolled in the true grounding group (experimental group, Group 1) and 12 people enrolled in the sham grounding group (control group, Group 0) during their hospitalization. There were no significant differences between the two groups in age, gender, weight, height, BMI, age at onset, number of years of illness, and all pre-test assessment scale scores. Compared with Group 0, Group 1 had a significant decrease in PSQI scores ($p=0.03$ between groups), indicating that the degree of insomnia was significantly improved due to the intervention of the grounding patch, and similar significant differences were found under longer-term use after discharge and return home ($p=0.02$ within group 1). There was no significant difference in PSQI scores between the pre-test and the post-test in Group 0 ($p=0.22$). After using the grounding patch, there was a significant difference between the two groups ($p=0.000$ in hospital beds and $p=0.007$ in home beds). The body voltage drop rate of Group 1 was 99.3-98.8%, while that of Group 0 was only 3.6-7.1%.

Conclusions: *Conclusion: The improvement in PSQI confirm that the earthing patch did reduce insomnia severity in cancer patients, and similar effects are also seen under long-term use. The grounding patch produce a very noticeable and rapid drop in body voltage. The AC voltage present in the electric beds in hospital wards is one of the reasons for the high body voltage values and should be managed.*

Acknowledgments: This study was supported by Chang Gung Memorial Hospital Research Grant (grant number CORPVN0051)

The Effect of CBT-I on Phasic/Tonic REM Microstructure in Patients with Insomnia: Preliminary Findings

A. Hruby^{1,2}, K. Janku¹, D. Dudysova¹, L. Soukupova^{1,2}, M. Klikova¹, M. Piorecky^{1,3}, J. Koprivova^{1,2}

¹National Institute of Mental Health, Sleep and Chronobiology Research Center, Klecany, Czech Republic, ²Charles University, 3rd Faculty of Medicine, Prague, Czech Republic, ³Czech Technical University in Prague, Faculty of Biomedical Engineering, Kladno, Czech Republic

Introduction: The cognitive behavioural therapy for insomnia (CBT-I) is a widely recognised and tested method for the treatment of insomnia and reducing hyper-arousal. However, very few studies have explored its impact on the objective markers of nocturnal arousal and next-day emotion regulation, specifically the balance between phasic and tonic rapid-eye movement (REM) sleep microstructure. Therefore, current research presents preliminary findings of a pilot study conducted on patients with

chronic insomnia, exploring the effects of a six-week CBT-I programme on subjective and objective sleep characteristics.

Materials and methods: A total of 33 adult participants (21 – 59 years, $M = 39.7 \pm 9.5$) meeting the ICSD-3 criteria for chronic insomnia took part in the randomised, wait-list-controlled pilot trial. Participants were either allocated to an “Experimental” ($n = 17$) or “Waitlist” ($n = 16$) group. Participants completed two experimental nights separated by a 6-week intervention period, where participants in the “Experimental” group undertook a group CBT-I programme. During the experimental measurements, participants first undertook an evening exposure followed by a whole night polysomnography and subsequent morning exposure.

To contextualise the polysomnography findings, participants completed the Insomnia Severity Index (ISI), Beck Anxiety Inventory (BAI), Dysfunctional Beliefs and Attitudes about Sleep Scale (DBAS), Hyperarousal Scale (HAS), Self-Assessment Manikin (SAM) at both pre- and post-intervention visits, providing trait-level and affective measures against which the effects of cognitive-behavioural therapy for insomnia (CBT-I) on REM-sleep microstructure could be interpreted.

Alongside this psychometric battery, each overnight polysomnography (PSG) night yielded several macro-structural indices—total sleep time (TST), wake after sleep onset (WASO), sleep efficiency (SE) and sleep-onset latency (SOL) as well as a profile of REM architecture, comprising REM latency, global phasic versus tonic REM percentages, REM arousal/density, and a band-specific micro-spectral decomposition of phasic and tonic REM (frontal/central alpha, beta, theta and delta relative power).

Results: The DBAS improved substantially - after CBT-I, the Time x Group interaction is statistically significant. BAI and ISI show promising trends, however, both interactions just miss conventional significance. Moreover, while non-significant hyper-arousal moves in the expected direction. SAM Intensity indicates a statistically significant Time x Group interaction while Valence and Arousal remain constant. Additionally, the Experimental group reports a statistically significant reduction in REM latency. Both phasic and tonic REM sleep percentages indicate a statistically significant Time x Group interaction, with phasic REM increasing and tonic REM decreasing in the Experimental group. A significant Time x Group interaction emerged in sleep-diary-based continuity (SOL, TST, SE and WASO) between the Experimental and Waitlist groups.

Conclusions: Along with the subjective and sleep-continuity outcomes, current findings suggest promising trends in exploring the REM sleep microstructure and indicate that the behavioural change of CBT-I potentially echoes the physiological change on the microstructural level. However, findings should be interpreted with caution due to their preliminary nature and the small sample size.

The effect of home-based auditory sleep stimulation on chronic insomnia: preliminary findings

D. Dudysova¹, A. Chudárková^{1,2}, L. Soukupová^{1,3}, S. Jongejan⁴, L.M. Talamini⁴, J. Kopřivová^{1,3}

¹National Institute of Mental Health, Sleep and Chronobiology Research Center, Klecany, Czech Republic, ²Faculty of Arts, Charles University, Department of Psychology, Prague 1, Czech Republic,

³Charles University, 3rd Faculty of Medicine, Praha, Czech Republic, ⁴University of Amsterdam, Department of Psychology, Amsterdam, Netherlands

Introduction: Closed-loop auditory stimulation (CLAS) is a promising non-invasive tool for studying and enhancing sleep. Chronic insomnia may be one candidate diagnosis that may be alleviated by CLAS. This study presents preliminary findings on the effectiveness and effects of a six-week CLAS program on both subjective and objective sleep characteristics in individuals with insomnia.

Materials and methods: A total of 14 participants (8 women, aged 21-44) with chronic insomnia took part in a within-subjects randomized crossover design. Each participant completed 3 weeks in the NREM stimulation condition and 3 weeks in the control condition. Sleep macrostructure indices assessed total sleep time (TST), wake after sleep onset, sleep efficiency, and time spent in each sleep phase. Furthermore, the slow oscillations amplitude and sleep spindle power were analysed. Analysed subjective sleep measures included the Insomnia Severity Index and Pittsburgh Sleep Quality Index.

Results: The effectiveness of CLAS in individuals with chronic insomnia was variable, with some patients demonstrating greater responsiveness than others. CLAS did not alter studied macro- or microstructural sleep indices. Notably, the overall TST was short due to limits of our data quality. Furthermore, CLAS showed no effect on subjective sleep quality or insomnia severity.

Conclusions: The study represents the first attempt to assess the long-term effects of CLAS on sleep in a home setting for individuals with insomnia. Preliminary results suggest that CLAS is effective but variable in delivery. CLAS did not alter artifact-free sleep macrostructure and did not produce any significant sleep improvements. However, these results should be interpreted with caution due to the small sample size and a high EEG signal variability, which may have introduced a measurement and stimulation error.

Acknowledgments: This work was supported by Ministry of Health of the Czech Republic, Czech Health Research Council, Grant/Award Number: NU23-04-00469 and NW24J-04-00083.

The effects of Cognitive behavioral therapy for insomnia (CBT-I) and Tai Chi on mood symptoms and cognitive functioning in older adults with insomnia: A pilot study

R. Wang¹, D.J. Yu^{2,3}, N.Y. Chan⁴, H.F. Sit¹, X. Li¹, P.M.F. Siu⁵, S.X. Li^{1,6}

¹Sleep Research Clinic and Laboratory, Department of Psychology, The University of Hong Kong, Hong Kong, SAR of China, ²School of Chinese Medicine, Hong Kong Baptist University, Hong Kong, SAR of China, ³Vincent V.C. Woo Chinese Medicine Clinical Research Institute, School of Chinese Medicine, School of Chinese Medicine, Hong Kong, SAR of China, ⁴Li Chiu Kong Sleep Assessment Unit, Department of Psychiatry, Faculty of Medicine, Hong Kong, SAR of China, ⁵School of Public Health, Faculty of Medicine, Hong Kong, SAR of China, ⁶The State Key Laboratory of Brain and Cognitive Sciences, The University of Hong Kong, Hong Kong, SAR of China

Introduction: Insomnia is prevalent in older adults. It is often accompanied by mood symptoms and poor cognitive functioning. While cognitive-behavioral therapy for insomnia (CBT-I) is considered the frontline treatment for adults with insomnia, Tai Chi (TC), a mind-body exercise, has emerged as a potential alternative intervention due to its documented health-related benefits, including improving sleep. However, there has been limited research comparing the effects of CBT-I and TC in addressing insomnia-related daytime symptoms and cognitive functioning among older adults. The present study aimed to compare the effects of CBT-I and TC on subjective sleep quality, mood symptoms, and cognitive functioning in older adults with insomnia.

Materials and methods: Forty-four participants with DSM-5 insomnia disorder (age:65.27±5.69, female:79.55%) were recruited. They received either CBT-I or TC (n=22 per group), both delivered over 3 months with two 60-min sessions each week. Sleep quality (Pittsburgh sleep quality index), mood symptoms (Hospital Anxiety and Depression Scale), and self-reported cognitive functioning (Cognitive Failure Questionnaire and Attention Function Index) were assessed at baseline and post-treatment. A mixed-design analysis of covariance (ANCOVA) was conducted, with time (baseline and post-treatment) as the within-subjects factor and group (CBT-I and TC) as the between-subjects factor, controlling for age and sex. Missing post-treatment data were imputed using the last observation carried forward method.

Results: There was a significant time*group interaction effect on sleep quality [$F(1, 42) = 7.102$, $p=0.011$, partial $\eta^2 = 0.165$] and cognitive failure [$F(1, 42) = 4.356$, $p=0.043$, partial $\eta^2 = 0.100$]. These results indicated that pre-post changes in sleep quality and cognitive functioning differed between the CBT-I and TC groups, where the CBT-I group showed greater improvement in sleep quality and the TC group showed greater improvement in cognitive functioning. In addition, there was a significant main effect of time on depressive symptom [$F(1, 42) = 5.428$, $p=0.026$, partial $\eta^2 = 0.138$] and anxiety symptom [$F(1, 42) = 4.183$, $p=0.048$, partial $\eta^2 = 0.107$], indicating mood symptoms improved significantly from pre- to post-treatment across both groups. There was a main effect of group on depressive symptoms [$F(1, 42) = 9.947$, $p=0.003$, partial $\eta^2 = 0.226$] and attention function [$F(1, 42) = 8.603$, $p=0.006$, partial $\eta^2 = 0.212$]. This result suggested that the TC group demonstrated fewer depressive symptoms and better attention across both pre- and post-treatment compared to the CBT-I group.

Conclusions: The findings of the current study highlighted the differential effects of CBT-I and TC in addressing sleep quality, mood symptoms and cognitive functioning. These findings collectively suggested that Tai Chi may serve as a valuable complementary intervention for elderly with insomnia, particularly for addressing mood and cognitive functioning. Further research is warranted to examine the sustainable effects of Tai Chi on mood symptoms and cognitive functioning and explore the potential mechanisms underlying these favorable outcomes.

The Effects of Lemborexant on Objective Sleep Parameters in Insomnia Patients Based on Sleep State Misperception

T. Yoshiike¹, M. Suzuki², M. Koebis³, K. Inabe³, Y. Kogo³, D. Kumar⁴, M. Moline⁴, K. Kuriyama¹

¹National Institute of Mental Health, National Center of Neurology and Psychiatry, Department of Sleep-Wake Disorders, Tokyo, Japan, ²Nihon University School of Medicine, Department of Psychiatry, Tokyo, Japan, ³Eisai Co., Ltd., Tokyo, Japan, ⁴Eisai Inc., Nutley, United States

Introduction: In insomnia patients, there is often a discrepancy between patient-reported (subjective) durations of sleep and objective sleep values. For those who underestimate their sleep, this may lead to high doses and/or multiple drug prescriptions, while those who overestimate their sleep may face increased mortality risk. For appropriate treatment of insomnia, improvement in objective sleep measures is necessary regardless of whether sleep state misperception is present. This is a challenge since polysomnography (PSG) is not standard of care and may not be reimbursable. However, no studies have examined the effects of hypnotics across different degrees of sleep state misperception. We investigated the effectiveness of lemborexant (LEM), a dual orexin-receptor antagonist, on objective total sleep time (TST), wake after sleep onset (WASO), and latency to persistent sleep (LPS) using PSG in groups with different degrees of sleep state misperception.

Materials and methods: Study E2006-G000-304 was a 1-month, randomized, double-blind, placebo (PBO)- and zolpidem extended-release (ZOL; not reported here)-controlled trial in patients aged 55 years and older who met *Diagnostic and Statistical Manual of Mental Disorders*, Fifth Edition, criteria for insomnia disorder with an Insomnia Severity Score ≥ 13 . Study drug (LEM 5 mg [LEM5]; LEM 10 mg [LEM10]; PBO; or ZOL) was taken immediately before bedtime. Participants completed a sleep diary each morning. Participants were classified into 3 groups of misperception index quartiles (Q; Q1: overestimation group, Q2-3: normal to moderate underestimation group, Q4: severe underestimation group) based on differences between baseline (BL) PSG (TST) and sleep diary values (subjective TST). Changes from BL (~2-week PBO run-in with BL PSG) in the average values of both days at Day 1/2 and Day 29/30 were compared for LEM5 and LEM10 versus PBO using a mixed-effects model for repeated measures. The trial was conducted with approval from the ethics review committee and with patients' voluntary consent, in accordance with relevant laws and regulations.

Results: A total of 712 patients were included (Q1/Q2-3/Q4: 183/353/176, respectively). Patient demographics were similar across the 3 groups, although Q1 had a higher proportion of patients aged over 75 years and Q4 had a higher proportion of females. At BL, mean TST for Q1/Q2-3/Q4 was 298.7/338.7/338.8 minutes, WASO was 135.8/104.6/105.8 minutes, and LPS was 50.1/42.9/41.0 minutes, respectively. Increases from BL in TST at each time point were greater in both LEM groups versus the placebo group across all Q1/Q2-3/Q4 groups. Decreases from BL in WASO and LPS at each time point were greater in both LEM groups compared with PBO across all Q1/Q2-3/Q4 groups. Changes in TST, WASO, and LPS tended to be greater in Q1 than in Q2-3 and Q4 for PBO and both LEM groups.

Conclusions: LEM improved objective sleep parameters in insomnia patients, regardless of the magnitude of sleep state misperception.

The Effects of Lemborexant on Subjective Sleep Parameters in Insomnia Patients Based on Sleep State Misperception

T. Yoshiike¹, M. Suzuki², M. Koebis³, K. Inabe³, Y. Kogo³, D. Kumar⁴, M. Moline⁴, K. Kuriyama¹

¹National Institute of Mental Health, National Center of Neurology and Psychiatry, Department of Sleep-Wake Disorders, Tokyo, Japan, ²Nihon University School of Medicine, Department of Psychiatry, Tokyo, Japan, ³Eisai Co., Ltd., Tokyo, Japan, ⁴Eisai Inc., Nutley, United States

Introduction: It is reported that up to 56% of insomnia patients experience a discrepancy between subjective and objective sleep measurements (ie, sleep state misperception). There may be differences in treatment responsiveness depending on the degree of sleep state misperception. Under-estimators show better response to cognitive behavioral therapy for insomnia compared with over-estimators. However, no studies have examined subjective responses to pharmacotherapy across different degrees

of sleep state misperception. We investigated the effectiveness of lemborexant (LEM), a dual orexin-receptor antagonist, on subjective total sleep time (sTST), wake after sleep onset (sWASO), sleep onset latency (sSOL), and sleep quality (sQual) using sleep diaries in groups with different degrees of sleep state misperception.

Materials and methods: Study E2006-G000-304 was a 1-month, randomized, double-blind, placebo (PBO)- and zolpidem extended-release (ZOL; not reported here)-controlled trial in patients aged 55 years and older who met *Diagnostic and Statistical Manual of Mental Disorders*, Fifth Edition, criteria for insomnia disorder with an Insomnia Severity Score ≥ 13 . Study drug (LEM 5 mg [LEM5]; LEM 10 mg [LEM10]; PBO; or ZOL) was taken immediately before bedtime. Participants recorded sQual (scale from 1–9: 1=extremely poor; 9=extremely good) in a sleep diary each morning. Participants were classified into 3 groups based on baseline (BL) misperception index quartiles (Q) comparing objective values from polysomnography (TST) with sleep diary values (sTST; Q1: overestimation group, Q2–3: normal to moderate underestimation group, Q4: severe underestimation group). Changes from BL (7-day average during PBO run-in) in average values for the first and last 7 days of the month were compared for LEM5 and LEM10 versus PBO using a mixed-effects model for repeated measures. The trial was conducted with approval from the ethics review committee and with patients' voluntary consent, in accordance with relevant laws and regulations.

Results: A total of 712 patients were included (Q1/Q2–3/Q4: 183/353/176, respectively). Mean BL sTST for Q1/Q2–3/Q4 was 352.3/289.2/155.6 minutes, mean sWASO was 106.3/149.3/260.8 minutes, mean sSOL was 42.4/55.2/80.7 minutes, and mean sQual was 4.2/3.8/3.4 points, respectively. Increases (improvements) from BL in ratings of sQual at each time point were greater in both LEM5 (mean, first 7 days, Q1/Q2–3/Q4: 1.0/1.3/1.0; last 7 days: 1.5/1.6/1.1) and LEM10 (first 7 days: 1.0/1.2/1.2; last 7 days: 1.2/1.4/1.6) groups versus the PBO group (first 7 days: 0.3/0.7/0.6; last 7 days: 0.5/1.0/1.0) across all Q1/Q2–3/Q4 groups. Increases (improvements) from BL in sTST were greater in both LEM5 (least squares mean, first 7 days: 27.1/51.0/76.3; last 7 days: 43.2/60.6/93.4) and LEM10 (first 7 days: 37.3/60.2/111.9; last 7 days: 47.6/69.9/128.5) groups versus the placebo group (first 7 days: 11.7/30.5/57.7; last 7 days: 11.1/46.9/57.8) across all Q1/Q2–3/Q4 groups. Changes from BL in subjective sleep measures (sTST, sWASO, and sSOL) tended to be greater in Q4 compared with Q1 and Q2–3 for PBO and both LEM groups.

Conclusions: LEM improved subjective sleep parameters in insomnia patients, regardless of the magnitude of sleep state misperception.

The Impact of Caregiving on Insomnia: Gender Differences, Long-Term Health Risks, Child Sleep Patterns, and Scalable Digital Interventions

S. Ooi¹

¹Princeton University, Princeton, United States

Introduction: Parents of young children often experience disrupted sleep due to nighttime awakenings, stress, and irregular schedules. These disturbances increase the risk of chronic insomnia and long-term health issues. Additionally, caregiver sleep behaviors significantly influence child sleep patterns, perpetuating an intergenerational cycle of sleep disruption.

While Cognitive Behavioral Therapy for Insomnia (CBT-I) is effective, caregivers face adherence challenges due to time constraints and competing demands. This study examines caregiver sleep behaviors, gender differences, long-term risks, and child sleep patterns while exploring scalable digital interventions to enhance treatment accessibility.

Materials and methods: A subset (20%) of 8,539 study participants were caregivers of young children. Their sleep patterns, behaviors, engagement with a digital CBT-I based program called Sleep Reset, and adherence were compared to non-caregivers (80%). Key variables included:

- **Sleep disruptions:** Nighttime awakenings, WASO, sleep efficiency, total sleep time.
- **Gender differences:** Variations in sleep disturbances, stress levels, and program adherence.
- **Behavioral factors:** Irregular schedules, caffeine/alcohol use, bedtime routines, wind-down activities.

- **Environmental influences:** Co-sleeping, bedroom noise, temperature, nighttime light exposure.
- **Psychological stressors:** Self-reported stress, racing thoughts, caregiving-related anxiety.
- **Health implications:** Fatigue, mood disturbances, weight changes, chronic stress.
- **Child sleep impact:** Consistency, nighttime awakenings, caregiver-reported disturbances.
- **Adherence analysis:** Sleep coaching engagement, confidence, dropout reasons.

Results:

- Caregivers had significantly higher sleep fragmentation than non-caregivers, with 70% waking at least once per night vs. 40% of non-caregivers.
- Gender disparities were notable. Female caregivers had longer WASO (45 min vs. 30 min for males), more stress-related awakenings, and lower adherence to structured sleep routines.
- Psychological stress was a major driver of sleep issues—78% of caregivers reported high stress and racing thoughts, leading to longer sleep latency and reduced sleep efficiency.
- Adherence to digital CBT-I based program was lower in caregivers (38% of females, 45% of males) compared to 60% of non-caregivers.
- Health risks included higher rates of fatigue (85%), mood disturbances (62%), and weight gain (45%).

Conclusions: Caregivers face persistent sleep challenges, with significant gender disparities and long-term health risks. Future digital insomnia interventions should be designed to meet caregivers' unique needs by integrating time-efficient, modular CBT-I based programs that fit into their demanding schedules.

The impact of insomnia disorder on the night and the day: analysis of polysomnography and subjective parameters from a large clinical trial database

M. Fernandes¹, A. Olivieri², O. Briasoulis², J. Laurent², C. Liguori³

¹University of Rome Tor Vergata, Department of Systems Medicine, Rome, Italy, ²Idorsia Pharmaceuticals Ltd, Allschwil, Switzerland, ³University Hospital of Rome Tor Vergata, Sleep Medicine Centre, Neurology Unit, Rome, Italy

Introduction: Insomnia is a heterogenic disorder, and its characterisation could help tailor the management of subjects in clinical practice. Patients with insomnia disorder, in addition to sleep problems, also experience daytime impairment. However, studies investigating both the nocturnal and diurnal clinical profiles of patients with insomnia disorder are limited. This analysis aimed to comprehensively evaluate the demographic data and the objective and subjective clinical data assessing sleep and daytime functioning, collected from the large sample of subjects with insomnia disorder screened in the two phase 3 daridorexant trials.

Materials and methods: Both trials (NCT03545191, NCT03575104) were global, multicentre, randomised, double-blind, placebo-controlled trials that, when combined, screened approximately 7000 subjects aged ≥ 18 years with insomnia disorder (defined according to DSM-5 criteria, plus a self-reported history of ≥ 30 min to fall asleep, wake time during sleep ≥ 30 min, and subjective total sleep time [sTST] ≤ 6.5 h on at least 3 days/week and for at least 3 months). During the screening period (7-18 days), subjects performed a one-night polysomnography (PSG) assessment and completed a daily eDiary which included morning and evening visual analogue scales (VAS) and the Insomnia Daytime Symptoms and Impacts questionnaire (IDSIG; completed every evening). This analysis included all subjects screened with ≥ 1 data record on the selected parameters. Subjects with an apnoea or hypopnea index ≥ 15 events/hour or an event associated with oxygen saturation $< 80\%$, or with periodic limb movement index ≥ 15 events/hour, restless legs syndrome, circadian rhythm disorder, rapid-eye-movement behaviour disorder or narcolepsy were excluded.

Results: In total, 5474 screened subjects were included in the analysis (female: 66%, White: 83%; ≥ 65 years: 40%). Mean insomnia severity index score was 20.2 (SD 3.6), indicating moderate/severe intensity of insomnia symptoms (score ≥ 15). Among the objective PSG measures, mean latency to persistent sleep was 63.1 min (SD 61.7), mean wake after sleep onset was 102.6 min (SD 57.5), and mean TST was 320.5 min (SD 81.1). Subjects had on average 12.4 (SD 5.5) awakenings/night and 2.8 (SD 1.9) long wake bouts/night (> 6 min) with 92% having ≥ 1 long wake bout (PSG-assessed). Among

the subjective measures, patients reported a mean sTST of 325.5 min (SD 68.2), and poor quality and depth of sleep and moderate/severe morning sleepiness, as reflected by low mean VAS values (range 0-100; lower values indicate poorer outcomes) for all three parameters (quality of sleep: 38.7 [SD 16.9]; depth of sleep: 39.4 [SD 17.2]; morning sleepiness: 39.6 [SD 17.6]). IDSIQ total scores (range 0-140; lower scores indicate better patient-perceived daytime functioning) indicated moderate/severe daytime impairment (mean 71.6 [SD 22.5]). Mean VAS daytime ability to function (43.2 [SD 18.5]) and daytime alertness (41.6 [SD 18.8]) scores also indicated moderate/severe daytime impairment.

Conclusions: This large dataset provides much needed comprehensive data on the burden of insomnia disorder on daytime functioning and sleep from a broad population of patients. The further analysis of these data can help clinicians better understand the clinical profile and the needs of patients with insomnia disorder.

Acknowledgments: This study was funded by Idorsia Pharmaceuticals Ltd.

The impact of insomnia disorder on the night and the day in males and females

M. Fernandes¹, A. Olivieri², O. Briasoulis², J. Laurent², C. Liguori³

¹University of Rome Tor Vergata, Department of Systems Medicine, Rome, Italy, ²Idorsia Pharmaceuticals Ltd, Allschwil, Switzerland, ³University Hospital of Rome Tor Vergata, Sleep Medicine Centre, Neurology Unit, Rome, Italy

Introduction: Insomnia disorder, affecting approximately 10% of adults globally, is prevalent in both men and women, although it occurs approximately 50% more frequently in women. However, studies investigating potential sex-related differences in the clinical manifestation of insomnia and its impact on daytime remain limited. Using the large dataset of screened patients with insomnia disorder from the daridorexant phase 3 clinical program, this analysis assesses nocturnal and diurnal clinical characteristics of males and females with insomnia disorder.

Materials and methods: Analyses by sex (male: n=1845 [34%]; female: n=3629 [66%]) were performed on data from 5474 screened patients from the two global, randomised, double-blind, placebo-controlled trials (NCT03545191, NCT03575104) in adults (≥18 years) with insomnia disorder. Insomnia disorder was defined according to DSM-5 criteria, plus a self-reported history of ≥30 min to fall asleep, wake time during sleep ≥30 min, and subjective total sleep time [sTST] ≤6.5 h on ≥3 days/week and for ≥3 months. During the screening period, subjects underwent a one-night polysomnography (PSG) and completed a daily eDiary that included morning and evening visual analogue scales (100 mm VAS) and the Insomnia Daytime Symptoms and Impacts questionnaire (IDSIQ [range: 0-140]). This analysis included all subjects screened with data records on selected parameters and without an apnoea/hypopnea index ≥15 events/hour or an event associated without oxygen saturation <80%, periodic limb movement index ≥15 events/hour, restless legs syndrome, circadian rhythm disorder, rapid-eye-movement behaviour disorder or narcolepsy.

Results: At screening, mean (SD) insomnia severity index score was 19.8 (3.8) in males and 20.4 (3.5) in females, indicating moderate/severe insomnia in both subgroups. Among objective PSG measures, males had a numerically shorter TST than females (mean [SD]: 312 [82] vs 324 [80] min). This was due primarily to a longer wake after sleep onset (WASO) in males (110 [59] vs 99 [57] min), particularly during the last two quarters (Q) of the night (Q3: 31.6 [27.0] vs 28.6 [27.3] min; Q4: 43.2 [32.1] vs 36.4 [28.6] min). Latency to persistent sleep was comparable (male vs female: 65 [63] vs 62 [61] min). There were no notable differences in PSG-reported total wake bouts (32 vs 29) or wake-bout mean duration (4.7 vs 4.4 min).

No sex-related differences were observed among subjective measures. Unlike TST, mean sTST was comparable in males and females (325 [66] vs 326 [69] min). IDSIQ total score (male vs female: 73 [23] vs 71 [22]), and VAS scores for quality of sleep (38 [17] vs 39 [17]), depth of sleep (39 [17] vs 40 [17]), daytime alertness (41 [19] vs 42 [19]), ability to function (42 [19] vs 44 [18]) and morning sleepiness (39 [17] vs 40 [18]) were all comparable.

Conclusions: These data indicate that insomnia disorder negatively impacts sleep and daytime functioning in males and females with no apparent sex-related differences in subjective parameters. Additionally, PSG data suggest that males may tend to overestimate their sTST since they have longer WASO than females, mainly in the latter part of the night.

The impact of insomnia disorder on the night and the day in older and younger adults

M. Fernandes¹, A. Olivieri², O. Briasoulis², J. Laurent², C. Liguori³

¹University of Rome Tor Vergata, Department of Systems Medicine, Rome, Italy, ²Idorsia Pharmaceuticals Ltd, Allschwil, Switzerland, ³University Hospital of Rome Tor Vergata, Sleep Medicine Centre, Neurology Unit, Rome, Italy

Introduction: The burden of insomnia increases with age; however, it remains unclear whether differences exist in subjective and objective sleep parameters between older and younger adults. Furthermore, data on how insomnia disorder affects the day of older and younger adults are limited. The large dataset of screened patients with insomnia disorder from the daridorexant phase 3 clinical program provides comprehensive data to address these gaps. Using these data, this analysis assesses the nocturnal and diurnal clinical characteristics of patients aged ≥ 65 years ("older") and those < 65 years ("younger" adults).

Materials and methods: Analyses by age group (≥ 65 years $n=2178$ [40%]; < 65 years: $n=3296$ [60%]) were performed on data from screened patients from the two global, randomised, double-blind, placebo-controlled trials (NCT03545191, NCT03575104) in adults (≥ 18 years) with insomnia disorder. Insomnia disorder was defined according to DSM-5 criteria, plus a self-reported history of ≥ 30 min to fall asleep, wake time during sleep ≥ 30 min, and subjective total sleep time [sTST] ≤ 6.5 h on ≥ 3 days/week and for ≥ 3 months. During the screening period, subjects underwent a one-night polysomnography (PSG) and completed a daily eDiary that included morning and evening visual analogue scales (100 mm VAS) and the Insomnia Daytime Symptoms and Impacts questionnaire (IDSIQ; completed each evening [range 0-140]). This analysis included all subjects screened with data records on the selected parameters. Subjects with significant sleep comorbidities (obstructive sleep apnea, periodic limb movements, restless legs syndrome, circadian rhythm disorder, rapid-eye-movement behaviour disorder or narcolepsy) were excluded.

Results: At screening, mean (SD) insomnia severity index score was 19.5 (3.6) and 20.6 (3.5) in older and younger adults, respectively, indicating moderate/severe insomnia in both subgroups. Among objective PSG measures, mean (SD) total sleep time (TST) was numerically lower (298 [83] vs 334 [77] min) in older vs younger adults, due to a greater mean wake after sleep onset (123 [59] vs 90 [53] min); latency to persistent sleep was comparable (64 [64] vs 62 [60] min). Rapid eye movement duration was numerically shorter in older vs younger adults (53 [27] vs 63 [27] min). Among subjective measures, older and younger subjects reported a similar mean sTST (326 [67] vs 325 [69] min). Comparing objective to subjective measures, younger adults quantified the duration of sleep accurately, whereas older adults tended to overestimate it. IDSIQ total score was numerically lower (i.e. better) in older versus younger adults (66.3 [(21.9)] vs 74.9 [22.2]). VAS scores for quality of sleep (41.9 [16.5] vs 36.8 [16.8]), depth of sleep (42.4 [16.7] vs 37.6 [17.2]), daytime alertness (46.5 [18.2] vs (38.7 [18.6]), ability to function (47.6 [17.9] vs 40.5 [18.4]) and morning sleepiness (44.4 [17.2] vs 36.7 [17.1]) were all numerically higher (i.e. better) in older adults versus younger adults.

