- This was a retrospective, single centre, observational study. 522 patients who underwent level 1 PSG during 2022-2024 in our sleep laboratory were included. All patients filled a self-administered 12-item questionnaire tool in vernacular language (Hindi) during time of admission.
- Eligibility
 - Inclusion:- Adult patients aged >18 years and have completely filled 12-item questionnaire during time of admission.
 - Exclusion :- Patients who have not filled the questionnaire, already on treatment for OSA, pregnant women and those with technically inadequate polysomnography studies.
- Statistical analysis was done in IBM-SPSS-version-26.0 statistical software. Exploratory factory analysis was done and 7 questions were selected. Sample was randomly divided into two parts:

development (80%, n=421) and testing subsample (20%, n=101). Multi-variate logistic regression analysis was done on development subsample to construct the model. Finally, we assessed the discriminative performance of this score in both development and test subsamples and determined cross-validation and diagnostic accuracy.

Results:

- TELE-OSA questionnaire includes five items (snoring, stops breathing while sleeping, wake up from sleep due to gasping/choking, nocturia and nocturnal GER).
- Cutoff score of 6 was identified, demonstrating high specificity (83%) and moderate sensitivity (55%).
- TELE-OSA had high specificity compared with existing screening questionnaires [STOP-BANG (59%), STOP (66%), GOAL (45%), NOSAS (78%) No-apnea (53%)] and highest diagnostic accuracy [AUC: TELE-OSA-0.77, STOP-BANG-0.76, STOP-0.71, GOAL-0.77, NOSAS-0.77, No-apnea-0.68].

Conclusions:

- This study introduces the Tele-OSA Questionnaire, a novel telephonic screening tool designed to facilitate the identification of individuals at risk for moderate to severe OSA.
- It includes only the construct of the disease (OSA) and does not include risk factors associated with the disease.
- It can be used via telephonic interview or surveys, even by proxy informants viz., bedpartners.
- The developed questionnaire has acceptable psychometric properties at the cutoff score of 6. Further, properties across different cut-offs and prevalence are also provided so that users may choose a specific cut-off according to the population in which they intend to use the questionnaire.
- Existing screening questionnaires have high sensitivity but less specific which increases the burden on sleep labs. Tele-OSA is a highly specific questionnaire and can reduce the burden on sleep centres, making diagnostic processes more accessible in resource-constrained settings.

Insomnia as a Symptom of REM-related OSA: A Retrospective Cross-Sectional Study in 1736 OSA Patients

T. Hoshino¹, T. Shiomi^{2,3}

¹Hoshino ENT Sleep and Breathing Center, Nishinomiya, Japan, ²Aichi Medical University, Nagakute, Japan, ³Hiroshima University, Hiroshima, Japan

Introduction: REM-related obstructive sleep apnea (REM-OSA) is a *polysomnographic phenotype* of OSA characterized by respiratory events predominantly occurring during REM sleep, affecting approximately 12–36% of all OSA patients.

Several studies have suggested that REM-OSA may be more prevalent in females, particularly in those presenting with depressive symptoms.

In our previous study of 3,234 OSA patients, we found that the main symptom of REM-OSA was not excessive daytime sleepiness.

Given the well-established bidirectional relationship between insomnia and depression, this raises important clinical questions.

Insomnia is frequently observed in patients with OSA, yet the specific relationship between REM-OSA and insomnia remains unclear.

We hypothesized that insomnia, rather than excessive daytime sleepiness, may be a primary complaint among patients with REM-OSA.

To test this hypothesis, we examined whether REM-OSA is independently associated with insomnia-related sleep disturbance as measured by the Pittsburgh Sleep Quality Index (PSQI).

Materials and methods:

We retrospectively analyzed 1736 adults with OSA ($AHI \geq 5$) who underwent overnight polysomnography and completed the PSQI at a sleep center in Japan. REM-OSA was defined using three stringent criteria:

- **REM-OSA 1:** overall $AHI \geq 5$ and AHI during REM ($AHI-REM$) / AHI during NREM ($AHI-NREM$) ≥ 2
- **REM-OSA 2:** overall $AHI \geq 5$, $AHI-REM/AHI-NREM \geq 2$, and $AHI-NREM < 15$
- **REM-OSA 3:** overall $AHI \geq 5$, $AHI-REM/AHI-NREM \geq 2$, $AHI-NREM < 8$, and REM sleep duration > 10.5 minutes

Patients who did not meet REM-OSA 1 criteria were categorized as having NREM-OSA. Multiple linear regression models were used to evaluate the association between REM-OSA and PSQI, adjusting for age, sex, BMI, and REM/NREM-AHI. Subgroup analyses were performed by sex.

Results: REM-OSA accounted for 24.4%, 16.8%, and 8.9% of patients according to definitions 1, 2, and 3, respectively. Across all definitions, patients with REM-OSA had significantly higher PSQI scores compared to those with NREM-OSA ($p < 0.001$). In multivariate analyses, REM-OSA was independently associated with higher PSQI scores, with the strongest effect observed for REM-OSA 3 ($\beta = 1.26$, 95% CI 0.54–1.98, $p = 0.001$). Subgroup analyses showed that this association was more evident in female patients, who consistently had higher PSQI scores than males.

Conclusions: REM-OSA is significantly associated with insomnia-related sleep disturbance, especially among female patients and when defined as REM-OSA 3. These findings suggest that insomnia, rather than excessive daytime sleepiness, may be a predominant complaint in REM-OSA. Clinicians should consider incorporating insomnia assessments such as the PSQI into the routine diagnostic evaluation and phenotyping of OSA patients, particularly those with REM-predominant respiratory events.

Integrative Prognostic Framework Linking Sleep-Disordered Breathing-Associated Genes to Tumor Hypoxia and Immune Evasion Across Cancers

T. Chen¹, K.-F. Chang¹, B.-S. Chen¹, Y.-K. Lee^{1,2}

¹Medical Laboratory, Medical Education and Research Center, Kaohsiung Armed Forces General Hospital, Kaohsiung, Taiwan, ²Institute of Medical Science and Technology, National Sun Yat-sen University, Kaohsiung, Taiwan

Introduction: Sleep-Disordered Breathing (SDB), characterized by intermittent hypoxia and sleep fragmentation, is increasingly recognized as a systemic physiological stressor influencing tumor progression and immune modulation. However, its molecular footprint across cancer types remains underexplored.

Materials and methods: We curated 164 genes associated with SDB from literature and sleep-related databases. Using transcriptomic data from 32 cancer types in The Cancer Genome Atlas (TCGA), we developed an SDB-related prognostic model via LASSO-Cox regression. This model generated a risk score used to stratify patients into high- and low-risk groups. Kaplan-Meier survival analyses, multivariate Cox regression, and time-dependent ROC curves evaluated model performance. Functional enrichment and immune deconvolution were performed to explore underlying biology.

Results: The SDB gene signature significantly predicted overall survival (OS), disease-specific survival (DSS), and progression-free interval (PFI) across multiple cancer types. High-risk groups were enriched in hypoxia, epithelial–mesenchymal transition, IL-17 signaling, and angiogenesis pathways. The SDB score correlated positively with immune checkpoint expression, stromal activity, and proliferative indices. Integration into a nomogram with clinical variables enhanced survival prediction accuracy (C-index > 0.70). External validation in independent datasets confirmed model robustness, especially in hypoxia-sensitive tumors such as lung adenocarcinoma, glioblastoma, and clear cell renal carcinoma.

Conclusions: This study is the first to establish a pan-cancer SDB-associated transcriptomic signature. Our findings suggest that SDB-induced molecular alterations may contribute to tumor aggressiveness

and immune evasion. This integrative framework bridges sleep medicine and oncology, supporting future investigations into SDB management as an adjunct cancer therapy strategy.

Inter-Gender Differences in Obstructive Sleep Apnoea Severity Across Age Groups

K.L. Choo¹, W.C. Chan¹, K.W. To², W.Y. So³, N.C. Sin⁴, S. Tang⁵

¹Hospital Authority - North District Hospital, Medicine, Hong Kong, Hong Kong, SAR of China, ²Prince of Wales Hospital, Medicine, Hong Kong, Hong Kong, SAR of China, ³North District Hospital, Hong Kong, Hong Kong, SAR of China, ⁴Alice Ho Miu Ling Nethersole Hospital, Hong Kong, Hong Kong, SAR of China, ⁵Hospital Authority, Hong Kong, Hong Kong, SAR of China

Introduction: Attended overnight polysomnography (PSG) is generally considered the diagnostic gold standard for sleep disorders. However, long waiting times have adversely affected patients' access to diagnostic and therapeutic tests. With the increasing demand for obstructive sleep apnea (OSA) diagnosis, level 3 tests have been used to expedite the diagnosis of patients with a high likelihood of OSA.

Materials and methods: Between 30 October 2023 and 31 March 2025, 2192 patients underwent level 3 sleep tests. 1093 patients were tested with NOX T3S device while 1099 patients were tested with Embletta MPR device. For those tested with NOX T3S, sleep stages were estimated using a combination of respiratory data and actigraphy. The Chi-square test was performed to assess the relationship between age groups, gender, and OSA severity. Apart from mild (Apnoea Hypopnoea Index AHI 5 to <15), moderate (AHI 15-30), and severe (AHI >30) OSA, patients with low total AHI (<5) but position- or REM-AHI > 5 and snoring > 10 % of sleep time were classified as borderline.

Results: Among the 1,489 males and 703 females in this review, mean age was 53±9.55 years (range 18 to 78 years). Patients were further divided into four age groups (AG 18-30, AG 31-45, AG 46-60, and AG 61-78). Both age group and gender showed statistically significant relationships with OSA severity in the AG 31-45 ($p \leq 0.05$) and AG 46-60 ($p \leq 0.05$) groups. [Chart 1: OSA Severity by Age Group and Sex](#)

A higher percentage of severe OSA was found in males compared to females, particularly in the AG 31-45 and AG 46-60 groups. There were statistically significant differences in AHI and Oxygen Desaturation Index (ODI) between males and females, with males having more severe disease. In the subgroup with sleep efficiency results ($n=1093$), sleep efficiency was similar between the two genders (male 82.6% versus female 83.89%). [Chart 2: Gender Analysis of Sleep Metrics](#)

As total AHI increased from normal to high, there was a corresponding increase in REM AHI, supine AHI and Snoring %. Patients with severe OSA exhibited significantly higher REM AHI (55.88) and supine AHI (61.02) compared to other severity levels. Snoring % was also highest in this group (39.92%). As expected, individuals with normal OSA had the lowest REM AHI (3.18), supine AHI (2.24), and Snoring % (8.15). However, in the borderline group, the snoring percentage, REM AHI, and supine AHI values were all significantly higher than those in the normal group ($p \leq 0.05$). [Table 3: Severity of OSA](#)

Conclusions: Severe OSA was more often present in males than females, particularly in the age range of 31 to 60 years old. In this population of symptomatic patients who underwent level III testing, the diagnosis of a group with snoring percentage, REM AHI and supine AHI that were higher than the normal group remained undefined. Further testing with PSG and longitudinal follow-up of this borderline group would help to elucidate the nature and course of disease.

Intermittent Hypoxia Accelerates Full-Thickness Cutaneous Wound Healing in Sprague-Dawley Rats: The Role of Upregulated TGF- β and YAP Expression

X. Du¹, C. Zhang², J. Dong³, J. Zhang⁴

¹Beijing Tiantan Hospital, Capital Medical University, Otolaryngology, head and neck surgery, Beijing, China, ²Beijing Friendship Hospital, Capital Medical University, Department of Otolaryngology-Head and Neck Surgery, Beijing, China, ³Beijing Tiantan Hospital, Capital Medical University, Department of Otorhinolaryngology Head and Neck Surgery, Beijing, China, ⁴Beijing Tsinghua Changgung Hospital,

School of Clinical Medicine, Tsinghua University, Department of Otolaryngology Head and Neck Surgery, Beijing, China

Introduction: Re-epithelialization is a critical step in the complex processes of cutaneous wound healing. Tissue oxygenation is a key microenvironmental determinant for wound healing involving re-epithelialization. This study investigated the effects of intermittent hypoxia (IH) on full-thickness skin wound healing in Sprague Dawley rats, focusing on transforming growth factor-beta signaling and Yes-associated protein expression dynamics.

Materials and methods: Eight male rats were equally randomized to receive either daily 8-hour cyclic hypoxia (10-21% oxygen) or normoxic conditions until complete re-epithelialization. Consistent round full-thickness skin wounds with a diameter of 1cm were made on the dorsum of both groups of rats. From the second day after wound surgery. The re-epithelialization processes were monitored, and blood and healed tissue samples were obtained until the wounds closed completely.

Results: Intermittent hypoxia reduced healing time by 21% compared to controls (20.0 ± 1.8 vs 24.3 ± 2.5 days, $P < 0.05$), with elevated serum transforming growth factor-beta levels (184.9 ± 10.9 vs 120.6 ± 8.7 , $P < 0.05$) but unchanged vascular endothelial growth factor and epidermal growth factor concentrations. Sustained upregulation of Yes-associated protein isoforms 1 and 2 ($P < 0.05$ for both) persisted throughout healing in hypoxic-exposed regenerating epithelium, correlating temporally with accelerated wound closure. The histological findings of the healed epithelium in NC group rats were closer to normal than in IH group rats.

Conclusions: These findings reveal that controlled hypoxic stimulation enhances cutaneous re-epithelialization through coordinated activation of TGF- β signaling pathways and concomitantly enhancing the expression of YAP protein. This finding suggests novel therapeutic targets in re-epithelialization remodeling and tissue regeneration in the wound healing progress.

Introduction: Upper airway (UA) surgery is commonly employed in the treatment of patients with obstructive sleep apnea (OSA). The intricate pathophysiology of OSA, variability in sites and patterns of UA collapse, and the interaction between anatomical and non-anatomical factors in individual patients may contribute to possible surgical failures. This clinical consensus statement aims to identify areas of agreement among a development group comprising international experts in OSA surgery, regarding the appropriate definition, predictive factors in patients, and management of surgical failure in OSA treatment.

Materials and methods: A clinical consensus statement (CCS) was developed using the Delphi method by a panel of 35 contributors from various countries. A systematic literature review adhering to PRISMA guidelines was conducted. A survey consisting of 60 statements was then formulated and presented to the experts.

Results: Following two rounds of the Delphi process, consensus or strong consensus was achieved on 36 items, while 24 items remained without consensus. Specifically, 5 out of 10 statements reached consensus regarding on the 'Definition of Surgical Success/Failure after OSA Surgery'. Regarding the 'Predictive Factors of Surgical Failure in OSA Surgery', consensus was reached on 10 out of 13 statements. In the context of the 'Diagnostic Workup in OSA Surgery', consensus was achieved on 9 out of 13 statements. Lastly, in 'Treatment in Surgical Failure Cases', consensus was reached on 12 out of 24 statements.

Conclusions: The management of OSA after surgical failure presents a significant clinical challenge for sleep specialists. This CCS provides valuable guidance for defining, preventing, and addressing surgical failures in the treatment of OSA syndrome.

Interceptive Dysfunction During Wakefulness in Obstructive Sleep Apnea: An Analysis of Heartbeat-Evoked Potentials

M. Alidadi¹, B. Mohammadzadeh Asl¹, M. Mohebbi²

¹Tarbiat Modares University, Biomedical Engineering, Tehran, Iran, Islamic Republic of, ²K. N. Toosi University of Technology, Biomedical Engineering, Tehran, Iran, Islamic Republic of

Introduction: Obstructive Sleep Apnea (OSA) is a prevalent sleep disorder characterized by recurrent episodes of partial or complete upper airway obstruction during sleep, leading to intermittent hypoxia, fragmented sleep, and excessive daytime sleepiness. While much research has focused on the nocturnal consequences of OSA, its effects during wakefulness remain underexplored. Emerging evidence suggests that OSA may disrupt interoceptive processing—the brain’s ability to perceive and integrate internal bodily signals such as heartbeats. Interoception plays a crucial role in self-awareness, emotional regulation, and decision-making. Impairments in this domain have been linked to mood disorders, cognitive decline, and reduced quality of life. However, how OSA affects cortical responses to cardiac activity during wakefulness remains poorly understood. Heartbeat-Evoked Potentials (HEP), derived from EEG recordings time-locked to R-peaks in the ECG signal, offer a non-invasive method to assess cortical sensitivity to cardiac activity and serve as a reliable biomarker of interoceptive processing. Prior studies have shown altered HEP amplitudes in populations with impaired interoception, such as those with depression and anxiety disorders. However, no study has yet systematically investigated HEP modulation in individuals with OSA during wakefulness.

Materials and methods: Data from 366 participants were analyzed using 5-minute EEG and ECG recordings from a pre-sleep wakeful period. EEG was recorded from six channels and ECG via Lead I and II. Signals were filtered, re-referenced, and eye-blink artifacts removed. Time-locked EEG epochs around R-peaks were averaged to compute HEP waveforms. Analysis focused on the 300–700 ms post-R-peak window to minimize cardiac field artifact contamination. Group comparisons between Normal and Apnea groups were performed using non-parametric cluster-based permutation tests, revealing significant differences in central and frontal regions. Mean HEP amplitudes were compared using t-tests, with effect sizes (Cohen’s d) and confidence intervals reported.

Results: Cluster-based permutation analysis revealed significant differences in HEP amplitudes between Normal and Apnea groups during wakefulness, particularly in central (320–480 ms) and frontal (540–680 ms) electrode regions. The Jonckheere-Terpstra test confirmed monotonic trends across OSA severity levels. Cohen’s d showed moderate-to-small effect sizes, especially at C3. Confidence intervals reflected distinct amplitude shifts with increasing severity. No differences were found in occipital electrodes, suggesting that OSA-related changes are localized to brain areas involved in interoceptive processing.

Conclusions: Our findings show that individuals with OSA exhibit altered cortical processing of cardiac signals during wakefulness, reflected in changes in HEP amplitudes. These changes correlate with apnea severity and suggest impaired interoceptive processing—an essential mechanism for emotional regulation, self-awareness, and autonomic balance. Clinically, this indicates that OSA is not just a sleep-related breathing disorder but also involves neuro-cardiac dysfunction during wakefulness, potentially contributing to daytime symptoms such as fatigue, mood disturbances, and cognitive deficits. HEP emerges as a promising non-invasive biomarker for the early detection of neurophysiological impairments in OSA, even before sleep onset. Its integration into routine EEG-based assessments could enhance diagnostic precision and monitoring of OSA-related brain-body interactions. In summary, this study identifies OSA as a systemic condition affecting brain-heart communication beyond sleep, offering new insights for more integrated and effective patient management.

Interpretable Machine Learning Using Questionnaire Data: A Scalable Approach for Sleep Apnea Screening

N.H. Hoang¹, Z. Liang¹

¹Kyoto University of Advanced Science, Kyoto, Japan

Introduction: Early detection of sleep apnea is critical to preventing long-term cardiovascular and metabolic complications. However, traditional screening methods often rely on costly bio-signal measurements or symptom-dependent questionnaires that may miss at-risk individuals. This study presents a clinically applicable machine learning framework that leverages easily obtainable questionnaire data to support large-scale, low-cost early screening of sleep apnea while providing clear, interpretable insights for clinical decision-making.

Materials and methods: We developed an XGBoost model to classify individuals into normal/mild and moderate/severe sleep apnea groups using only demographic and lifestyle-related variables. Data were drawn from the Sleep Heart Health Study (SHHS), with relevant features selected from 12 questionnaires, during the first (SHHS1) and second (SHHS2) visits. These features cover physiological, behavioral, medical history, and treatments information. For interpretability, we applied SHapley Additive exPlanations (SHAP) and TreeExplainer2Rule (Te2Rule) to generate rule-based explanations aligned with clinical reasoning. These methods enable clear visualization of the model's decision-making process, making the results easier to interpret and more convincing. They also offer valuable insights into which features most influence the predictions.

Results: The model achieved an AUC of 0.793, with 64.88% accuracy, 60.84% precision, 55.59% sensitivity, 72.11% specificity, and F1-score of 0.581 in identifying moderate to severe cases using questionnaire data from the first visit. When combined with follow-up visit data—reflecting physiological and behavioral changes over a 5-year period—the additional information improved model performance. Specifically, the model achieved an AUC of 0.753, with 68.45% accuracy, 65.90% precision, 63.13% sensitivity, 72.88% specificity and F1-score of 0.645. Key clinical predictors included neck circumference (with a common decision threshold of 35-38 cm), age, waist circumference, and BMI (common decision threshold of 25.5). Male sex and a history of hypertension were linked to increased risk, while coffee consumption showed a surprising negative association with sleep apnea severity. Most of these insights align with known clinical risk factors and offer practical decision rules that can be easily applied in clinical settings. Additionally, SHAP values have an additive property, allowing for transparent breakdowns of how predictions are calculated for each patient—providing useful insights that may support personalized behavioral interventions.

Conclusions: Despite the inherent limitations of self-reported data, our model achieved significant improvement in AUC and specificity compared to existing sleep apnea screening questionnaires (e.g., STOP-BANG). The enhanced model's performance—particularly the improved class balance when incorporating both first-visit and follow-up information—highlights the value of long-term monitoring and data collection. This study demonstrates the potential of explainable AI to support cost-effective, scalable, and interpretable sleep apnea screening. The SHAP method explains the impact of each feature on the model's output, while Te2Rule illustrates how the model combines high-impact features to arrive at a final decision.

Investigation of nasal obstruction as a risk factor for SDB: prevalence of SDB in patients who underwent endoscopic nasal sinus surgery

M. Suzuki¹

¹Teikyo University Chiba Medical Center, Otorhinolaryngology, Ichihara, Japan

Introduction: To investigate the prevalence of sleep-disordered breathing (SDB) in patients with nasal diseases who underwent endoscopic nasal sinus surgery (ESS) compared with control patients without nasal disease who underwent tonsillectomy.

Materials and methods: An observational retrospective case-control study was conducted of 150 adults with nasal diseases who underwent ESS (ESS group) as well as 94 adults with no nasal symptoms or diseases who underwent tonsillectomy due to infection of the tonsils (tonsillectomy group). Patients with obstructive sleep apnea, patients with a chief complaint of snoring or excessive daytime sleepiness, or patients having large tonsils were excluded from the study. Home sleep apnea testing was performed prior to admission for surgery.

Results: The prevalence in normal, mild, moderate, and severe SDB was respectively 30.0%, 38.0%, 22.7%, and 9.3% in the ESS group and 50.0%, 39.4%, 10.6%, and 0% in the tonsillectomy group. There were significant differences in the mean 3% oxygen desaturation index (3%ODI) score between the ESS and tonsillectomy groups in men but not in women. Obese men in the ESS group were much more susceptible to having moderate or severe SDB when they were aged ≥ 40 years. Regression analysis revealed that the preoperative 3%ODI score had two significant determinants in the ESS group—BMI and male sex—whereas age, nasal resistance, and CRS with nasal polyps were not significant predictors.