Conclusions: These data show that insomnia disorder negatively impacts sleep and daytime functioning in the two age subgroups, with more severe deficits in objective sleep parameters in older adults but less severe deficits in daytime functioning, as compared to younger adults.

The Impact of Insomnia on Cardiometabolic Health: Importance of Sleep Assessment

J. Kim¹, N. Parast², A. Jain³, J. Alonso⁴

¹Vineyard Medical Clinic & University of Calgary, Calgary, Canada, ²University of Ottawa Heart Institute, Cardiac Prevention and Wellness Centre & Canadian Women's Heart Health Centre, Ottawa, Canada, ³TLC Diabetes and Endocrinology & University of British Columbia, Vancouver, Canada, ⁴Canadian Sleep Consultants, Calgary, Canada

Introduction: Insomnia, characterized by difficulty initiating or maintaining sleep, or early morning awakenings, affects up to one-third of adults. Emerging evidence identifies insomnia as a significant, modifiable risk factor for cardiometabolic diseases, including type 2 diabetes, cardiovascular disease,

chronic kidney disease, and metabolic dysfunction-associated steatotic liver disease (MASLD). Insomnia is associated with increased sympathetic nervous system activity, dysregulation of the hypothalamic-pituitary-adrenal axis, and elevated inflammatory markers, all of which contribute to cardiometabolic risk. Evidence suggests that insomnia significantly impacts glucose metabolism, insulin resistance, and the development of type 2 diabetes. Additionally, insomnia is linked to obesity, MASLD, and cardiovascular diseases such as hypertension, myocardial infarction, and heart failure. Despite its prevalence and impact on health, insomnia remains underdiagnosed and inadequately managed. Integrating sleep health into cardiometabolic care is crucial for reducing the global burden of chronic diseases. Healthcare providers should prioritize screening for insomnia and implementing evidence-based management strategies to improve patient outcomes.

Materials and methods: Objective: This multiphase study aimed to assess the feasibility and need for sleep assessment in specialist clinics and to empower healthcare providers in primary care networks through knowledge translation of phase one of the study.

Methods: The study was conducted in two phases. Phase one involved assessing the feasibility and need for sleep assessments in specialty endocrinology clinic. Data were collected from 69 patients with diabetes and/or obesity, focusing on their sleep patterns, satisfaction with sleep, and the impact of sleep problems on daily functioning. Phase two involved knowledge translation to healthcare providers in primary care networks, aiming to empower them with the findings from phase one to improve sleep health management.

Results: Only 46% of patients reported that their sleep was assessed by their primary care physician or nurse practitioner before the study. Surprisingly, 9% of patients were required and agreeable to start on medication but 23% of patients preferred to talk to their primary care health providers (e.g. GP, NP) about their sleep issues. Around 70% of patients agreed that asking about their sleep helped them understand its importance. Overall, majority of patients were satisfied or very satisfied with their sleep being assessed at the specialty endocrinologist clinic.

The knowledge translation phase aimed to empower healthcare providers in primary care networks with the findings from phase one. This phase included training sessions and distribution of educational materials. Post survey revealed that the degree of comfort level increased after staff received education.

Conclusions: The study highlights the critical need for integrating sleep assessments into specialist clinics and empowering primary care providers through knowledge translation. Addressing insomnia in patients with cardiometabolic diseases can significantly improve patient outcomes and potentially reduce the global burden of chronic diseases. Healthcare providers should prioritize sleep health as a fundamental component of cardiometabolic care.

The Impact of Lemborexant on Gut Microbiota Composition in Insomnia Treatment

S. Miyata¹, K. Iwamoto¹, I. Okada¹, K. Kawai¹, M. Ito², N. Matsuyama¹, A. Fujimoto³, Y. Kogo³, H. Nishiwaki², J. Ueyama⁴, K. Ohno², N. Ozaki⁵

¹Nagoya University Graduate School of Medicine, Department of Psychiatry, Nagoya, Japan, ²Nagoya University Graduate School of Medicine, Division of Neurogenetics, Center for Neurological Diseases and Cancer, Nagoya, Japan, ³Eisai Co., Ltd., Medical Headquarters, Tokyo, Japan, ⁴Nagoya University Graduate School of Medicine, Department of Biomolecular Sciences, Field of Omics Health Sciences, Nagoya, Japan, ⁵Nagoya University Graduate School of Medicine, Pathophysiology of Mental Disorders, Nagoya, Japan

Introduction: Emerging research highlights the gut microbiota's critical role in sleep regulation through the microbiota-gut-brain axis. While sleep restriction shows minimal microbiome alterations, insomnia is characterized by reduced microbial diversity. Lemborexant, an innovative insomnia treatment, has demonstrated promising improvements in sleep parameters. This study investigates how lemborexant might modulate gut microbiota composition and explores the intricate relationship between sleep medication and the microbiome.

Materials and methods: A prospective study was conducted on 29 adults aged 50 and older with insomnia. These individuals were participants in the FLUID study, which explored lemborexant's potential to improve sleep. Participants initially received a 5 mg dose of lemborexant for 12 weeks, with the option to increase to 10 mg if symptoms did not improve, after consulting with a physician. Throughout the study, existing medication doses remained unchanged, and participants' lifestyle and

dietary habits were monitored during each visit. The comprehensive study included sleep electroencephalography and stool microbiome analyses at baseline, 4 weeks, and 12 weeks of open-label lemborexant treatment. Researchers used 16S rRNA sequencing to examine microbial composition and performed metabolite analysis of short-chain fatty acids (SCFAs). The study received ethical approval from the Nagoya University Clinical Research Review Board.

Results: Beta diversity, assessed by Jaccard dissimilarity, significantly increased at week 12 compared to week 4. The Firmicutes/Bacteroidetes ratio was significantly elevated at week 12 relative to baseline. At the taxonomic level, *Tannerellaceae Parabacteroides* remained significantly different at week 12 after statistical correction. Notably, *Parabacteroides* showed a significant decrease throughout the study period. The *Anaerovoracaceae Family XIII AD3011 group* demonstrated persistent, albeit not statistically significant, increases. Additional exploratory trends included potential increases in *Streptococcus*, *Akkermansia*, and *Lactobacillales*, though these did not consistently reach statistical significance. No significant variations in SCFAs were detected during the treatment period.

Conclusions: Our findings suggest that prolonged lemborexant treatment in individuals with insomnia may induce subtle yet meaningful shifts in gut microbiota composition. The significant decrease in the genus *Parabacteroides* is particularly interesting given that it is associated with an increase when sleeping less than 6 hours in a mouse study. This highlights the potentially complex interactions between hypnotic medications and gut microbial ecology, offering a promising avenue for future research into the microbiota-sleep relationship.

Acknowledgments: This study was financially supported by Eisai Co., Ltd., the owner and manufacturer of lemborexant, and grants from JSPS KAKENHI (Grant Number 23K10934).

The impact of sleep duration, sleep debt and insomnia on infection risk: A longitudinal cohort study with one-year follow-up

B. Bjorvatn^{1,2}, S. Waage^{1,2}, R. Lundetræ¹, L. Larsen¹, N. Pristaj¹, M. Fossum¹, I.K. Rebnord¹, K.E. Emberland¹

¹University of Bergen, Department of Global Public Health and Primary Care, Bergen, Norway,

²Haukeland University Hospital, Norwegian Competence Center for Sleep Disorders, Bergen, Norway

Introduction: Insufficient sleep is associated with increased risk of mental and somatic disorders, such as depression, anxiety, obesity, diabetes, cardiovascular disorders, and cancer. Whether insufficient sleep increases the risk of infections has received less attention. The objective of this study was to investigate whether self-reported short and long sleep duration, different levels of sleep debt (difference between subjective sleep need and sleep duration), and insomnia severity at baseline would predict increased prevalence of different types of infections at one-year follow-up.

Materials and methods: From March 2022 to January 2023, participants aged 25-70 years were recruited from the Norwegian Primary Care Research Network (PraksisNett) to complete a baseline survey about sleep. One year later, they were invited to a follow-up survey. In total, 861 participants completed the baseline survey and the response rate at follow-up was 60.5%, rendering 521 participants eligible for the present study. At baseline the participants completed questions about sleep habits and insomnia symptoms (Insomnia Severity Index, ISI), and at follow-up they responded to whether they had experienced various infections during the last three months and whether they experience more infections than peers. Data were analyzed with chi-square tests and logistic regressions, adjusted for gender, age, and children living at home.

Results: In general, participants with normal sleep duration (6-9 hours), no sleep debt and no insomnia (ISI <8) at baseline reported the lowest prevalences of infections at one-year follow-up. In the adjusted logistic regression analyses, long sleep duration (>9 hours) increased the odds of influenza-like illness (odds ratio 3.99, 95% confidence interval 1.13-14.11), gastrointestinal infection with vomiting and/or diarrhea (4.31, 1.25-14.86), and experiencing more infections than peers (3.74, 1.09-12.82), whereas short sleep duration (<6 hours) doubled the odds of skin infection (2.03, 1.22-3.38). Compared to no sleep debt, ≤2 hours of sleep debt doubled the odds of skin infection (2.13, 1.21-3.74) and >2 hours of sleep debt tripled the odds of experiencing more infections than peers (2.95, 1.46-5.96). Insomnia (ISI 15-28) increased the odds of any type of infection (1.95, 1.10-3.45) and influenza-like illness (1.96, 1.16-3.33), and more than tripled the odds of gastrointestinal infection (3.54, 1.84-6.79) and experiencing more infections than peers (3.09, 1.73-5.51). Subthreshold insomnia (ISI 8-14) increased

odds of gastrointestinal infection (2.35, 1.32-4.19) and experiencing more infections than peers (1.68, 1.01-2.79).

Conclusions: This longitudinal study supports the notion that people who have insufficient sleep are at increased risk of contracting infections. Sleep debt and insomnia severity dose-dependently increased the prevalence of some of the reported infections.

The Impact of Sleep Vulnerability on Sleep Misperception in Healthy Adults

H.-L. Lin¹, Y.-C. Huang^{1,2}, Y.-J. Wang¹, T.-Y. Deng¹, C.-M. Yang^{1,2}

¹National Cheng-Chi University, Department of Psychology, Taipei, Taiwan, ²The Research Center for Mind, Brain, and Learning, National Cheng-Chi University, Taipei, Taiwan

Introduction: Sleep misperception, defined as the discrepancy between subjective and objective sleep, is commonly observed in individuals with insomnia but remains poorly understood. It may represent a premorbid trait of insomnia or develop over the course of chronic insomnia. Stress-related sleep vulnerability, defined as the tendency to experience sleep disruption under stress, is considered a predisposing trait for insomnia. Previous studies have reported that various stress conditions can enhance sleep misperception. Thus, sleep vulnerability may be associated with heightened sensitivity to minor sleep disturbances under stress, leading to distorted sleep perception. Therefore, the present study aims to examine the association between sleep vulnerability and sleep misperception, to determine whether sleep misperception is a predisposing trait of insomnia linked to sleep vulnerability.

Materials and methods: Thirty-five healthy participants without reported sleep disturbances (M:F = 1.7:1.8; mean age = 23.91 ± 3.54) completed the Ford Insomnia Response to Stress Test (FIRST) to assess their sleep vulnerability. They also wore an actigraphy device and completed a sleep diary for seven days. Sleep onset latency (SOL), total sleep time (TST), wake after sleep onset (WASO), and sleep efficiency (SE) were derived from both actigraphy and sleep diaries. The 7-day average discrepancies between subjective and objective measures were calculated. The index of sleep misperception used included: 1) subjective values minus objective values, 2) the discrepancy between subjective and objective values divided by the objective values, 3) subjective values divided by objective values. Pearson's correlation between sleep vulnerability and indices of sleep misperception were conducted.

Results: The results showed no significant correlations between the FIRST score and all the indices of sleep misperception of SOL, TST, WASO and SE.

Conclusions: The findings suggest that sleep vulnerability under stress in healthy populations is not associated with sleep misperception. Sleep misperception does not appear to be a characteristic of individuals predisposed to developing insomnia, but rather may emerge over the course of chronic insomnia. Future research could benefit from investigating these relationships in clinical populations or under experimentally induced stress conditions.

The link between improvement in sleep and depressed mood: Exploring the role of repetitive negative thinking and behavioural activation

V. Lall¹, R. Bucks¹, P. McEvoy^{2,3}, B. Campbell², L. Smith², M. Ree¹

¹The University of Western Australia, School of Psychology, Crawley, Australia, ²Centre for Clinical Interventions, Perth, WA, Australia, ³Curtin University, School of Population Health & enAble Institute, Perth, Australia

Introduction: There is extensive evidence supporting a link between poor sleep and worse depression outcomes. Moreover, improvement in sleep disturbance contributes to enhanced depression outcomes. However, processes underlying this sleep–depression link are unclear. The current study examined whether changes in potential underlying processes, namely repetitive negative thinking (RNT) and behavioural activation (BA) can explain the relationship between improvement in reported sleep disturbance (reduction in the number of days participants experience sleep difficulties) is related to improvement in depressed mood.

Materials and methods: Data were analysed from 127 participants (mean [SD] age 39.16 [14.81], 60.6% women) who attended a group CBT mood management program at a government mental health

service. Pre and post-treatment changes in depressed mood were assessed using PROMIS-D, whilst the frequency of participants' sleep difficulties was assessed via CUDOS item 5 (sleep item).

Results: Our study found a significant association between improvement in sleep difficulties and improvement in depressed mood, however, this relationship was no longer significant (no direct association) when controlling for improvements in RNT, $ab = 0.56$, CI [0.21, 1.01], and BA, $ab = 1.08$, CI [0.41, 1.84]. Furthermore, 1 SD improvement in sleep was indirectly associated with a 1.83-point change in depressed mood (a 0.612-point improvement in depression via RNT, and a 1.22-point improvement in depression via BA).

Conclusions: The preliminary findings suggest that reduced RNT and enhanced BA may play an important role in explaining how improvement in sleep is related to improvement in depressed mood. Future research should investigate whether early improvements in sleep contributes to subsequent improvements in depressed mood via improvements in RNT and BA. To establish temporal ordering and assess causality, future studies should collect data across multiple time points and incorporate a more comprehensive measure of sleep.

The mediating role of impulsivity on the association of insomnia with suicidal ideation: A national study of Chinese population

B. Lei¹, Q. Yan², Y. Zhou², J. Zhang²

¹Guangzhou University of Chinese Medicine, School of Public Health and Management, Guangzhou, China, ²The Affiliated Brain Hospital, Guangzhou Medical University, Guangzhou, China

Introduction: Increasing evidence suggests that insomnia is one of the key risk factors of suicidal ideation. However, the underlying mechanisms remain unclear. Previous studies indicated that impulsivity might be the associations of both insomnia and suicidal ideation. Therefore, the current study aimed to determine the mediating role of impulsivity in the association between insomnia and suicidal ideation.

Materials and methods: This study is a cross-sectional study, with data extracted from the national prospective cohort study, Digital multi-modal approaches to subtyping insomnia disorder (DiMOSI). A total of 1924 adult participants with diagnosis of insomnia disorder (65.9% female, age: 35.9 ± 12.1 years old) were recruited. All the participants were invited to accomplish the standardized questionnaires of severity of insomnia (Insomnia Severity Index, ISI), impulsivity (Barratt Impulsiveness Scale-11, BIS-11), suicidal ideation (Beck Scale for Suicidal Ideation, BSI), and demographics. Mediation analysis was conducted by the PROCESS in SPSS 26.0.

Results: A significant total effect of severity of insomnia on suicidal ideation was found ($\beta = 0.16$, 95% CI: 0.12-0.20). Impulsivity partially mediated the association, with a significant indirect effect ($\beta = 0.02$, 95% CI: 0.01-0.03). In the mediating model, the direct effect remained significant ($\beta = 0.14$, 95% CI: 0.10-0.18), suggesting additional pathways beyond impulsivity. The model explained 11.85% of the variance in suicidal ideation ($R^2 = 0.1185$). In terms of the two dimensions of impulsivity, including non-planning impulsiveness and motor impulsiveness, both of them partially mediated the association of severity of insomnia on suicidal ideation as well.

Conclusions: These findings highlight impulsivity as a modifiable target for suicidality intervention, especially among those suffering insomnia disorder. Moreover, interventions of each components of impulsivity might reduce suicidal ideation. Further cohort studies and randomized controlled clinical trials are warrant.

Acknowledgments: insomnia, impulsivity, suicidal ideation, mediation analysis

The Moderating Effect of Chronotype on the Relationship Between Insomnia Severity and Working Memory Performance in Youths

X.X. Chen¹, X. Li¹, J.W.Y. Chan², A.M. Li³, Y.K. Wing^{2,4}, S.X. Li^{1,5}

¹The University of Hong Kong, Department of Psychology, Sleep Research Clinic & Laboratory, Hong Kong, Hong Kong, SAR of China, ²The Chinese University of Hong Kong, Faculty of Medicine, Department of Psychiatry, Li Chiu Kong Family Sleep Assessment Unit, Hong Kong, Hong Kong, SAR of

China, ³The Chinese University of Hong Kong, Faculty of Medicine, Department of Paediatrics, Hong Kong, Hong Kong, SAR of China, ⁴The Chinese University of Hong Kong, Faculty of Medicine, Li Ka Shing Institute of Health Sciences, Hong Kong, Hong Kong, SAR of China, ⁵The University of Hong Kong, The State Key Laboratory of Brain and Cognitive Sciences, Hong Kong, Hong Kong, SAR of China

Introduction: Insomnia is highly prevalent among youths and adversely affect their neurocognitive development and daily functioning. Youth is also characterized by an increased preference for eveningness, often leading to a misalignment between sleep schedule and early school times, as well as other societal demands. Increased eveningness has been linked to higher levels of insomnia severity and may compromise neurocognitive development. While both insomnia severity and chronotype have independently been linked to cognitive deficits in youth, the interplay between these factors—especially on working memory—remained underexplored. The present study aimed to examine whether chronotype moderated the association between insomnia severity and working memory performance in youth.

Materials and methods: A total of 154 participants meeting DSM-5 insomnia disorder (mean age: 19.87, SD = 2.10, 62.7% female) were included in the present analyses. 73 (47.4%) participants were classified as eveningness (E-group) (Reduced Morningness–Eveningness Questionnaire, rMEQ, rMEQ score ≤ 11), and 81 (52.6%) participants were classified as morningness or neither type as Non-Eveningness (Non-E group) (rMEQ score > 11). Participants completed self-reported measures for insomnia severity (Insomnia Severity Index, ISI), depression (Hospital Anxiety and Depression Scale–Depression subscale, HADS-D) and anxiety (Hospital Anxiety and Depression Scale–Anxiety subscale, HADS-A). Working memory was objectively assessed by Digit Span Task and Dual N-back Task. Multiple linear regression models were used to examine the moderation effect of chronotype on the relationship insomnia severity and working memory performance, controlling for timing of cognitive assessment, depression and anxiety.

[Table 1: Sample Characteristics](#)

Results: There were significant Chronotype $\times$ Insomnia Severity interactions on both forward digit span ($F(1,100) = 6.47, p = .013$), and accuracy in N-back task (2-back, $F(1,121) = 6.55, p = .012$). For the youths with eveningness chronotype, greater insomnia severity was significantly associated with worse working memory, including poorer performance on forward digit span ($\beta = -0.11, p = .015$) and lower accuracy on the 2-back d-prime score ($\beta = -0.09, p = .014$), whilst no significant association between insomnia severity and working memory performance was found among those with non-eveningness (all $p > 0.05$).

[Table 2: Multiple Linear Regression Outcome; Figure 1-2: Moderation Effect Graphs; Figure 3: Illustration of N-back Test.](#)

Conclusions: The findings showed the moderating role of chronotype on the association between insomnia severity and working memory performance in youths with insomnia disorder. This study underscored the need to consider circadian preferences when assessing insomnia-related cognitive deficits in youth. Future research may explore whether interventions integrating both sleep and circadian components could improve cognitive functioning in youths with insomnia and eveningness.

Transcranial Alternating Current Stimulation (tACS) for Chronic Primary Insomnia: A Systematic Review and Meta-Analysis of Randomized Controlled Trials on Efficacy

P. Prawiroharjo¹, V. Martalia², A. Gabrielle³, A. Fakhri², S. Alya⁴

¹University of Indonesia, Department of Neurology, DKI Jakarta, Indonesia, ²University of Indonesia, DKI Jakarta, Indonesia, ³University of Hang Tuah, Surabaya, Indonesia, ⁴Sebelas Maret University, Surakarta, Indonesia

Introduction:

Chronic primary insomnia is a pervasive sleep disorder with limited effective non-pharmacological treatments. Transcranial alternating current stimulation (tACS) has emerged as a potential neuromodulatory therapy, but its efficacy remains inconclusive due to variability in study designs and

small sample sizes. This meta-analysis synthesizes evidence from randomized controlled trials (RCTs) to evaluate the effects of tACS on sleep quality and architecture in chronic primary insomnia.

Materials and methods:

A systematic search of PubMed, Cochrane Library, ScienceDirect, and Scopus was conducted through May 2025, following PRISMA guidelines. Included were randomized controlled trials (RCTs) involving tACS intervention in chronic primary insomnia patients compared to sham. Four RCTs (n=131 participants) were included. Pooled mean differences (MD) with 95% confidence intervals (CI) were calculated using a random-effects model due to high heterogeneity. Outcomes were synthesized for PSQI, sleep onset latency (SOL) in minutes, total sleep time (TST) in hours, and sleep efficiency (SE) in percentage. Risk of bias was assessed using the Cochrane RoB 2 tool.

Results: tACS demonstrated significant improvements across all measured sleep parameters in patients with chronic primary insomnia. PSQI scores improved markedly with tACS (MD = -4.02, 95% CI [-6.55, -1.30], $p = 0.008$), though substantial heterogeneity was observed ($I^2 = 95\%$). SOL decreased by an average of 28.55 minutes (MD = -28.55, 95% CI [-35.56, -21.53], $p < 0.00001$), with moderate heterogeneity ($I^2 = 81\%$). TST increased by 0.62 hours (MD = 0.62, 95% CI [0.39, 0.86], $p < 0.00001$), similarly accompanied by high heterogeneity ($I^2 = 81\%$). SE also showed improvement (MD = -0.93%, 95% CI [-1.45, -0.42], $p = 0.0004$), but results were highly variable across studies ($I^2 = 91\%$). All studies have low risk of bias.

Conclusions: tACS appears to be a promising intervention for improving sleep quality, latency, duration, and efficiency in chronic primary insomnia, despite significant heterogeneity among studies. tACS likely improves insomnia by modulating hyperactive thalamocortical circuits and enhancing slow-wave/alpha oscillations, promoting sleep initiation and maintenance. Unlike pharmacotherapy, it offers targeted neuromodulation without systemic side effects. While high heterogeneity exists due to variable protocols, consistent improvements in sleep latency, duration, and quality support its therapeutic potential. These findings support further large-scale, standardized RCTs to optimize tACS protocols and confirm clinical applicability.

Treatment response, remission, and adherence across the delivery methods of cognitive behavioral therapy for insomnia: A systematic review and meta-analysis

Y. Takano¹, I. Okajima², M. Osao¹, R. Ibata³, N. Machida⁴, K. Higami⁵, S. Takagi⁶, Y. Inoue¹

¹Tokyo Medical University, Department of Somnology, Tokyo, Japan, ²Tokyo Kasei University, Department of Psychological Counseling, Faculty of Humanities, Tokyo, Japan, ³Sapporo Mental and Physical Health Clinic, Hokkaido, Japan, ⁴Osaka Counseling Center Bellflower, Osaka, Japan, ⁵Institute of Neuropsychiatry, Japan Somnology Center, Tokyo, Japan, ⁶Institute of Science Tokyo, Department of Psychiatry and Behavioral Science, Tokyo, Japan

Introduction: Previous meta-analyses of cognitive behavioral therapy for insomnia (CBT-I) have not clarified the treatment response levels and dropout rates across different CBT-I delivery methods. This study aims to address these gaps in the literature and identify patients who would benefit most from various CBT-I formats.

Materials and methods: A literature search was conducted in PubMed, PsycINFO, and Embase on November 6, 2023 (The search is currently being updated, and more recent data will be available at the presentation.). CBT-I was defined as incorporating both sleep restriction and stimulus control techniques. This study included randomized controlled trials using individual, group, fully automated Internet-based, or supported Internet-based formats. Treatment response was defined as a decrease of 8 or more points in the Insomnia Severity Index from baseline to end of treatment (Morin et al., 2011). Remission from insomnia symptoms was evaluated at the end of treatment. When the number of remitters and/or responders were not reported in the original publications, it was estimated based on self-reported scale values at the end of treatment (Furukawa et al., 2005). Adherence was assessed using dropout rates, with dropouts were defined as participants who did not complete the assigned treatment. Odds ratio (OR) was used to synthesize outcome measures. In meta-regression analyses, each outcome measure was used as the dependent variable, and the delivery methods of CBT-I, comorbidities, and types of control groups were used as independent variables.

Results: A total of 120 trials from 110 studies were analyzed, with 15,060 participants (65.7% female, 27.9% male, 6.4% unknown/other). Treatment response was significantly higher in all delivery methods of CBT-I compared with the control group (overall: OR = 6.84 [5.56, 8.40]; individual: OR = 8.51 [5.94, 12.19]; group: OR = 8.12 [4.38, 15.05]; fully automated Internet-based: OR = 5.23 [3.95, 6.94]; supported Internet-based: OR = 8.54 [5.50, 13.27]). Meta-regression analysis showed that fully automated Internet-based CBT-I, presence of psychiatric diseases, and active treatment control were significantly negatively associated with treatment response. Remission was significantly higher in all delivery methods of CBT-I compared with the control group (overall: OR = 5.53 [4.62, 6.61]; individual: OR = 7.76 [5.70, 10.57]; group: OR = 5.13 [3.16, 8.35]; fully automated Internet-based: OR = 4.39 [3.39, 5.67]; supported Internet-based: OR = 7.31 [5.10, 10.48]). Meta-regression analysis showed that fully automated Internet-based CBT-I and presence of psychiatric diseases were significantly negatively associated with remission. Dropout rates significantly increased for Internet-based formats (overall: OR = 1.36 [1.14, 1.62]; fully automated Internet-based: OR = 1.87 [1.42, 2.47]; supported Internet-based: OR = 1.63, 95% CI [1.07, 2.49]; individual: OR = 0.94 [0.69, 1.27]; group: OR = 0.97 [0.73, 1.29]). Meta-regression analysis showed that Internet-based formats and presence of psychiatric diseases were significantly positively associated with dropout rate.

Conclusions: CBT-I is consistently effective in improving insomnia symptoms, regardless of the delivery method. Importantly, individuals who do not respond to the Internet-based format may require an individual approach. Additionally, it is necessary to devise strategies to prevent dropout, especially in Internet-based interventions.

Ultrasound-Guided Stellate Ganglion Block Combined with Cervicotemporal Myofascial Trigger Point Needling in Insomnia with Anxiety and Depression: A Retrospective Study

Y. Wang¹, Z. Li¹

¹Shandong Second Provincial General Hospital, Department of Anesthesiology, Jinan, China

Introduction: This retrospective study aimed to investigate the therapeutic potential of integrating ultrasound-guided stellate ganglion block (SGB) with cervicotemporal myofascial trigger point (MTrP) needling for patients with insomnia accompanied by anxiety and depression, proposing a novel multimodal intervention to enhance treatment outcomes.

Materials and methods: A total of 42 patients diagnosed with insomnia accompanied by anxiety and depression at the Anesthesia and Sleep Medicine Department of Shandong Second Provincial General Hospital between November 2024 and February 2025 were included. The patients were treated by ultrasound-guided SGB combined with MTrP needling. Ultrasound-guided SGB was performed through bilateral alternating injections of 4 mL 1% lidocaine, once daily for a total of 8 sessions. Cervicotemporal MTrP needling targeted the upper scalene (C2/C4 anterior tubercle), sternocleidomastoid (mid-internal border), upper trapezius, and temporalis trigger points. Disposable sterile 0.35 × 50 mm needles were used for percutaneous multidirectional stimulation of the targeted sites, followed by rapid punctures (7–10 insertions per MTrP) at twitch-response points, and then hemostatic compression was applied for 30 seconds to stop any bleeding. Needling was performed once per week for 3 consecutive weeks. The outcome of the combination therapy was evaluated by comparing changes in Pittsburgh Sleep Quality Index (PSQI), Hamilton Anxiety Scale (HAMA), and Hamilton Depression Scale (HAMD) scores after 4 weeks of treatment.

Results: All 42 patients met the inclusion criteria for insomnia with anxiety and depression. Post-treatment analysis revealed statistically significant reductions in PSQI ($P < 0.05$), HAMA ($P < 0.05$), and HAMD ($P < 0.05$) scores compared to pre-treatment values.

Conclusions: Ultrasound-guided SGB combined with cervicotemporal MTrP needling demonstrates clinically meaningful improvements in sleep architecture and symptoms of anxiety and depression, with minimal adverse reactions.

Acknowledgments: The authors would like to thank Dr Zheping Chen, Shanghai Key Laboratory of Anesthesiology and Brain Functional Modulation, Translational Research Institute of Brain and Brain-Like Intelligence, Clinical Research Center for Anesthesiology and Perioperative Medicine, Department of Anesthesiology and Perioperative Medicine, Shanghai Fourth People's Hospital, School of Medicine, Tongji University Department of Anesthesiology, Dr Zhenzhen Li and Dr Lifeng Wang, Department of Anesthesiology, Shandong Second Provincial General Hospital for their helpful advice.

Ultrasound-Guided Stellate Ganglion Block Combined with Myofascial Trigger Point Needling for Refractory Insomnia with Depression: A Case Report

Y. Wang¹, Z. Li¹

¹Shandong Second Provincial General Hospital, Department of Anesthesiology, Jinan, China

Introduction: To investigate the clinical efficacy of ultrasound-guided stellate ganglion block (SGB) combined with myofascial trigger points (MTrPs) needling in a patient with refractory insomnia and comorbid depression, and to explore the regulatory effects of this combined therapy on prefrontal cortex functional activity of the patient.

Materials and methods: The patient was a 58-year-old female, presented with a 10-year history of insomnia accompanied by depressed mood, exacerbated over the past year, with poor response to hypnotic medications and antidepressants. The diagnosis was refractory insomnia and depression. Following informed consent, the patient received ultrasound-guided SGB (administered alternately on left and right sides, once daily for 8 consecutive sessions) combined with MTrPs needling targeting the cervical and temporal regions (including the upper part of scalene muscle at C2 and C4 anterior tubercles, the medial border of the sternocleidomastoid muscle, the upper trapezius, and the temporal muscle; administered once a week for 3 sessions). Pre- and post-treatment Pittsburgh Sleep Quality Index (PSQI), Hamilton Depression Scale (HAMD), and Hamilton Anxiety Scale (HAMA) scores were collected and analyzed to evaluate the therapeutic effects on the sleep architecture and affective symptoms of the patient. Functional near-infrared spectroscopy (fNIRS) was employed to analyze prefrontal cortex functional activity.

Results: The patient demonstrated immediate sleep improvement on the day of initial treatment. After two weeks of intervention, significant improvements were observed in both insomnia and depressive symptoms. Comparative analysis revealed statistically significant reductions in PSQI, HAMD, and HAMA scores, indicating substantial improvements in sleep quality and affective symptoms. fNIRS data demonstrated markedly increased oxyhemoglobin (HbO) concentration in the prefrontal cortex region following treatment, suggesting enhanced prefrontal activation.