Conclusions: Among patients who underwent ESS, 32.0% had moderate to severe SDB, including 9.3% with severe SDB. Nasal obstruction could be a potential risk factor for SDB in male patients.

Acknowledgments: The Ethics Committee of Teikyo University approved this study (Approval No. Teirin 24-048). No financial support was received in relation to this study.

Ischemic Preconditioning as a Potential Cardioprotective Mechanism of Obstructive Sleep Apnea in Patients with Acute Coronary Syndrome

O. Ludka¹, R. Stepanova², T. Kara³

¹Faculty of Medicine, Masaryk University and University Hospital Brno, Department of General Internal Medicine, Brno, Czech Republic, ²Masaryk University, Faculty of Medicine, Brno, Czech Republic, ³Mayo Clinic and Foundation, Division of Cardiovascular Diseases, Department of Internal Medicine, Rochester, United States

Introduction: Obstructive sleep apnea (OSA) is associated with intermittent hypoxemia, which may induce myocardial ischemic preconditioning - a mechanism potentially attenuating ischemic injury. This effect could influence the clinical presentation of acute coronary syndromes by favoring non-ST-elevation myocardial infarction (NSTEMI) over ST-elevation myocardial infarction (STEMI). We prospectively examined the relationship between OSA severity and the type of myocardial infarction (MI).

Materials and methods: We prospectively enrolled 607 consecutive patients hospitalized with a diagnosis of acute myocardial infarction (NSTEMI or STEMI). The study was conducted at two tertiary care centers where primary percutaneous coronary intervention (PCI) is the standard treatment for acute MI. Sleep evaluations were performed using a portable diagnostic device in all patients who remained clinically stable for at least 48 hours following admission.

Results: OSA was present in 65.7% of patients; NSTEMI was diagnosed in 30%. NSTEMI prevalence increased with OSA severity ($p < 0.001$). In patients without or with mild OSA, the NSTEMI-to-STEMI ratio was 59.4% vs. 70.1% ($p = 0.01$); in those with moderate to severe OSA (apnea-hypopnea index ≥ 15 events/hour), this ratio reversed to 40.6% vs. 29.9% ($p = 0.01$). Moderate to severe OSA independently predicted NSTEMI ($p = 0.021$). Patients with NSTEMI and moderate to severe OSA had significantly lower peak troponin T levels than those with STEMI ($1.538 \pm 2.771 \mu\text{g/L}$ vs. $3.085 \pm 3.127 \mu\text{g/L}$; $p < 0.001$).

Conclusions: Greater OSA severity is associated with higher NSTEMI prevalence and less myocardial injury, supporting a potential cardioprotective role via ischemic preconditioning. This mechanism may partly explain reduced cardiovascular mortality in some OSA populations and the limited efficacy of CPAP in secondary prevention. Personalized CPAP strategies considering ischemic preconditioning may improve patient outcomes.

Is CPAP enough? Real-life burden of residual events in treated OSA patients

Introduction: Continuous positive airway pressure (CPAP) is the first-line treatment for patients with moderate to severe Obstructive sleep Apnea (OSA) and is highly effective when used consistently. However, optimal adherence to CPAP therapy remains a major challenge, often limited by discomfort and adverse effects. As a result, patients on CPAP may still experience residual obstructive events, particularly during periods of non-use, a phenomenon we here refer to as "hidden Apnea Hypopnea Index" (hAHI). Our objective was to estimate the residual burden, based on hAHI, during a relative long period of time in a cohort of patients on CPAP treatment.

Materials and methods: This analysis is based on the *MetaSleep* project (NCT05986487), a prospective, observational, multicenter study conducted across 10 regions in Spain. The *MetaSleep* study included adult patients with hypertension and OSA who had been prescribed CPAP therapy based on routine clinical criteria. The hAHI was evaluated by the *Withings Sleep Analyzer*, an FDA-cleared, under-the-mattress contactless device. Simultaneously, objective daily CPAP usage data were collected to assess adherence.

Results: A total of 116 patients were recruited, leading to 5909 monitored nights. The median (Q1; Q3) monitoring duration was 14 (5; 20.25) days before and 46 (14; 76) days after CPAP initiation. The median age of participants was 58.0 (51.0; 64.0) years, 30.2% were female. Patients had a median CPAP adherence of 5.4 (3.9; 6.7) hours per night. According to home monitoring data, patients exhibited a mean (SD) pre-CPAP AHI of 39.6 (26.6) events/hour. Following the initiation of CPAP therapy, a significant reduction in hAHI was observed, with a mean change (95% CI) of -13.25 (-18.4 to 8.01) events/hour. Despite this improvement, patients still showed a substantial OSA burden while on CPAP, with a mean (95% CI) hAHI of 22.36 (18.27 to 25.45) events/hour. Additionally, 51.1% of patients experienced more than half of their nights with an hAHI ≥ 15 events/hour. A significant inverse and non-linear association between hAHI and the number of hours of CPAP use was observed.

Conclusions: Despite a good CPAP compliance, patients treated with CPAP continue to experience a considerable burden of residual obstructive events. The hAHI remains elevated in a substantial proportion of patients. These findings highlight the importance of personalized monitoring to better understand the true effectiveness of CPAP therapy and to identify patients with insufficient control of obstructive events.

Jaw Corrective Surgery in patients with jaw deformities having Obstructive Sleep Apnea

M. Al-Abri¹, K. Al-Hasani², A. Al-bakri³, A. Al-Hashmi⁴, S. Jaju¹

¹Sultan Qaboos University, Muscat, Oman, ²Universty Medical City, Muscat, Oman, ³Royal Oman Police Hospital, Muscat, Oman, ⁴Al-Nahda Hospital, Muscat, Oman

Introduction: The study aims to assess the prevalence of obstructive sleep apnea (OSA) among patients with jaw deformities and to study the outcome of jaw corrective surgery on these patients.

Materials and methods: This prospective study was conducted among patients previously not diagnosed with OSA who were scheduled for jaw corrective surgery between 2021 and 2022. Home Sleep Apnea testing (HSAT) was used in addition to the Epworth Sleepiness Scale (ESS) and STOP-BANG questionnaire. Consented patients did HSAT preoperatively and postoperatively. Experienced surgeons performed jaw corrective surgery at Oman's foremost oral and maxillofacial surgery center.

Results: A total of 64 patients (24 males and 40 females; mean age of 28.23 years) were included in the study. The study indicated that 43.75% of patients with jaw deformities have OSA. The effect of jaw corrective surgery on the severity of OSA was also evaluated in 39 patients only. There was an improvement in the clinical OSA symptoms postoperatively (p-value < 0.05). However, no significant difference was observed in the Apnea-Hypopnea Index (AHI) (p-value > 0.05).

Conclusions: Silent OSA is common among patients with jaw deformity. However, jaw corrective surgery does not significantly improve it and does not improve substantially mild sleep apnea.

Lactylation-Related Gene Signatures Define Molecular Subtypes and Therapeutic Targets in Obstructive Sleep Apnea

Z. Li¹, H. Yi², P. Guo¹, F. Han²

¹Peking University People's Hospital, Emergency Surgery, Beijing, China, ²Peking University People's Hospital, Sleep Medicine, Beijing, China

Introduction: Obstructive sleep apnea (OSA) is a widespread sleep disorder driven by chronic intermittent hypoxia (CIH), contributing to serious complications such as cardiovascular and metabolic diseases. Recent studies suggest that epigenetic modifications, particularly lactylation, play a pivotal role in OSA pathogenesis by interacting with CIH. Despite this, the specific contributions of lactylation-related genes to OSA remain largely unexplored. Our study aims to elucidate the expression patterns and functional significance of lactylation-related genes in OSA, with a focus on identifying molecular subtypes and their associated immune signatures. Through advanced computational analyses, we aim to reveal novel epigenetic insights that could drive the development of precision therapies for OSA.

Materials and methods: A total of 332 lactylation-related genes were obtained from the Molecular Signatures Database. Adipose tissue expression data were sourced from GEO datasets GSE135917 (8 controls, 34 OSA cases) and GSE38792 (8 controls, 10 OSA cases) on the GPL6244 platform. Differential genes (adjusted $P < 0.01$) were identified using limma in R. Functional enrichment and co-expression analyses were performed via clusterProfiler and GeneMANIA. Key genes were selected by LASSO and SVM-RFE, ranked by SHAP, and validated in GSE38792. A nomogram was evaluated by decision curve analysis. Subtypes were identified by consensus clustering using PCA-derived lactylation scores. Immune infiltration was analyzed via ssGSEA, with regulatory networks constructed in NetworkAnalyst. Validation included ELISA and qPCR in OSA patient and CIH mouse models.

Results: In the GSE135917 dataset, 79 lactylation-related genes were differentially expressed in OSA patients. Consensus clustering defined two subtypes. Group B showed higher lactylation scores and increased immune infiltration. LASSO and SVM-RFE identified four key genes, with TMSB4X upregulated and PRAM1 downregulated in OSA. Their expression patterns were validated in GSE38792 and CIH mouse adipose tissue via qPCR. SHAP confirmed their discriminative value. A nomogram incorporating TMSB4X and PRAM1 showed strong clinical utility. ELISA revealed elevated lactate in OSA patients and CIH mice. Serum IL-6 and TNF- α levels correlated positively with TMSB4X and negatively with PRAM1, supporting links between lactylation and immune dysregulation.

Conclusions: This study identifies distinct molecular subtypes of OSA based on lactylation-related gene expression, highlighting their roles in disease heterogeneity. TMSB4X and PRAM1 were identified as potential diagnostic and therapeutic targets, with consistent trends across human and mouse models. A nomogram incorporating these genes showed strong clinical utility. Elevated lactate and inflammatory cytokines further support the association between lactylation and immune dysregulation. These findings provide new epigenetic insights into OSA and suggest potential for lactylation-based precision therapies.

Acknowledgments: This study was supported by National Key Research and Development Program of China (Grant No. 2023YFC2412005) and Peking University Medicine Fund of Fostering Young Scholars' Scientific & Technological Innovation (Grant No. 2025236205207). We thank Prof. Fang Han for his valuable guidance throughout the study. We also acknowledge all collaborators for their contributions to data collection and analysis, the GEO database for transcriptomic resources, and our lab members for technical assistance and insightful discussions.

Links of sleep-disordered breathing with dementia risk and healthcare utilization

C. Choo¹, R.P.-Y. Chiang^{*2}, E. Shamim³, A. Spira⁴

¹China Medical University, College of Medicine, Taichung City, Taiwan, ²Sam Houston State University, College of Osteopathic Medicine, Medical AI Institute, Conroe, United States, ³Kaiser Permanente Mid-Atlantic States, Mid-Atlantic Permanente Neuroscience Institute, Largo, United States, ⁴Johns Hopkins Bloomberg School of Public Health, Department of Mental Health, Baltimore, United States

Introduction: In this study, potential associations of sleep-disordered breathing (SDB) with incident mild cognitive impairment (MCI), dementia, and healthcare utilisation will be examined using Kaiser Permanente (KP) Mid-Atlantic States electronic health record (EHR) data. Additionally, how these associations differ by race, sex, and adherence to continuous positive airway pressure (CPAP) therapy will be examined. Moreover, finding relevant influences of these associations, such as race/ethnicity, sex, and adherence to CPAP treatment, is one of the goals. Another is to verify the relationship between SDB diagnosis in KP EHR and the later development of MCI and dementia, as well as subsequent health service utilization.