Conclusions: This case provides neuroimaging evidence supporting the "hyperarousal" hypothesis in insomnia with comorbid depression, confirming the pivotal role of prefrontal cortex in sleep-wake regulation. The findings elucidate the neurofunctional mechanisms underlying the therapeutic effects of ultrasound-guided SGB combined with MTrP needling, offering novel insights for treatment target selection in refractory insomnia.

Acknowledgments: The authors would like to thank Dr Zheping Chen, Shanghai Key Laboratory of Anesthesiology and Brain Functional Modulation, Translational Research Institute of Brain and Brain-Like Intelligence, Clinical Research Center for Anesthesiology and Perioperative Medicine, Department of Anesthesiology and Perioperative Medicine, Shanghai Fourth People's Hospital, School of Medicine, Tongji University, Dr Zhenzhen Li and Dr Lifeng Wang, Department of Anesthesiology, Shandong Second Provincial General Hospital for their helpful advice.

Validation and reliability of a Thai version of The Insomnia Severity Index

N. Intaragumhaeng¹, C. Pimolsri², W. Chotinaiwattarakul¹, J. Srikajon¹, J. Lortrakul³, S. Bussaratid³, P. Nurak¹

¹Mahidol university, Siriraj Sleep Center, Bangkok, Thailand, ²Mahidol University, Siriraj Sleep center, Bangkok, Thailand, ³Mahidol university, Department of Psychology, Siriraj Hospital, Bangkok, Thailand

Introduction: Insomnia is highly prevalent worldwide and has a significant impact on health outcomes. However, it is often underrecognized and untreated, as its diagnosis typically requires a comprehensive medical evaluation by experienced professionals. The Insomnia Severity Index (ISI) is a brief self-assessment tool specifically designed for screening and evaluating the severity of insomnia. This study aimed to translate and validate the ISI into a Thai version to enhance insomnia patient care in Thailand.

Materials and methods: Thai version of insomnia severity index (Thai-ISI) was developed under a standard linguistic translation protocol. Validity with Thai-Pittsburgh Sleep Quality Index (Thai-PSQI) and Thai-Athens Insomnia scale (Thai-AIS) was tested. Test-retest reliability was evaluated at 2–4-week interval.

Results: A total of 72 adult participants (70% female) with insomnia complaint were recruited. Twenty-nine percent had comorbid obstructive sleep apnea and 47.2% reported a history of sleep medication use. Based on the Thai-ISI, most participants ($n = 42$, 58.3%) were classified as having clinically significant insomnia. Thai-ISI demonstrated a strong correlation with the Thai-Athens Insomnia Scale (Thai-AIS) ($r = 0.784$, $p < 0.01$) and a moderate correlation with the Thai-Pittsburgh Sleep Quality Index (Thai-PSQI) ($r = 0.44$, $p < 0.01$). Cronbach's alpha of 0.703 indicated good internal consistency of the questionnaire items. Pearson's correlation for test-retest reliability of the total Thai-ISI score was 0.638 ($p < 0.01$) also reflexed good consistency.

Conclusions: We demonstrated validity and reliability of Thai-ISI. The data also supported the utility of Thai-ISI for capturing insomnia in Thai subjects with and without co-morbidity.

Acknowledgments: This research project was supported by Faculty of Medicine Siriraj Hospital, Mahidol University, Grant Number (IO) **R016731048**

Wearable sleep tracking in digital CBT-I: Clinical impact and the subjective-objective sleep discrepancy

Y. Lee¹, D.U. Moon², E. Lee³

¹WELT corp, Clinical, Seoul, Korea, Republic of, ²Charite Universitätsmedizin, Department of Psychiatry and Neurosciences, Berlin, Germany, ³Yonsei University College of Medicine, Department of Psychiatry and the Institute of Behavioral Science in Medicine, Seoul, Korea, Republic of

Introduction: Insomnia is a prevalent disorder, affecting up to 30% of the population, and is associated with poor physical and mental health outcomes. Cognitive Behavioral Therapy for Insomnia (CBT-I) is the first-line treatment, but its accessibility is limited by a shortage of trained providers and high costs. Digital Cognitive Behavioral Therapy for Insomnia (dCBT-I) has emerged as an effective and scalable alternative.

Wearable devices are increasingly used to track sleep patterns, offering objective data on sleep parameters. However, how well these wearable-derived sleep measures align with traditional subjective assessments remains unclear.

This study evaluates the combined effect of dCBT-I with wearable sleep tracking and examines discrepancies between subjective (sleep diaries) and objective (smart ring) sleep measures in individuals undergoing digital insomnia treatment.

Materials and methods: A single-arm, pre-post study was conducted to evaluate the clinical outcomes of an 8-week dCBT-I intervention with smart ring sleep tracking.

Inclusion:

- 30 adults with chronic insomnia (DSM-V)
- ISI score of 11 or above

Methods:

- dCBT-I for 8 weeks
- comparison of daily sleep data from smart ring and sleep diary

Results: Result 1: Insomnia severity improved significantly ($\Delta ISI = -6.16$, $p = 0.011$), while anxiety symptoms decreased ($\Delta GAD-7 = -2.38$, $p = 0.038$). No significant change was observed in depressive symptoms (PHQ-9, $p = 0.807$).

Result 2: Smart ring adherence was significantly higher than the sleep diary (52.5 vs. 44.5 days, $p = 0.002$).

Result 3: Significant discrepancies were observed between sleep diary and smart ring measurements. SOL, TST, SE WASO all showed significant improvements in sleep diaries ($p < 0.001$, $p = 0.004$, $p < 0.001$, $p = 0.007$, respectively), but no significant changes were detected by the smart ring. Interaction effects for SOL and TST indicate divergent trends between subjective and wearable-derived data.

Conclusions: • Digital CBT-I with smart rings reduces insomnia severity and anxiety symptoms.

- Smart ring adherence was significantly higher than the sleep diary.
- Smart rings did not capture improvements observed in sleep diaries.
- Significant discrepancies exist between subjective and wearable-derived sleep data.
- Subjective assessments remain essential in insomnia management.

What is the optimal treatment for co-occurring insomnia and anxiety? An RCT comparing internet CBT for insomnia to internet CBT for anxiety

E. Mason^{1,2}, A. Grierson¹, A. Sie¹, M. Sharrock¹, I. Li¹, A. Chen¹, S. Tang¹, J. Newby^{2,3}

¹Clinical Research Unit for Anxiety and Depression, St Vincent's Hospital, Sydney, Australia, ²University of New South Wales, School of Psychology, Faculty of Science, Sydney, Australia, ³Black Dog Institute, Sydney, Australia

Introduction: Insomnia and anxiety are highly prevalent and frequently co-occur. Given their comorbidity and bidirectional relationship, the study aimed to compare which treatment – internet CBT for insomnia or internet CBT for anxiety – leads to the best outcomes in individuals with comorbid insomnia and anxiety. We also examined mediators of treatment response.

Materials and methods: 120 participants with comorbid insomnia and clinical anxiety were randomized to receive internet-based cognitive behavioral therapy (iCBT) for insomnia or iCBT for anxiety. The primary outcome measures were the insomnia severity index and the generalized anxiety disorder 7-item scale. These were assessed before treatment, at mid-treatment, at post-treatment, and 3 months after treatment. Secondary outcome measures assessed depression symptoms, distress, and sleep diary parameters, as well as sleep effort, pre-sleep arousal, dysfunctional beliefs about sleep, and rumination.

Results: Large reductions in symptoms of insomnia, anxiety, depression, and distress were experienced by participants in both groups, as well as improvements in sleep efficiency and total sleep time. Critically, at the end of treatment, the insomnia treatment was more effective in reducing symptoms of insomnia than the anxiety treatment, and equally effective in reducing symptoms of anxiety. Treatment gains were maintained at 3-month follow-up, however, there were no differences between groups at that time point. Dysfunctional beliefs about sleep emerged as a key mediator of the differences between the interventions in insomnia symptoms at post-treatment.

Conclusions: These results suggest that in the common case of a patient presenting with comorbid insomnia and anxiety, treatment for insomnia may be the most efficient treatment strategy. Mechanisms of treatment will be discussed.

Memory

Age-Related Alterations in SO–Spindle Coupling and Their Impact on Sleep-Dependent Memory Consolidation: A Magnetoencephalography Study

S. Wang¹, L. Shi², L. Lu²

¹Wuhan University, Department of Psychiatry, Wuhan, China, ²Peking University Sixth Hospital, Beijing, China

Introduction: Cognitive decline is common in aging, with memory loss reducing life quality. Sleep, especially the coupling of slow oscillations (SO) and spindles during NREM sleep, is vital for memory consolidation. How aging-related changes in SO–Spindle coupling affect this process remains unclear. Using MEG, this study examined age differences in neural information flow during SO–Spindle coupling. Findings shed light on sleep-dependent memory mechanisms and potential intervention targets.

Materials and methods:

A total of 99 healthy participants (aged 18–35 and 60–75) were recruited and assigned to nap or wake conditions. All participants completed an episodic memory encoding task. Those in the nap condition underwent a 120-minute MEG-recorded sleep session; wake participants remained at rest for an equivalent duration. Memory performance was assessed pre- and post-intervention.

1. Behavioral outcomes were analyzed using ANOVA to assess the interaction between age group and nap/wake condition.
2. Phase-amplitude coupling analysis was used to extract SO–Spindle coupling phases during NREM sleep, followed by group comparisons (Watson-Williams test) and circular-linear correlations with memory performance.
3. SO–Spindle events were source-localized to the hippocampus, thalamus, and medial prefrontal cortex (mPFC), including the medial orbitofrontal cortex (mOFC) and rostral anterior cingulate cortex (rACC). Granger causality was used to construct directed brain networks. Connectome-based predictive modeling with leave-one-out cross-validation and permutation testing was used to predict memory retention. Group differences in network-memory associations were tested using the Cocor package.

Results:

- **Behavioral Performance:**
Nap-related memory enhancement was age-dependent. Younger adults in the nap condition showed significantly better memory retention than in the wake condition ($p < 0.05$), while no such effect was observed in older adults.
- **SO–Spindle Coupling Phase:**
The mean coupling phase differed significantly between age groups ($p < 0.05$). In younger adults, spindles peaked near SO peaks and were significantly associated with memory retention ($r = 0.48$, $p = 0.047$). In older adults, spindles occurred earlier during the SO upstate and showed no significant memory association ($r = 0.18$, $p = 0.739$), suggesting disrupted temporal precision in coupling may contribute to age-related memory decline.
- **Neural Information Flow:**
 - **Temporal Dynamics:** Two key windows were identified: SO trough (-250 to $+250$ ms) and SO peak ($+300$ to $+800$ ms).
 - **Age-Group Differences:** During the SO peak period, younger adults exhibited significantly stronger directed connectivity from the right thalamus to the left medial orbitofrontal cortex (mOFC) and the right rostral anterior cingulate cortex (rACC) compared to older adults ($P_{FDR} < 0.05$).
 - **Predictive Value:** In younger adults, directed thalamus-to-mPFC connections during the SO peak predicted memory retention. These associations were absent in older adults. Cocor analyses revealed significantly stronger correlations in the younger group for right thalamus to left mOFC ($z = 2.317$, $p = 0.010$) and right rACC ($z = 2.013$, $p = 0.022$).

Conclusions: Sleep supports memory consolidation, but efficacy wanes with age. While younger adults benefit from napping via precise SO–Spindle coupling and thalamocortical connectivity, older adults exhibit decoupling and diminished directional connectivity, particularly in thalamus–mPFC circuits. These disruptions may underlie age-related memory impairment and represent potential targets for intervention.

An Sleep-Active Hippocampal Interneuron for Memory Consolidation

M. Xu¹

¹CAS Center for Excellence in Brain Science and Intelligence Technology, Shanghai, China

Introduction: Sleep has been recognized as critical for memory. Research in recent decades has established that hippocampal memory replay during sharp-wave ripples is central to memory consolidation in sleep. However, the neural circuits that control ripple generation and memory consolidation remain poorly understood, particularly whether there are specialized cell types or dedicated neural circuits for this process. Here, we systematically investigated the involvement of specialized interneuron circuits for memory consolidation, as the interneurons are the fundamental building blocks of neural circuits that control hippocampal information processing.

Materials and methods: We have systematically examined the activity of different interneurons during the sleep-wake cycle in the hippocampus. Particularly, using a new strategy and single-cell RNA

sequencing data, we developed a new transgenic mouse model, specifically targeting the hippocampal sleep-active interneurons. We further examined its contribution to memory consolidation during sleep. **Results:** While the majority of hippocampus interneurons are more active during Wake or REM rather than NREM sleep, the primary state for memory consolidation, we identified a genetically defined interneuron population that is selectively active during NREM sleep and is essential for controlling ripple generation and memory consolidation.

Conclusions: We have identified a specialized neural circuit that is dedicated to memory consolidation in the hippocampus.

Aperiodic slope changes track encoding and sleep-based memory consolidation

A. Chatburn¹, A. Anesbury¹, M. Al Safadi¹, H.B. Caldwell¹, K. Lushington¹

¹University of South Australia, Adelaide, Australia

Introduction: Whilst ample research has investigated the relationships between oscillatory EEG, encoding and memory consolidation, the effects of the aperiodic component of the EEG are relatively undescribed in this realm. The aperiodic component of the EEG has been linked with brain state changes (i.e., different sleep stages) and memory performance, but not the two in conjunction despite their demonstrated link. Here, we assess the capacity of changes in the aperiodic slope to index learning and memory consolidation.

Materials and methods: 28 Participants (25F, age range 18-34) were required to learn different object-word paired associates on two separate days, then underwent either an afternoon nap (2-hour TIB) or 2 hours of wakefulness each session. They were tested on their recognition memory before and after the nap or wake intervention. EEG was recorded with a 64 channel EEG cap *in situ* throughout. The aperiodic slope was calculated through the IRASA method as implemented in the YASA toolbox. Linear mixed models were used to provide statistical analysis.

Results: The aperiodic slope steepened across learning and subsequently flattened across the nap ($\chi^2(1) = 15.20, p < .001$), but not across wake ($p > .05$) condition. Importantly, this renormalisation of the aperiodic slope was predictive of N400 amplitudes at delayed testing ($\chi^2(1) = 11.73, p < .001$). Learning-related, but not intervention-related slope changes were predictive of behavioural memory outcomes ($\chi^2(1) = 5.12, p < .023$).

Conclusions: These results provide first evidence for measures of aperiodic slope change as a method to track learning and consolidation-related changes across sleep, and suggest that this may be due to expectancy effects specific to sleep.

Associations between REM OSA, White Matter Microstructure, and Cognition in Community-Dwelling Cognitively Unimpaired Older Adults

J. Gills¹, P. Pahari², E. Valkanova³, J. McBride⁴, S. Shah⁴, R. McCray⁴, K. Kam⁵, A. Mullins⁵, A. Parekh⁵, I. Ayappa⁵, D. Rapoport⁵, R. Osorio⁶, O. Bubu⁷

¹NYU Langone Health, Psychiatry, Neurology, and Population Health, New York City, United States, ²NYU Langone Health, Psychiatry and Population Health, New York City, United States, ³University of South Florida, Epidemiology, Tampa, United States, ⁴NYU Langone Health, Psychiatry, New York City, United States, ⁵Ichan School of Medicine at Mount Sinai, Division of Pulmonary, Critical Care, and Sleep Medicine, New York City, United States, ⁶NYU Langone Health, Psychiatry and Neurology, New York City, United States, ⁷NYU Langone Health, Psychiatry, Neurology, Neuroscience, and Population Health, New York City, United States

Introduction: Obstructive sleep apnea (OSA) severity increases Alzheimer's disease (AD) and cognitive decline risks. OSA during rapid eye movement (REM) sleep is sometimes more severe than non-REM OSA, however the relationship between REM-OSA severity and cognition is not well characterized. Emerging evidence also suggests that white matter microstructure alterations may contribute to cognitive deficits in patients with OSA. We examined associations between white matter tract integrity, cognition, and REM OSA severity in cognitively unimpaired older adults.

Materials and methods: This cross-sectional study included 70 community-dwelling cognitively unimpaired older adults (35 non-OSA, 35 REM-OSA; mean $\pm$ SD: age = 66.3 $\pm$ 4.9y) participating in NYU

studies of sleep, aging, and memory. Participants had diffusion-weighted imaging, neuropsychological battery tests, overnight polysomnography, and clinical data. REM-OSA was characterized as REM AHI4% (>15 events/hour). Neuropsychiatric testing included processing speed, working memory, and visuospatial ability measures. Cingulum, uncinate fasciculus (UF), and fornix microstructure properties were estimated using diffusional tensor imaging metrics. Multivariable linear regression models examined associations of white matter microstructure (exposure) on cognitive measures (outcome measure) between OSA and non-OSA, and white matter microstructure by REM-OSA severity on cognition. Models were adjusted for age, race, education, sex.

Results: Of the 70 participants (35 non-OSA, and 35 REM-OSA), 68.8% and 62.9% were female, respectively. Mean±SD education was 16.5±2.4y REM-OSA(vs. 16.3±2.5y controls). Participants with REM-OSA had lower attention (β [REM AHI4%]=-1.07[-2.1 - -0.04], $p<0.050$) and slower processing speeds (β [REM AHI4%]=0.29[0.05 - 0.54], $p<0.050$) compared to controls. REM-OSA was associated with white matter microstructure alterations within both hemispheres of the cingulum($p=0.01$) and fornix($p=0.040$). Furthermore, decrements in the UF were associated with worse working memory β [UF] = -0.25 [-0.45 - -0.05], $p < 0.050$) and slower processing speed β [UF] = 0.26 [0.04 - 0.50], $p < 0.050$). Moreover, REM OSA severity interaction with white matter microstructure demonstrated lower working memory β [REM AHI4% x cingulum, right]=-0.20[-0.37- -0.03], $p < 0.050$; β [REM AHI4% x cingulum, left]=-0.23 [-0.44 - -0.02], $p<0.050$) and reduced visuospatial ability β [REM AHI4% x fornix]=-0.23 [-0.44 - -0.01], $p<0.050$).

Conclusions: Our findings demonstrate the critical role of white matter microstructure in the relationship between REM-OSA and cognition. Longitudinal studies are needed to investigate the mediating role of white matter microstructure alterations between REM-OSA and cognitive decline.

Auditory Suppression Cue Exposure During Sleep Promotes Targeted Memory Forgetting

X. Wang¹, X. Lin², Q. Wang³, H. Zhao¹, J. Shi⁴, L. Lu²

¹Peking Univeristy, Peking-Tsinghua Centre for Life Sciences and PKU-IDG/McGovern Institute for Brain Research, Beijing, China, ²Peking University Sixth Hospital, Beijing, China, ³Beijing Normal University, Beijing Key Laboratory of Applied Experimental Psychology, Beijing, China, ⁴Peking Univeristy, National Institute on Drug Dependence and Beijing Key Laboratory of Drug Dependence, Beijing, China

Introduction:

Previous research shows that individuals can intentionally suppress unwanted memories through retrieval suppression, leading to Suppression-Induced Forgetting (SIF). However, this training often requires prolonged exposure to memory cues, causing discomfort. Recent studies suggest that sleep, a period of memory consolidation and sensory processing, may offer a unique opportunity for memory manipulation. Auditory cues presented during sleep could reactivate inhibitory control training learned while awake, promoting the forgetting of specific memories. This approach may bypass discomfort and provide an efficient method for inducing the forgetting of unwanted memories. Thus, this study explores whether sleep-based auditory cues can reactivate retrieval suppression and induce targeted memory forgetting.

Materials and methods: Thirty-six healthy participants were recruited. Before sleep, participants engaged in declarative memory learning and underwent an initial memory test to establish baseline performance. Subsequently, while awake, they participated in Suppression-Induced Forgetting (SIF) training using the Think/No-Think (TNT) paradigm. This training involved two distinct auditory cues signaling the Think and No-Think conditions and the presentation of learned verb cues. The effectiveness of retrieval suppression was assessed through a memory test immediately after the TNT training. During the subsequent non-rapid eye movement (NREM) sleep phase, participants were exposed to continuous auditory cues, including the instructional cues and verb sounds used during the TNT paradigm. Upon awakening, participants completed another memory test and a Localizer task to assess the neural correlates of memory processing. Notably, the instructional cues presented during sleep were identical to those used in the wakeful TNT paradigm to reactivate retrieval suppression,

while the verb sounds following the cues differed to distinguish the effects of retrieval suppression between wakefulness and sleep. Throughout the experiment, 64-channel EEG monitoring was employed to explore the neurophysiological mechanisms underlying SIF during sleep.

Results: The study found that participants could effectively reactivate the Suppression-Induced Forgetting (SIF) process through auditory cues during sleep, leading to the active forgetting of targeted memories. Specifically, compared to the Think condition, the No-Think condition elicited greater electrophysiological potential changes after the instructional cues ended and inhibited the formation of sleep spindles, which are known to be associated with memory consolidation. Furthermore, cross-temporal representational similarity analysis (RSA) between EEG data from post-cue exposure during sleep and corresponding category-related EEG data from wakefulness revealed distinct neural correlates for the Think and No-Think conditions. While cues and stimuli in the Think condition successfully reinstated target category representations, the No-Think condition surpassed this reinstatement. This suggests that auditory cues presented during sleep can selectively modulate memory representations, supporting the hypothesis that sleep-based interventions can enhance targeted forgetting.

Conclusions: These results suggest that sleep-based interventions using auditory cues can enhance targeted forgetting, bypassing the discomfort associated with prolonged exposure to memory cues during wakefulness. This approach provides a novel mechanism for memory control and has significant clinical implications. Future research should further explore the long-term effects of sleep-based memory interventions and their applicability in clinical settings.

Does intentional integration influence the fate of reactivated memories during sleep?

J. Antony¹, H. Ross¹, M. Babb¹, A. Loehr¹, A. Vandevort¹, E. Ruvalcaba¹, J. Tarica¹, C. Schwake¹, A. Horner², E. Schechtman³, K. Bennion¹

¹Cal Poly, SLO, San Luis Obispo, United States, ²University of York, York, United Kingdom, ³University of California, Irvine, Irvine, United States

Introduction: Growing evidence suggests that memories benefit from sleep. For example, neural investigations of new memory traces formed during learning show that they become reactivated during sleep, which offers a putative mechanism by which sleep benefits memories via rehearsal. Intriguingly, this process can be manipulated by presenting some stimulus (odor or sound) during learning and reinstating it again without waking the sleeper up. When this occurs, memories for simple associations generally improve, and the same neurons or neural regions that contributed to forming the memory become reactivated. Therefore, memory reactivation does not need to only occur spontaneously but can be targeted (in a technique known as targeted memory reactivation, or TMR). Many scientists have now realized that they can use TMR as a tool to understand how memories are formed and when/how they can be modified. For example, memories in these paradigms can be classified as simple (with one specific reactivation cue per tested memory) or complex (>1 cue per tested memory). Simple memories nearly always benefit from cueing, but it appears that the outcome of complex memories will depend on how they are learned. One hypothesis is that if memories were learned in such a way as to encourage integrating all the various elements together, such as with the creation of a concept map, all memories can benefit from reactivation. Conversely, if they were learned such that some information is prioritized over other information or if they were simply learned separately but contained overlapping associations, parts of the memories may get stronger while the other parts get weaker.

Materials and methods: Here, we tested whether a simple instructional manipulation – asking participants to integrate conflicting associations – would lead to different outcomes when memories are later cued during sleep. Participants learned A-B, A-C pairs with instructions to either integrate them or learn them separately, after which half of the associations were cued via low-volume sounds during an afternoon nap. All associations were then tested after the nap.

Results: In line with prior findings, behavioral results indicated that cued items were recalled better than uncued items ($p < 0.05$), though the extent to which instructions changed memory was unclear ($p > 0.1$). Physiological analyses showed typical post-cue responses like K-complex-influenced ERPs between 500-800 ms, theta bursts between 400-700 ms, and sigma (spindle) bursts between 1000-1500 ms.

Conclusions: These results have important implications for employing TMR in educational settings, as real-world learning involves complex networks of associations.

Effects of Intraindividual Variability in Sleep on Long-Term Memory Encoding

D. Lin¹, T.B. Koa^{1,2}, S.A. Jamaluddin¹, J.H. Poh¹, J. Cousins^{1,3}, J.C. Lo^{1,2,4}

¹National University of Singapore, Centre for Sleep and Cognition, Yong Loo Lin School of Medicine, Singapore, Singapore, ²National University of Singapore, Human Potential Translational Research Programme, Yong Loo Lin School of Medicine, Singapore, Singapore, ³Radboud University Medical Centre, Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands, ⁴National University of Singapore, Department of Medicine, Yong Loo Lin School of Medicine, Singapore, Singapore

Introduction: Greater variability in sleep across nights has been linked with poorer cognitive outcomes, but some recent evidence suggests that for sleep-restricted individuals, a variable sleep schedule that allows for prophylactic and/or recovery sleep might result in less impairment in some basic cognitive functions compared to a stable schedule. This study aimed to investigate whether multiple nights of curtailed sleep opportunities with either consistent or variable sleep duration affected declarative memory encoding differently.

Materials and methods: After two baseline nights of 8-h time-in-bed (TIB), in the following five nights, 44 participants (24 females, age: 21 – 26 years) had a nightly 8-h TIB (control group), a nightly 6-h TIB (stable short sleep group), or 8, 4, 8, 4, and 6 h of TIB from the first to the fifth manipulation night (variable short sleep group). Following the fifth manipulation night, participants performed a picture encoding task. Memory performance was measured after two recovery nights of 8-h TIB, thus minimising the effects of fatigue in the recognition test, where participants needed to indicate whether they had previously seen each picture by selecting one of five options: “definitely did not see”, “probably did not see”, “unsure”, “probably saw”, “definitely saw”. “Definite” and “probable” responses were combined to generate hits, misses, false alarms, and correct rejections. The numbers of unsure responses to new and old pictures were also derived.

Results: Compared to the control group, “no” responses to new pictures were more common and thus, correct rejection rate was higher ($p = .04$) in the stable short sleep group; a similar tendency was found for old pictures (i.e. miss rate, $p = .09$), suggesting that these participants adopted a more conservative response style. As for the variable short sleep group, they had significantly more “unsure” responses to old pictures than the control group ($p = .05$), and a similar tendency was observed for new pictures ($p = .09$), indicating that response certainty was reduced by this short sleep schedule. Between the two short sleep groups, for old pictures, the variable short sleep group had more “unsure” responses ($p = .003$) but fewer “yes” responses (and hence, a lower hit rate, $p = .02$); for new pictures, the variable short sleep group also had more “unsure” responses ($p = .003$) but fewer “no” responses (and hence, a lower correct rejection rate, $p = .01$).

Conclusions: In young adults, multiple nights of sleep restriction affected declarative memory encoding such that even after recovery sleep, performance was different from the well-rested control. These effects differed depending on the variability of sleep duration before memory encoding. A stable short sleep schedule induced a more conservative response style, whereas a variable short sleep schedule appeared to have weakened memory traces and increased uncertainty in responses. Consistent and sufficient sleep remains the most effective strategy for optimising declarative memory encoding.

Effects of Monophasic and Polyphasic Sleep on Prospective Memory

A.F. Kusnadi¹, T.B. Koa^{1,2,3}, J.C. Lo^{1,2,3}

¹National University of Singapore, Centre for Sleep and Cognition, Yong Loo Lin School of Medicine, Singapore, Singapore, ²National University of Singapore, Department of Medicine, Yong Loo Lin School of Medicine, Singapore, Singapore, ³National University of Singapore, Human Potential Translational Research Programme, Yong Loo Lin School of Medicine, Singapore, Singapore

Introduction: Many struggle to sleep the recommended amount because of competing wake activities. In fact, some actively search for short sleep schedules to maximise their wake duration to cope with demands from their study and work. Polyphasic sleep—deliberately distributing multiple sleep episodes over a 24-h day, typically with the goal of reducing time spent asleep—has been claimed by its advocates to enable optimised performance, and improve productivity, memory and mood despite the short sleep durations. While neurobehavioural deficits, such as impairments in memory, induced by monophasic short sleep have been documented, the impact of polyphasic sleep on memory is unknown. This study aimed to determine whether prospective memory (PM) differed after following a monophasic and a polyphasic short sleep schedule for 24 h.

Materials and methods: Forty healthy young adults (22 females, age: 18-35) participated in this 29-h laboratory-based study. They were randomly assigned to either a monophasic sleep schedule consisting of a single 2-h sleep opportunity, or a polyphasic sleep schedule comprised of six 20-min sleep opportunities equally distributed across the 24-h manipulation period. At the beginning of the manipulation period (before the polyphasic group's first sleep opportunity), participants first performed a word categorisation (WC) task where they decided if a word is an exemplar of the given category in each trial. Task performance was indicated by accuracy and speed measures. The PM task was then introduced: participants were given a list of eight target words (e.g. "desk"), each paired with an action (e.g. looking under their table) which they needed to perform when they encountered the target word during the next WC task administered 24 h later (i.e. after the polyphasic group's last sleep opportunity). PM performance was indicated by the time taken to complete the action and the proportion of correct and on-time actions within the same trial.

Results: The monophasic and the polyphasic short sleep groups did not differ in the proportion of correct responses (mean $\pm$ SEM: 0.93 ± 0.01 ; 0.92 ± 0.01 , $p > .44$) and reaction times (1231.11 ± 115.82 ; 1236.52 ± 77.92 ms, $p > .97$) for the first WC task. Relative to the first WC task, during the second WC task, accuracy reduced slightly (monophasic: 0.90 ± 0.01 , $p < .001$; polyphasic: 0.88 ± 0.01 , $p < .001$), and reaction time increased prominently (1604.40 ± 150.51 , $p < .001$; 1510.69 ± 55.72 ms, $p < .001$), but no significant group difference was found for these two measures ($p > .57$). In the PM task, both groups did not differ in the proportion of correct responses (0.86 ± 0.03 ; 0.85 ± 0.03 , $p > .82$), on-time responses (0.75 ± 0.05 ; 0.80 ± 0.04 , $p > .41$), and the time taken to complete the correct action (9427.45 ± 746.74 ; 9606.95 ± 804.15 ms, $p > .87$).

Conclusions: Polyphasic and monophasic sleep schedule over a 24-h period resulted in similar PM performance. The increase in reaction time from the first to the second WC task might reflect both the effects of sleep curtailment and the efforts deployed in strategic monitoring for the target words, which did not differ between the two short sleep schedules.

Impact of Melatonin on Progression of Cognitive Impairment

E. Rom, D.O.¹, N. Mattek², J. Quinn³

¹Oregon Health & Science University, Neurology, Portland, United States, ²Oregon Health & Science University, Oregon Alzheimer's Disease Research Center, Portland, United States, ³Oregon Health & Science University, OHSU Parkinson Center and Movement Disorders Program, Portland, United States

Introduction: Melatonin is an antioxidant and anti-inflammatory molecule produced in the pineal gland. It has been proposed by animal models that exogenous supplementation of melatonin may act as a protective intervention in elderly participants with cognitive impairment and dementia. This study aimed to evaluate the impact of melatonin supplementation on cognitive function and the rate of progression from healthy to mild cognitive impairment (MCI), and from MCI to dementia postulating that melatonin could provide neuroprotection from the inflammatory state of the various dementia pathologies.

Materials and methods: Retrospective data was collected from the National Alzheimer's Coordinating Center (NACC) uniform data set (UDS) for this case-control study. Prevalence of melatonin use by demographic and clinical characteristics was analyzed in the cross-sectional portion of the study. Diagnosis codes were utilized to identify severity of cognitive status and Clinical Dementia Rating Sum of Boxes (CDR-SB) and Montreal Cognitive Assessment (MoCA) scores were analyzed for cognitive

function. Rates of conversion from normal cognition to MCI and from MCI to dementia at intervals of approximately 1 year were analyzed between melatonin and non-melatonin groups.

Results: A total of 17,264 participants aged 60 years and above (mean age 71.9, SD 7.0) from 2015-2024 completed the medication questionnaire and cognitive evaluations at the initial study visit. Of those, 1,120 (6.5%) reported melatonin supplementation (melatonin-group) compared to 16,144 who did not (non-melatonin group).

The melatonin group was 52.1% female, 88.7% white, and obtained a mean education of 16.3 years. Comparatively, the non-melatonin group was 58.3% female, 75.2% white ($p<0.0001$), and with a mean education of 15.3 ($p<0.0001$).

Of all participants at the initial visit, 45.5% had normal cognition, 4.2% had impaired cognition not MCI, 26.4% had MCI, and 23.9% had dementia. The melatonin group had a higher prevalence of cognitive impairment at baseline compared to non-melatonin, 64% vs 54% ($p<0.0001$). Mean CDR-SB was 2.4 among melatonin users and 1.8 in non-melatonin users. ($p<0.0001$). Mean MoCA total score was 22.2 among melatonin users and 22.4 in non-users ($p=0.64$).

A subset of 4,464 participants with normal cognition at baseline completed the second annual visit and 11.7% converted to MCI. Multivariate logistic regression was used to examine the association between melatonin use vs. non-use at baseline and conversion to MCI at subsequent annual visit after adjusting for covariates: age, sex, education, race, prevalence of sleep disorder, depression scale. The risk of conversion to MCI was not different between melatonin users vs non-users (Odds Ratio 1.18, $p=0.44$).

Conclusions: The large diverse NACC database was used to estimate prevalence of melatonin use among older adults with varying degrees of cognitive health. Melatonin users were more evenly distributed male and female and more likely White with longer education. Moreover, the melatonin-group had a higher prevalence of cognitive impairment than non-users at baseline. Melatonin use did not significantly impact the rate of conversion from healthy to MCI between baseline and annual evaluations.

Impact of Post-Stroke Insomnia on Cognitive Decline: Evidence from the TriNetX Global Database

F. Hasan¹, M.S. Muhtar², H.-Y. Chiu^{3,4,5}

¹Faculty of Nursing, Chulalongkorn University, Bangkok, Thailand, ²Graduate Institute of Data Science, Taipei Medical University, Taipei, Taiwan, ³School of Nursing, Taipei Medical University, Taipei, Taiwan, ⁴Research Center of Sleep Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan, ⁵Department of Nursing, Taipei Medical University Hospital, Taipei, Taiwan

Introduction: Insomnia is a prevalent sleep disorder among stroke survivors and is recognized as an independent risk factor for cognitive impairment. However, the longitudinal relationship between post-stroke insomnia and subsequent cognitive decline remains inadequately explored. This study aimed to investigate the association between post-stroke insomnia and the risk of developing cognitive impairment over time.

Materials and methods: We conducted a retrospective cohort study utilizing data from the TriNetX database, encompassing hospital-based records from January 1, 2004, to September 30, 2017. The study included patients aged 20 years and older with a diagnosis of stroke, insomnia, or cognitive impairment, as defined by the International Classification of Diseases. Stroke patients were categorized into two groups: those with insomnia (cohort 1, $n = 35,514$) and those without insomnia (cohort 2, $n = 1,309,838$). Propensity score matching (1:1) was employed to balance baseline characteristics, resulting in 35,144 patients in each cohort. Kaplan-Meier survival analysis was utilized to assess the risk of cognitive impairment.

Results: A total of 70,288 stroke patients (mean age: 67.3 years) were analyzed post-matching. During the follow-up period, 6,476 patients in the insomnia group and 5,197 in the non-insomnia group developed cognitive impairment. The analysis revealed a significantly higher risk of cognitive

impairment in the post-stroke insomnia group (hazard ratio [HR] = 1.288; 95% confidence interval [CI]: 1.242–1.336).

Conclusions: Post-stroke insomnia is associated with a significantly increased risk of subsequent cognitive impairment. These findings underscore the importance of early detection and management of insomnia in stroke survivors to mitigate long-term cognitive decline.

Impact of Sleep Disturbance and Hypnotics on the Risk of Dementia: a longitudinal follow-up study

C.-Y. Wei^{1,2}, P.-Y. Chiu^{3,4}

¹Chang Bing Show Chwan Memorial Hospital, Department of Neurology, Lugang Township, Taiwan,

²Chinese Culture University, Department of Exercise and Health Promotion, College of Kinesiology and Health, Taipei, Taiwan, ³Show Chwan Memorial Hospital, Department of Neurology, Changhua City, Taiwan, ⁴Tunghai University, Department of Applied Mathematics, Taichung, Taiwan

Introduction: Sleep quality is often impaired in individuals with dementia. However, the relationship between sleep disturbances and dementia remains unclear. This study investigated the association between various sleep domains and the risk of developing dementia in older adults.

Materials and methods: In this retrospective longitudinal study, we enrolled 2,679 adults from three centers in Taiwan. We collected baseline data on age, gender, education, medication use, Clinical Dementia Rating (CDR) scale, Cognitive Abilities Screening Instrument (CASI), Neuropsychiatric Inventory (NPI), History-based Artificial Intelligence Activities of Daily Living (HAIADL), and History-based Artificial Intelligence Clinical Frailty Scale (HAICFS).

Results: We examined demographic, clinical, and neuropsychiatric differences between individuals who converted to dementia (Converters, N=957) and those who did not (Non-Converters, N=1,722) over an average follow-up of approximately 2.3 years. Compared to non-converters, converters were significantly older, had fewer years of education, lower CASI scores, and higher scores on the CDR-Sum of Boxes (CDR-SB), HAIADL, HAICFS, and NPI. Multivariate analyses identified nighttime awakenings and antipsychotic use as significant predictors of dementia conversion, whereas insomnia was associated with a reduced risk. Interestingly, the use of benzodiazepines and Z-drugs did not increase the risk of dementia.

Conclusions: These findings underscore the importance of early identification and monitoring of specific neuropsychiatric symptoms and medication use in older adults at risk of developing dementia.

Napping and Prospective Memory: Investigating Cue Type and the Selective Benefits on Memory Retrieval

P. Ojha¹, N. Kashyap²

¹Manipal University Jaipur, Department Of Psychology, Jaipur, India, ²Indian Institute of Technology Guwahati, Department of Humanities and Social Sciences, Guwahati, India

Introduction:

Prospective memory represents our ability to remember to do things in the future (Einstein & McDaniel, 1990) and is more prone to forgetting. Tasks ensuring attending meetings or taking medications punctually, require forming intentions to execute these tasks upon encountering relevant external cues like future events (visiting grocers while returning from work) or time (waiting for 6 pm). Napping is a natural practice that can provide insights into sleep organization. Research shows that daytime naps help effectively help process information that is often easily forgotten. (Dijk et al., 2014; Ficca et al., 2010; Duthiel et al., 2021; Sugawara et al., 2018).

Materials and methods:

Participants in the study were asked to memorize four letters (e.g., f, r, q, s). Each letter was presented for 2 seconds, followed by a 1-second interval without stimuli. The instructions for prospective memory tasks varied between event cue and mixed cue tasks. After memorization, participants either took a 90-minute nap or remained quietly awake in the laboratory. During the nap condition, participants wore an Actiwatch (PHILIPS Respironics, Inc.) and a Dreem Headband to record physiological data, including EEG activity and body movement. Following the distraction task, participants began the ongoing working memory task, which consisted of five blocks of experimental trials. Each block included 20 individual trials, and prospective memory cues appeared once in each block at the same position across all blocks. The entire experiment took approx. 45 minutes to complete, concluding with feedback.

Results: *Accuracy:* Responses were marked as correct if participants pressed the correct response key for the PM target in the WM task. Mixed factorial ANOVA was used for statistical analysis. Significant interaction effect between type of PM and nap [$F(1, 22) = 6.278, p < 0.05, \eta^2 = 0.22$] was found with mixed PM more benefited by nap. For event based PM task, no significant accuracy results were obtained. Significant main effect of pm type was also found [$F(1, 22) = 6.02, p < 0.05, \eta^2 = .02$]. *Reaction Time:* Significant main effect of nap [$F(1, 22) = 8.9, p > 0.05, \eta^2 = 0.01$] suggests that participants responses were quicker after nap ($M=0.82$ sec) as compared to no-nap ($M=1.2$ sec). Significant main effect of types of PM [$F(1, 22) = 10.08, p > 0.05, \eta^2 = 0.005$] was found indicating that participants were slower to respond in event based PM task ($M=1.4$ seconds) as compared to mixed PM ($M=0.9$ sec).

Conclusions: The study investigated the impact of napping on PM across type of cues. Despite established benefits of sleep on memory, napping did not significantly enhanced future memory performance in young adults. The research considered factors such as sleep stages (NREM and REM) and conscious monitoring of cues. The study emphasized the importance of contextual cues, particularly the association of mixed cues, and suggested a selective beneficial impact of naps on prospective memory cued by mixed cues. RT analysis indicated faster responses in PM trials after napping, supporting that sleep aids in the spontaneous retrieval of prospective memory over time.

Reactivating spatial memories during sleep using multi-sensory cueing and an immersive virtual environment

²Hebrew University of Jerusalem, Department of Cognitive and Brain Sciences, Jerusalem, Israel,

³University of California, Irvine, Department of Pediatrics, Irvine, United States

Introduction: Sleep plays an active role in the consolidation of memories. During sleep, the neural traces supporting newly formed declarative memories are spontaneously reactivated. Targeted memory reactivation (TMR) is a technique that uses non-invasive sensory cues, such as odors or sounds, to preferentially reactivate associated memories during sleep. One avenue of TMR research that has not yet been explored involves the combined use of odors and sounds to selectively enhance memories.

Materials and methods: Here, we examine the interactive effects of multi-modal reactivation cues during sleep on consolidation in a realistic first-person memory task. We used the Minecraft Memory and Navigation task, a first-person, engaging spatial task that demonstrates sleep's contribution to spatial memory (Simon et al., 2022). Following memory encoding of unique object locations and the environment which we enriched with odors and sounds, we reactivated the encoded memories during NREM sleep using the odors, sounds, or both. We hypothesized that rich, multisensory synergetic reactivation during sleep, compared to the unisensory reactivation, would maximally benefit spatial memory recall. Additionally, we use EEG to explore the effect of different cueing regimes on sleep spindles and slow oscillations during NREM sleep.

Results: Data collection for this study is ongoing, with a target sample of 160 participants across two sites. Preliminary behavioral data ($N=60$) will show the effects of the different cueing regimes on object placement accuracy, as well as on other navigation metrics. Preliminary spectral data ($N=60$) will show the relative change in sleep spindles and slow oscillations, upon cue delivery, and will be compared across experimental conditions. Furthermore, we will evaluate the relationship between the change in spindle power upon cue delivery and subsequent spatial memory performance on our task.

Conclusions:

Our study reveals the contribution of memory consolidation during sleep to real-life spatial memories and provides insight into whether multisensory cueing has synergistic, additive, or competitive benefits for consolidation.

REM sleep promotes overnight emotional memory in a picture recognition task

A. Mullins¹, K. Kam¹, K.R. Martillo¹, S. Ravi¹, A. Parekh¹, D.M. Rapoport¹, S.-E. Lu², J. Sunderram³, A.W. Varga¹, I. Ayappa¹

¹Icahn School of Medicine at Mount Sinai, Pulmonary, Critical Care and Sleep Medicine, New York, United States, ²Rutgers University, School of Public Health, Piscataway, United States, ³Rutgers Robert Wood Johnson Medical School, Division of Pulmonary & Critical Care, New Brunswick, United States

Introduction: World Trade Center (WTC) Disaster Responders suffer a high prevalence of obstructive sleep apnea (OSA), insomnia and mental health comorbidities such as post-traumatic stress disorder (PTSD), depression and anxiety. In picture tasks of emotional memory in OSA and PTSD, REM sleep instability impairs sleep-related consolidation of emotionally valenced images. We aim to test the effect of PTSD and sleep disorders on an overnight emotional picture recognition task and investigate whether REM sleep promotes emotional memory in WTC Disaster Responders.

Materials and methods: Nineteen (4 female) WTC Disaster Responders, mean age 61.8 (range 49-75) years encoded consensus-rated negatively valent and neutral pictures from the International Affective Picture System (IAPS) in the evening before sleep with attended polysomnography (PSG). Image recognition testing occurred within 1 hour of wake time. We compared memory performance for consensus and subjectively-rated negative and neutral image memory using paired signed-rank tests and 2-way ANOVA for comparisons between those with and without PTSD, insomnia symptoms, OSA or periodic limb movements of sleep (PLMs). We also investigated the relationship of memory performance to metrics of REM sleep (duration, proportion, REM bouts & latency) with Pearson's coefficients.

Results: Five participants (26%) had a diagnosis of PTSD and 9 (47%) had an insomnia severity index score ≥ 8 . On PSG, 11 participants (58%) had OSA ($AHI \geq 15$) and 7 (37%) had periodic limb movement disorder (PLMD) ($PLM \text{ index} \geq 15$). Correct image recognition (Hit Rate) was significantly greater for subjectively negative valenced compared to consensus neutral images ($p=0.01$). However, no effect of PTSD, insomnia, OSA or PLMD was observed. Accuracy (Hit Rate–False Alarms) for consensus negative images was correlated with %REM ($R=0.52, p=0.02$) and REM duration ($R=0.47, p=0.04$). Accuracy for subjectively negative images was not correlated with REM sleep metrics.

Conclusions: In this group of WTC Disaster responders, negatively valenced images are more readily recognized compared to neutral images, particularly for subjectively negative images. Proportion and duration of REM sleep appears to promote overnight memory of negatively valenced images but a greater understanding of REM sleep neurophysiology underpinning this observation may come from further analysis with the available 19 channel EEG. Additionally, the effect of sleep disorders, mood and PTSD on these findings in WTC Responders requires investigation with a larger sample.

REM-sleep saw-tooth waves: cortical topography and associations with cognition

I. Filchenko¹, C. Bernasconi¹, C.L.A. Bassetti¹, A.K. Eberhard-Moscicka¹, M.H. Schmidt²

¹Bern University Hospital (Inselspital) and University of Bern, Department of Neurology, Bern, Switzerland, ²University of Bern, Department of Psychology, Bern, Switzerland

Introduction: Saw-tooth waves (STWs) are a hallmark of rapid-eye movement sleep, reflecting widespread, coordinated brain activity (Frauscher et al., 2020). However, their function remains poorly understood. Given that STW were associated with altered thalamo-cortical connectivity (Peter-Derex et al., 2023) and that thalamo-cortical circuits play a crucial role in cognition (Filchenko et al., 2023,

2025), we investigated the associations between STW properties and cognitive functioning in an exploratory analysis.

Materials and methods: The “Sleep and cognitive functioning” study included volunteers in good or excellent health condition (Eastern Cooperative Oncology Group grade of 0-1) without known structural brain damage (e.g., previous stroke). Demographics, medical history, cognition, and sleep architecture by polysomnography were assessed at study inclusion. The neurocognitive battery (11 tests) assessed attention, executive functioning as well as short- and long-term visual and verbal memory. Electroencephalography (EEG) was recorded using either a 6-electrode setup (a montage with frontal, central, and occipital electrodes) or a 256-electrode setup. STW were detected using a custom feature-based algorithm in MATLAB (Manual of the American Academy of Sleep Medicine, v3). The detection was validated against the manual scoring of 5-second STW segments according to Simor et al., 2021. Associations between STW properties as dependent variables and cognition were explored using multivariate linear regression adjusted for age and arousal index. The significance level was set at $\alpha=0.05$.

Results: 60 participants were included (age: 52.7 [32.9, 64.6] years; 55% men; total recording time: 7.25 [6.50, 8.20] hours, apnea-hypopnea index: 5.1 [1.6; 15.9] events/hour; hd-EEG in 52%). STW were mostly expressed in the fronto-central areas, reaching there the maximal amplitude. 0.5–6 Hz and 20–40 Hz activity was dominating in the frontal regions, and 12–16 Hz activity was prominent in the posterior regions. EEG analysis based on the mean of 6 electrodes showed limited associations between STW and cognition (e.g., negative association of STW amplitude with reaction time in alertness and psychomotor vigilance task; negative association of EEG power in 8-12 Hz with task completion time in Bells test). HD-EEG analysis on the level of individual electrodes identified multiple associations of interest with a distinct topography, which were directionally consistent with the 6-electrode EEG analysis (e.g., STW amplitude in the fronto-central regions bilaterally with standard deviation of reaction time of Go-no-Go task [negative]; STW amplitude in the right frontal, temporal, and occipital region with the interference score of Victoria Stroop Task [positive]; STW amplitude and EEG power in 20-40 Hz in the right temporal and parietal region with immediate recall of Brief Visuospatial memory tasks [positive]).

Conclusions: This is the first description of the automatically detected STW in clinical polysomnography and in hd-EEG. STW properties showed distinct associations with cognition that depended on their underlying topography. Overall, higher STW activity was negatively associated with attention and executive functioning, but positively associated with visual memory. We will further investigate functional connectivity during STW.

Sleep Disorders and Sarcopenia: Exacerbating Cognitive Decline in Chinese Women with Mild-to-Moderate Alzheimer's Disease

S.-w. Liu¹, Y. Shen¹, H. Hu¹

¹The Second Affiliated Hospital of Soochow University, Neurology and Suzhou Clinical Research Centre of Neurological Diseases, Suzhou, China

Introduction: Sleep disorders and sarcopenia are both risk factors for cognitive deterioration and contribute to the development of Alzheimer's disease (AD). However, few studies have evaluated the relationship between sarcopenia and sleep disturbances in women with AD. The purpose of this study was to investigate the relationship between sarcopenia and sleep status in Chinese women with mild to moderate AD.

Materials and methods: This cross-sectional study recruited 112 female outpatients aged between 60 and 85 years. Demographic characteristics, appendicular skeletal muscle mass index (ASMI), grip strength, and gait speed were assessed. Sarcopenia was diagnosed according to criteria of the Asian Working Group for Sarcopenia. Pittsburgh Sleep Quality Index (PSQI) assessed sleep variables. Mini-Mental State Examination (MMSE) and Montreal Cognitive Assessment (MoCA) assessed cognitive function. Binary logistic regression models explored the relationship between sleep variables and cognitive function and sarcopenia, adjusting for potential cofounders.

Results: 门诊患者分为 36 例 AD 合并肌肉减少症 (ADSa) 和 76 例无肌肉减少症的 AD 患者 (ADNSa), 患病率为 32.1%。ADSa 的 ASMI 较低, 握力较弱, 步态速度较慢, 睡眠质量差的发生率较

高，认知功能较差。多因素二元 logistic 回归分析显示，PSQI 总分高（OR = 1.13）、睡眠质量差（OR = 2.73）、主观睡眠质量差（OR = 1.83）、低 MMSE（OR = 0.77）和 MoCA（OR = 0.76）评分与肌肉减少症的高几率相关。与睡眠时间 ≤ 15 min 相比，> 60 min（OR = 5.01）与肌肉减少症相关。与 7-8 小时相比，< 6 小时（OR = 3.99）、8-9 小时（OR = 4.48）和 ≥ 9 小时（OR = 6.33）的睡眠持续时间与肌肉减少症相关。

Conclusions: More sleep symptoms and cognitive impairment exist in female patients with sarcopenia. The higher total scores of PSQI, poorer subjective sleep quality, longer sleep latency, excessive and insufficient sleep duration and poorer cognitive function are associated with higher odds of sarcopenia in female patients with mild to moderate AD.

Acknowledgments: The authors thank the study participants and their relatives, and the staff of the Second Affiliated Hospital of Soochow University for their cooperation and assistance.

Sleep quality, attitudes, cognition and APOE in older adults in the SleepQuest and Great Minds cohorts

T. Lemke^{1,2}, D. Woodstoke¹, V.G. Gabb¹, J. Blackman¹, S. Young³, I. Koychev⁴, E. Coulthard¹

¹University of Bristol, Bristol Medical School, Bristol, United Kingdom, ²University of Bath, Bath, United Kingdom, ³University of Oxford, Department of Psychiatry, Oxford, United Kingdom, ⁴Imperial College London, Brain Sciences, Division of Psychiatry, London, United Kingdom

Introduction: Poor sleep quality impairs cognition and increases risk of neurodegenerative diseases such as Alzheimer's Disease (AD). Sleep disturbance is common in older adults, and poor sleep is a symptom of AD. Poor sleep and its adverse consequences have been linked with anxiety which may arise from unhelpful beliefs and attitudes about the importance of sleep. Apolipoprotein E (APOE) ε4 is an established genetic risk factor for AD, independently linked to both impaired sleep and behavioural disturbance. Here, we capitalise on two existing longitudinal datasets that probe sleep, cognition, sleep anxiety and APOE genotype to examine the relationships between these factors. We hypothesise that i) poor sleep predicts future cognitive decline; ii) APOE ε4 is associated with poor sleep independent of cognition; and iii) unhealthy beliefs about sleep predict poorer sleep and cognitive decline.

Materials and methods: A retrospective analysis was conducted on longitudinal data from the SleepQuest study and Great Minds register. Participants completed Pittsburgh Sleep Quality Index (PSQI), depression and anxiety (PHQ-8 and GAD-7) questionnaires at three timepoints (Spring 2020 – Winter 2022), Dysfunctional Beliefs about Sleep (DBAS-16) questionnaire twice, CANTAB Paired Associates Learning (PAL) task 1-9 times (median: 4, Winter 2020-2024), and baseline demographics and cardiovascular risk factors. The primary outcome was PAL score. Total PSQI score was a secondary outcome. Separate simple or mixed-effects linear models evaluated factors associated with mean and longitudinal PAL and PSQI scores, controlling for confounders such as age and sex.

Results: 585 UK adults without a cognitive diagnosis participated in both studies (mean age: 63 years, 71% female). 62 participants had a diagnosed sleep disorder. A sub-group (N = 276) underwent APOE genotyping; 89 carried at least one ε4 allele. There was no significant association between mean or baseline PSQI score on PAL score in the main- and sub-groups, and no significant effect of APOE allele status on sub-group PSQI score. Older age and being male were associated with poorer PAL performance. Increasing DBAS score was associated with a small decrease in PAL score over time ($p < 0.001$) – suggesting unhealthy attitudes to sleep, rather than the subjective sleep report itself, was associated with cognitive decline.

Conclusions: Sleep quality at baseline did not predict cognitive decline, in contrast to existing literature, however the robustness of the models was hampered by sample size and the limited follow-up period. There was insufficient evidence to support a link between APOE genotype and sleep quality. Unhealthy beliefs about sleep were associated with worsening cognitive performance. The presumptive link between attitudes to sleep and cognitive decline may be through disturbed objective sleep. A limitation is that the PSQI is a self-reported, subjective measure of sleep quality with reduced accuracy compared to objective measures such as polysomnography. The relationship between attitudes to sleep, subjective and objective sleep and future cognitive decline deserves future exploration as it may yield behavioural interventions that protect brain health.

Acknowledgments: Many thanks to all participants who took part, and Dementias Platform UK (DPUK) for access to the Great Minds Register data and resources in the DPUK Data Portal.

Targeted Memory Reactivation During NREM Sleep Selectively Modulates Fear Memory Extinction

Y. Sun¹, Z. Zhao², Y. Zhong³, G. Li³, C. Zhao¹, X. Zhang¹, L. Lu⁴, J. Shi⁵, S. Ai³

¹The First Affiliated Hospital of Xinxiang Medical University, Department of Cardiology, Life Science Research Center, Weihui, China, ²Xinxiang Medical University, School of Mathematical Medicine, School of Medical Engineering, Xinxiang, China, ³The Affiliated Brain Hospital, Guangzhou Medical University, Center for Sleep and Circadian Medicine, Guangzhou, China, ⁴Peking University, Peking University Sixth Hospital, Peking University Institute of Mental Health, Beijing, China, ⁵Peking University, National Institute On Drug Dependence and Beijing Key Laboratory of Drug Dependence, Beijing, China

Introduction: Sleep plays a crucial role in memory consolidation, with neural oscillations during non-rapid eye movement (NREM) sleep, particularly slow oscillations (SO, 0.5-2 Hz) and sleep spindles (12-16Hz), considered key neurophysiological mechanisms facilitating memory integration. Targeted memory reactivation (TMR), which presents cues associated with specific memories during sleep, has been shown to selectively modulate memory processing. However, its effects on fear memory remain controversial: some studies suggest TMR promotes fear extinction, while others find it enhances fear memory consolidation. Importantly, whether and how TMR influences fear memory processing by modulating sleep-specific oscillatory features, and the precise neural mechanisms involved remain unclear.

Materials and methods: We employed a fear conditioning paradigm where participants learned to associate two distinct tones (CS+) with mild electric shocks, and a third tone served as a control stimulus (CS-). Following conditioning, participants were randomly assigned to either a sleep group (1.5-hour nap) or a wake group (reading task). During NREM sleep or wakefulness, only one CS+ tone (cued tone) was presented without the associated shock, while the other CS+ (uncued tone) served as a within-subject control. Throughout the study, we recorded electroencephalography (EEG) and skin conductance responses (SCR) to assess neural oscillations and autonomic nervous system responses to fear stimuli, respectively.

Results: Participants in the sleep group showed significantly reduced SCR to the cued tone, with no significant changes to the uncued tone; the wake group exhibited no significant response changes to either tone. Event-related potential (ERP) analysis further confirmed that neural response patterns to the cued tone gradually resembled those elicited by the CS- that was never paired with shock. Neural oscillation analysis revealed that presenting the cued tone during NREM sleep significantly enhanced slow wave activity (SW, 0.5-4 Hz) and SO, both of which positively correlated with post-nap fear expression. More importantly, TMR specifically promoted phase-amplitude coupling between SO and sleep spindles, characterized by spindle activity preferentially occurring during the SO up-state. This precise spatiotemporal coupling pattern was observed exclusively in the cued tone condition.

Conclusions: TMR during NREM sleep selectively attenuates fear responses through enhanced SW activity that correlates with fear expression and SO-spindle coupling that may facilitate extinction, demonstrating potential applications for fear-related disorders.

Targeted memory reactivation during slow-wave sleep prompts systems-level changes in the neural basis of episodic memory

S. Cairney¹, J. Ashton¹, M. Harrington²

¹University of York, York, United Kingdom, ²University of East Anglia, Norwich, United Kingdom

Introduction: Slow-wave sleep (SWS) supports memory consolidation through the reactivation and reorganisation of newly formed memory traces. The emergence of a non-invasive memory cueing

technique known as targeted memory reactivation (TMR) has provided some of the most compelling evidence that episodic memories are reactivated during SWS. However, whether TMR prompts a reorganisation in the neural basis of episodic memory has yet to be established. In the current study, we used a multi-session, functional magnetic resonance imaging (fMRI) protocol to examine changes in the neural basis of episodic memories that were cued (vs not cued) with TMR during SWS.

Materials and methods: N=43 healthy young adults (27 female) learned adjective-object pairs—where the adjectives were presented both visually and aurally—in the evening before a night of polysomnographically-monitored sleep. TMR was administered throughout SWS, such that a subset of the adjectives was continuously replayed via loudspeaker in a bid to reactivate the adjective-object pairs. The next morning, while undergoing fMRI, participants were presented with each adjective in isolation and instructed to retrieve the associated object from memory. The same test was repeated in the fMRI scanner 24 hours later, allowing us to examine both immediate and delayed changes in the neural basis of episodic memories that had undergone TMR.

Results: An initial whole-brain analysis of object recall showed widespread activation, including bilateral hippocampus, at each test session. A contrast between object memories that were cued vs not cued with TMR revealed no significant difference in neural activity immediately after sleep. Critically, however, the same contrast performed at the 24-hour follow-up showed stronger activation for cued (vs non-cued) memories in bilateral precuneus, suggesting that TMR had initiated a systems-level change in the neural basis of episodic memory that emerged over multiple nights of sleep.

Conclusions: Our findings demonstrate that TMR delivered during post-learning SWS triggers a process of neural reorganisation that unfolds over multiple days. These data lend support to the idea that memory reactivation in sleep supports systems-level consolidation processes that extend far beyond the first night after learning.

The Beneficial Effects of Sleep in Reducing Interference

K. Bennion¹, M. Vitullo¹, L. Flores¹, J. Antony¹

¹Cal Poly, SLO, San Luis Obispo, United States

Introduction:

A steadily mounting set of findings suggests that sleep benefits memory, in part by reducing interference between competing memories. Indeed, prior findings suggest that sleep reduces retroactive interference (i.e., when later learning negatively affects earlier learning) (Ellenbogen et al., 2006; Abel et al., 2023) and proactive interference (i.e., when earlier learning negatively affects later learning) (Abel & Bäuml, 2014). However, the effects of sleep on retroactive interference and proactive interference have never been found within the same study, nor have they been compared to each other.

Materials and methods: Here, we investigated the effects of sleep on retroactive interference and proactive interference using a paired associate paradigm in which participants learned an initial list of word pairs (A-B; e.g., pious-slurp) followed by a list with new targets linked to the same cue (A-C; e.g., pious-west). Participants learned and tested on unrelated A-B word pairs in the morning or evening, after which they learned A-C pairs for half of the A-B words either immediately or after a 12-hour delay (which included either sleep or wake). After this, they took a cued-recall test on both A-B and A-C pairs.

Results: For groups that stayed awake during the 12-hour retention interval, interference for A-B pairs was significantly greater for those who learned A-C directly before testing ($p = 0.04$) than for those who learned A-C immediately after A-B, which accords with our prior findings and those of others (Antony & Bennion, 2022; Antony et al., 2022; Chandler, 1993). However, there was no difference in interference for A-B pairs for groups that slept during the 12-hour retention interval ($p = 0.51$). For A-C learning, we found main effects of sleep and timing (both $p < 0.01$), such that memory was better when the interval included sleep than only wake and when A-C was learned closer to the test (vs. immediately after learning).

Conclusions: In sum, sleep appears to protect both earlier-learned information overall and facilitate new learning relative to wake intervals. These results suggest that sleep reduces both retroactive and proactive interference, with implications for recommending quality sleep in educational contexts in order to improve memory performance.

The contribution of theta activity preceding cortical down-states to the slow oscillatory-spindle dynamics of human non-REM sleep

F. Salvi¹, D. Corigliano¹, G. Amicucci¹, A. D'Atri¹, M. Ferrara¹

¹University of L'Aquila, Department of Biotechnological and Applied Clinical Sciences, L'Aquila, Italy

Introduction: The sequential progression of cortical down-states, up-states, and spindle events constitutes a core electrophysiological basis for memory consolidation during non-REM sleep. Whether other oscillatory dynamics contribute to this well-characterized sequence has yet to be established. In this study, we applied phase-targeted auditory stimulation (PTAS) at cortical phases of maximal excitability (up-state, PTAS-up) or inhibition (down-state, PTAS-down) within the slow oscillation (SO) cycle, aiming to identify the spectral signatures associated with slow wave generation and their coordination with spindles. Moreover, by analyzing stimulus-evoked slow waves alongside spontaneous SOs and K-complexes, we investigated whether a shared spectral fingerprint differentiates these oscillatory events and accounts for their spindle synchronization.