Materials and methods: To investigate the relationship between OSA diagnosis and MCI and dementia diagnosis in the KP EHR, we will use an observational study design. ICD-10 codes for SDB and a variety of cognitive outcomes (such as moderate impairment and dementias) will be used to determine our key indicator, SDB diagnostic status, and cognitive outcomes. KP's vast database, which contains data on hospitalised patients, outpatients, and pharmacies, will be one of the data sources for our mixed effects models. Under the guidance of frameworks, cost-utility analysis will assess outcomes using information such as QALYs and medical costs. This approach can be put into practice in less than a year by focusing on direct and indirect cost comparisons and using the data that is now available.

Results: Our findings are supported by initial outcomes from previously published investigations. Over a five-year period, older women with sleep-disordered breathing had a 1.85-fold higher risk of mild cognitive impairment or dementia (Yaffe et al., 2011). Similarly, older persons with untreated obstructive sleep apnoea showed a noticeably higher rate of cognitive decline than those without SDB (Gosselin et al., 2019). Our preliminary data shows SDB may be a significant risk factor for neurocognitive impairment, especially for MCI.

Furthermore, even after treatment, individuals with OSA used healthcare resources and related expenses significantly more than controls (Sterling et al., 2024). Our study also highlights the financial cost of OSA and the importance of determining the factors that affect results, such as adherence to treatment and population inequalities.

Conclusions: This study provides important knowledge gaps about the relationship between SDB and healthcare burden and cognitive impairment, as well as how these relationships may differ among demographic groups. The information gathered will help develop accessible methods of diagnosing, treating, and controlling OSA, which could enhance healthcare and cognitive outcomes for a variety of demographics. The results will also help guide future research to see whether treatments, including the use of CPAP, and comprehensive sleep surgical procedures, can lower the risk of dementia.

Acknowledgments: This work is supported by the KP Mid-Atlantic States and Johns Hopkins collaborative research initiative. We acknowledge contributions from biostatistical and data analysis teams at both institutions. We also thank Prof. med Rayleigh Chiang (rayleighchiang@jhu.edu), the corresponding author, for his overall supervision and guidance throughout the project.

Long-term effects on blood pressure of soft tissue surgery for obstructive sleep apnea treatment in adults: a systematic review and meta-analysis

N. Charakorn^{1,2}, S. Ruengpolviwat¹, P. Hirunwiwatkul¹

¹King Chulalongkorn Memorial Hospital, Otolaryngology, Bangkok, Thailand, ²Faculty of Medicine, Chulalongkorn University, Otolaryngology, Bangkok, Thailand

Introduction: We conduct a systematic review and meta-analysis to evaluate long term effect of soft tissue surgery on blood pressure (BP) in adults with obstructive sleep apnea (OSA).

Materials and methods: PubMed, Scopus, the Cochrane library, and Ovid Medline databases were searched through January 2024. Manual searches were also obtained. This review included studies assessing impact of soft tissue surgery for the treatment of OSA in adults on long-term BP.

Results: A total of five studies (299 patients) met our inclusion criteria. Pooled random effects analysis demonstrated a statistically significant long-term postoperative reduction of BP, with average systolic BP reduction of 14.04 mmHg [95%CI (-21.97, -6.11); P=0.0005]. Pooled random effects analysis of data from four studies (277 patients) also demonstrated statistically significant long-term postoperative reduction of diastolic BP by 6.88 mmHg compared with preoperative baseline [95%CI (-13.31, -0.45); P=0.04].

Conclusions: Soft tissue surgery for OSA treatment in adults significantly resulted in long-term blood pressure reduction.

Acknowledgments: We would like to thank Narumol Jariyasophit, PhD, for providing consultation on data analysis and for editing the text of this paper.

Long-Term Outcomes of Combined Sleep Surgery for Obstructive Sleep Apnea: A 14-Year Retrospective Study in Hong Kong Patients

H.Y.T. Lo¹, W.Y. Ng¹, S.C. Fung¹, V. Abdullah², W.S. Choi¹, L.I. Ho¹

¹United Christian Hospital, Hospital Authority, Dentistry & Maxillofacial Surgery, Hong Kong, Hong Kong, SAR of China, ²United Christian Hospital, Hospital Authority, Ear, Nose and Throat, Hong Kong, Hong Kong, SAR of China

Introduction: This is the first retrospective study to evaluate long-term outcomes of combined sleep surgery for OSA patients in Hong Kong over a 14-year period (2010-2024). The study aims to assess postoperative outcomes during early (<2 years), intermediate (2-4 years), long-term (4-8 years), and very long-term (>8 years) follow-ups for patients who underwent sleep surgery at the Department of Dentistry and Maxillofacial Surgery, United Christian Hospital, Hospital Authority.

Materials and methods: All subjects underwent maxillomandibular advancement surgery and advancement genioplasty as primary treatments. Simultaneous intra-pharyngeal surgery and/or staged transverse expansion surgery were performed based on individual clinical needs. Inclusion criteria included pre-operative Apnea-Hypopnea Index (AHI) ≥ 5 and age at surgery ≥ 16 . Objective outcomes were evaluated at various post-operative time points using polysomnography including Apnea-hypopnea index (AHI), Respiratory Disturbance Index (RDI), Oxygen Desaturation Index (ODI) and Lowest Oxygen Saturation (LSAT). Subjective outcomes were assessed using Epworth Sleepiness Scale (ESS).

Results: A total of 44 OSA subjects (male: 38, female: 6; age: 43.61 $\pm$ 13.15 [mean $\pm$ SD], range: 22-67; BMI: 24.11 $\pm$ 3.85) underwent sleep surgery. Significant improvement in AHI was observed with reduction from 44.64 $\pm$ 18.59 to 9.64 $\pm$ 8.10 events per hour in the early post-operative stage (<2 years, $p < 0.001$), to 16.80 $\pm$ 11.06 events per hour in the intermediate term (2-4 years, $p < 0.001$), 18.48 $\pm$ 9.45 events per hour in the long term (4-8 years, $p < 0.001$) and to 20.35 $\pm$ 10.33 events per hour in the very long term (>8 years, $p < 0.01$).

However, partial relapse was observed with AHI increasing significantly between the early postoperative stage (<2 years) and the intermediate term (2-4 years) ($p = 0.02$) and between the early postoperative stage and the long term (4-8 years) ($p < 0.001$) and the very long term (>8 years) though it was not statistically significant ($p = 0.15$). A similar trend was observed in RDI and ODI values. LSAT significantly improved from preop 75.30 $\pm$ 10.76 to 85.72 $\pm$ 5.91 (<2years, $p < 0.001$), then dropped to 85.36 $\pm$ 2.74 (2-4years, $p = 0.001$) and 81.46 $\pm$ 5.87 (4-8years, $p < 0.001$) and 80.88 $\pm$ 6.47 (>8years, $p = 0.480$). Nonetheless, improvement in ESS score was reported post-operatively after combined sleep surgery. Possible reasons for AHI increase in long term & very long term could be due to laxity of upper airway soft tissue with time, skeletal relapse, normal aging and weight gain.

Conclusions: This retrospective study highlights the short-and long-term effectiveness of combined sleep surgeries for OSA patients in Hong Kong. There was significant reduction in AHI and was sustained even in the very long term (>8 years), although partial relapse in AHI was observed during long term follow-ups. These findings emphasize the importance of continued monitoring and adjunct therapies to sustain the benefits of MMA-based OSA surgery.

Acknowledgments: The authors wish to express their gratitude to ENT colleagues Dr. Zion To and Dr. Bonnie Lam, as well as Orthodontist Dr. Frank Wong for their valuable contributions. Special thanks to Mr. Alex Sum for his expert support in polysomnography and to Mr. Thomas Hui for his assistance with statistical analysis.

Low Arousal Threshold as a Predictor of Hypoglossal Nerve Stimulation Therapy Adherence

T. Kaffenberger^{1,2}, P. Kaki³, S. Ravuri⁴, J. Kim³, R. Soose¹, N. Parker⁵, B. Edwards⁶, D. Vena⁷, M. Boon⁸, C. Huntley⁸

¹University of Pittsburgh Medical Center, Otolaryngology, Pittsburgh, United States, ²Veterans Affairs Pittsburgh Healthcare System, Pittsburgh, United States, ³Sidney Kimmel Medical College Thomas Jefferson University, Philadelphia, United States, ⁴University of Pittsburgh School of Medicine, Pittsburgh, United States, ⁵University of Indiana School of Medicine, Otolaryngology, Indianapolis, United States, ⁶Monash University, School of Psychological Sciences, Melbourne, Australia, ⁷Harvard Medical School, Division of Sleep and Circadian Disorders, Boston, United States, ⁸Thomas Jefferson University, Otolaryngology, Philadelphia, United States

Introduction: Obstructive sleep apnea (OSA) entails a complex interplay between anatomic vulnerability and pathophysiologic endotypes such as low arousal threshold (ArTH). Low ArTH is present in >33% of OSA patients and causes frequent arousals from sleep in response to small changes in airflow. Low ArTH has been linked to poor sleep quality, increased daytime symptoms, and poor long-term CPAP adherence. We evaluate the importance of ArTH on outcomes following Hypoglossal Nerve Stimulation (HGNS).

Materials and methods: Patients who underwent HGNS placement between 2020-2023 at two academic institutions were included. ArTH was determined using the following formula: $[AHI < 30 \text{ events/h}] + [SpO_2 \text{ nadir} > 82.5\%] + [\text{Hypopnea}\% > 58.3\%]$. A score of 1 was added for each criterion (low ArTH ≥ 2). Hypopneas were defined as a 30% reduction in airflow associated with a $\geq 4\%$ oxygen desaturation. HGNS adherence was defined as $\geq 4\text{h/night}$ for $>70\%$ of nights. Wilcoxon-rank-sum and Chi-squared tests were performed in R studio.

Results: Of 160 patients, 65 (40.6%) patients had low ArTH preoperatively. 88% and 76% of all patients were adherent to HGNS therapy at 3 and 6 months, respectively. Patients with low ArTH had lower average AHI at baseline (22.2 vs 39.0 events/h, $p < 0.001$), experienced smaller reductions in AHI following therapy, and were more likely to shift from adherence (at 3 months) to non-adherence (at 6 months) (26% vs. 5.3%, $p < 0.001$). Low ArTH patients had decreased % of nights used (82.6% vs 88.8%, $p = 0.037$) and % of nights used ≥ 4 hours (72.6% vs 81.6%, $p = 0.014$) but there was no statistical difference in hours/night (6.8 vs 7.2, $p = 0.11$) or pauses/night (0.68 vs 0.48, $p = 0.2$).

Conclusions: Low ArTH was associated with an unfavorable shift from HGNS adherence to nonadherence over time. Identifying patients with low ArTH preoperatively may improve precision care for OSA patients.

Machine learning-based prediction of sleep apnea and insomnia using objective sleep data from a contactless smartphone application

E. Gottlieb¹, L. Gahan², A. Lynch², K. Prakash², N.F. Watson³

¹SleepScore Labs, Carlsbad, United States, ²SleepScore Labs, Dublin, Ireland, ³University of Washington, School of Medicine, Seattle, United States

Introduction: Rates of underdiagnosis for obstructive sleep apnea (OSA) and insomnia remain unacceptably high. We developed machine learning models leveraging ecologically valid, objective sleep data from contactless consumer sleep technology to predict insomnia and OSA risk, supporting early diagnosis and treatment.