Materials and methods: Twenty-six healthy participants (mean age $\pm$ standard deviation: 23.23 ± 2.61 years, 17 females) slept at home wearing a portable EEG system (Fpz-M1, AF8-M1) coupled with a laptop-based sine-fitting algorithm for real-time SO phase prediction. Pink noise bursts (50 ms, 45 dB) were delivered via loudspeakers and randomly alternated between the SO up-state (targeted phase angle: 90° , mean stimulations: 115.32 ± 40.69) and down-state (270° , 115.52 ± 40.99), with a minimum inter-stimulus-interval of 4000 ms. EEG responses were analyzed through event-related potentials (ERPs) and event-related spectral perturbations (ERSPs). Furthermore, slow waves were automatically detected post hoc throughout the night to characterize the spectral signatures of stimulus-evoked events, spontaneous SOs (stage N3), and spontaneous K-complexes (stage N2). Phase-amplitude coupling (PAC) metrics were computed to investigate the presence of cross-frequency dynamics surrounding SOs.

Results: The PTAS procedure accurately targeted the SO up-state (trial-level mean phase angle: $97.67^\circ \pm 37.95^\circ$, $R=0.78$) and down-state ($271.41^\circ \pm 44.94^\circ$, $R=0.69$). PTAS-up elicited larger ERPs than PTAS-down, with ampler negative and positive peaks at ~ 500 and ~ 1000 ms post-stimulation, respectively (both $p<0.001$). ERSP analyses indicated greater theta power (5-8 Hz) following PTAS-up in the 200 ms preceding the individual stimulus-evoked negative peak ($p<0.001$) and higher spindle activity (12-16 Hz) at ± 200 ms around the positive peak ($p<0.001$). Critically, pre-down-state theta response robustly predicted ERP peak-to-peak amplitude and subsequent spindle activity across stimulation conditions (both $r=0.70$, $p<0.001$), fully mediating the difference between PTAS-up and PTAS-down on spindle power ($p=0.001$, proportion mediated=75.27%).

An ERSP comparison of the three detected slow wave categories revealed that stimulus-evoked events and spontaneous K-complexes exhibited overlapping spectral profiles, with greater pre-down-state theta activity and higher up-state-coupled spindle power compared to spontaneous SOs (all $p<0.001$). Early theta strongly predicted subsequent spindle activity across all categories ($r=0.78$, $p<0.001$), fully mediating the spindle difference between K-complexes and SOs ($p<0.001$) and accounting for 95.16% of the effect.

Finally, PAC analysis confirmed the physiological integration of theta activity into slow oscillatory rhythms, indicating the existence of a SO phase-theta envelope coupling peaking at $245.06^\circ \pm 13.44^\circ$ ($p<0.001$, group-level $R=0.93$).

Conclusions: Findings indicate that PTAS-up maximizes cortical responsiveness by recruiting a theta-driven mechanism. Moreover, stimulus-evoked events primarily display the spectral fingerprint of K-complexes rather than resembling endogenous SOs. Finally, this study highlights theta activity as a previously unrecognized mechanism linking cortical down-states to spindle dynamics, expanding the electrophysiological landscape of non-REM processes supporting memory consolidation.

The Effect of Melatonin on Hippocampal Synaptic Plasticity in an Acute Sleep Deprivation Model

Y. Dong¹, R. Nishika², H. Sun³, L.-W. Wong², S. Sajikumar²

¹National University of Singapore, Alice Lee Centre of Nursing Studies, Singapore, Singapore, ²National University of Singapore, Department of Physiology, Singapore, Singapore, ³Peking University Sixth Hospital, Peking University Institute of Mental Health, Beijing, China

Introduction: Sleep is essential for the consolidation of long-term memory. Consequently, sleep deprivation (SD) has well-documented detrimental effects on memory performance and overall cognitive function. Melatonin, a hormone primarily secreted by the pineal gland, plays a key role in regulating circadian rhythms and has also been implicated in modulating synaptic plasticity. Specifically, melatonin has been shown to influence the maintenance of long-term potentiation (LTP) in the hippocampus—a form of synaptic strengthening widely considered a cellular mechanism underlying long-term memory formation. Recent studies have demonstrated that melatonin supplementation enhances long-term memory in both non-sleep-deprived (non-SD) and chronically SD models. To further investigate the potential therapeutic role of melatonin, this study examined its effects on both long-term and associative synaptic plasticity in the hippocampi of non-SD and SD mice.

Materials and methods: For the SD procedure, mice were subjected to five hours of SD using the gentle handling technique. The functional properties of the hippocampal CA1 region were assessed through field electrophysiological recordings.

Results: Our findings indicate that five hours of SD significantly impairs LTP in the hippocampal CA1 region (mean fEPSP slope = $97.96 \pm 7.74\%$, $P = 0.1304$). Interestingly, melatonin supplementation in non-SD control mice led to a reduction in both long-term (mean fEPSP slope = $102.09 \pm 9.01\%$, $P = 0.8219$) and associative plasticity (mean fEPSP slope = $90.86 \pm 5.31\%$, $P = 0.1194$), suggesting that in the absence of SD, melatonin may exert a dampening effect on synaptic strengthening. However, in SD mice, melatonin supplementation effectively rescued the deficits in both long-term (mean fEPSP slope = $150.33 \pm 3.99\%$, $P = 0.0156$) and associative plasticity (mean fEPSP slope = $194.27 \pm 21.51\%$, $P = 0.0156$). These results suggest that melatonin can prevent or reverse the impairments in hippocampal synaptic plasticity and memory processes induced by acute SD.

Conclusions: Therefore, melatonin may hold promise as a therapeutic agent for mitigating memory deficits associated with sleep loss.

Introduction: Sleep enhances memory retention; conversely, sleep deprivation degrades brain functions and memory performance. Exercise may potentially counteract the detrimental effects of sleep loss on memory. However, there is limited evidence from human studies to indicate that exercise offsets the memory deficits caused by sleep restriction and whether sleep architecture, especially slow-wave sleep (SWS) mediates the compensatory effects. We evaluated whether acute moderate-intensity exercise compensates for the detrimental effects of nighttime sleep restriction on declarative memory and if SWS mediates the compensatory effect in healthy young adults.

Materials and methods: A total of 88 (52% female) healthy young adults (24.0 ± 3.8 years) were randomly allocated to one of four evening groups based on exercise and sleep opportunity: average sleep only (S_8 , 8.5 hours/night), sleep restriction only (S_5 , 4.5 hours/night), and moderate-intensity exercise before sleep restriction (ExS_5) or an average sleep (ExS_8). Groups either performed a 30-minute moderate-intensity exercise or rested in the evening (7:00 p.m.) prior to learning 80 face-name pairs (10:00 p.m.), followed by an immediate recall task (10:10 pm). In the morning after their respective polysomnographic-recorded sleep opportunity, a delayed recall task was administered. The discriminability index (d') during the recall tasks was used to assess long-term memory performance.

Results: Total sleep time differed between the average and restricted sleepers ($p < 0.001$). We found significant exercise-sleep interaction effects ($p = 0.033$, $\eta_p^2 = 0.056$) on d' at delayed recall and the difference between delayed and immediate recalls ($p = 0.012$, $\eta_p^2 = 0.077$). Post hoc analyses showed that the delayed retrieval d' of ExS_5 ($M = 0.07$, $SD = 0.89$) was not statistically different from those of the S_8 ($M = 0.58$, $SD = 1.20$, $p = 0.115$, $d = 0.48$) and ExS_8 ($M = 0.21$, $SD = 1.30$, $p = 0.747$, $d = -0.13$) but was significantly better than the S_5 (-0.60 ± 1.38 , $p = 0.028$, $d = -0.58$). Similarly, the delayed retrieval d' of S_5 was significantly lower compared to those of S_8 ($p < 0.001$, $d = 0.91$) and ExS_8 ($M = 0.21$, $SD = 0.30$, $p = 0.029$, $d = -0.61$). Likewise, the difference in d' of ExS_5 (0.36 ± 0.79) was comparable to those of the S_8 (0.23 ± 1.3 , $p = 0.699$, $d = -0.12$) and ExS_8 (0.63 ± 0.63 , $p = 0.516$, $d = -0.36$), but significantly higher than the S_5 (-1.13 ± 1.02 , $p < 0.001$, $d = -1.12$). The percentage of SWS mediated the compensatory effects of the ExS_5 vs. S_8 condition on long-term memory [$B = 20.38$, $SE = 16.49$, 95% bootstrap CI (5.70, 59.99)].

Conclusions: These results suggest that acute moderate-intensity evening exercise enhances sleep-dependent memory consolidation and compensates for the detrimental effects of sleep restriction on long-term declarative memory in healthy young adults. Slow-wave sleep provides a potential mechanism for conveying the effects of acute exercise on long-term memory in sleep restriction.

The Role of Adenosine Receptors and Their Antagonist Caffeine in the Mouse Hippocampal CA2 Region Associated with Sleep Deprivation

L.W. Wong¹, M.Z. Bin Ibrahim¹, A.L. Kannan¹, S. Sajikumar¹

¹National University of Singapore, Physiology, Singapore, Singapore

Introduction: Sleep plays a crucial role in facilitating learning and memory, and sleep deprivation (SD) has been associated with deficits in memory formation and consolidation. Research on rodents has revealed that as little as a few hours of experimental SD can interfere with the consolidation of hippocampal-dependent associative memory, object-place memory, and contextual fear memory. Numerous studies have also shed light on the biochemical and molecular pathways implicated in memory impairment caused by sleep loss. The CA2 subregion of the hippocampus plays a critical role in social memory and emotion processing and is involved in modulating brain activity and memory performance. The integrity of CA2 neurons is crucial for the normal functioning of this hippocampal subregion and is essential for social memory formation. Despite its importance, how sleep influences social memory through the CA2 region remains relatively unexplored. In this study, we investigated whether and how sleep deprivation affects synaptic plasticity and social memory in the CA2 region of mice.

Materials and methods: For SD procedure, mice were subjected to 5 hours of SD using the gentle handling technique. The functional properties of the hippocampal CA2 region were assessed using field electrophysiology. Field excitatory postsynaptic potentials (fEPSPs) were recorded from both the Schaffer collateral (SC) and entorhinal cortex (EC) pathways. Western blotting was performed to examine the expression of key plasticity-related proteins, including adenosine A1 receptors, PDE4A5, PKM ζ , ERK, and BDNF. In experiments involving caffeine administration, mice received a 0.3 g/L caffeine solution in their drinking water, provided *ad libitum* for 7 days prior to experimentation. The Direct Interaction Recognition Test was used to assess social recognition memory before and after SD.

Results: We found that 5-hour SD impaired long-term potentiation in the hippocampal EC-CA2 pathway, accompanied by an increased expression of adenosine A1 receptors. In addition, caffeine-induced synaptic potentiation in the CA2 subregion was significantly reduced following sleep loss. Adenosine A1 receptors are known to be coupled to the adenylyl cyclase-protein kinase A (AC-PKA)

signaling pathway, and several adenylyl cyclase isoforms—such as AC1, AC5, and AC6—are highly expressed in the CA2 region. Consistent with the observed deficits in synaptic plasticity, sleep-deprived mice exhibited impaired social recognition memory, failing to distinguish novel mice from familiar ones in the behavioral test compared to non-sleep-deprived controls. Sleep loss also led to reduced expression of key plasticity-related proteins in the CA2 region, including PKM ζ , ERK, and BDNF. Notably, caffeine supplementation reversed the impairments in both long-term synaptic plasticity and social memory in sleep-deprived mice.

Conclusions: In conclusion, our findings highlight the critical vulnerability of the hippocampal CA2 region to SD and its profound impact on long-term synaptic plasticity and social memory in mice. Moreover, our results reveal a key role for adenosine signaling within the CA2 area in mediating the effects of sleep on social memory, underscoring its potential as a therapeutic target for sleep-related cognitive dysfunction.

Updating Social Evaluation During Sleep

H. Zhao¹, X. Lin², X. Wang¹, K. Yuan², X. Hu³, W. Su⁴, J. Shi⁵, Q. Wang⁴, L. Lu²

¹Peking University, Peking-Tsinghua Centre for Life Sciences and PKU-IDG/McGovern Institute for Brain Research, Beijing, China, ²Peking University Sixth Hospital, Beijing, China, ³The University of Hong Kong, Hong Kong SAR, China, ⁴Beijing Normal University, Beijing Key Laboratory of Applied Experimental Psychology, Beijing, China, ⁵Peking University, National Institute on Drug Dependence and Beijing Key Laboratory of Drug Dependence, Beijing, China

Introduction: Current research on sleep often focuses on memory consolidation, with limited exploration of its role in updating social images. Social images, including mental facial representations, significantly influence social biases and stigmatization. Addressing these biases is essential for promoting inclusive social relations. Recent studies have shown that sleep can modulate memory content and influence social attitudes. Building on these findings, we hypothesized that sleep could be leveraged to improve the social image of unattractive individuals by forming new associations through acoustic cues during slow-wave sleep (SWS).

Materials and methods: A total of 138 healthy adults (73 females, mean age 21.69 ± 2.75 years) were recruited, and 106 completed the study. The study consisted of four phases: encoding, baseline testing, sleep intervention, and post-sleep testing. During the encoding phase, participants learned two faces paired with names and personality traits (five positive and five negative). Baseline testing included memory recall and an Implicit Association Test (IAT) to measure initial attitudes toward the faces. During the sleep intervention, participants took a 90-minute nap while one group was exposed to name-positive description pairs during slow-wave sleep (SWS), and a control group was exposed only to names. Post-sleep tests included memory recall, IAT, an ultimatum game to measure social trust, and a reverse correlation image classification task to assess mental facial representations. The study aimed to determine whether sleep-based exposure to positive descriptions could enhance social perceptions of unattractive individuals.

Results: The study found that sleep-based exposure to name-positive description pairs significantly enhanced the attractiveness of mental facial representations for the SI-reshape target (mean $\pm$ SD; SI-reshape: 2.32 ± 0.54 , non-SI-reshape: 2.14 ± 0.55 , $p < .001$), while mere name exposure had no significant effect. This suggests that the positive associations formed during sleep specifically improved mental representations. Memory recall tests revealed that participants remembered more positive traits for the SI-reshape target after sleep (mean $\pm$ SD; SI-reshape: 0.52 ± 0.13 , non-SI-reshape: 0.42 ± 0.11 , $p < .001$), indicating a bias towards positive memory recall. Explicit attitude measures showed higher likeability and social willingness towards the SI-reshape target (mean $\pm$ SD; likeability: SI-reshape: 4.21 ± 1.01 , non-SI-reshape: 3.61 ± 1.10 , $p < .001$; social willingness: SI-reshape: 4.25 ± 1.18 , non-SI-reshape: 3.43 ± 1.19 , $p < .001$). Implicit attitudes, measured by the Implicit Association Test (IAT), also improved significantly after sleep (mean $\pm$ SD; pre-sleep: 0.00 ± 0.64 , post-sleep: 0.18 ± 0.67 , $p < .001$). Additionally, the number of slow oscillations during sleep was positively correlated with the attractiveness of mental facial representations for the SI-reshape target ($r = 0.40$, $p = .002$), suggesting that sleep-related neural activity supports the reshaping of social images. These findings collectively

demonstrate that sleep can be leveraged to enhance social perceptions through targeted acoustic cue exposure.

Conclusions: Our study demonstrates that sleep can be used to reshape social images through acoustic cue exposure, improving mental facial representations, memory of positive traits, and both explicit and implicit attitudes. Future research should explore the neural mechanisms and long-term effects of sleep-based social image reshaping.

Wakefulness activity-dependent regulation of memory

Y. Li¹

¹Shanghai Jiao Tong University, Songjiang Research Institute, Shanghai, China

Introduction: Sleep plays a critical role in memory consolidation, however, both memory encoding and retrieval take place during wakefulness, underscoring its fundamental importance in maintaining and regulating these memory processes. In contrast to the extensive studies on the role of sleep in memory consolidation, there is a relative lack of studies addressing the impact of wakefulness and the specific circuits that support it on memory.

Materials and methods: We used in vivo calcium imaging, chemogenetics, optogenetics, multi-omics, electrophysiological recording, and EEG/EMG recording with memory behavior tests to explore how wakefulness regulates memory encoding and retrieval.

Results: We first found the structural basis of how wakefulness regulates memory, focusing on the wakefulness system's influence on brain regions involved in memory. Specifically, we targeted a hypothalamic wake-promoting region, the Supramammillary nucleus, which sends dense projections to the memory-related brain region, the dentate gyrus. Then, we highlight that wakefulness regulates memory in an activity-dependent manner, influenced by arousal levels from three perspectives: memory engram cells, synaptic plasticity, and neural oscillations. Additionally, wakefulness promotes memory by regulating adult hippocampal neurogenesis, which represents a novel mechanism to influence memory on a distinct timescale.

Conclusions: Our study demonstrates that wakefulness activity-dependently regulates memory via memory engram cells, synaptic plasticity, and neural oscillations.

Movement Disorders

A diagnostic model for Parkinson's disease based on circadian rhythm-related genes

L. Wang¹, Y. Bao¹, H. Li², D. Huang³

¹Tongji University, School of Medicine, Department of Neurology, Shanghai East Hospital, Shanghai, China, ²Tongji University, School of Medicine, Department of Neurology, Shanghai East Hospitalchian', Shanghai, China, ³School of Medicine, Tongji University, Department of Neurology, Shanghai East Hospital, Shanghai, China

Introduction: Circadian rhythm (CR) disturbance is intricately associated with Parkinson's disease (PD). However, the involvement of CR-related mechanisms in the pathogenesis and progression of PD remains elusive.

Materials and methods: A total of 141 PD patients and 113 healthy participants completed CR-related clinical examinations in this study. To further investigate the CR-related mechanisms in PD, we obtained datasets (GSE7621, GSE20141, GSE20292) from the Gene Expression Omnibus database to identify differentially expressed genes between PD patients and healthy controls and further selected CR-related genes (CRRGs). Subsequently, the least absolute shrinkage and selection operator (LASSO) followed by logistic algorithms were employed to identify the hub genes and construct a diagnostic

model. The predictive performance was evaluated by area under the curve (AUC), calibration curve, and decision curve analyses in the training set and external validation sets. Finally, RT-qPCR and Western blotting were conducted to verify the expression of these hub genes in blood samples. In addition, Pearson correlation analysis was utilized to validate the association between expression of hub genes and circadian rhythm function.

Results: Our clinical observational study revealed that even early-stage PD patients exhibited a higher likelihood of experiencing sleep disturbances, nocturnal hypertension, reverse-dipper blood pressure, and reduced heart rate variability compared to healthy controls. Furthermore, 4 CR-related hub genes (AGTR1, CALR, BRM14, and XPA) were identified and subsequently incorporated as candidate biomarkers to construct a diagnostic model. The model showed satisfactory diagnostic performance in the training set (AUC=0.941), an external validation set GSE20295 (AUC=0.842), and our clinical centre set (AUC=0.805). Additionally, the up-regulation of CALR, BRM14 and the down-regulation of AGTR1, XPA were associated with circadian rhythm disruption.

Conclusions: CR disturbance seems to occur in the early stage of PD. The diagnostic model based on CR-related genes demonstrated robust diagnostic efficacy, offering novel insights for future clinical diagnosis of PD and providing a foundation for further exploration into the role of CR-related mechanisms in the progression of PD.

Acknowledgments: We thank all contributors to the GEO database and all the participants who made this research possible.

Age-Related Changes in Large Muscle Movements During Sleep and Their Impact on Sleep Architecture

M.P. Mogavero¹, P. Congiu², G. Lanza³, L. Ferini Strambi¹, S. Marelli¹, A. Castelnuovo¹, M. Puligheddu², O. Bruni⁴, R. Ferri⁵

¹Vita Salute San Raffaele University, Sleep Disorders Center, Division of Neuroscience, San Raffaele Scientific Institute, Milan, Italy, ²University of Cagliari, Sleep Disorder Research Center, Department of Medical Sciences and Public Health, Cagliari, Italy, ³University of Catania, Sleep Research Centre, Oasi Research Institute-IRCCS, Troina, Catania, Italy, ⁴Sapienza University, Rome, Department of Social and Developmental Psychology, Rome, Italy, ⁵Oasi Research Institute-IRCCS, Sleep Research Centre, Troina, Italy

Introduction: Large Muscle Group Movements during sleep (LMM) are closely associated with sleep architecture instability and disruptions in sleep continuity. This study explores LMM across the lifespan, from school-aged children to older adults, examining their relationship with sleep architecture (REM and NREM) to better understand the factors contributing to age-related differences in sleep patterns and motor activity during sleep.

Materials and methods: The study included 141 healthy participants divided into five age groups: school-aged children (n=43), adolescents (n=31), young adults (n=27), adults (n=16), and older adults (n=24). Polysomnography (PSG) was used to record sleep data, with LMM, LMM associated with arousals (LMMA), and LMM associated with awakenings (LMMW) scored according to established criteria. LMM indices and durations were analyzed across groups, and statistical comparisons were made between age groups and between REM and NREM sleep.

Results: LMM indices increased significantly with age, with older adults showing the highest frequency of LMM, LMMA, and LMMW. Conversely, LMM duration was longer in younger participants and shorter in older adults. Significant differences in LMM patterns between REM and NREM sleep were noted, particularly in adults and older adults, where LMM and LMMA were more prevalent during REM sleep. No significant sex differences were observed across age groups. Overall, LMM increased in frequency and decreased in duration with age, with older adults exhibiting higher prevalence of these movements during REM sleep.

Conclusions: Our findings demonstrate an age-related increase in LMM indices, particularly in older adults, who also exhibited more frequent awakenings, potentially linked to heightened sympathetic activity. In contrast, children showed the lowest LMM indices, reflecting the more consolidated sleep and reduced motor activity associated with lower sympathetic activity. Adults displayed higher LMMA indices during REM sleep, suggesting a strong association between motor activity and arousal mechanisms, potentially influenced by cholinergic circuits. These results highlight the evolution of LMM

with age, its close relationship with changes in sleep architecture, and its potential neurophysiological underpinnings. Understanding these patterns provides valuable insights into the mechanisms of sleep-related motor activity and its implications for age-specific sleep management strategies.

Altered Circadian Patterns of Diurnal Blood Pressure in Clinical Phenotypes of Bruxism: A Signal of Autonomic Imbalance?

M. Meira e Cruz¹, S. Pereira², M.J. Rodrigues², D. Gozal³

¹Faculdade de Medicina da Universidade de Lisboa (CCUL@RISE), Cardiovascular Center of University of Lisbon, Lisbon, Portugal, ²Faculdade de Medicina, Universidade de Coimbra, Coimbra, Portugal,

³Joan C. Edwards School of Medicine, Marshall University, Huntington, United States

Introduction: Bruxism, defined as repetitive masticatory muscle activity involving clenching or grinding of the teeth and/or mandibular thrusting, has recently been reclassified as a behavior rather than a disorder, with its circadian expression—awake bruxism (AB) versus sleep bruxism (SB)—increasingly recognized as clinically relevant. The impact of these phenotypes on systemic physiology remains underexplored. Given that blood pressure (BP) follows a circadian rhythm in healthy individuals—marked by a morning surge, postprandial dip, and afternoon stabilization—this study aimed to assess whether bruxism subtypes exhibit distinct patterns of diurnal BP variation that might reflect underlying autonomic dysregulation.

Materials and methods: A total of 178 healthy university students (mean age 21.3 ± 1.5 years; 74.6% female) were assessed using validated self-report instruments, including bruxism screening tools, the Morningness-Eveningness Questionnaire, Pittsburgh Sleep Quality Index, Insomnia Severity Index, and Epworth Sleepiness Scale. From these, a subsample of 59 participants with probable bruxism—confirmed via diary and clinical signs—was classified into circadian bruxism phenotypes: morning AB, evening AB, SB, and undefined. BP was measured at three standardized timepoints (morning, postprandial, and afternoon) on three non-consecutive days under controlled conditions using a calibrated manual sphygmomanometer.

Results: Overall, none of the bruxism subtypes followed the expected physiological BP circadian rhythm. The SB group demonstrated a significantly lower postprandial diastolic BP (mean 74.1 mmHg) compared to the AB group (79.6 mmHg; $p = 0.045$), consistent with a more pronounced parasympathetic-mediated dip. However, this phenomenon may reflect not parasympathetic integrity but rather an impaired autonomic compensation mechanism, mirroring dysautonomia features reported in insomnia and obstructive sleep apnea. Morning AB subjects also showed a postprandial dip followed by afternoon rebound—suggesting early sympathetic arousal with delayed recovery. The evening AB group, in contrast, presented a flattened BP profile, possibly indicative of diminished autonomic flexibility. Notably, over 40% of participants reported poor sleep quality or signs of circadian misalignment, both of which are known contributors to vascular autonomic dysfunction.

Conclusions: Bruxism phenotypes appear to disrupt normal diurnal BP rhythms, with distinct profiles emerging between AB and SB subtypes. These deviations suggest that bruxism may be more than a localized motor behavior, serving instead as a clinical signal of circadian-autonomic imbalance. Time-of-day-based bruxism phenotyping may thus offer a novel pathway for early identification of individuals at increased cardiometabolic risk—even within asymptomatic populations.

A Minimally Invasive Framework for Home-Based Sleep Tracking in Parkinson's Disease With Wearables

I. Rechichi¹, L. Di Gangi¹, G.S. Giarrusso¹, U. Mosca¹, A. Cicolin^{2,3}, G. Olmo¹, M. Zibetti^{2,4}

¹Politecnico di Torino, Control and Computer Engineering, Torino, Italy, ²University of Turin, Neuroscience "Rita Levi Montalcini", Torino, Italy, ³Centre for Sleep Medicine, Torino, Italy, ⁴University of Turin, Neurology, Torino, Italy

Introduction: Sleep disorders are among the most prevalent and disabling non-motor symptoms of Parkinson's Disease (PD), significantly impacting patients' quality of life. Nocturnal hypokinesia and akinesia, characterized by reduced or absent movement during sleep, often emerge in the early stages of the disease, contributing to poor sleep quality and increased caregiver burden. Despite their clinical

relevance, clinical assessment of such disorders typically relies on infrequent neurological evaluations and subjective scales, which are susceptible to bias and often fail to capture nightly variability or symptom fluctuations. This highlights the need for objective, scalable, and reproducible frameworks for long-term monitoring of sleep-related motor disorders in PD patients in real-world settings. This study presents a lightweight approach for the unsupervised, home-based monitoring of sleep disturbances in PD using objective and reproducible metrics derived from wearable sensors.

Materials and methods: We included overnight recordings of 40 subjects (12 PD, 28 healthy/controls); data were collected during sleep with wearable inertial measurements units (IMUs) in home settings. The analysis pipeline followed two main objectives: (1) to automatically identify PD-specific sleep-related motor patterns and (2) to objectively evaluate sleep quality, with the Pittsburgh Sleep Quality Index (PSQI) as clinical reference. Given the current lack of standardized features to characterize PD sleep-related motor disorders, this study adopted a multi-domain approach that combines clinical features with motion-based parameters. The latter included both novel descriptors and features previously employed in night-time actigraphy studies. The raw IMU data were processed as follows: first, a series of features characterizing body movements throughout the night were extracted, related to axial movements, turning velocity, and overall nocturnal motility. Then, these were used as inputs to various Machine Learning models (Support Vector Machine, K-Nearest Neighbors, XGBoost), to carry out the two classification tasks. To ensure robust population-level analysis and mitigate potential bias, the dataset was stratified according to sleep quality (PSQI-based) and the presence of PD.

Results: Classification performance was evaluated through accuracy and F1 score, to counteract class imbalance. In automatic detection of PD, the SVM achieved the best results (accuracy: 96.2%, F1 score: 93.4%). Across all models, sleep posture and velocity of turns in bed emerged as the most discriminative features, reflecting the motor rigidity and reduced turning frequency typical of PD patients. For sleep quality assessment, the best performance was achieved with the XGBoost classifier (accuracy: 85.7%, F1: 82.5%). The nocturnal motility index and the time interval between movements, both indicative of sleep fragmentation emerged as most correlated features with PSQI. Subgroup analyses confirmed the significance of these specific features in differentiating between healthy and PD participants with poor sleep quality.

Conclusions: This study presented a home-based monitoring framework to objectively assess sleep-related motor symptoms in PD using wearable technology. The approach demonstrated high classification performance, supporting scalable and objective disease monitoring. Though preliminary, the findings highlight the potential to improve clinical follow-up and patient outcomes, moving toward continuous and personalized disease management, with positive impact on the quality of life for individuals with PD.

Autonomic Function Test and Polysomnographic Findings in Parkinson's Disease and Multiple System Atrophy: A Comparative Correlational Study

S.-M. Cheon¹, B.-A Yoon¹, Y. Lee¹, B. Jin¹

¹Dong-A University School of Medicine, Neurology, Busan, Korea, Republic of

Introduction: Parkinson's disease (PD) and multiple system atrophy (MSA) are both α -synucleinopathies characterized by autonomic dysfunction and sleep disturbances. However, their clinical presentations and underlying pathophysiology differ considerably. This study aimed to compare polysomnographic (PSG) and autonomic function test (AFT) profiles between drug-naïve patients with PD and MSA, and to investigate disease-specific correlations between sleep-related and autonomic parameters.

Materials and methods: We retrospectively analyzed 136 patients with PD and 67 patients with MSA who underwent PSG, cardiac [I-123] MIBG scintigraphy, and standardized AFTs prior to initiating any treatment. All subjects reported sleep-related complaints (e.g., excessive daytime sleepiness, snoring, or dream enactment behavior). Group comparisons were performed for PSG and AFT parameters. Pearson or Spearman correlation analyses were used to identify significant associations between sleep and autonomic metrics within each disease group.

Results: Compared to PD, patients with MSA exhibited more severe respiratory disturbances and poorer sleep quality, as evidenced by higher apnea index, arousal index, and lower oxygen saturation and sleep efficiency. AFT measures indicated more advanced autonomic dysfunction in MSA across cardiovagal, cardiadrenergic, and sudomotor domains.

In PD, higher apnea-hypopnea index (AHI) correlated with greater cardiovagal dysfunction, while higher REM sleep percentage was associated with lower blood pressure variability. In MSA, greater AHI was correlated with higher composite autonomic severity scores, longer pressure recovery time (PRT), and exaggerated systolic and diastolic blood pressure (BP) drops. Additionally, reduced sleep efficiency, increased Stage 1 and decreased Stage 2 sleep percentage, and frequent arousals were associated with greater sudomotor dysfunction. Oxygen desaturation and AHI were inversely correlated with Valsalva ratio, reflecting compromised parasympathetic integrity.

Conclusions: PD and MSA show fundamentally different patterns of association between sleep architecture and autonomic dysfunction. Further studies are needed to clarify the mechanisms linking sleep and autonomic dysfunction. Given that sleep-related breathing disorders are potentially modifiable, investigating their impact on autonomic function and long-term clinical outcomes may offer valuable opportunities for early therapeutic intervention, especially in MSA.

Circadian Clock Gene *Per1/Per2* Knockout Leads to Motor Dysfunction in Mice

B. Li^{1,2}, Y. Fan^{1,2}, N. Zheng^{1,2}, B. Lin^{1,2}, J. Zhang^{1,2}, H. Feng^{1,2}

¹Center for Sleep and Circadian Medicine, The Affiliated Brain Hospital of Guangzhou Medical University, Guangzhou, China, ²Key Laboratory of Neurogenetics and Channelopathies of Guangdong Province and the Ministry of Education of China, Guangzhou, China

Introduction: The circadian clock plays a crucial role in maintaining neurological function and behavioral rhythms. *Per1* and *Per2* are core clock genes essential for circadian regulation. Although many studies have reported altered expression of *Per1* and *Per2* in patients with movement disorders such as Parkinson's disease, direct evidence from animal models assessing motor function in *Per1/Per2* knockout mice remains limited.

Materials and methods: *Per1/Per2* double knockout (DKO) mice and age-matched wild-type (WT) C57BL/6J mice were assessed at 6 and 9 months of age. Behavioral tests included the open field test, rotarod test and pole test to evaluate locomotor activity, motor coordination, and bradykinesia-like features. Circadian rhythm disruptions were verified using ClockLab analysis.

Results: *Per1/Per2* DKO mice exhibited significant motor impairments compared to WT controls. At both 6 and 9 months of age, DKO mice performed worse in the rotarod and pole tests, with statistically significant differences indicating deficits in motor coordination and bradykinesia-like feature. In the open field test, no significant difference in locomotor activity was observed at 6 months; however, DKO mice demonstrated a marked reduction in spontaneous activity compared to WT controls at 9 months. Disrupted circadian activity patterns were also confirmed in DKO mice.

Conclusions: These findings suggest that deletion of *Per1* and *Per2* impairs motor function, with observable deficits in coordination and movement control. The results underscore the potential role of circadian clock genes in modulating movement disorders.

Clinical and polysomnographic characteristics of periodic limb movements during sleep in obstructive sleep apnea patients and the effect of positive airway pressure therapy

K. Kasemsap^{1,2}, N.C. Chirakalwasan¹, D. Muntham³

¹Chulalongkorn University / Excellence Center for Sleep Disorders, King Chulalongkorn Memorial Hospital, Department of Medicine, Bangkok, Thailand, ²Udonthani Hospital, Department of Medicine, Udonthani, Thailand, ³Rajamangla University of Technology Suvarnabhumi, Section for Mathematics, Phranakhon Si Ayutthaya, Thailand

Introduction: Periodic limb movements during sleep (PLMS) are frequently observed in patients with obstructive sleep apnea (OSA). However, data on the clinical and polysomnographic characteristics of individuals with coexisting OSA and PLMS remain limited. Additionally, the effect of positive airway pressure (PAP) therapy on PLMS remains controversial.

This study aimed to investigate the clinical and polysomnographic profiles of patients with concurrent OSA and PLMS, assess the effect of PAP therapy on PLMS, and identify predictors associated with PLMS outcomes following PAP therapy.

Materials and methods: This retrospective analytical study included randomly selected patients diagnosed with OSA who underwent split-night polysomnography between January and December 2024. Clinical, demographic, and polysomnographic data were collected. PLMS was defined as a periodic limb movement index (PLMI) ≥ 15 events/hour. PLMI was compared between the diagnostic and optimal PAP portions of the study. Optimal PAP therapy was defined by a respiratory disturbance index (RDI) < 5 events/hour for at least 15 minutes, including supine REM sleep.

Results: A total of 155 patients were included, with mean age of 58.51 ± 15.33 years; 49.03% were male, and mean BMI was 26.59 ± 5.56 kg/m². Baseline polysomnographic findings included mean sleep efficiency of $79 \pm 12.02\%$, median AHI of 41 (25.9–62.8) events/hour, mean nadir oxygen saturation of $82.51 \pm 10.39\%$, and mean optimal CPAP pressure of 8.87 ± 2.48 cm of water. The median PLMI was 26.2 (18.2–35.8) events/hour. Only 4.5% of the patients met criteria for restless legs syndrome (RLS). During optimal PAP therapy, PLMS improved in 67.7% of the patients, remained unchanged in 1.9%, and worsened in 30.4%. Overall, PLMI normalized in 58% of the patients. Obstructive apnea index (OR 1.037, 95% CI 1.013–1.062; $p=0.003$) and hypopnea index (OR 1.022, 95% CI 1.006–1.039; $p=0.007$) were significant predictors of non-response to PAP therapy.

Conclusions: In patients with OSA and coexisting PLMS, most did not meet criteria for RLS. Notably, PLMS improved in nearly 70% of patients after effective OSA treatment with optimal PAP therapy. Obstructive apnea and hypopnea indices were significant predictors of persistent PLMS despite treatment.

Acknowledgments: The authors would like to thank the sleep technologists at the Excellence Center for Sleep Disorders, King Chulalongkorn Memorial Hospital, Thai Red Cross Society, as well as the patients and their families for their participation. We also express our gratitude to our colleagues and sleep medicine physicians for conducting and organizing the sleep studies.

Clinical Research of Acupuncture and Medication Combined Treatment for Restless Legs Syndrome(RLS)

G. Fu¹

¹China Academy of Chinese Medical Science, internal medicine of TCM, Beijing, China

Introduction: RLS is a neurological sensory and motor disorder characterized by an indescribable and irresistible lower limb discomfort during rest, which seriously affecting patients' sleep and quality of life. Clinical drug treatments often use dopaminergic drugs, but they may have side effects and unstable efficacy. This study aims to evaluate the clinical efficacy of acupuncture combined with Traditional Chinese Medicine (TCM) compared with Western medicine in the treatment of RLS.

Materials and methods: A total of 96 patients with RLS who visited the TCM outpatient department of Beijing Changping Hospital of Integrated Chinese and Western Medicine, from March 2022 to March 2024 were selected as the research subjects. They were randomly divided into an observation group and a control group according to the randomized controlled trial (RCT) method, with 48 cases in each group. The observation group was treated with modified TCM formula (Yangxue Roujin Decoction) and acupuncture (acupoints: Zusanli, Sanyinjiao, Yanglingquan, Taichong, etc.), while the control group was treated with oral Levodopa. The clinical efficacy and sleep quality of the two groups were observed after 8 weeks of treatment and followed up for 12 weeks. Evaluation indicators: International Restless Legs Syndrome Rating scale (IRLS); Pittsburgh Sleep Quality Index (PSQI).

Results: The total effective rate of the observation group (89.6%) was significantly higher than that of the control group (64.6%), and the difference was statistically significant ($P < 0.05$). After treatment, the improvement rate of the IRLS and PSQI score in the observation group were significantly better than those in the control group, and the difference was statistically significant ($P < 0.05$).

Conclusions: The combined treatment of acupuncture and medication for RLS can significantly improve clinical symptoms and sleep quality, with few adverse reactions. It provides new ideas for the future

integrated traditional Chinese and Western medicine therapy and precision targeted therapy of RLS, and is worthy of clinical promotion and application .

Acknowledgments: The subject group of the Department of TCM, Beijing Changping Hospital of Integrated Chinese and. western Medicine .

Combined Cardiovascular Autonomic Failure and Cognitive Impairment as Independent and Additive Predictors of Progression and Phenoconversion in Isolated REM Sleep Behavior Disorder: A Prospective Cohort Study

L. Baldelli^{1,2}, F. Di Laudo¹, L. Sambati², D. Cimatti¹, P. Guaraldi², G. Giannini^{1,2}, A. Cecere², G. Loddo³, G. Mainieri², F. Mignani², G. Barletta¹, P. Cortelli¹, G. Calandra-Buonaura^{1,2}, F. Provini^{1,2}

¹University of Bologna, Department of Biomedical and Neuromotor Sciences, Bologna, Italy, ²IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy, ³Azienda USL di Bologna, Department of Primary Care, Bologna, Italy

Introduction: Isolated REM Sleep Behavior Disorder (iRBD) is a prodromal state of α -synucleinopathies, where early identification of high-risk individuals remains a clinical challenge. While both cardiovascular autonomic failure (cAF) and cognitive impairment (CI) are established biomarkers of disease progression, their combined prognostic significance has not been fully explored. This study aimed to: (1) explore the cross-sectional and longitudinal interplay between autonomic and cognitive dysfunctions in iRBD; (2) assess their respective and combined roles in predicting phenoconversion.

Materials and methods: Seventy-four iRBD patients (73% male, mean age at onset 62.2 ± 8.1 years) were prospectively recruited and followed annually (mean follow-up: 3.17 ± 1.88 years). All underwent cardiovascular reflex testing (CRT) including Tilt Table Test, Valsalva Maneuver, Deep Breathing, Cold Face, and Handgrip tests, as well as a standardized neuropsychological battery. Cognitive and autonomic changes were assessed both cross-sectionally and longitudinally. Survival analyses (Kaplan-Meier and Cox regression) were used to estimate phenoconversion risk.

Results: At baseline, 17 patients (25.4%) had mild cognitive impairment (MCI), and 12 (17.9%) exhibited neurogenic orthostatic hypotension (nOH). No significant association was found between CI and nOH either cross-sectionally (MCI prevalence: 33.3% with nOH vs 23.6% without; $p = 0.484$) or longitudinally. Over time, we observed a significant increase in MCI with multiple domain involvement (OR = 1.65, 95% CI: 1.02–2.66; $p = 0.038$) and deterioration in visuospatial (OR = 1.17, 95% CI: 1.07–1.28; $p = 0.001$) and memory domains (OR = 1.50, 95% CI: 1.00–2.25; $p = 0.050$). Meanwhile, nOH showed a significant progression with time (e.g., OH at 3 min: OR = 1.66, 95% CI: 1.06–2.60; $p = 0.026$).

Fifteen patients (20.3%) phenoconverted (6 to DLB, 5 to PD, 2 to MSA, 2 to unspecified atypical parkinsonism) over a mean follow-up of 3.17 ± 1.88 years. Cox regression revealed that both MCI (HR = 3.71, 95% CI: 1.22–11.22; $p = 0.020$) and nOH (HR = 3.64, 95% CI: 1.20–10.98; $p = 0.022$) independently increased conversion risk. Their concomitant presence further amplified the hazard ratio to 12.12 (95% CI: 2.76–53.29; $p = 0.001$), indicating a four-fold higher risk compared to either factor alone.

Conclusions:

In iRBD, cognitive and autonomic dysfunctions follow parallel but independent progression pathways. While they do not significantly influence each other in their evolution, their coexistence markedly enhances the risk of developing α -synucleinopathies. These findings support the use of a multidimensional biomarker model integrating autonomic and cognitive assessments to improve phenoconversion risk stratification and patient monitoring in prodromal α -synucleinopathies.

Effects of Light Therapy on Parkinson's Disease-Related Brain Dysconnectivity and Sleep Disorders

Y. Shen¹, H. Hu², C.-F. Liu³

¹The Second Affiliated Hospital of Soochow University, Department of Neurology and Clinical Research Center of Neurological Disease, Suzhou,, China, ²The Second Affiliated Hospital of Soochow

University, Department of Neurology and Clinical Research Center of Neurological Disease, Suzhou, China, ³The Second Affiliated Hospital of Soochow University, Suzhou, China

Introduction: Light therapy (LT) may improve the clinical symptoms of Parkinson's disease (PD), a common neurodegenerative disease, especially sleep disorders. The objective of this study was to verify the effect of LT and identify differences between bright light therapy (BLT) and dim light therapy (DLT) on the clinical symptoms, objective sleep parameters, and functional brain networks of PD patients.

Materials and methods: Thirty-three PD patients were randomized to receive either 1 month of BLT or DLT, separated by a 1-month washout period, in a crossover fashion. All patients filled out comprehensive clinical questionnaires and underwent polysomnography (PSG) at baseline and after each period of intervention. A subset (11 patients in each group) also underwent 64-channel resting-state electroencephalogram (EEG) recording.

Results: BLT and DLT both decreased the Pittsburgh Sleep Quality Index (PSQI) score of PD patients. Compared with DLT, BLT significantly reduced the excessive daytime sleepiness (ESS) score and sleep latency and increased the slow-wave energy (SWE) during sleep in PD patients. BLT significantly increased the phase locking value (PLV) between the frontal and temporal lobes. It also increased global efficiency in the delta, alpha, and beta bands and reduced the characteristic path length in the alpha and beta bands relative to DLT.

Conclusions: LT improved sleep disorders associated with PD. BLT, in particular, has therapeutic potential to enhance sleep stability and improve daytime sleepiness, possibly due to its ability to restore functional brain dysconnectivity and enhance information integration and transmission efficiency.

Acknowledgments: No.

Efficacy and tolerability of extended-duration tonic motor activation for treating middle of the night awakenings associated with restless legs syndrome

H. Alawieh¹, S. Rigot¹, L. Camacho¹, J. Charlesworth¹

¹Noctrix Health, Inc., Pleasanton, United States

Introduction: Restless Legs Syndrome (RLS) is often associated with symptoms during the middle of the night that increase sleep fragmentation and wake after sleep onset (WASO). Prior studies have shown that bilateral high-frequency peroneal nerve stimulation – also known as tonic motor activation (TOMAC) – reduces RLS symptoms and improves sleep quality. These studies evaluated a TOMAC device that stimulates for 30 minutes (TOMAC-30). Here, we tested if a novel investigational TOMAC device that stimulates for an extended duration of 180 minutes (TOMAC-180) could lead to greater improvements in WASO and middle of the night RLS symptoms.

Materials and methods: This two-phase open-label feasibility study enrolled 14 patients with RLS who reported RLS symptoms during middle of the night awakenings ≥ 3 nights per week. During weeks 1-2 (phase 1), all participants received TOMAC-30 and were instructed to activate stimulation whenever they had RLS symptoms at bedtime or during the sleep period. During weeks 3-4 (phase 2), all participants received TOMAC-180 and were instructed to activate stimulation each night at bedtime. To enable 180-minutes of stimulation on a single battery charge, a novel investigational device was developed. WASO was assessed objectively by calculating the average minutes awake during the sleep period based on wrist actigraphy (Philips Actiwatch 2). Participant-rated questionnaires assessed the frequency of middle of the night RLS symptoms. The analysis population comprised all participants who started phase 2 (n=11). Baseline data were collected for frequency of middle of the night symptoms but not for actigraphy.

Results: The frequency of middle of the night RLS symptoms decreased significantly during TOMAC-180 treatment relative to baseline (3.36 vs. 4.95 days per week, Difference: -1.69, $p < 0.01$) and relative to TOMAC-30 (Difference: -1.09, $p = 0.04$). The mean duration of WASO per night decreased significantly for TOMAC-180 relative to TOMAC-30 (56.2 vs. 85.5 minutes, Difference: -29.3 minutes, $p = 0.03$); 51% of this improvement (14.8min) occurred during the first 180-minutes of sleep (i.e. during TOMAC-180) and the remaining 49% (14.5min) occurred later in the sleep period. There were 3 dropouts during TOMAC-30 (none due to tolerability or adverse events), no dropouts during TOMAC-180, and no serious or severe device-related adverse events during either treatment.

Conclusions: Compared to 30-minute TOMAC, extended-duration 180-minute TOMAC improved WASO, reduced middle of the night RLS symptoms, and was similarly well-tolerated. These results support additional development and validation of extended-duration TOMAC. Further studies with additional baseline assessments would be helpful to characterize the extent of sleep improvement with extended-duration TOMAC relative to baseline.

Acknowledgments: We thank Jatin Tekchandani and Sabrina Sifat for support with study execution.

Efficacy of transcutaneous spinal direct current stimulation and pneumatic compression in restless legs syndrome and augmentation

N. Gorbachev¹, A. Obukhova¹, M. Balabanova¹, A. Zakharova¹, M. Poluektov¹

¹Sechenov university, Moscow, Russian Federation

Introduction: Dopaminergic medications represent one of the most effective treatments for Restless Legs Syndrome (RLS). However, their use can lead to augmentation - a paradoxical worsening of symptoms characterized by an earlier onset, increased intensity, and spread of RLS manifestations with increasing drug doses. While some individual studies suggest the efficacy of non-pharmacological therapies for RLS, their impact on augmentation remains underexplored. The aim of this study was to assess the effectiveness of transcutaneous spinal direct current stimulation (tcSDCS) and pneumatic compression (PC) in patients with and without augmentation.

Materials and methods: A total of 40 patients with RLS were enrolled: 20 with augmentation and 20 without. The median age in the augmentation group (main group, MG) was 63.5 years (male/female: 5/15), and in the non-augmentation group (control group, CG) it was 62 years (male/female: 7/13). Among participants, 22 were taking pramipexole, 2 levodopa, 2 gabapentin, 1 pregabalin, while 13 were not taking any medications.

Patients were assessed using clinical examination and the International RLS Study Group rating scale (RS). All patients underwent the Suggested Immobilization Test (SIT) at 7:00–8:00 PM (SIT1) and 9:00–10:00 PM (SIT2) to evaluate the urge to move (via a 10-point numerical rating scale) and periodic limb movements while awake (PLMW). Twenty patients (10 with and 10 without augmentation) received tcSDCS, while the other 20 (10 with and 10 without augmentation) underwent PC therapy. Treatment effectiveness was evaluated based on changes in RS scores, NRS ratings of the urge to move, and PLMW counts during SIT.

Results: In the MG, tcSDCS significantly reduced PLMW during SIT1 (pre-treatment: 59 [15–105]; post-treatment: 11.5 [5–96], $p = 0.03$), NRS urge scores (pre: 7.0 [5.2–8.8]; post: 3.4 [1.8–6.8], $p = 0.03$), and RS scores (pre: 33.5 [30–35]; post: 25.5 [21–32], $p = 0.03$). In the CG, tcSDCS also led to RS score improvement (pre: 21 [20–28]; post: 21 [15–24], $p = 0.04$).

PC therapy in the CG resulted in a reduction of PLMW during SIT1 (pre: 10.5 [0–13]; post: 0 [0–5], $p = 0.048$) and a decrease in RS score (pre: 24 [20–29]; post: 21 [15–23], $p = 0.048$). However, neither tcSDCS nor PC showed any significant effect on SIT2 outcomes.

Conclusions: tcSDCS appears to offer symptomatic relief in both augmented and non-augmented RLS, particularly when administered before 8:00 PM. This effect may be related to reduced spinal excitability during earlier phases of the disease. PC demonstrated efficacy only in patients without augmentation, suggesting its role may be limited in more advanced or drug-complicated cases.

Acknowledgments: We would like to thank Dr. Ekaterina D. Spektor for her valuable statistical consultation during data analysis and study development.

Electroencephalographic slowing during REM sleep is a marker of cholinergic dysfunction in Lewy body disorders

J. Anderson^{1,2}, A. Konuri¹, L. Churchill^{1,2}, A. Ignatavicius¹, G. Cho^{2,3}, Y. Tian^{1,3}, H. Thompson², D. Welagedera¹, A. Lam⁴, S. Naismith⁴, R.R. Grunstein^{2,3,5}, S.J. Lewis³, E. Matar^{1,2,5}

¹The University of Sydney, Central Clinical School, Sydney, Australia, ²The Woolcock Institute of Medical Research, Sydney, Australia, ³Macquarie University, Sydney, Australia, ⁴The University of Sydney, The Brain and Mind Centre, Sydney, Australia, ⁵Royal Prince Alfred Hospital, Sydney, Australia

Introduction: Lewy body diseases, including Parkinson's disease (PD) and dementia with Lewy bodies (DLB), represent the second most common neurodegenerative disease in older adults. Recent work has implicated progressive cholinergic system dysfunction as a key contributor to cognitive decline and disease progression in Lewy body disorders. Despite this, simple, non-invasive biomarkers of cholinergic impairment are lacking. Given that cholinergic neurons are actively involved in REM sleep and play a central role in cortical activation, alterations in EEG during REM sleep may offer a unique window into cholinergic network dysfunction.

In this study, we investigated whether REM EEG slowing in particular reflects disruption of key cholinergic hubs, the nucleus basalis of Meynert (NBM) and pedunculopontine nucleus (PPN), and whether this electrophysiological marker relates to cognitive impairment in Lewy body disorders.

Materials and methods: This cross-sectional study included 105 participants: 25 with DLB (mean age = 74.6 ± 6.0 years), 40 with PD (mean age = 64.2 ± 8.6 years), and 40 controls without cognitive impairment (mean age = 66.3 ± 7.7 years). All participants underwent comprehensive neuropsychological assessment and overnight polysomnography. A subset of participants also completed structural and resting-state fMRI within 12 months of their other assessments. Absolute REM spectral power was computed across frontal, central, and occipital regions for standard frequency bands (δ , θ , α , σ , β), and a slowing ratio was defined as $[(\delta+\theta)/(\alpha+\sigma+\beta)]$. NBM volumes were extracted from T1-weighted images, and seed-based functional connectivity was assessed between the NBM and resting-state networks, and between the PPN and thalamus, using the Schaefer 400, Tian subcortical, and probabilistic NBM atlases. Group differences in REM spectral power were assessed using general linear models with permutation testing. Linear regressions were used to examine associations between neuroimaging variables and REM EEG slowing across α -synucleinopathies. All analyses included age and sex as covariates, applying FDR correction where appropriate.

Results: DLB participants showed significantly greater REM EEG slowing in occipital regions compared to PD and controls ($p_{FDR} = 0.006$). Power spectral changes were not associated with NBM volume. However, occipital REM slowing was significantly correlated with; aberrant NBM functional connectivity to the visual ($p_{FDR} = 0.034$), ventral attentional ($p_{FDR} = 0.034$), default mode ($p_{FDR} = 0.037$), and frontoparietal ($p_{FDR} = 0.037$) networks; and deficits in global cognition (MMSE; $p_{FDR} = 0.020$), verbal learning (RAVLT recall; $p_{FDR} = 0.009$), and executive function (Trails B; $p_{FDR} = 0.020$). Altered PPN connectivity to the thalamus was correlated with REM slowing across regions (frontal, $p_{FDR} = 0.008$; central, $p_{FDR} = 0.033$; occipital, $p_{FDR} = 0.033$).

Conclusions: This study demonstrates that REM EEG slowing is associated with cholinergic network dysfunction across Lewy body diseases, and correlates with cognitive impairment across multiple domains. These findings suggest REM EEG slowing may be a non-invasive and transdiagnostic marker of cholinergic dysfunction and cognitive decline in Lewy body disorders, with relevance for disease monitoring, prognosis, and stratification in clinical trials.

Exploring Sleep Bruxism through Sleep Physiology and Posture: Implications for Risk Prediction

K.-C. Hsu¹, P.-T. Wu^{2,3}, C.-W. Chen^{2,4,5}, C.-H. Wu^{1,2}

¹National Taipei University of Nursing and Health Science, Department of Information Management, Taipei, Taiwan, ²National Yang Ming Chiao Tung University, Sleep Research Center, Taipei, Taiwan, ³National Yang Ming Chiao Tung University, Institute of Brain Science, Taipei, Taiwan, ⁴National Chengchi University, Institute of Neuroscience, Taipei, Taiwan, ⁵National Chengchi University, Research Center for Mind, Brain and Learning, Taipei, Taiwan

Introduction:

Sleep bruxism (SB) is a sleep-related behavior involving rhythmic masticatory muscle activity, classified into phasic, tonic, or mixed patterns. While traditionally viewed as a disorder, emerging evidence suggests SB may act as a compensatory mechanism to maintain airway patency or respond to arousals during sleep. Although SB has been linked to sleep disturbances, the relationship between its patterns, severity, and physiological sleep parameters remains unclear. Sleep posture may also influence SB expression, yet this factor is often overlooked. We hypothesized that SB severity and pattern are associated with specific sleep-related physiological markers and that body position modulates these associations. This study explores these relationships to provide insights for future risk assessment and predictive modeling.

Materials and methods:

We recruited 35 participants (mean age 29.2 ± 6.6 years) with self-reported sleep bruxism (SB). Exclusion criteria included neurological, respiratory, or systemic conditions and medication use affecting sleep or muscle function. Participants underwent overnight polysomnography (PSG) in a sleep lab (24 °C, 60% RH), with recordings including EEG, ECG (wireless patch), oxygen saturation, and body position. The sleep protocol included both **natural posture** and **controlled posture segments**, during which participants were instructed to maintain specific positions (supine, prone, left, right) using positioning aids and monitored in real-time. Body position was tracked continuously, and SB episodes were classified as phasic, tonic, or mixed, and quantified using the Bruxism Episode Index (BEI). Sleep architecture and spectral EEG parameters were analyzed by SB severity and posture.

Results: Our findings revealed that the frequency and type of sleep bruxism (SB) episodes—phasic, tonic, and mixed—differed significantly among groups classified by SB severity. Greater severity was associated with increased wake after sleep onset (WASO) and lower subjective sleep efficiency. Furthermore, variations in brain activity were observed, with significant differences in whole-night theta wave percentages and non-rapid eye movement stage 2 (N2) proportions among severity groups. Sleep position played a critical role: the frequency of SB events varied across natural, supine, prone, left, and right positions. Specifically, non-supine positions were associated with fewer SB events and better sleep quality metrics, such as total sleep time and reduced arousals. Correlation analyses showed that SB severity and type were inversely associated with poor sleep indicators in non-supine positions, while the opposite was observed in supine positions.

Conclusions: Sleep bruxism (SB) may not solely represent a pathological sleep disorder but could reflect a physiological response to airway instability during sleep. The present findings suggest that sleep posture may influence SB expression, with non-supine positions potentially associated with improved sleep continuity and fewer arousals. All three SB types—phasic, tonic, and mixed—exhibited posture-dependent associations with sleep parameters, indicating that body position might play a modulatory role in the occurrence and functional significance of SB.

Impact of Dopamine Agonists and Clonazepam on LMM and PLMS in RLS Patients

M.P. Mogavero¹, P. Congiu¹, G. Lanza², S. Marelli², A. Castelnuevo², M. Puligheddu¹, O. Bruni⁵, L. Ferini Strambi², R. Ferri⁴

¹Vita Salute San Raffaele University, Sleep Disorders Center, Division of Neuroscience, San Raffaele Scientific Institute, Milan, Italy, ²University of Cagliari, Sleep Disorder Research Center, Department of Medical Sciences and Public Health, Cagliari, Italy, ³University of Catania, Sleep Research Centre, Oasi Research Institute-IRCCS, Troina, Catania, Italy, ⁴Sapienza University, Rome, Department of Social and Developmental Psychology, Rome, Italy, ⁵Oasi Research Institute-IRCCS, Sleep Research Centre, Troina, Italy

Introduction: Restless Legs Syndrome (RLS) is a heterogeneous sensorimotor disorder characterized by disrupted sleep architecture. Evidence from numerous studies indicates that therapies for RLS can modulate various polysomnographic (PSG) parameters, aiming to restore normal sleep homeostasis. Recent findings suggest that Large Muscle Group Movements during sleep (LMM) are significantly increased in RLS and may have distinct neurophysiological and neurobiological mechanisms compared to Periodic Leg Movements during Sleep (PLMS). This study investigates the effects of dopamine agonists (DAs) and clonazepam (CLO) on LMM in patients with RLS.

Materials and methods: A retrospective analysis was conducted on 51 drug-free adult RLS patients, divided into three groups: 33 received a DA (pramipexole or ropinirole), 15 received CLO, and 18 received a placebo. Each patient underwent two consecutive nocturnal PSG recordings: one at baseline

and one following treatment administration. LMM and PLMS were scored. Between-group differences were analyzed using ANCOVA, with the International RLS Study Group severity scale as a covariate. Within-group changes were evaluated using paired t-tests.

Results: At baseline, no significant differences in LMM or PLMS were observed between groups. Post-treatment, DAs significantly reduced PLMS and periodicity indexes but had minimal impact on LMM indexes, except for a slight increase in LMM duration. The placebo group demonstrated a significant reduction in the LMM index during the second night, potentially due to a first-night effect (FNE). CLO did not significantly affect either PLMS or LMM.

Conclusions: This study underscores the complexity of motor disturbances in RLS, highlighting that while DAs effectively reduce PLMS, they have limited impact on LMM, suggesting distinct underlying mechanisms for these motor activities. These findings emphasize the need for a more comprehensive therapeutic approach in RLS that addresses the full spectrum of motor abnormalities. The persistence of arousals and NREM sleep instability despite DA treatment further suggests the inadequacy of current therapies in fully resolving sleep disruptions in RLS. Future research should prioritize the development of targeted interventions capable of addressing both PLMS and LMM to enhance treatment outcomes in RLS patients.

Impact of Large Muscle Group Movements on Sleep Neurophysiology in Restless Legs Syndrome

M.P. Mogavero¹, P. Congiu², G. Lanza³, S. Marelli¹, A. Castelnovo¹, L. DelRosso¹, M. Puligheddu², L. Ferini Strambi², R. Ferri⁵

¹Vita Salute San Raffaele University, Sleep Disorders Center, Division of Neuroscience, San Raffaele Scientific Institute, Milan, Italy, ²University of Cagliari, Sleep Disorder Research Center, Department of Medical Sciences and Public Health, Cagliari, Italy, ³University of Catania, Sleep Research Centre, Oasi Research Institute-IRCCS, Troina, Catania, Italy, ⁴University of California San Francisco, Fresno, Fresno, United States, ⁵Oasi Research Institute-IRCCS, Sleep Research Centre, Troina, Italy

Introduction: Restless Legs Syndrome (RLS) is a highly heterogeneous sensorimotor disorder rooted in a complex and interconnected network of neurotransmitters. These networks influence the clinical presentation, phenotype variability, severity of the disorder, and its response to treatment. Neurophysiological assessments, which reflect the functioning of neuronal and neurotransmitter systems, offer valuable insights into understanding RLS. Recently, criteria have been established for assessing Large Muscle Group Movements during sleep (LMM). This study aims to characterize LMM in RLS to better evaluate their impact on the sleep neurophysiology of the disorder in adults.

Materials and methods: Consecutive drug-free patients diagnosed with RLS and healthy controls aged 18 years or older were retrospectively enrolled. Leg movement activity was assessed and scored, including short-interval leg movements (SILMS), periodic leg movements during sleep (PLMS), isolated leg movements (ISOLMS), and LMM.

Results: A total of 100 RLS patients and 67 controls were included. All movement indices were significantly higher in RLS patients compared to controls. A significant positive correlation was observed between the LMM and ISOLMS indices in both groups, but not between LMM and PLMS indices. In RLS patients, the LMM index showed a significant negative correlation with total sleep time, sleep efficiency, and the percentage of sleep stages N3 and R. Conversely, it demonstrated a significant positive correlation with the number of awakenings and the percentage of sleep stages N1 and N2. No significant correlations were found between LMM or PLMS indices and RLS severity.

Conclusions: Different types of leg movements contribute uniquely to the sleep neurophysiology of RLS. LMM, in particular, are associated with sleep architecture instability, fragmentation, arousals, and awakenings, indicating potential clinical implications. These disruptions are supported by a complex neural network involving serotonergic and noradrenergic neurons and modulatory influences from glutamatergic, acetylcholinergic, dopaminergic, histaminergic, and orexinergic systems. Since homeostatic sleep pressure is regulated by neurotransmitters also implicated in RLS, targeting one or more of these systems to reduce LMM and their adverse effects on sleep neurophysiology could yield significant clinical benefits.