Materials and methods: Objective sleep metrics from the PSG-validated SleepScore mobile application were linked to OSA and insomnia labels in two cohorts. Dataset 1, the survey-threshold-labelled set, comprised 2,813 users (423,085 nights) with Athens Insomnia Scale scores ≥ 6 (indicating insomnia; 74.4 %) or NoSAS scores ≥ 8 (high risk for OSA; 54.9 %). Dataset 2, the self-reported-diagnosis set, contained 68,230 users (2.27 million nights) who self-reported insomnia (6.2 %) or OSA (9.1 %) diagnosis; users with comorbidities (Insomnia or Apnea and RLS or Narcolepsy or Bruxism) or ongoing treatment were excluded. Dataset 1 inclusion criteria was based on objective sleep; insomnia = sleep-onset latency > 30 min, wake after sleep onset > 30 min, and total sleep time < 6.5 h with sleep efficiency $< 80\%$ or sleep-maintenance index $< 85\%$; OSA = ≥ 12 awakenings on ≥ 3 consecutive nights or ≥ 7 on ≥ 3 nights/week for ≥ 4 of the past 8 weeks. Identical preprocessing generated 262 per-user features capturing nightly distributions, weekday-weekend contrasts, temporal trends and frequency metrics. Automated Machine Learning (PyCaret) compared classifiers using 10-fold cross-validation with 20 % holdout, optimising kappa and retaining the ten most informative features. Models were evaluated with AUROC, confusion matrices and standard metrics. Generalizability was tested by

training on the self-reported cohort and validating on the survey-threshold cohort, using user-level 80/20 splits to prevent target leakage.

Results: In Dataset 1, OSA was best predicted by a user-level logistic regression model (accuracy 68 %, AUC 0.74, recall 67 %, precision 72 %, F1-score 0.69). In Dataset 2, a different logistic regression model performed best (accuracy 71 %, AUC 0.77, recall 69 %, precision 27 %, F1-score 0.38). Among users who completed the NoSAS questionnaire, the logistic model achieved 63 % accuracy, 0.73 AUC, 74 % recall, 15 % precision, and 0.24 F1-score, outperforming the questionnaire itself (accuracy 51 %, AUC 0.72, recall 82 %, precision 12 %, F1-score 0.21). For insomnia, the top-performing model in Dataset 1 was a user-level LDA (accuracy 59 %, AUC 0.62, recall 61 %, precision 80 %, F1-score 0.70), while a different LDA model led in Dataset 2 (accuracy 70 %, AUC 0.68, recall 53 %, precision 14 %, F1-score 0.23).

Conclusions: The developed models demonstrate promising capability in predicting insomnia and OSA risks using exclusively app-derived sleep stage data. App-based screening outperformed the AUC of well-established screeners such as NoSAS and approximated the Athens Insomnia Scale. This research demonstrates the promise of consumer sleep technologies to flag potential sleep disorders for users in order to motivate diagnosis and treatment to improve sleep health.

Management of Sleep Apnoea and Insomnia in Primary Care: effectiveness of pilot feasibility study

E. Ross¹, A. Vakulin², A. Sweetman², N. Lovato², N. Grivell², M. O'Grady², K. Bassett^{2,1}, S. Appleton², J. Haycock², B. Toson², R. Adams^{2,1}, C.L. Chai-Coetzer^{2,1}

¹Southern Adelaide Local Health Network, Adelaide, Australia, ²Flinders Health and Medical Research Institute/Adelaide Institute for Sleep Health, Adelaide, Australia

Introduction: Obstructive sleep apnoea (OSA) and insomnia are the two most common sleep disorders in Australia but remain under-recognised. Access to timely care is limited by over-reliance on specialist-led models. A mixed-methods pilot study evaluated the effectiveness and feasibility of a guideline-based approach to general practitioner (GP) and practice nurse-led OSA and insomnia management in primary care. This poster presents findings from the quantitative analysis only.

Materials and methods: Adults at a single primary care facility were screened for chronic insomnia and OSA using the Epworth Sleepiness Scale (ESS), OSA-50, and Sleep Condition Indicator (SCI). Patients were eligible if they screened positive for chronic insomnia (SCI $\leq$ 16 with symptoms $>$ 3 months) or were at high risk for symptomatic OSA (ESS $\geq$ 8 and OSA-50 $\geq$ 5). Participants at high risk of OSA underwent home-based diagnostic testing using a limited channel sleep study (ApneaLink, ResMed). Moderate-severe OSA was defined as 3% oxygen desaturation index (ODI) $\geq$ 16/hour, these participants were offered continuous positive airway pressure (CPAP) therapy as first-line therapy. Participants with chronic insomnia were offered cognitive behavioural therapy for insomnia (CBTi), delivered by a trained nurse or sleep psychologist, or via Sleepio (Big Health), an evidence-based digital CBTi platform. Mood and psychological health were assessed using the Generalised Anxiety Disorder 7 (GAD-7), Patient Health Questionnaire 9 (PHQ-9), and Kessler Psychological Distress Scale (K10). Primary effectiveness outcomes were change in ESS for the OSA group and SCI for the insomnia group at 3, 6, and 12 months. Secondary outcomes included mood measures (GAD-7, PHQ-9, K10), CPAP adherence, and residual apnoea-hypopnoea index (AHI).

Results: Nineteen patients at high risk for OSA (68% male, age 50.2 $\pm$ 15.2 [mean $\pm$ SD]years, BMI 33.3 $\pm$ 7.8kg/m²) were recruited. Of these, nine (47%) were diagnosed with moderate-severe OSA (3%ODI 29.6 $\pm$ 5.8/hr). Mean ESS significantly improved from baseline (11.2 $\pm$ 0.5[mean $\pm$ SE]) at 3, 6 and 12 months (5.2 $\pm$ 0.5, 4.2 $\pm$ 0.6 and 4.5 $\pm$ 0.5, respectively; F=45.51, p<0.001). At 12 months CPAP was used by 7 of the 9 (78%) patients, with mean usage 4.3 $\pm$ 3.1[SD]hrs/night and a residual AHI of 1.5 $\pm$ 0.8/hr. Fifteen patients with chronic insomnia (53% male, age 55.2 $\pm$ 15.9[mean $\pm$ SD]years, BMI 28.2 $\pm$ 4.4kg/m²) were recruited. Eight (53%) patients opted for nurse-led CBTi, four (27%) used Sleepio, one (7%) saw a sleep psychologist and two (13%) opted for no treatment. Mean SCI at 3, 6 and 12 months (20.9 $\pm$ 1.2[mean $\pm$ SE], 18.9 $\pm$ 1.3 and 21.1 $\pm$ 1.2 respectively) was significantly improved compared to baseline (11.9 $\pm$ 1.1, F=14.42, p<0.001). Significant improvements in GAD-7, PHQ-9 and K10 were observed at 6 and 12 months for both OSA and insomnia groups (p<0.05).

Conclusions: Sustained improvements in sleepiness, insomnia and mood suggest early evidence of clinical benefit from primary care-led management of OSA and chronic insomnia. These findings

suggest that structured, guideline-based care for OSA and chronic insomnia can be effectively delivered by general practice staff.

Acknowledgments: This study was supported by the National Health and Medical Research Council (NHMRC) Partnership Grant (2005779). The authors also acknowledge the grant and equipment support provided by ResMed, Philips and Big Health.

Mandibular advancement device versus CPAP on cardiovascular health and quality of life in OSA — a pre-specified 12 months follow up of outcome

Y.H. Ou¹, J. Colpani², C. Cheong³, A.t. Thant¹, E.C. Shih³, S.P. Chan¹, C. Chin⁴, P. Kojodjojo⁵, Y.Y.M. Chan⁵, A. Richards^{5,6}, P. Cistulli⁷, R.C.H. Lee^{1,5}

¹National University of Singapore, Singapore, Singapore, ²National University of Singapore, Faculty of Dentistry, Singapore, Singapore, ³National University Hospital, Singapore, Singapore, ⁴National Heart Center, Singapore, Singapore, ⁵National University Heart Center, Singapore, Singapore, ⁶University of Otago, Christchurch Heart Institute, Dunedin, New Zealand, ⁷University of Sydney, Faculty of Medicine and Health, Sydney, Australia

Introduction: Obstructive sleep apnoea (OSA) is a significant cause of hypertension. Guidelines recommended screening and treatment of hypertension in OSA; however, evidence comparing mandibular advancement devices (MAD) to continuous positive airway pressure (CPAP) on cardiovascular health is lacking. We presented the relative effectiveness of MAD versus CPAP in long-term sleep and heart health.

Materials and methods: In a, randomized, non-inferiority trial (margin 1.5 mmHg), 321 participants, aged over 40, with hypertension and high cardiovascular risk were recruited. Of these, 220 participants with OSA (apnoea-hypopnea index ≥ 15 events/h) were randomized to either MAD or CPAP (1:1). This report presents the secondary outcomes at 12-month follow-up on the relative effectiveness of MAD versus CPAP in ambulatory BP reduction, quality of life (QoL) (sleep-specific: ESS, SAQLI, FOSQ; general: SF-36, EQ-5D), cardiac arrhythmia, and myocardial remodelling.

Results: A total of 89 (80.9% of 110) participants from MAD, and 91 (82.7% of 110) participants from CPAP completed 12-month follow-up. The median daily usage was 5.5 hours for MAD and 4.9 hours for CPAP. The between-group difference in 24h mean BP from baseline to 12-month was - 0.57 mmHg (95% confidence interval: -2.53 to 1.39, non-inferiority $P < 0.001$). Compared with the CPAP group, MAD group demonstrated a larger reduction in all the 24h with the most pronounced differences observed in the asleep BP parameters [between group difference in asleep mean BP: -2.33 mmHg (95% confidence interval: -5.08 to 0.42, $P = 0.003$); asleep systolic BP: -2.54mmHg (95% confidence interval: -6.19 to 1.11, $P = 0.015$); asleep diastolic BP: -2.26mmHg (95% confidence interval: -4.73 to 0.22, $P = 0.002$)]. Both the MAD and CPAP improved QoL, and the improvement is more pronounced in sleep-specific questionnaires ($P < 0.001$ for all sleep-specific questionnaires). CPAP had greater improvement in FOSQ from sleep-specific questionnaires ($P=0.038$), and social QoL in SF-36 from general questionnaires ($P=0.013$). The ambulatory ECG monitoring showed no between-group differences in % atrial fibrillation($P=0.209$), % ventricular ectopic isolated count ($P=0.790$) and % supraventricular ectopic isolated count ($P= 0.333$). The cardiac MRI sub-study (101 participants : MAD= 45, CPAP= 56) showed CPAP had greater improvement in right ventricular stroke volume ($P=0.023$) and MAD had greater improvement in circumferential strain favours the MAD group ($P=0.015$).

Conclusions: At 12 months , MAD was non-inferior to CPAP for reducing 24h mean arterial BP. MAD showed greater reduction in 24h BPs, especially during asleep. Our findings show that MAD treatment is a viable alternative to CPAP in the treatment of OSA, with non-inferior effects across many important cardiac and health outcomes.

Measures of OSA by baseline BMI classification in participants from SURMOUNT-OSA trials: post-hoc analyses

R. Grunstein¹, C. Xie², J. P. Dunn², J. Bednarik², B. Falcon²

¹University of Sydney, Woolcock Institute of Medical Research, Sydney, Australia, ²Eli Lilly and Company, Indianapolis, United States

Introduction: In SURMOUNT-OSA, tirzepatide reduced apnoea-hypopnoea index (AHI), sleep apnea specific hypoxic burden (SASHB), and body weight (BW). Here we evaluated weight reduction (WR) and measures of OSA based on baseline body mass index (BMI) category.

Materials and methods: SURMOUNT-OSA (NCT05412004) evaluated tirzepatide versus placebo for 52 weeks in participants with moderate-to-severe obstructive sleep apnoea (OSA) with obesity. Study 1 (N=234) and 2 (N=233) included participants not using, or using positive airway pressure (PAP) therapy, respectively. These post-hoc analyses analyzed WR and measures of OSA by baseline BMI categories (<35, ≥35 and <40, and ≥40 kg/m²) using on-treatment data. Mixed-model repeated measures were applied for continuous variables, and logistic regression for binary outcomes.

Results: Study 1 included 77, 74, and 83 participants; and Study 2 had 66, 88, and 79 participants in the baseline BMI categories <35, ≥35 and <40, and ≥40 kg/m², respectively. Baseline demographics, AHI, and Epworth sleepiness scale (ESS) were generally similar across subgroups, with higher BMI categories tending to have more female participants, be slightly younger, and have higher AHI and ESS. In Study 1, at Week 52, the placebo-corrected decrease associated with tirzepatide across BMI categories was 19.0-26.4 events/hour or 46.7-54.4% for AHI, 53.5-67.5% for SASHB, and 16.0-17.8% for BW. The odds ratio for a ≥50% reduction in AHI associated with tirzepatide compared to placebo was 6.92-11.91; and it was 3.10-18.84 for AHI<5, or AHI 5-14 with ESS≤10. In Study 2, at Week 52, the placebo-corrected decrease associated with tirzepatide across BMI categories was 21.8-27.8 events/hour or 47.1-62.4% for AHI, 58.4-73.4% for SASHB, and 17.3-18.6% for BW. The odds ratio for a ≥50% reduction in AHI associated with tirzepatide compared to placebo was 6.94-11.06; and it was 6.35-9.97 for AHI<5, or AHI 5-14 with ESS≤10. All results were statistically significant versus placebo (p<0.01), except for the odds ratio for AHI<5, or AHI 5-14 with ESS≤10 in Study 1 with baseline BMI≥40 kg/m² subgroup. There was no consistent trend in WR or OSA measures between baseline BMI categories across both studies.

Conclusions: These post-hoc analyses suggested that OSA measures associated with tirzepatide treatment were generally improved compared to placebo, regardless of baseline BMI.

Measures related to obstructive sleep apnea after tirzepatide treatment by baseline OSA severity: post-hoc analyses of SURMOUNT-OSA

B. Liao¹, B. Falcon¹, J. Bednarik¹, C. Xie¹, D. M. Rapoport²

¹Eli Lilly and Company, Indianapolis, United States, ²Icahn School of Medicine at Mount Sinai, Sleep Medicine Program, New York, United States

Introduction: In the SURMOUNT-OSA clinical studies, tirzepatide improved measures of obstructive sleep apnea (OSA) and cardiometabolic parameters in participants with moderate-to-severe OSA and obesity, including apnea hypopnea index (AHI), sleep apnea specific hypoxic burden (SASHB), systolic blood pressure (SBP), C-reactive protein (CRP), and body weight (BW). Here we evaluate the associations between tirzepatide treatment and changes in these parameters versus placebo by baseline OSA severity.

Materials and methods: SURMOUNT-OSA (NCT05412004) comprised two Phase 3 studies comparing the effects of tirzepatide maximum tolerated dose (10 mg or 15 mg once weekly) versus placebo in adults with moderate-to-severe OSA and obesity over 52 weeks. Study 1 participants were not on positive airway pressure (PAP) therapy; Study 2 participants were on PAP. These post-hoc analyses classified on-treatment participants with non-missing baseline AHI measurements into approximately evenly weighted OSA severity subgroups by baseline AHI (moderate, AHI ≥15 to <30; severe, AHI ≥30 to <70; very severe, AHI ≥70). Measures related to OSA were analyzed by logistic regression for binary outcomes and mixed-model repeated measures for continuous variables.

Results: In our analyses, we did not observe consistent associations between baseline OSA severity and changes in measures of OSA or cardiometabolic parameters across both studies. Significant differences between severity subgroups were observed for change difference in AHI ($p=0.032$) and percent body weight reductions ($p=0.042$) among participants not on PAP in Study 1. In Study 1 and 2, tirzepatide was associated with significant reductions versus placebo in AHI, SASHB, SBP, and BW across all severity subgroups. In both studies, the odds of achieving $\geq 50\%$ AHI reduction with tirzepatide were significantly higher than with placebo in all severity groups. The odds of achieving AHI < 5 or AHI 5-14 with Epworth Sleepiness Scale ≤ 10 were also significantly higher with tirzepatide than placebo in all subgroups except the Study 1 very severe subgroup. Greater reductions were observed in high-sensitivity CRP with tirzepatide than placebo across all severity groups, though significant differences were only associated with the severe subgroup in both studies.

Conclusions: In these post-hoc analyses of the SURMOUNT-OSA studies, tirzepatide was associated with significant improvements versus placebo in measures of OSA and cardiometabolic parameters irrespective of participants' OSA severity at baseline or PAP therapy use.

Mechanism Analysis of the REM-Related Oxygen Desaturation in Patients with Moderate to Severe OSA

Y. Zhou¹, G. Yin¹, J. Xu¹, X. Cao¹, J. Ye¹

¹Beijing Tsinghua Changgung Hospital, School of Clinical Medicine, Tsinghua University, Otolaryngology-Head Neck Surgery and the Sleep Medicine Center, Beijing, China

Introduction: This study aimed to determine the factors underlying rapid eye movement (REM) sleep-related oxygen desaturation (OD) in patients with obstructive sleep apnea (OSA).

Materials and methods: All subjects underwent overnight polysomnography with synchronous genioglossus electromyography (GGEMG) using intraoral electrodes. For those subjects diagnosed with moderate or severe OSA (AHI > 15 events/h), we respectively calculated the average OD during rapid eye movement (REM-OD) and non-rapid eye movement sleep (NREM-OD). The ratio of REM-OD/NREM-OD ≥ 1.5 was defined as patients with REM-related OD. The upper airway anatomy was measured by three-dimensional computed tomography (3D-CT) in all subjects.

Results: Comparing the REM-related OD group ($n=15$, AHI 68.01 ± 18.35 events/h) to the NREM-related OD group ($n=18$, AHI 57.48 ± 28.81 events/h), the former had a more severe lowest oxygen saturation overnight (56.14 ± 7.06 vs. 70.92 ± 14.49 , $p=0.009$). GGEMG variables were similar between the two groups, except for apnea time in the REM period ($p<0.001$). Parameters measured by 3D-CT of the UA showed that the REM-related OD group had a narrower glossopharyngeal airway, with a smaller minimal anteroposterior airway dimension (12.41 ± 2.99 vs. 17.58 ± 4.78 , $p=0.020$) and smaller minimal cross-sectional airway area (119.81 ± 30.94 vs. 199.78 ± 75.02 , $p=0.005$).

Conclusions: REM-related OD in OSA patients is closely associated with glossopharyngeal airway narrowing, which is the leading factor in the prolongation of apnea events during REM sleep, while the contribution of genioglossus myoelectric activity to this mechanism is not obvious.

Mechanism analysis of the site, pattern, and degree of upper airway obstruction during drug-induced sleep endoscopy in patients with obstructive sleep apnea

Y. Zhou¹, G. Yin¹, J. Xu¹, X. Cao¹, J. Ye¹

¹Beijing Tsinghua Changgung Hospital, School of Clinical Medicine, Tsinghua University, Otolaryngology–Head Neck Surgery and the Sleep Medicine Center, Beijing, China

Introduction: Drug-induced sleep endoscopy (DISE) is an effective way to locate the pattern of upper airway obstruction; however, it is unclear how anatomical and functional factors affect DISE findings in patients with obstructive sleep apnea. To assess the anatomical and genioglossus electromyography (ggEMG) indicators in obstruction patterns classified by the VOTE system.

Materials and methods: This cross-sectional prospective study was conducted at the Beijing Tsinghua Chang Gung Hospital between September 2019–April 2023. obstructive sleep apnea patients, aged 20–60 years with an AHI $\geq$ 15 without treatment, were included. The anatomical factors were measured by UACT and the ratio of unit phasic ggEMG / inspiratory negative pressure was used to evaluate genioglossus function. Based on VOTE system, the complete velum (V) obstruction was divided into anterior-posterior, lateral and concentric groups, and the oropharynx lateral walls (O) or tongue base (T) collapse were divided into six types (O₁₋₂T₀₋₂) for comparison. The epiglottic (E) patterns were grouped by the score of collapse.

Results: The study included 107 participants aged 38.8 $\pm$ 8.0 years with an AHI of 48.2 $\pm$ 19.6 events/h. The V pattern groups showed no statistical ggEMG differences; however, the lateral group exhibited the highest BMI (H=11.467, P=0.003), narrowest velopharynx mLAT (H=6.405, P=0.041), and largest glossopharynx mAP (H=8,395, P=0.015). In the O/T groups, we found that O₂T₁ tended to have a higher BMI (t=-2.833, P=0.007), longer glossopharynx length (t=-2.595, P=0.014), narrower glossopharynx mLAT (t=2.585, P=0.017), and were more likely to combine genioglossus dysfunction against the negative inspiratory pressure (χ^2 =7.502, P=0.023). In the E groups, E₂ exhibited the narrowest mAP (velopharynx: H=11.007, P=0.004; glossopharynx: H=7.057, P=0.029) and the longest glossopharynx length (H=9.653, P=0.008), whereas E₀ showed the lowest ggEMG activation while awake (R1, H=8.591, P=0.014) and during sleep-onset (R2, H=9.792, P=0.007).

Conclusions: In obstructive sleep apnea, various anatomical and functional factors affect the upper airway obstructive site, pattern, and degree. O₂T₁ had a high tendency for genioglossus dysfunction that needed a comprehensive etiological treatment.

Medullary Transcriptome and Proteomics Converge on Energy Homeostasis in the Pause-Prone C57BL/6J Mouse

K. Strohl¹, S. Azzam², C. Gillombardo³

¹Case Western Reserve University, Medicine, Cleveland, United States, ²Case Western Reserve University, Nutrition, Cleveland, United States, ³University Hospitals Cleveland Medical Center, Medicine, Cleveland, United States

Introduction: GWAS reports on sleep apnea have been unsuccessful in linking gene polymorphisms to obstructive sleep apnea using AHI (Salman, Shulman et al. 2020, Trzepizur, Blanchard et al. 2022). When this happens one can turn to animal models to uncover traits that underpin the appearance of sleep disordered breathing. Ventilatory instability- burst irregularity and post-hypoxic pauses- occurs in the C57BL/6J (B6) and not in the A/J in-bred mouse strain in wakefulness and sleep, is linked to brainstem presence of apolipoprotein A2 (apoA2), and is absent in the chromosomal substitution strain B6a1, and both *in vivo* and *in vitro* in apoA2 homozygote knock out (KO) mice (Gillombardo et al. 2017). The purpose was to uncover biologic functions linked to the *in vivo* pause physiology affected by the B6 apoA2 polymorphism.

Materials and methods: Part 1: medulla and pons mRNA extracted from B6, A/J and B6a1 mice were comparatively profiled using mouse Gene Expression Array 1.0 array (Affymetrix).

Part 2: Complete brainstem samples from *apoa2* KO and B6 (wild type) mice underwent comparative proteomic profiling using Rosetta Elucidator quantitative software. Network analyses were conducted using the Ingenuity Pathway Analysis (IPA).

Results: Part 1: Genes consistently downregulated in the brainstem of stable breathing strains were *apoa2* (as expected), but also *Tnni1*, *Arl4c*, *CDH20*, and *DARC*; the genes upregulated in both the medulla and pons were *SDHC* (the fourth protein of Complex II) and *Wdfy1* (one of other genes associated with RETT syndrome).