Impaired transition from wake to sleep and hyperarousal may not resolve with a dental guard in sleep-related bruxism

D. Neu^{1,2,3}, A. Quillet^{4,1}

¹CHIREC Delta Hospital, Center for the Study of Sleep Disorders, Brussels, Belgium, ²Erasme Academic Hospital Université Libre de Bruxelles, Sleep Laboratory Department of Neurology, Brussels, Belgium, ³Université Libre de Bruxelles, Neurosciences Institute, Brussels, Belgium, ⁴Erasme Academic Hospital, Dentistry and Maxillo-Facial Surgery, Brussels, Belgium

Introduction: Sleep related bruxism (SB) is a common sleep-related movement disorder, defined by involuntary rhythmic recurrences of increased masticatory muscle tone during sleep. The present study aims to compare polysomnographic parameters and clinical assessments (oro-dental examination) along with daytime symptoms, in SB patients and a control group of similar age. In addition, exploratory associations between recorded sleep variables and clinical parameters are performed. An evaluation of the therapeutical impact of SB treatment with a dental guard (DG), has been conducted in a subgroup of SB patients. The main hypotheses are that, despite subjective symptom complaints, sleep structure does not show significant impairments in SB and that Rhythmic Masticatory Muscle Activity (RMMA) is not significantly associated with daytime symptoms or sleep variables.

Materials and methods: 22 SB patients and 13 good sleeper controls, of similar age, underwent polysomnography (PSG), clinical evaluations and assessments with structured symptom scales, in a cross-sectional observational study, between September 2024 and January 2025. Secondly, a clinical follow-up evaluation of SB patients, treated with DG (n=6) in comparison to untreated SB (n=11), has been conducted, at least 3 months after PSG.

Results: Excepted for a significant (p=.014) reduction of light sleep (Non-REM stage 1) and a significantly higher arousal index (p<.001), comparisons of sleep structure variables, revealed broadly similar sleep stage durations between groups. Sleep efficiency was significantly lower in SB patients (p=.028). Although being significantly increased in SB patients, apnea-hypopnea index did not show any association to the RMMA index. The latter was however significantly related to the decrease of N1 sleep duration (p=.033). SB patients displayed significantly greater teeth wear, higher levels of insomnia (p=.022) and daytime sleepiness (p=.012) than control subjects. While gingival recession was more frequent in untreated SB patients, comparative follow-up evaluations, solely showed significantly higher levels of insomnia complaints and higher levels of masseteric muscle hypertrophy among the DG treated subsample of SB patients.

Conclusions: The present study indicates that wake to sleep transitions may be impaired in SB patients. Our results also underline associated symptom intensities and suggest that hyperarousal or insomnia may not show sufficient therapeutic responses to purely mechanical treatments in SB patients.

Real-world evidence of tonic motor activation (TOMAC) for refractory restless legs syndrome (RLS): Interim 180-day results from the THRIVE study

J. Ojile¹, M. Buchfuhrer², H. Singh³, A. Roy⁴, R. Bogan⁵, R. Thomas⁶, K. Swartz⁷, J. Preciado⁷, J. Charlesworth⁷

¹Clayton Sleep Institute, St. Louis, United States, ²Stanford University School of Medicine, Stanford, United States, ³iSleep Physicians, San Ramon, United States, ⁴Ohio Sleep Medicine Institute, Dublin, United States, ⁵Bogan Sleep Consultants, Columbia, United States, ⁶Beth Israel Deaconess Medical Center, Boston, United States, ⁷Noctrix Health, Inc., Pleasanton, United States

Introduction: Tonic motor activation (TOMAC) is a therapeutic medical device for refractory restless legs syndrome (RLS) that transmits bilateral high-frequency electrical stimulation to the peroneal nerve in the legs. TOMAC has previously been demonstrated as safe and efficacious in randomized controlled trials. Here, we report interim results from the THRIVE study, which evaluates the real-world safety and effectiveness of TOMAC in clinical practice.

Materials and methods: Patients prescribed Nidra TOMAC (Noctrix Health, Inc.) after study initiation in November 2023 were invited to participate in the THRIVE multicenter prospective observational post-market study. The prespecified indicated intent-to-treat (IITT) population comprised participants who met the U.S. FDA indication of moderate-severe refractory RLS; data were imputed for participants who withdrew. Interim analysis was conducted on all participants enrolled ≥180 days before March 18,

2025, the date of interim database lock. Baseline measures were assessed prior to starting TOMAC and interim outcomes were assessed at Day-180 relative to baseline. The primary efficacy endpoint was mean change to International RLS Study Group (IRLS) score and key secondary outcomes included clinical global impressions of improvement (CGI-I) and mean change to Medical Outcomes Study Sleep Problem Index II (MOS-II) score. The frequency and nature of adverse events and medication changes were assessed.

Results: For IITT participants (n=73) at study entry, mean age was 66.4 years (SD: 11.0), average duration of RLS symptoms was 29.9 years (SD: 17.9), 63% were female, and mean IRLS score was 25.9 points (SD: 5.6). From baseline to Day 180, mean IRLS change was -8.5 (95% CI: -6.9 to -10.2), CGI-I responder rate was 60%, and mean MOS-II change was -14.1 (95% CI: -9.4 to -18.9). The only device-related adverse events were administration site skin irritation (5%) and administration site discomfort (4%), which were never serious nor severe. Of the 66 participants prescribed RLS medication at baseline, 24 (36%) reduced RLS medication dose and 9 (14%) increased RLS medication dose (odds ratio: 2.7). Participants who reduced medication had average dose reduction of 51%, mean IRLS change of -8.4 points (95% CI: -6.2 to -10.6) and MOS-II change of -9.3 points (95% CI: -2.5 to -16.1).

Conclusions: These interim results suggest that TOMAC treatment is safe and effective in real-world treatment of refractory RLS. After 180 days of TOMAC treatment, there were improvements to both RLS symptoms and sleep quality. Reductions to adjunctive RLS medication were more common than increases and were well-tolerated.

Acknowledgments: We thank the THRIVE study team, with special thanks to Dennell Vargas, Van Lieou, Stephanye Rodriguez, and Sabina Alisic.

REM sleep deprivation promotes the spread of pathological α -synuclein and dopaminergic neuronal degeneration in Parkinson's disease

L. Kou¹, Y. Xia¹, L. Liu¹, Z. Jin¹, J. Huang¹, N. Xiong¹, T. Wang¹

¹Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Neurology, Wuhan, China

Introduction: Rapid eye movement sleep behavior disorder (RBD), as an important prodromal symptom of Parkinson's disease (PD), often emerges several years or even decades earlier than typical motor symptoms. Moreover, most RBD patients will gradually progress to synucleinopathies such as PD, suggesting that REM sleep disorders play a key role in the occurrence and development of PD. The latest research shows that the level of α -synuclein (α -syn) in cerebrospinal fluid shows obvious diurnal fluctuations, manifested as an increase during the awakening period and a decrease during the sleep period. Based on these findings, this study aims to explore the effects of chronic REM sleep deprivation on the pathological transmission of α -syn and the survival of dopaminergic neurons in a PD model.

Materials and methods: 12-week-old male C57BL/6J mice were randomly divided into four groups: 1) Normal sleep + PBS (CON+PBS); 2) Sleep deprivation + PBS (SD+PBS); 3) Normal sleep + α -syn preformed fibrils (CON+ α -syn PFF); 4) Sleep deprivation + α -syn preformed fibrils (SD+ α -syn PFF). The PD mouse model was established by stereotactic injection of 5 μ g α -syn PFF into the striatum. Beginning 48 hours post-injection, mice underwent daily REM sleep deprivation for 20 hours using the modified multiple platform water maze method, maintained for 4 consecutive weeks. At the 6-month endpoint, brains were collected for quantitative assessment of phosphorylated α -syn (Ser129) deposition and stereological counting of tyrosine hydroxylase-positive (TH+) dopaminergic neurons in the substantia nigra pars compacta (SNpc) using immunofluorescence microscopy.

Results: No obvious phosphorylated α -syn (pSer129) deposition was detected in the SNpc of PBS control groups (CON+PBS and SD+PBS). Compared with the CON+ α -syn PFF group, the SNpc of mice in the SD+ α -syn PFF group showed: 1) significantly enhanced immunopositive signals of phosphorylated α -syn; and 2) significantly reduced numbers of tyrosine hydroxylase-positive (TH+) dopaminergic neurons.

Conclusions: This study confirmed that chronic REM sleep deprivation can significantly promote the spread and abnormal aggregation of pathological α -syn in the SNpc of PD models and aggravate degenerative changes in dopaminergic neurons.

Restless arms syndrom - an uncommon presentation of restless-leg syndrom

M. Roßkopf¹, R. Popp², K. Obermeier³

¹University Regensburg, Department of Psychiatry and Psychotherapy, Center of Sleep Medicine, Regensburg, Germany, ²University, Department of Psychiatry and Psychotherapy, Center of Sleep Medicine, Regensburg, Germany, ³LMU Munich, University Hospital, Department of Oral and Maxillofacial Surgery and Facial Plastic Surgery, Munich, Germany

Introduction: Restless Legs Syndrome (RLS) also known as Willis-Ekbom-Disease is assigned to neurological disorders. It is characterized by an uncontrollable urge to move the legs, due to uncomfortable sensation. These conditions in term can lead to daytime sleepiness, fatigue and depression, which is mostly found in RLS patients. In extreme cases, these symptoms can be so stressful for patients that they develop suicidal thoughts. RLS may occur also in other parts of the body other than the legs. Especially, isolated restless arm syndrome (RAS) is very rare. Most commonly, the legs are in some way also affected by symptoms. These two following Case reports are about two patients with special forms of RLS.

Materials and methods: Overall 2 patients were included in this study. Diagnose was performed according to the International RSL Group (IRLSSG). All demographic and clinical data of patients were collected. Both patients received polysomnography. All demographical information and medical reports were examined. Polysomnography was available in both patients as well as follow up data.

Results: Both patients suffered from uncommon forms of RLS: The male patient, aged 50 years, suffered from isolated RAS of both arms. He suffered from depression and sleep disorder with consecutive day time sleepiness. The female patient, aged 66 years suffered from RLS isolated affecting the left body side. Iron-values were normal in both patients. Clinically, RAS presented with uncomfortable and painful burning sensation of the arms. The both patients were diagnosed using the IRLSSG-criteria and both met all criteria.

Conclusions: Restless arms syndrome is either a part of restless legs syndrome or a seldom variant of restless legs syndrome. It is part of discussions, if restless arms syndrome is a distinct disease. Due to its rarity, RAS is often underdiagnosed. Patients usually do not associate the distinct symptoms only affecting the arms or only one side of the body with restless legs syndrome. So far, clinicians are requested to ask patients with sleep disorders specifically about the distinct restless legs symptoms with regard to the arms. And they should consider, that RLS can appear one sided only. Especially the first case shows the effects of RAS on the quality of life. RAS can coincide with psychiatric disorders such as depression.

Restless Legs Syndrome during Pregnancy and Puerperium

S. Hackethal¹, A. Maculano Estevens², S. Riccardi¹, C. Garbaza³, M. Manconi¹

¹Sleep Medicine Unit, Nueocenter of Southern Switzerland, Lugano, Switzerland, ²Faculdade de Ciências Aplicadas, Universidade Estadual de Campinas, Sao Paulo, Brazil, ³Centre for Chronobiology, University of Basel, Basel, Switzerland, Basel, Switzerland

Introduction: Pregnancy is a significant risk factor for the development of Restless Legs Syndrome. Apart from it's negative impact on sleep and general quality of life, RLS is also associated with pregnancy complications and negative outcomes.

Materials and methods: To elucidate the prevalence, trajectory, severity, and risk factors of RLS throughout pregnancy and the postpartum period we analysed data from the multicenter Life-ON Cohort Study (NCT02664467) which recruited 439 pregnant women in the 10-15th gestational week and followed them up until 12 months after delivery.

Results: 26% of women (n=113) met the diagnostic criteria for RLS in at least one of the three visits during pregnancy. RLS severity was similar during all trimesters and during the postpartum period with however higher values in women who screened positive for RLS in all the three or two trimesters compared to those who screened positive in just one. A previous history of RLS was found in 50.68% of women who reported RLS during the current pregnancy and 18.7% had a positive family history. During the entire follow-up period out of 386 women, 134 were diagnosed with RLS, corresponding to a cumulative incidence of 34.7%. Previous history of depression, positive family history for RLS and previous RLS were statistically significant risk factors for RLS during pregnancy. Around 20% of women

experienced severe to very severe symptoms (IRLS >20 pts), representing a possible target to be carefully considered for a pharmacological treatment

Conclusions: The correct identification and treatment of RLS during pregnancy could potentially greatly improve women's sleep quality and generally quality of life during pregnancy and reduce associated pregnancy complications and negative pregnancy outcomes.

Sex and Age Differences in PLMS Among RLS Patients: A Lifespan Perspective

M.P. Mogavero¹, G. Lanza³, L. DelRosso⁵, B. Lanuzza⁶, O. Bruni¹, L. Ferini Strambi², R. Ferri⁶

¹Vita Salute San Raffaele University, Sleep Disorders Center, Division of Neuroscience, San Raffaele Scientific Institute, Milan, Italy, ²University of Catania, Sleep Research Centre, Oasi Research Institute-IRCCS, Troina, Catania, Italy, ³University of California San Francisco, Fresno, Fresno, United States, ⁴Oasi Research Institute-IRCCS, Sleep Research Centre, Troina, Italy, ⁵Sapienza University, Rome, Department of Social and Developmental Psychology, Rome, Italy

Introduction: Restless Legs Syndrome (RLS) and Periodic Leg Movements during Sleep (PLMS) are common sleep disorders with significant health impacts. While sex-related disparities in RLS and PLMS prevalence are well-documented, a comprehensive understanding of these differences across the lifespan remains limited. This study investigates sex differences in PLMS among RLS patients across various age groups, ranging from 2 to over 80 years, and explores the potential mechanisms underlying these differences, with important clinical implications.

Materials and methods: A retrospective analysis was conducted on drug-free patients diagnosed with RLS, comprising 95 females (ages 2–83.2) and 89 males (ages 2–79.5). Polysomnographic recordings were used to evaluate leg movement activity, including the PLMS index and Periodicity index. Exclusion criteria included other sleep disorders, psychiatric diagnoses, and central nervous system drug use.

Results: In females, the PLMS index showed a rapid increase starting before age 10, plateauing below male levels until about age 55, after which it rose significantly for over a decade. In males, the PLMS index increased steadily, peaking after age 75. The Periodicity index followed a simpler trajectory, progressively increasing from prepuberty to around age 35 in males and age 45–50 in females. Females maintained a slightly higher Periodicity index than males for over a decade after this period.

Conclusions: The findings highlight the complex interplay between PLMS, age, and sex, with critical differences emerging during puberty and menopause. These trends suggest a significant influence of sex hormones and autonomic nervous system modulation on sleep motor activity across developmental stages. Our results emphasize the importance of personalized approaches to managing movement-related sleep disorders, tailored to demographic and physiological differences across age and sex.

Sex-Related Differences in Dopamine Agonist Response in Restless Legs Syndrome: A PSG-Based Study

M.P. Mogavero¹, E. Antelmi², G. Lanza³, S. Marelli¹, A. Castelnuovo¹, M. Tinazzi², R. Silvestri⁴, L. DelRosso⁵, R. Ferri⁶, L. Ferini Strambi¹

¹Vita Salute San Raffaele University, Sleep Disorders Center, Division of Neuroscience, San Raffaele Scientific Institute, Milan, Italy, ²University of Verona, Neurology Unit, Parkinson Disease and Movement Disorders Division, Verona, Italy, ³University of Catania, Sleep Research Centre, Oasi Research Institute-IRCCS, Troina, Catania, Italy, ⁴University of Messina, Messina, Italy, ⁵University of California San Francisco, Fresno, Fresno, United States, ⁶Oasi Research Institute-IRCCS, Sleep Research Centre, Troina, Italy

Introduction: Restless Legs Syndrome (RLS) is a sensorimotor sleep disorder characterized by significant heterogeneity in clinical manifestations, symptom onset, progression, and response to pharmacological treatments. Epidemiological studies indicate a higher prevalence of RLS in women

compared to men from adolescence onwards. This study aimed to examine sex-related differences in the therapeutic response to dopamine agonists, specifically ropinirole and pramipexole, in adult patients with RLS. By analyzing clinical parameters and polysomnographic (PSG) findings, we sought to explore the potential implications of sex disparities on treatment efficacy and sleep quality in RLS management.

Materials and methods: A retrospective analysis was conducted on 41 drug-free RLS patients aged 18 years or older. All participants underwent two consecutive nocturnal PSG recordings, the first without medication (baseline) and the second following treatment. Prior to the second night, 26 participants received a single oral dose of 0.25 mg pramipexole, while 15 received a single oral dose of 0.5 mg ropinirole in the evening. After each PSG recording, patients assessed the severity of their previous night's symptoms using an ad hoc Visual Analogue Scale (VAS).

Results: On the treatment night, women exhibited higher sleep efficiency and a greater percentage of stage N2 sleep, whereas men experienced significantly higher wakefulness after sleep onset. Additionally, women showed significantly lower total leg movements during sleep (LMS), periodic LMS (PLMS), and periodicity indexes compared to men. While VAS scores decreased significantly across all patients after treatment, no significant sex differences were observed in subjective symptom relief.

Conclusions: Both pramipexole and ropinirole primarily act through D3 receptors, which exhibit sex-specific expression patterns. This differential expression may underlie the higher pharmacological response observed in women, particularly with respect to reductions in PLMS. These findings align with emerging research on sex differences in the pharmacokinetics and pharmacodynamics of cardiovascular therapies, underscoring the importance of considering sex as a critical factor in personalized medicine. Our study provides valuable insights for developing more tailored, sex-specific treatment approaches for RLS and highlights the need to incorporate sex differences into future pharmacological guidelines.

Sleep Disturbances and Quality of Life in Children with Developmental Coordination Disorder

C. Thompson¹, A. Timler², M. Plumb³, G. Rigney⁴

¹Central Queensland University, Psychology, Melbourne, Australia, ²University of Notre Dame, Perth, Australia, ³University of New England, Armidale, Australia, ⁴Central Queensland University, Psychology, Adelaide, Australia

Introduction: Children aged 6–12 years with Developmental Coordination Disorder (DCD) often experience reduced health-related quality of life (QOL). While sleep disturbances are common in neurodevelopmental disorders (NDDs) and have been linked to lower QOL, little is known about this relationship in children with DCD. This study aimed to examine the association between parent-reported sleep behaviours and QOL in children with DCD or those showing symptoms but not yet formally diagnosed (probable DCD; pDCD).

Materials and methods: A total of 92 caregivers (97% mothers) of children aged 6–12 years with DCD or pDCD participated in an online survey. Child sleep behaviours were measured using the Children's Sleep Habits Questionnaire (CSHQ), and QOL was assessed using the KIDSCREEN-10 parent-proxy version. Descriptive statistics were used to summarise QOL and sleep. Spearman correlations were conducted to assess the strength and direction of associations between sleep and QOL.

Results:

Most children were male (67.4%), with a formal DCD diagnosis (83.7%), and aged 9–12 years. The majority had at least one comorbid condition (54.3%), most commonly ADHD (35.6%) and ASD (14.1%). Parents reported low QOL scores ($M = 34.10$, $SD = 6.49$), and 92% indicated their child experienced at least one sleep disturbance. The most commonly reported issues were daytime sleepiness ($M = 14.04$, $SD = 3.64$), bedtime resistance ($M = 8.63$, $SD = 3.20$), and parasomnias ($M = 10.36$, $SD = 2.59$). Overall sleep disturbance significantly and negatively correlated with QOL ($r = -.348$, $p < .001$), explaining 12.1% of the variance. Daytime sleepiness had the strongest association ($r = -.415$, $p < .001$; 17.2% variance explained), followed by parasomnias ($r = -.261$, $p < 0.001$). Bedtime resistance was not significantly correlated with QOL ($r = -.107$, $p > 0.05$).

Conclusions: Children with DCD or pDCD frequently experience both poor sleep and reduced QOL, particularly in relation to daytime sleepiness and parasomnias. These findings suggest that addressing sleep disturbances may be a promising avenue to support wellbeing in this population. Clinical

assessment and intervention planning for children with DCD should routinely consider sleep behaviours. Future research using objective sleep measures and child self-reports is recommended to strengthen and extend these findings.

Sleep Stage-Specific Aperiodic EEG Spectral Slope Alterations in isolated REM Sleep Behavior Disorder and Neurodegenerative Disorders

J. Ni^{1,2}, N. Li^{1,2}, Z. He^{1,1,2}, Y. Ye^{1,2}, S. Tang^{1,2}, Y. Yang^{1,2}, S. Gong^{1,2}, J.W.Y. Chan^{1,2}, V. Lam^{1,2}, B. Huang^{1,2,3}, Y.K. Wing^{1,2,3}

¹Department of Psychiatry, Faculty of Medicine, The Chinese University of Hong Kong, Shatin, N.T., Hong Kong, SAR of China, ²Li Chiu Kong Family Sleep Assessment Unit, Department of Psychiatry, Faculty of Medicine, The Chinese University of Hong Kong, Shatin, Hong Kong, SAR of China, ³Li Ka Shing Institute of Health Sciences, Faculty of Medicine, The Chinese University of Hong Kong, Shatin, Hong Kong, SAR of China

Introduction: Quantitative electrophysiological biomarkers capturing alterations in neural activity during sleep hold promises for improving the early detection and monitoring of Parkinson's disease (PD) and its prodromal stages, isolated REM sleep behavior disorder (iRBD). The spectral slope of the EEG power spectrum provides a frequency-independent measure of cortical excitability. However, there has been limited data in characterizing stage-specific alterations of spectral slope in iRBD and PD populations and its association with the conversion risk of iRBD.

Materials and methods: 404 video-polysomnography recordings from 270 patients with clinically diagnosed iRBD (70.30 ± 6.62 years, 78% male), 46 patients with PD (70.68 ± 6.75 years, 83% male), and 88 age- and sex-matched controls (70.14 ± 7.66 years, 66% male) were studied. Among the iRBD patients, 25 patients eventually converted to neurodegeneration (16 PD, 7 dementia with Lewy bodies, 2 multiple system atrophy) at 5.21 ± 2.86 years follow up. Sleep stages were manually scored according to AASM criteria by experienced technicians. The aperiodic spectral slope, defined as the exponent of the $1/f$ decay in the EEG power spectrum, were estimated using the FOOOF package. The 1–45 Hz spectral slope was computed for each clean 8-second epoch. The spectral slopes were averaged across Wake (prior to sleep onset), N1, N2, N3, and REM stages and all EEG channels (F4,C4,O2). Group differences in mean slope values per stage were assessed via generalized linear model adjusted for age and sex with Bonferroni-corrected post hoc tests. The conversion risk was estimated via Cox proportional hazards regression model.

Results: Spectral slopes demonstrated a clear, progressive flattening from healthy controls to iRBD to PD across all sleep stages. In light sleep (N1), mean slopes were -1.70 ± 0.18 in controls, -1.53 ± 0.25 in iRBD, and -1.38 ± 0.26 in PD ($p < 0.001$). This pattern persisted in N2 (controls: -1.96 ± 0.17 ; iRBD: -1.73 ± 0.27 ; PD: -1.55 ± 0.28 ; $p < 0.001$) and slow wave sleep (N3: controls -2.33 ± 0.21 ; iRBD -2.14 ± 0.23 ; PD -1.88 ± 0.37 ; $p < 0.001$). During REM sleep, slopes averaged -1.74 ± 0.18 in controls, -1.56 ± 0.25 in iRBD, and -1.43 ± 0.29 in PD ($p < 0.001$). In contrast, wake stage showed only a slight flattening (controls -1.20 ± 0.46 ; iRBD -1.12 ± 0.45 ; PD -0.92 ± 0.44 ; $p = 0.011$), with post hoc tests revealing a significant difference between PD and controls (mean difference = 0.27, p -corrected = 0.003) as well as between PD and iRBD (mean difference = 0.204, p -corrected = 0.015). A more flattening spectral slope at wake stage was associated with significantly increased risk of phenoconversion (HR = 5.15; 95%CI: 1.73–15.3; $p = 0.003$), but not in other sleep stages (N1 $p = 0.152$, N2: $p = 0.104$, REM: $p = 0.095$).

Conclusions: There was progressive flattening of aperiodic EEG spectral slopes from healthy controls to iRBD to PD across all sleep stages. A more flattening of spectral slope at wake stage predicts phenoconversion in iRBD. These findings support the role of spectral slope as a non-invasive biomarker for both staging and risk stratification in prodromal neurodegeneration.

Introduction: Recent advances in smartphone-based digital measurements for neurodegenerative α -synucleinopathies, including Parkinson's disease (PD), have demonstrated promising results in symptom assessment. Nevertheless, existing applications generally have a narrow scope of symptom coverage (e.g., focusing solely on motor features). Thus, we developed a smartphone application *SmartBrainApp* in Hong Kong to comprehensively assess both motor (e.g., movement, speech and facial expression) and non-motor (e.g., psychomotor, cognition, impulsivity) functions of PD (26 tests total). In the current study, we aimed to: 1) validate *SmartBrainApp* among clinical PD patients, and 2) evaluate the ability of the App to detect subtle motor and non-motor changes in the prodromal stage of α -synucleinopathies, i.e., idiopathic/isolated rapid eye movement sleep behaviour disorder (iRBD).

Materials and methods: The validation study was conducted in 44 PD patients (mean age: 67.6 ± 5.5 years; 79.6% male) and 44 age- and sex-matched controls (67.1 ± 5.5 years; 79.6% male), who underwent clinical and traditional paper-and-pencil-based neurocognitive assessments and also completed the *SmartBrainApp* assessment. The content (expert review), construct (correlation with traditional tests), criterion (PD vs. control discrimination) validity, acceptability, and feasibility were evaluated. Test-retest reliability was assessed in a subset of 37 subjects (19 controls and 18 PD). A further assessment was conducted in 125 iRBD patients (68.4 ± 6.5 years; 72.8% male) and 95 age- and sex-matched controls (67.6 ± 5.4 years; 72.6% male), and a comparison of traditional and App features was carried out.

Results: Among 26 tests, 21 (81%) showed satisfactory validity (significant correlation with the traditional assessment and group differences), and 17 of these (81%) also showed acceptable test-retest reliability (intraclass correlation coefficient > 0.6). When combining all digital tests, the sensitivity and specificity for distinguishing PD patients from controls were 88.9% and 85.2%, respectively, reaching an area under the curve (AUC) of 0.93. Among them, pronation-supination movement (AUC = 0.88, accuracy = 84.1%) and leg agility (AUC = 0.84, accuracy = 80.7%) were the optimal App-based motor tests predicting PD. The feasibility was supported by high completion rates ($\geq 97.7\%$) across the assessments, with 97.0% of subjects indicating that the assessments were not difficult to complete and 75.8% preferred the digital format over traditional paper-based methods. In addition, our smartphone-based App was able to capture subtle but significant PD-like abnormalities of iRBD patients in some motor (leg agility, finger tapping, reading and monologue) and non-motor (executive and attentional cognitive functions) tasks that were not detected by conventional assessments. By using all the features of *SmartBrainApp*, the AUC for distinguishing iRBD from controls reached 0.72.

Conclusions: *SmartBrainApp* demonstrated satisfactory validation properties in most motor and non-motor tasks and effectively identified a series of early motor/non-motor deficits in iRBD that were not detected by conventional assessments. This innovative approach addresses the critical need for accessible and objective assessments that can capture the multifaceted nature of PD, potentially enabling earlier detection and more precise monitoring of symptom evolution compared to conventional clinical evaluations.

The Double-Edged Pill: Pediatric Augmentation of RLS with Gabapentin

A. Valenzuela¹, A. Nguyen², D. Dominguez¹

¹Banner Health, Sleep Medicine, Mesa, United States, ²University of Arizona - College of Medicine, Phoenix, United States

Introduction: The American Academy of Sleep Medicine (AASM) updated its guidelines on restless leg syndrome (RLS), advising reduced use of dopamine agonists due to side effects like augmentation. While gabapentin shows low augmentation rates (~0.9%) in adults, limited data exist for pediatric cases. This report highlights treatment-resistant RLS in a 10-year-old male, potentially involving gabapentin-related augmentation.

Materials and methods: A 10-year-old with mild pediatric obstructive sleep apnea (OSA) and significant atopy presented with chronic nocturnal leg tingling relieved by movement. Adherence to PAP was reasonable. Family history included RLS in his father and pregnancy-related symptoms in mother.

Results: Labs were unremarkable, including ferritin at 85 ng/mL. X-rays ruled out lower extremity anatomic issue. Gabapentin was initiated and titrated with resolution of symptoms. After one year, symptoms worsened despite ongoing adherence to gabapentin, which was maximized at 600mg at night. The mother explored alternative therapies including transcutaneous electrical nerve stimulation unit, compression garments, massages, magnesium, and various homeopathic supplements with minimal relief. Repeat ferritin was 47 ng/mL and oral iron was started for 3 months without improvement. Given severity, intravenous ferric carboxymaltose therapy was ordered and also failed to improve symptoms. Symptoms escalated and began to occur earlier in the day and more persistent, raising concerns of gabapentin-induced augmentation. Neurology consultation yielded no additional guidance. Gabapentin was weaned, and pregabalin was considered but declined due to parental concerns of side effects. Benzodiazepines were also avoided due to a family history of substance misuse and parental concerns.

Conclusions: This adolescent initially responded to gabapentin, requiring higher and higher doses to control RLS. Occurrence of symptoms earlier in the day with increasing severity suggested augmentation. Unclear trigger. This case highlights a fairly underreported phenomenon of gabapentin-induced augmentation in pediatric RLS. This highlights the challenges of managing restless leg syndrome in children and emphasizes the need for more research and treatment strategies in the pediatric population.

Narcolepsy

Abnormal brain functional network dynamics in narcolepsy type 1 patients

F. Xiao¹, M. Wang¹, W. Wang¹, L. Wu¹, X. Dong¹, F. Han¹, K. Spruyt²

¹Peking University People's Hospital, Division of Sleep Medicine, Beijing, China, ²Université Paris Cité, INSERM, NeuroDiderot, Paris, France

Introduction: To investigate the dynamic functional connectivity in narcolepsy type 1 (NT1) patients and whether clinical features are associated with abnormal connectivity.

Materials and methods: We investigated dynamic functional connectivity (dFC) of 80 drug-naïve NT1 patients, 30 idiopathic hypersomnia (IH) patients and 60 age- and sex-matched healthy controls using sliding-window approach, clustering state analysis and graph-theory methods. Relationships between clinical features and abnormal dFC properties were evaluated.

Results: Three dFC brain states were identified to characterize and compare dynamic functional connectivity patterns: a more frequent and sparsely connected State I (46.96%), a less frequent and more strongly connected State II (26.3%), and a less frequent and sparsely connected State III (26.74%). In NT1 patients, the occurrence of the State II increased, corresponding with a prolonged dwell time of State II. While State III are predominant for healthy controls and IH. The occurrence and dwell time of State III are negatively correlated with sleep latency in NT1 patients.

Conclusions: The abnormal temporal patterns and functional segregation coupled with the severity of sleepiness and abnormal local integration in topological properties confirmed the vulnerability of functional networks in NT1 patients.

Abnormal Connectivity between Visual and Intrinsic Networks as Biomarkers for Differentiating Idiopathic Hypersomnia from Narcolepsy Type 1

F. Xiao¹, M. Wang¹, H. Zhang¹, X. Dong¹, F. Han¹

¹Peking University People's Hospital, Division of Sleep Medicine, Beijing, China

Introduction: Differentiating between idiopathic hypersomnia (IH) and narcolepsy type 1 (NT1) remains challenging in clinical practice. This study aimed to investigate whether dynamic functional network connectivity (FNC) can effectively distinguish between NT1 and IH based on group differences.