Part 2: a total of 6307 peptides were identified and quantified, with 1150 peptides mapping to 298 unique proteins differentially expressed based on three cutoff criteria (P-value ≤ 0.05 , two or more peptides per protein, and fold change of 2 or greater). IPA analysis identified oxidative phosphorylation, citric acid cycle and respiratory electron transport as the top canonical pathways. Differences in ATP-citrate synthase, V-type proton ATPase subunit C1, cytochrome c oxidase subunit 5A, and cytochrome b-c1 complex subunit 2 were confirmed by SRM analysis.

Conclusions: Brainstem *apoa2* presence requires homozygotic B6 SNPs and will affect biological expression in genes and proteins other than *apoa2*. Pathways identified in cellular bioenergetics and mitochondrial function converge in both Part 1 and Part 2 datasets, uncovering a novel mechanism that may produce repetition of obstructive and non-obstructive apneas during sleep.

Mineralocorticoid Receptor Blockade Attenuates Cardiovascular Dysfunction in Obese Mice Subjected to Intermittent Hypoxia

M. Badran¹, C. Bailey², J. Russel², S. Bender², D. Gozal³

¹University of Missouri, Pediatrics, Columbia, United States, ²University of Missouri, Biomedical Science, Columbia, United States, ³Marshall University, Joan C Edwards School of Medicine, Huntington, United States

Introduction: Obstructive sleep apnea (OSA), particularly prevalent in obesity, is marked by cycles of intermittent hypoxia (IH) and substantially increases cardiovascular disease (CVD) risk and mortality. Mineralocorticoid receptor antagonists (MRAs) improve outcomes across CVD spectra. We evaluated whether spironolactone (SPL) and the next-generation MRA finerenone (FIN) preserve coronary and cardiac function in mice subjected to chronic IH

Materials and methods: Male and female C57BL/6J mice received a high-fat diet (HFD) or low-fat diet (LFD) for 10 weeks, then underwent daily 16-week exposures to IH (90 s at 21% O₂ alternating with 90 s at 6% O₂) or room air. Cohorts were treated with SPL, FIN, or placebo. We measured mean arterial pressure (MAP), echocardiographic ejection fraction (EF) and E/A ratio (diastolic function), and coronary flow velocity reserve (CFVR). In vitro vascular reactivity of left anterior descending coronary and renal arteries was assessed using acetylcholine (ACh)-induced dilation and U46619-mediated constriction.

Results: Both SPL and FIN normalized IH- and HFD-elevated MAP in male mice. In LFD-IH males, SPL and FIN improved EF, whereas HFD and HFD-IH groups did not benefit. Diastolic dysfunction (E/A ratio) persisted post-MRA in HFD-IH mice. FIN—but not SPL—restored CFVR in HFD-IH males, indicating superior coronary protection. In coronary rings, both MRAs reduced U46619-induced constriction under LFD-IH, but only FIN rescued ACh-mediated relaxation in both LFD-IH and HFD-IH males. Female mice showed no improvement in vasoconstriction or vasodilation after either MRA in HFD-IH

Conclusions: Chronic IH compounded by diet-induced obesity impairs cardiac and coronary function in a sex- and diet-dependent manner. MRA therapy, particularly with the selective FIN, reverses key aspects of IH- and obesity-induced cardiovascular dysfunction in male mice. These findings support FIN's potential as a targeted adjunct to mitigate CVD risk in OSA patients.

More Than Muscle: Revealing the Cortical Effects of Myofunctional Therapy in OSA

E. Castrillon W.¹, O. Colomer¹, M. Kothari², M.C. Carra³, P. Svensson⁴, H. van der Meer⁵, K. Zainali-Gill⁶, W. Poncin⁷

¹University of Aarhus - Faculty of Health Sciences, Department of Dentistry and Oral Health - Section for Orofacial Pain and Jaw Function, Aarhus C, Denmark, ²University of Aarhus, Hammel Neurorehabilitation Center and University Research Clinic (HNRC), Department of Clinical Medicine, Hammel, Denmark, ³University of Ferrara, Department of Translational Medicine, Ferrara, Italy, ⁴National University of Singapore, Faculty of Dentistry, Singapore, Singapore, ⁵Academic Center for Dentistry Amsterdam (ACTA), Department of Orofacial Pain and Dysfunction, Amsterdam, Netherlands, ⁶Gødstrup Regional Hospital – Rhinology and Sleep, Department of Otorhinolaryngology, Gødstrup, Denmark, ⁷UCLouvain, Institute of Experimental and Clinical Research (IREC), Louvain, Belgium

Introduction: Obstructive Sleep Apnea (OSA) is a major health concern characterized by repeated upper airway collapse during sleep, resulting in fragmented sleep and increased cardiovascular risk (1). Continuous Positive Airway Pressure (CPAP) remains the standard treatment but suffers from poor long-term adherence due to poor compliance/bulkiness, noise, and discomfort (2). Mandibular advancement device (MAD) offers a better-tolerated mechanical alternative; however, MAD efficacy is variable, and they can cause dental side effects, such as occlusal changes (3). Both therapies primarily address the mechanical aspect of airway patency without targeting the underlying neuromuscular dysfunction. Myofunctional Therapy (MFT), consisting of targeted oropharyngeal exercises, has emerged as a promising non-invasive alternative/intervention. Our previous studies demonstrated that both MAD and brief MFT sessions can induce corticomotor neuroplasticity, assessed via Transcranial Magnetic Stimulation (TMS) (4-7). However, the long-term neurophysiological and clinical effects of MFT remain to be fully elucidated.

The primary aim of this project is to determine whether a structured MFT program induces corticomotor neuroplasticity in oropharyngeal muscles, and sleep outcomes in OSA patients. Secondary aims include, 1) comparing baseline corticomotor control between OSA patients and healthy controls, 2) assessing the sustained effects of MFT over 12 weeks, and 3) evaluating whether combining MFT with MAD results in superior neurophysiological and clinical outcomes compared to MAD alone.

Materials and methods: The project consists of three integrated studies. **Study 1** (cross-sectional) evaluates baseline corticomotor control and immediate neuroplastic responses to a single MFT session in OSA patients versus healthy controls. **Study 2** (randomized controlled trial) assesses the effects of a 12-week MFT program on corticomotor excitability, and sleep outcomes. **Study 3** (prospective nested cohort) tests whether the combination of MFT and MAD provides greater benefits than MAD therapy alone. Participants will undergo home sleep-apnea testing, patient-reported outcomes (ESS, PSQI, EQ-5D-5L, MoCA), and TMS-based neurophysiological assessments. Statistical analyses include t-tests, Mann-Whitney U tests, repeated measures ANOVA.

Results: Expected Results: Study 1 will clarify whether OSA patients exhibit baseline corticomotor impairments and immediate neuroplastic responses to MFT. Study 2 will evaluate whether daily MFT over 12 weeks enhances corticomotor control and clinical sleep outcomes. Study 3 will investigate the potential synergistic effects of combining MFT with MAD therapy on corticomotor control and clinical sleep outcomes. We hypothesize that MFT will induce measurable neuroplastic adaptations associated with improved airway function and sleep quality.

Conclusions: Demonstrating that MFT drives corticomotor neuroplasticity and sleep outcomes would establish it as a clinically valuable, patient-centered therapy for OSA. Beyond functioning as a standalone intervention, MFT may also enhance the effects of traditional treatments such as MAD, offering a more comprehensive, functionally oriented approach to OSA management. This integrated strategy could reduce reliance on mechanical therapies alone, lower healthcare costs, and may contribute to improve patients' quality of life.

Morphological phenotypes of the oral cavity and hard palate in Thai adults with obstructive sleep apnea: A case-control study

S. Poomkonsarn^{1,2}, T. Wattanapaibulkul¹

¹Rajavithi Hospital, Otolaryngology Head and neck surgery, Bangkok, Thailand, ²Rangsit University, College of Medicine, Bangkok, Thailand

Introduction: Obstructive sleep apnea (OSA) is a prevalent condition influenced by a range of anatomical and functional factors. Among these, morphological variations in the oral cavity, hard palate, and tongue significantly contribute to OSA pathogenesis and severity. While craniofacial morphology differs across ethnicities, data specific to the Thai population remain limited. Understanding these structural characteristics is essential for guiding individualized diagnostic and therapeutic strategies. This study aimed to characterize and compare the anatomical characteristics of the oral cavity, including the hard palate and tongue, between Thai patients with OSA and individuals at low risk for OSA.

Materials and methods:

This prospective case-control study was conducted at Rajavithi Hospital. Sixty participants were enrolled: 30 patients with OSA confirmed by polysomnography and 30 low-risk control subjects identified via the STOP-BANG questionnaire. Anatomical evaluation comprised: (1) hard palate morphology (palatal width and height measured at specific dental landmarks using intraoral scanning), (2) palatal roof-to-tongue width ratio, and (3) ankyloglossia-related measures, including mouth opening with tongue tip to incisive papilla (MOTTIP), maximal interincisal mouth opening (MIO), and Kotlow's free-tongue length. Statistical analysis was performed with a significance threshold of $p < 0.05$.

Results: Patients with OSA had significantly narrower palatal roof width compared to controls (mean 18.85 mm vs. 22.41 mm; $p < 0.001$), and significantly greater palatal height at the inter-canine ($p = 0.038$) and inter-first premolar ($p = 0.017$) positions. Although the overall palatal roof-to-tongue width ratio did not significantly differ between groups ($p = 0.147$), patients with severe OSA showed a strong association between narrow palates and increased tongue width (ratio 1:3, $p = 0.049$). No statistically significant differences were observed in ankyloglossia-related measurements: MOTTIP ($p = 0.268$), MIO ($p = 0.572$), or Kotlow's measurement ($p = 0.102$).

Conclusions: Thai patients with OSA exhibit a narrow, high-arched palatal vault and a proportionately wider tongue, especially in cases of severe disease. Integrating comprehensive evaluations of oral cavity morphology into standard clinical assessments may improve diagnostic accuracy and facilitate the selection of targeted interventions, such as palatal expansion or localized surgical therapies, intended to alleviate airway obstruction and enhance outcomes in OSA.

Acknowledgments: The author gratefully acknowledges Associate Professor Stanley Yung-Chuan Liu for his invaluable guidance and insightful contributions to the conceptual development of this study.

Multidisciplinary Speciality Sleep Clinic: a novel approach to sleep medicine in India

S. Tody¹, V. Jayakumar¹, S. Bansal¹, R. Mehta^{1,2}

¹Vaayu Chest and Sleep Specialists, Bengaluru, India, ²Apollo Hospitals, Bengaluru, India

Introduction: Sleep disorders are complex conditions and require the involvement of multiple providers; however, sleep care globally is fragmented and compartmentalised. A comprehensive sleep centre should house specialities like pulmonology, otolaryngology, dentistry, psychiatry, neurology and weight management under one roof. This paper presents a novel approach implemented in a outpatient chest and sleep centre in Bengaluru, India.

Materials and methods: The sleep disorders clinic was envisaged as a multidisciplinary team (MDT) that sees each patient, followed by a multidisciplinary discussion (MDD) culminating in a comprehensive treatment plan. Patients underwent a level 1 or 3 PSG before or after the first consultation. Each patient first consulted a pulmonologist where an initial plan was proposed; followed by ENT and dental consultations. This was followed by an MDD and involvement of dieticians, psychologists, and physical therapists as indicated. A detailed management protocol was generated with priority-based therapy options. This study compares the initial treatment plan with the final plan and evaluates the impact of the MDT and MDD on therapeutic recommendations.