Materials and methods: The study involved 36 drug-naïve NT1 patients and 14 age- and sex- group matched IH patients, employing group spatial independent component analysis, sliding-window techniques, and clustering state analysis methods. Logistic regression, support vector machines, and random forest algorithms were then utilized to develop models for distinguishing between NT1 and IH based on the group comparison results from dynamic functional network connectivity (FNC).

Results: The dynamic functional network connectivity (FNC) analysis revealed five distinct connectivity configurations. State III, which accounts for 52% of all windows, resembles a stationary FNC and represents a more frequent but relatively sparse connected state. State I (19%) is characterized by stronger interconnectivity, while State II (2%) shows robust interconnections between intrinsic connectivity networks (ICNs), featuring both positive and negative connections. State IV (13%) is notable for sparse internal connections within the frontal-parietal network (FPN) and limited external connections between the FPN and other ICNs. In contrast, State V (14%) is marked by strong internal connections within the dorsal attentional network, sensorimotor network (SMN), and visual network (VIN). Notably, NT1 patients were observed more frequently in State IV than IH patients, while IH patients were more prevalent in State V. In State V, functional connectivity between VIN and other ICNs shows significant group differences between IH and NT1. For these connectivity, three diagnostic models demonstrated exceptional predictive performance in detecting IH within both training and test sets.

Conclusions: Abnormal connectivity between VIN and other networks, such as auditory network, SMN and FPN, may serve as potential biomarkers to differentiating IH from NT1.

Amelioration of Sleep-Related Eating Disorder After Switching From Twice-to Once-Nightly Oxybate

L. Kass^{1,2}

¹Westchester Pediatric Pulmonology & Sleep Medicine, Mount Kisco, United States, ²Valley Health System, Paramus, United States

Introduction: In a disproportionality analysis (Merino D, et al. *J Clin Med.* 2022;11:3890), sodium oxybate (SXB) treatment was associated with sleep-related eating disorder (SRED), a parasomnia characterized by somnambulism and compulsive eating. Immediate-release twice-nightly oxybate (TN-OXB) formulations (ie, SXB and calcium, magnesium, potassium, and sodium oxybates [mixed-salt oxybates]) are administered at bedtime and again 2.5-4 hours later. SRED coincides with the first dose of TN-OXB if patients remain awake. This retrospective, single-site analysis assessed the effect of switching from TN-OXB to extended-release once-nightly SXB (ON-SXB) on SRED among individuals with narcolepsy.

Materials and methods: Retrospective chart review was conducted from a single clinical site. Data were collected from individuals with narcolepsy who experienced SRED while taking TN-OXB and were switched to ON-SXB from the time of switch to ON-SXB through currently available data. Patient demographics, medical history, oxybate treatment duration, dosage, and weight-related measures before and after the treatment switch were recorded. Data were described and analyzed descriptively.

Results: Of 8 individuals with narcolepsy who experienced SRED, the mean (SD) age was 21 (4.1) years, 6 (75%) were female, and 6 (75%) and 2 (25%) had narcolepsy type (NT) 1 and NT2, respectively. Before switching to ON-SXB, median (range) TN-OXB dose and mean (SD) treatment duration were 8.8 (4.8-10.5) g and 40.6 (21.1) months, respectively, with 3 individuals (37.5%) taking asymmetric doses. After switching to ON-SXB, median (range) ON-SXB dose was 9 (6-9) g. Sleep eating episodes were resolved in all individuals within 6 months of switching to ON-SXB. Five (63%) individuals experienced a reduction in BMI after switching to ON-SXB.

Conclusions: In this retrospective chart analysis, individuals with narcolepsy and SRED experienced positive clinical outcomes after switching from TN-OXB to ON-SXB. Individuals switching to an oxybate that did not require a middle-of-the-night dose had resolution of sleep eating, and nearly two-

thirds experienced a reduction in BMI. SRED is an underappreciated challenge with TN-OXB dosing that may be ameliorated with a single, extended-release dose of SXB, as provided by ON-SXB.

A Phase 2, Randomized, Placebo-Controlled, Parallel-Group Study Evaluating the Safety and Efficacy of Alixorexton (ALKS 2680) in Patients With Idiopathic Hypersomnia: Study Design and Methods for Vibrance-3

D. Plante¹, R. Grunstein², G. Plazzi³, K. Maski⁴, J. Ramos⁵, Y. Du⁵, A. Lovett⁵, M. Yountz⁵, B. Rege⁵
¹University of Wisconsin School of Medicine and Public Health, Madison, United States, ²Woolcock Institute of Medical Research, Macquarie University and Sydney Health Partners, Sydney, Australia, ³IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy, ⁴Boston Children's Hospital, Department of Neurology, Boston, United States, ⁵Alkermes, Inc., Waltham, United States

Introduction: Idiopathic hypersomnia (IH) is a rare, chronic central disorder of hypersomnolence characterized by excessive daytime sleepiness and frequently accompanied by sleep inertia, long and unrefreshing naps, and prolonged nighttime sleep. Alixorexton (ALKS 2680) is a highly potent, oral, and selective orexin 2 receptor agonist in clinical development as a once-daily treatment for narcolepsy and IH. In a phase 1b study, patients with IH experienced statistically significant, clinically meaningful improvements in mean sleep latency on the Maintenance of Wakefulness Test (MWT) and self-reported alertness on the Karolinska Sleepiness Scale (KSS) following single doses of alixorexton at 5, 12, and 25 mg. Alixorexton was generally well tolerated with no serious or severe treatment-emergent adverse events (TEAEs). The objective of the phase 2 Vibrance-3 study (NCT06843590) is to evaluate the safety and efficacy of alixorexton compared with placebo in patients with IH across 8 weeks of treatment.

Materials and methods: Vibrance-3 is a randomized, double-blind, parallel-group, dose-range-finding study. Eligibility criteria include age 18 to 70 years, a diagnosis of IH based on the International Classification of Sleep Disorders (ICSD-3-TR) criteria, a body mass index between ≥ 18 and ≤ 40 kg/m², no significant comorbid sleep-related illness that could interfere with the sleep-wake cycle, no unstable medical conditions, and no shift work or other activities that may disrupt regular nighttime sleep. Patients will undergo an initial 2-week washout period from current medications used to manage IH symptoms, after which approximately 96 patients with IH will be randomized 1:1:1:1 to placebo or 10, 14, or 18 mg dose of alixorexton once daily for 8 weeks. The primary efficacy endpoint of Vibrance-3 is the change in the Epworth Sleepiness Scale score from baseline to week 8. Change in the Idiopathic Hypersomnia Severity Scale score from baseline to week 8 is the key secondary endpoint. Safety will be assessed by TEAEs, laboratory assessments, vital signs, electrocardiograms, and the Columbia-Suicide Severity Rating Scale. Mean sleep latency (assessed across MWT sessions), Clinical Global Impression of Severity, and patient-reported outcomes, including the KSS, are exploratory endpoints of the study.

Results: Results of Vibrance-3 are pending study completion.

Conclusions: Findings from the Vibrance-3 study will inform further clinical development of alixorexton in patients with IH. The phase 2 Vibrance-1 (NCT06358950) and Vibrance-2 (NCT06555783) studies are evaluating alixorexton in patients with narcolepsy type 1 and narcolepsy type 2, respectively.

Acknowledgments: This study is sponsored by Alkermes, Inc. Medical writing support is provided by Envision Pharma Group, funded by Alkermes, Inc.

Assessing Usability of Once-Nightly Sodium Oxybate Extended-Release Oral Suspension for Narcolepsy

M. Lavender¹, E. Wermter², L.E. Ortiz³, A.M. Morse⁴, M. Horsnell⁵, J. Gudeman⁶

¹Comprehensive Sleep Medicine Associates, Houston, United States, ²Restorative Sleep Medicine, Charlottesville, United States, ³Johns Hopkins Medical Institutions, Johns Hopkins All Children's Hospital, St. Petersburg, United States, ⁴Geisinger Commonwealth School of Medicine, Geisinger

Medical Center, Janet Weis Children's Hospital, Danville, United States, ⁵Patient Author, Erin, United States, ⁶Avadel Pharmaceuticals, Chesterfield, United States

Introduction: Sodium oxybate, available in once-nightly and twice-nightly formulations, is indicated for treatment of cataplexy or excessive daytime sleepiness in narcolepsy. Once-nightly sodium oxybate extended-release oral suspension (ON-SXB; LUMRYZ™) may alleviate potential dosing challenges associated with immediate-release twice-nightly formulations. Human factors validation testing was conducted to confirm safe use of ON-SXB, using the product packaging, mixing cup, and Instructions for Use (IFU).

Materials and methods: Two summative studies evaluated simulated usability of ON-SXB in individuals (16–65 years of age) with narcolepsy, who were categorized as either experienced (having current or previous experience self-administering SXB) or naive (no current or previous experience). Both studies were conducted in lab settings modeled after a home bedroom environment. Study 1 (S1) assessed all critical and noncritical tasks related to storage, preparation, administration, and disposal of ON-SXB. After S1, IFU updates were implemented for additional risk control. Study 2 (S2) assessed tasks associated with these updates. Tasks were evaluated through observed performance or participant responses to a labeling comprehension activity.

Results: Of the S1 participants enrolled (mean [range] age, 37.0 [16–57] years; female, 77%), 77% (24/31) successfully prepared and administered the full ON-SXB dose. Critical use errors included failure to administer dose at bedside (experienced, 8/15; naive, 12/16) and preparing >1 dose packet (experienced, 1/15; naive, 1/16). Multiple critical use errors occurred during the label comprehension activity, which S1 participants attributed to difficulty in locating certain safety-critical warnings in the labeling. Using these data, the IFU was updated. In S2, 87% (26/30) of participants (mean [range] age, 35.8 [17–64] years; female, 83%) successfully prepared and administered the dose. Fewer S2 participants encountered critical errors observed in S1 (not administering dose at bedside [experienced, 4/15; naive, 5/15] and preparing >1 dose packet [none]), indicating that IFU updates effectively reduced the associated use risks. Only 2 use errors, which occurred with naive participants and were related to product storage, occurred in the S2 label comprehension activity.

Conclusions: Validation to confirm that individuals with narcolepsy can follow labeled instructions for safe use and self-administration of oxybates is important and has been conducted with ON-SXB.

Attention and Inhibition Deficits in Narcolepsy Type 1 : Behavioral and Electrophysiological Markers

Z. Li¹, L. Zhang¹

¹Sir Run Run Shaw Hospital, School of Medicine, Zhejiang University, Department of Neurology, Hangzhou, China

Introduction: Cognitive impairments in narcolepsy type 1 (NT1) significantly compromise daily functioning, but their neural mechanisms remain unclear.

Materials and methods: This study employed multimodal electroencephalography (EEG) analyses to investigate electrophysiological substrates of attention and inhibition deficits in NT1 and their association with clinical characteristics, particularly orexin deficiency. High-density EEG recordings were acquired during a Go/NoGo task from 39 NT1 patients and 41 age-/sex-matched healthy controls. Behavioral analyses revealed that compared to controls, NT1 patients exhibited significantly prolonged reaction times and increased errors across both Go and NoGo conditions.

Results: Electrophysiological analyses demonstrated that NT1 patients showed: (1) delayed Go-P3 latencies, meaning impaired response preparation; (2) reduced NoGo-P3 amplitudes, reflecting deficient inhibitory control; and (3) attenuated theta-band power and inter-trial phase consistency across conditions. Notably, decreased theta-band power correlated with both lower orexin levels and slower reaction times.

Conclusions: These findings suggest that orexin deficiency may mediate theta-band oscillation impairments in NT1, which mechanistically contribute to cognitive dysfunction. Thus, we propose theta-band oscillations as a clinically translatable biomarker for NT1-related cognitive deficits, with

promising implications for objective monitoring of disease progression and developing EEG-targeted neuromodulation therapies.

Acknowledgments: We thank the individuals who participated in this trial, their families, and the clinical and research teams in the neurology department and school of physics of Sir Run Run Shaw Hospital, School of Medicine, Zhejiang University, China.

BP1.15205, a novel orexin-2 receptor agonist, demonstrates wake-promoting effects in monkeys and successfully completed the preclinical regulatory program

M. Missaire¹, X. Ligneau¹, P. Robert¹, M. Uguen¹, O. Réale¹, G. Nicolas¹, F. Belloir¹, S. Kometani², Y. Umemori², S. Chikura², K. Okada², D. Seiden³, K. Budur³, O. Finance¹

¹Bioprojet, Paris, France, ²Teijin Pharma Limited, Tokyo, Japan, ³Harmony Biosciences, Plymouth Meeting, United States

Introduction: Narcolepsy is a chronic sleep disorder often caused by selective deficiencies in orexin, a brain neurotransmitter that regulates wakefulness. BP1.15205 is a novel, highly potent, and orally bioavailable orexin-2 receptor agonist that previously demonstrated wake-promoting and anti-cataplectic effects in a mouse model of type 1 narcolepsy. The objectives of the current studies were to confirm the wake-promoting effects of BP1.15205 in wild-type monkeys, and to complete the preclinical regulatory program prior to Phase 1 clinical studies.

Materials and methods: For the *in vivo* pharmacology study, polysomnographic recordings were performed in wild-type male Cynomolgus monkeys. Following regulatory studies were GLP-compliant. For general toxicity studies, BP1.15205 was administered orally to Wistar rats (30 to 1000 mg/kg/day) and Beagle dogs (10 to 100 mg/kg/day) for 13 weeks, followed by a 4-week recovery period. The different dose ranges were chosen after preliminary non-GLP 14-day toxicity studies. Safety pharmacology studies included Irwin and respiratory plethysmography in Wistar rats, cardiovascular telemetry in vigil Beagle dogs, and patch-clamp assay in HEK-293 cells expressing the hERG channel. Genotoxicity studies included the Ames mutagenicity test, and *in vitro* and *in vivo* micronucleus tests in human lymphocytes and rat bone marrow, respectively. Finally, phototoxicity was assessed on human fibroblasts.

Results: The polysomnography study in monkeys demonstrated BP1.15205 to produce a robust wake-promoting effect (increase in total wakefulness time at the expense of both NREM and REM sleeps), significant from the dose of 1 mg/kg. The 13-week toxicity studies in rats and dogs revealed no BP1.15205-related adverse changes in body weight, food consumption, hematology, coagulation, organ weights, gross pathology, or histopathology at the maximal doses (100 mg/kg/day in dogs, 300 mg/kg in female rats, and 1000 mg/kg in male rats). These top doses were thus considered as NOAEL doses and corresponding toxicokinetics data provided satisfactory safety margin estimates. The Irwin and plethysmography studies revealed no adverse effects of BP1.15205 on the central nervous system and respiratory function at doses up to 300 mg/kg and 1000 mg/kg in female and male rats respectively. No cardiovascular concern was raised for BP1.15205 with an IC₅₀ value >30 µM at the hERG channel and without any adverse effect on the cardiovascular function at the maximal dose of 100 mg/kg in dogs. The Ames, *in vitro* and *in vivo* micronucleus studies demonstrated the absence of genotoxicity induced by BP1.15205. Finally, no BP1.15205-related phototoxicity was depicted.

Conclusions: BP1.15205 wake-promoting properties were demonstrated across species, including wild-type and narcoleptic mice and monkeys. Moreover, the GLP preclinical program demonstrated that BP1.15205 was not toxic at the highest doses tested in two species, did not alter the central nervous system, respiratory or cardiovascular functions, and was neither genotoxic nor phototoxic. Taken together, these results will support an IND application submission, and Phase 1 clinical study is planned to start in H2 2025.

Characterization of the nature, severity, and subjective experience of Cognitive Symptoms Associated with Narcolepsy Type 1

G.J. Lammers^{1,2}, P. Maruff³, T. Banerjee⁴, R.H. Pietrzak⁵, H. Romero⁴, E. Stukalin⁴, S. Crawford⁴, B.T. Harel⁴

¹Sleep-Wake Centre, Stichting Epilepsie Instellingen Nederland, Heemstede, Netherlands, ²Department of Neurology, Leiden University Medical Centre, Leiden, Netherlands, ³Cogstate, Melbourne, Victoria, Australia, ⁴Takeda Development Center Americas, Inc., Cambridge, MA, United States, ⁵Department of Psychiatry, Yale School of Medicine, New Haven, CT, United States

Introduction: Narcolepsy Type 1 (NT1) is a chronic neurological disorder marked by excessive daytime sleepiness, cataplexy, and fragmented nocturnal sleep. In addition to these hallmark symptoms, accumulating evidence indicates that cognitive symptoms are common, persistent, and clinically important in adults with NT1. Notably, cognitive symptoms can persist even when core sleep-related symptoms are well controlled and can adversely impact daily functioning and quality of life. Despite their clinical relevance, the nature and extent of cognitive symptoms in NT1 remain poorly understood. This analysis aimed to characterize these symptoms in adults with NT1 using validated tests of objectively assessed cognitive impairments and patient-reported cognitive difficulties.

Materials and methods: Baseline data were analyzed from three independent cohorts of adults with confirmed NT1 diagnoses. Each cohort was compared to a cohort of 120 healthy, age- and sex-matched controls with no evidence of any sleep disorder. Cohort 1 (N=111) was drawn from a Phase 2 clinical trial (NCT05687903), Cohort 2 (N=126) from a parallel observational study, and Cohort 3 (N=14) was a subset from a separate Phase 2 trial (NCT04096560). In Cohort 1, objective cognitive function was assessed using four validated neuropsychological tests: the Psychomotor Vigilance Task (PVT) for sustained attention, the Continuous Paired Associate Learning Test (CPAL) for visual learning and memory, the One-Back Test (ONB) for working memory, and the International Digit Symbol Substitution Test (IDSST) for processing speed. In Cohort 2, patient-reported cognitive function over the past week was measured using the validated Functional Impacts of Narcolepsy Instrument Cognitive Functioning domain (FINI CF). In Cohort 3, both PVT and FINI CF were assessed. For each NT1 Cohort, differences from normal performance were investigated for each outcome using independent-samples t-tests, and effect sizes were calculated using Cohen's *d*.

Results: In Cohort 1, individuals with NT1 performed significantly worse than healthy controls, with a large magnitude impairment in sustained attention ($d=1.34$, $p<0.001$), and moderate magnitude impairments in processing speed ($d=0.68$, $p<0.001$) and working memory ($d=0.73$, $p<0.001$); impairments in associate memory were not statistically significant ($d=0.14$, $p>0.1$). In Cohort 2, patient-reported subjective cognitive difficulties were significantly greater in the NT1 group than healthy controls with a large magnitude difference ($d=2.51$, $p<0.001$). In Cohort 3, large-magnitude differences were again observed in both sustained attention ($d=1.49$, $p<0.001$) and patient-reported cognitive difficulties ($d=2.58$, $p<0.001$).

Conclusions: This analysis of three independent cohorts show that cognitive symptoms are an important feature of NT1 as evidenced by large magnitude cognitive impairment on objective neuropsychological tests, particularly in attention, and substantial patient-reported cognitive difficulties on scales. The pattern of cognitive impairments observed in these well-characterized cohorts of adults with NT1 aligns closely with recent meta-analytic findings (Harel et al., *Sleep Advances*, 2024), supporting their robustness and replicability. These results suggest cognitive symptoms should be considered in the diagnosis and treatment of individuals with NT1.

Clinical and Polysomnographic Differences Among Child-, Adolescent-, and Adult-Onset Type 1 Narcolepsy: A Chinese Cohort Study

M. Peng¹, Y. Wang², L. Xu¹, Y. Gao³, J. Li¹, L. Zhao¹, B. Zhou¹, X. Zhang¹, Y. Zuo¹, L. Wu¹, W. Wang¹, F. Han¹, X. Dong¹

¹Peking University People's Hospital, Department of Sleep Medicine, Beijing, China, ²The University of Melbourne, Centre for Epidemiology and Biostatistics, Melbourne School of Population and Global Health, Melbourne, Australia, ³Peking University International Hospital, Department of Sleep Medicine, Beijing, China

Introduction: The study aimed to evaluate the differences in clinical presentation and polysomnographic parameters across different onset-age groups of type 1 narcolepsy (NT1).

Materials and methods: This retrospective study included patients with definitive diagnosis of NT1. Participants were categorized into child-onset (<10 years), adolescent-onset (10-19 years), and adult-

onset (>19 years) groups. Demographic and clinical information were collected and statistically analyzed.

Results: 2,344 NT1 cases were included in the final analysis (Child-onset 1,160, adolescent-onset 902, adult-onset 282). A bimodal age distribution of narcolepsy onset was observed, with peaks at approximately 7 and 30 years of age. Diagnostic delays persisted across all three age-of-onset groups (median: 1 vs 5 vs 4 years, $p < .001$). An age-dependent progression was observed in symptom prevalence, with sleep paralysis and hallucinations showing increasing frequency from child- through adolescent- to adult-onset groups (sleep paralysis: 19.0% vs 56.2% vs 71.5%, $p < .001$; hallucinations: 47.2% vs 59.6% vs 62.1%, $p < .001$). Etiological patterns differed significantly among groups: childhood-onset cases were predominantly associated with infections and vaccinations (49.0%), while adult-onset cases mainly involved non-infectious/vaccination triggers (92.9%). Adolescent-onset patients demonstrated an intermediate clinical profile between these two patterns (71.6% non-infection/vaccination). Polysomnographic (PSG) and multiple sleep latency test (MSLT) analyses demonstrated gradual variations in apnea-hypopnea index (AHI) and sleep architecture across the three groups (AHI median: 1.2 vs 2.2 vs 9.2 events/hour). Although all groups showed similar objective sleepiness levels (as measured by PSG sleep latency [median: 1.5 vs 1.0 vs 1.0 minutes, $p = .144$] and MSLT mean sleep latency [median: 2.2 vs 2.0 vs 2.0 minutes, $p = .319$]), childhood-onset NT1 patients exhibited more pronounced rapid eye movement (REM) sleep dysregulation, evidenced by shorter REM latency in nocturnal PSG (median: 2.5 vs 3.5 vs 7.3 minutes, $p = .009$) and a higher frequency of sleep-onset REM periods (SOREMPs) in MSLT (median: 5 vs 4 vs 4, $p < .001$).

Conclusions: Child-, adolescent-, and adult-onset NT1 exhibit distinct clinical profiles, including differences in symptom presentation, etiological triggers, and polysomnographic features. These disparities may reflect divergent yet potentially overlapping pathogenic mechanisms.

Acknowledgments: We sincerely thank all participants, colleagues, and funding agencies for their contributions. This study was supported by National Natural Science Foundation of China (32441101), National Key Research and Development Program of China (2023YFE0118500), and Peking University People's Hospital (RDGS2023-03).

Clinically Meaningful Improvement in Daytime Sleepiness With ON-SXB in People With Narcolepsy and Severe Sleepiness

R. Bogan^{1,2}, T. Roth³, M.J. Thorpy³, C.A. Kushida⁴, J. Gudeman⁸

¹University of South Carolina School of Medicine, Columbia, United States, ²Medical University of South Carolina, Charleston, United States, ³Sleep Disorders and Research Center, Henry Ford Health System, Detroit, United States, ⁴Albert Einstein College of Medicine, New York, United States, ⁵Stanford University School of Medicine, Stanford, United States, ⁶Avadel Pharmaceuticals, Chesterfield, United States

Introduction: Efficacy of once-nightly sodium oxybate (ON-SXB; LUMRYZ™) for narcolepsy was demonstrated in the phase 3 REST-ON trial (NCT02720744). Efficacy on daytime sleepiness in REST-ON participants with the most severe sleepiness at baseline was analyzed post hoc.

Materials and methods: Participants (≥ 16 years; narcolepsy type 1 [NT1] or NT2) were randomized 1:1 to ON-SXB (week 1, 4.5 g; weeks 2-3, 6 g; weeks 4-8, 7.5 g; weeks 9-13, 9 g) or placebo. Sleep latency on the Maintenance of Wakefulness Test (MWT) and Epworth Sleepiness Scale (ESS) scores were calculated in tertiles of participants from the modified intent-to-treat (mITT) population (randomized participants with ≥ 1 efficacy measurement after receiving 6-g dose) with lowest mean sleep latency on the MWT (MWT tertile) or highest ESS scores (ESS tertile) at baseline. Data are median (Q1, Q3) observed values.

Results: In the mITT population (ON-SXB, $n=97$; placebo, $n=93$), mean age for MWT tertile participants (ON-SXB, $n=33$; placebo, $n=30$) was 30.5 years (65.1% female, 76.2% NT1, 60.3% taking concomitant alerting agents), and for ESS tertile participants (ON-SXB, $n=33$; placebo, $n=41$), it was 32.4 years (63.5% female, 90.5% NT1, 37.8% taking concomitant alerting agents). Respective sleep latency on the MWT (min) for ON-SXB and placebo groups of MWT tertile participants was 1.5 (1.0, 2.3) and 2.0 (1.3, 2.5) at baseline and 7.0 (2.5, 15.0) and 4.9 (1.8, 8.3) at week 13 (9 g), and for ESS tertile participants was 4.7 (2.8, 7.5) and 4.6 (2.1, 6.6) at baseline and 11.5 (6.9, 21.7) and 5.0 (2.0, 13.0) at week 13 (9 g). Respective ESS scores for ON-SXB and placebo groups of MWT tertile participants were 16.0 (14.0, 19.0) and 19.0 (16.0, 20.0) at baseline and 10.0 (6.0, 16.5) and 16.0 (13.0, 19.0) at week 13 (9 g), and of

ESS tertile participants were 21.0 (19.0, 22.0) and 21.0 (19.0, 22.0) at baseline and 9.0 (6.0, 19.5) and 18.0 (14.0, 22.0) at week 13 (9 g).

Conclusions: The most severely sleepy REST-ON participants at baseline experienced clinically meaningful improvement in daytime sleepiness with ON-SXB treatment, as ESS scores were at or below the normal threshold at the end of the study.

Acknowledgments: This study was funded by Avadel Pharmaceuticals (Chesterfield, MO). Medical writing support was provided by Zoe McCord, PharmD, from The Curry Rockefeller Group, LLC, a Citrus Health Group, Inc., company (Chicago, IL), and was funded by Avadel Pharmaceuticals (Chesterfield, MO).

Clinical Phenotypes and Longitudinal Evolution Patterns in Narcolepsy: A Prospective Cohort Study Based on Symptom Cluster Analysis

Y. Zhang¹, H. Zhang¹, Y. Yang¹, Z. Huang¹, H. Li¹, S. Zhan¹

¹Xuanwu Hospital of Capital Medical University, Beijing, China

Introduction: To explore the heterogeneity and dynamic evolution of clinical phenotypes in narcolepsy by constructing a longitudinal subtype framework using prospective cohort data, and to assess the feasibility of phenotype-based prediction models in clinical practice.

Materials and methods: This study included 252 patients diagnosed with narcolepsy or idiopathic hypersomnia from a prospective cohort at Xuanwu Hospital, Capital Medical University (2021–2024). Baseline and follow-up data were collected at five time points, including clinical symptoms, Epworth Sleepiness Scale (ESS), Ullanlinna Narcolepsy Scale (UNS), REM Sleep Behavior Disorder Questionnaire (RBDQ-HK), polysomnography (PSG), Multiple Sleep Latency Test (MSLT), and cerebrospinal fluid (CSF) hypocretin-1 levels. Principal component analysis (PCA) was used to extract core symptom domains. Hierarchical clustering was conducted at each time point to define clinical phenotypes. The stability of cluster structures was evaluated by Adjusted Rand Index (ARI) and Feature Overlap Index (FOI). Symptom trajectories were visualized using Sankey diagrams. Generalized linear mixed models (GLMM) were used to model the longitudinal occurrence probability of cataplexy, hallucinations, and sleep paralysis. A random forest model was constructed to predict phenotypes based on clinical features.

Results: Five principal components were identified, representing cataplexy, hallucinations, sleep paralysis, sleep initiation/maintenance, and REM sleep behavior abnormalities. Four stable clinical phenotypes were observed across timepoints: (1) non-cataplexy, (2) hallucination-dominant, (3) isolated cataplexy, and (4) paralysis-dominant. These phenotypes demonstrated robust structural stability (baseline ARI=0.78; follow-up peak ARI=0.85) and external generalizability (validation cohort ARI=0.69; FOI > 0.95 across phenotypes). Longitudinally, phenotypes showed both symptom persistence and dynamic switching, with distinct trajectories in treatment-naïve vs. treated patients. The simplified prediction model using top 10 clinical variables achieved comparable accuracy to the full model (accuracy > 80%).

Conclusions: Narcolepsy exhibits diverse and evolving clinical phenotypes that are not fully captured by conventional NT1/NT2 classification. Our data-driven clustering approach reveals symptom-specific trajectories and provides a stable, generalizable framework for clinical subtype identification. These findings support the development of phenotype-informed diagnostic and treatment strategies for narcolepsy.

Comparison of Circadian Rhythm and Sleep Between Type 1 Narcolepsy, Delayed Sleep-Wake Phase Disorder, and Healthy Controls

S. Wu¹, Y. Liu¹, L. Xu¹, Q. Ding¹, F. Xiao¹, Y. Zuo¹, M. Wang¹, Z. Feng¹, H. Wang¹, X. Dong¹, F. Han¹

¹Peking University People's Hospital, Division of Sleep Medicine, Beijing, China

Introduction: This study aimed to compare the circadian rhythm and sleep parameters among individuals with Type 1 Narcolepsy (NT1), Delayed Sleep-Wake Phase Disorder (DSWPD), and healthy controls (HC) to explore their respective rhythm characteristics and potential differences in underlying mechanisms.

Materials and methods: The study enrolled 25 patients with NT1 and recruited 25 patients with DSWPD and 25 HC subjects as controls, with all three groups matched for age and gender. All participants underwent actigraphy to monitor sleep and had their serum melatonin levels measured via continuous 24-hour blood sampling to assess circadian rhythm parameters such as Dim Light Melatonin Onset (DLMO), offset (DLMOff), and peak time (Acrophase).

Results: Compared to the HC group, NT1 patients showed no significant difference in core circadian rhythm phase (DLMO), but their biological night duration (DLMOff - DLMO) was significantly prolonged ($12:07 \pm 1.5$ h vs. $10:51 \pm 1.6$ h). Their sleep efficiency (72.2%) was also significantly lower than that of the HC group (89.2%) and the DSWPD group (82.5%). The DSWPD group exhibited a significant rhythm phase delay (mean DLMO = 01:01), and the phase angle (SleepOnset - DLMO) was significantly shorter than in the NT1 group (0.7 ± 2.7 h vs. 2.9 ± 1.3 h).

Conclusions: This study found that the main difference between patients with Type 1 Narcolepsy (NT1) and healthy controls is the prolongation of their biological night. Although their DLMO is similar, the delayed melatonin offset (DLMOff) may contribute to increased daytime sleepiness. Compared to the DSWPD group, the circadian rhythm and sleep coupling in the NT1 group remained normal, suggesting different mechanisms of rhythm regulation in these two diseases.

Consciousness Denied: The First Cross-National Autoethnographic Study of Diagnostic and Treatment Pathways in Type 1 Narcolepsy

H. Wang¹

¹Stockholm University, Stockholm, Sweden

Introduction: Type 1 narcolepsy (T1N) is a rare neurological condition characterized by orexin deficiency, affecting approximately 1 in 2,000 individuals globally. While clinical features and diagnostic criteria are well established, real-world patient diagnostic journeys across different healthcare systems remain critically underexplored. This study presents the first autoethnographic account of a Type 1 narcolepsy patient navigating six healthcare systems over an 11-year period, validated by cerebrospinal fluid analysis confirming undetectable orexin levels (<50 pg/mL).