Results: From April 2024 to July 2025, 149 patients presented with sleep related complaints. Of these, 121 completed the full diagnostic workflow and underwent MDD.

Among them, 106 of 121 (87.60%) were diagnosed with OSA, 10 (8.26%) with COMISA, and 2 (1.65%) each with insomnia and UARS, and 1 (0.83%) no conclusive diagnosis.

Following the initial pulmonary consult, 113 (93.38%) patients were advised CPAP, 5 (4.13%)

Mandibular Advancement Device (MAD), and 12 (9.92%) behavioural intervention.

After the MDD, management options were optimised: 90 (74.38%) patients were recommended PAP therapy, 12 (9.92%) ENT surgery, 21 (17.36%) MAD and 28 (23.14%) behavioural intervention, among other adjunctive management.

Of the 21 patients recommended MAD, 8 were intolerant to PAP, 2 were diagnosed with UARS and were ineligible for PAP and 11 were offered MAD as first-line therapy.

ENT surgery was recommended to 12 patients to optimize PAP therapy or manage OSA; of which it was first line therapy for 7 patients. Adjunctive therapies and further investigations post MDD included DISE for 31, repeat PSG for 10, myofunctional therapy for 37 and weight management for 79 patients. PAP therapy before ENT intervention was advised for 23 and drug therapy to improve nasal airflow for 71 patients.

Of the 28 patients advised behavioural intervention, 12 received it as primary treatment for insomnia/COMISA while 16 for secondary care of anxiety, depression, and for reducing barriers to healthcare and CPAP.

Following MDD, PAP recommendations decreased by 20.35%, MAD increased by 320%, and behavioural therapy increased by 133%. ENT interventions (DISE/ surgery/ pharmacological therapy), myofunctional therapy and weight management were recommended only after MDD.

Conclusions: The integration of multiple fields in a single centre minimises redundancy and is time and cost efficient for patients. It alters the default initiation of PAP therapy for patients with sleep-disordered breathing. Major challenges revealed in the study were reluctance for invasive therapeutic/ diagnostic procedures and patients lost to follow up after PSG. In conclusion, this model allows for individualised strategies and a multi-pronged approach for managing sleep disorders.

Multifactorial Relationships among the Waist-to-hip Ratio, Insulin Resistance, and Obstructive Sleep Apnea: A Large-scale Cohort Study

X. Li¹, H. Xu¹, J. Guan¹, S. Yin¹

¹Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China

Introduction: Metabolic comorbidities related to obstructive sleep apnoea (OSA) are a major concern in regarding OSA prognosis and complexity. However, few studies have investigated the interrelationships among these metabolic comorbidities. We explored the associations among insulin resistance (IR), the waist-to-hip ratio (WHR), and OSA using innovative and rigorous statistical methods.

Materials and methods: We enrolled 5,326 subjects after meticulous recording anthropometric, biochemical, and standard polysomnographic parameters. The relationships among IR, WHR, and OSA were analyzed using confirmatory factor analysis (CFA) as well as moderation and mediation analyses.

Results: CFA showed that IR and obesity were strongly correlated (loading = 0.73, $p < 0.001$). OSA was associated with both obesity and IR (loading = 0.57, $p < 0.001$; loading = 0.46, $p < 0.001$, respectively). Obesity was strongly associated with both the body mass index (BMI) and the WHR (loading = 0.82, $p < 0.001$; loading = 0.67, $p < 0.001$, respectively). WHR served as a moderator; the interaction effect between WHR and IR on the apnoea-hypopnea index (AHI) was significant (coefficient = -2.451; $p = 0.023$). Mediation analyses showed that WHR explained 14.93%, 14.02%, and 13.10% of the associations between IR and AHI, the oxygen desaturation index, and the micro-arousal index, respectively.

Conclusions: Multifactorial relationships are apparent among IR, WHR, and OSA. The complex interrelationships highlight the intricate clinical interactions among metabolic dysfunction, central obesity, and sleep-disordered breathing, emphasizing the multifaceted nature of OSA and its related health implications.

Multi-night monitoring of variability in OSA severity and associated impacts on daytime impairment and quality of life

S. Proctor^{1,2}, B. Lechat¹, J. Manners¹, A. Leviton¹, K. Loffler³, B. Toson¹, A. Vakulin¹, J. Fitton¹, R. Adams¹, D. Eckert¹, S. Mukherjee^{1,2}

¹Adelaide Institute for Sleep Health and FHMRI Sleep Health, Flinders University, Bedford Park, Australia, ²Southern Adelaide Local Health Network, Department of Respiratory, Sleep and Ventilation, Bedford Park, Australia, ³Flinders Clinical Trials, Flinders University, Bedford Park, Australia

Introduction: Night-to-night variability in obstructive sleep apnoea (OSA) severity limits the utility of single-night polysomnography (PSG) for both diagnostic accuracy and ability to accurately detect associated clinical outcomes. This study investigated if longitudinal assessment of variability in OSA severity with under-mattress multi-night monitoring of the apnoea-hypopnea index (AHI) or other baseline disease characteristics are associated with key daytime clinical outcomes.

Materials and methods: A total of 100 participants with suspected OSA were recruited to the Simplified Assessment and Monitoring of OSA (SAMOSA) observational cohort study. Each participant underwent a clinical interview and physical examination. Validated questionnaires were administered, including the Epworth Sleepiness Scale (ESS), Insomnia Severity Index (ISI), and EuroQol 5-dimension health-related quality of life scale (EQ-5D-5L). Participants were prospectively observed for 30 days using an FDA-cleared under-mattress device (Withings Sleep Analyser, Withings, France). All underwent single-night PSG prior to or during the monitoring period. Night-to-night variability in the AHI (hereafter referred to as “AHI variability”) was determined using the root-mean-squared of successive differences in nightly AHI estimates from the under-mattress device. Multiple regression analyses were performed to identify PSG and under-mattress device measurements associated with symptom severity and quality of life (visual analogue scale).

Results: There were 81 participants included in the final analysis, after exclusion of 14 due to OSA treatment prior to or during baseline monitoring, and 5 due to failure to obtain nightly AHI measurements during the baseline period. The remaining participants (51% female) had a mean±SD age of 52±16 years and BMI of 31±8 kg/m². At baseline, participants were, on average, normotensive (blood pressure 126/83±15/10 mmHg), reported daytime sleepiness within the normal range (ESS 7±5), subthreshold insomnia (ISI 12±6.1) and had moderate OSA on PSG (AHI 22±27 events/hr). High AHI variability was associated with high OSA severity (by one-way ANOVA, $F [3, 77] = 34.5, p < 0.001$). High average in-home AHI was associated with increased ESS ($B[95\%CI] = 0.071[0.009 - 0.13], p = 0.024$), whereas single-night PSG AHI was not ($B[95\%CI] = 0.027[-0.014 - 0.069], p = 0.19$). AHI variability was not associated with ESS or quality of life. High AHI variability was associated with lower ISI ($B[95\%CI] = -0.23[-0.46 - -0.006], p = 0.044$), adjusting for age, sex, BMI and OSA severity.

Conclusions: This study is the first to prospectively evaluate multi-night under-mattress monitoring in OSA and links with key daytime outcomes. These data demonstrate that multi-night AHI estimates are more closely associated with severity of daytime sleepiness than single night PSG, a finding which could help clinical decision making for OSA management. Improved reported insomnia with higher AHI variability represents a hypothesis generating finding, and further evaluation of the effects of sleep timing and architecture on variability are needed.

Acknowledgments: This study was supported by Withings. DJE is supported by a National Health and Medical Research Council of Australia Leadership Fellowship (1196261).

Multi-night phenotypes of sleep-disordered breathing are associated with increased arterial stiffness

L. Pinilla¹, B. Lechat¹, K. Sansom^{1,2}, A. Vakulin¹, P. Escourrou³, J.-L. Pepin⁴, R. Adams¹, P. Catcheside¹, D.J. Eckert¹

¹Adelaide Institute for Sleep Health and FHMRI Sleep Health, College of Medicine and Public Health, Flinders University, Adelaide, Australia, ²Centre for Healthy Ageing, Health Futures Institute, Murdoch University, Perth, Australia, ³Centre Interdisciplinaire du Sommeil, Paris, France, ⁴HP2 Laboratory, Inserm U1300, Grenoble Alpes University, Grenoble, France

Introduction: Arterial stiffness is a robust predictor of end-organ damage and cardiovascular mortality, beyond traditional risk factors. Pulse-wave velocity (PWV) is a well-established, non-invasive measure of arterial stiffness, serving as a proxy of vascular aging and cardiovascular risk. Prior studies examining the relationship between obstructive sleep apnea (OSA) and PWV, based on single-timepoint assessments, have yielded inconsistent results. Emerging multi-night sleep-disordered breathing (SDB) phenotypes, including high night-to-night variability in OSA severity and regular snoring, are

independent predictors of adverse cardiovascular outcomes (e.g. hypertension). However, the role of multi-night SDB metrics on arterial stiffness remains unexplored. This study investigates the associations between multi-night OSA severity, OSA variability, and snoring with repeated multi-year measurements of arterial stiffness.

Materials and methods: Longitudinal data (January 2021–November 2024) were collected from adult users of two FDA-cleared consumer health tracking devices: an under-mattress sleep sensor and a smart scale. Nightly apnea-hypopnea index (AHI) and snoring metrics were derived from the sleep sensor using ballistography and sound analysis (validated against gold-standard polysomnography). Aortic-leg PWV measurements were derived from the scale using impedance plethysmography and ballistocardiography (validated against gold-standard applanation tonometry). Participants with <52 sleep or <12 PWV readings per year were excluded. OSA severity was categorized by average AHI: <5 (no OSA), 5–15 (mild), 15–30 (moderate), and 30+ events/h (severe). OSA variability was calculated using the root mean square of successive nightly AHI differences. Snoring was quantified as the average percentage of total sleep time spent snoring. Multivariable linear regression models examined the associations between multi-night sleep metrics and average PWV, adjusting for age, sex, and BMI. Models for OSA variability and snoring further accounted for OSA severity and each other. Associations of age with PWV were also analysed for context. Results are reported as β coefficient and 95%CI.

Results: The study included 29,653 participants from 20 countries (mean age 52 ± 12 years; 84% male; BMI 27.3 ± 4.9 kg/m²). Participants had a median [IQR] of 252 [103] sleep and 38 [64] PWV measurements per year. OSA prevalence was 34% mild, 17% moderate, and 8% severe. Mean PWV was 7.56 ± 1.02 m/s. Compared to participants without OSA, higher OSA severity was significantly associated with increased PWV: mild OSA ($+0.17$ [0.15–0.19] m/s), moderate OSA ($+0.27$ [0.24–0.30] m/s), and severe OSA ($+0.24$ [0.20–0.29] m/s). Among those with mild OSA, greater OSA variability (75th vs. 25th; 12.0 vs. 6.8 events/h) was significantly associated with a further $+0.11$ [0.07–0.15] m/s PWV increase. High snoring burden (75th vs. 25th; 16.5% vs 1.9%) was significantly associated with a $+0.19$ [0.16–0.21] m/s PWV increase. For reference, a 16-year age difference (75th vs. 25th; 61 vs. 45 years) was associated with a $+0.68$ (0.67 to 0.70) m/s PWV increase.

Conclusions: In this large, real-world study, multi-night OSA severity, night-to-night OSA variability, and regular snoring were each independently associated with a clinically meaningful increase in arterial stiffness. These novel findings underscore the value of multi-night sleep monitoring for improved cardiovascular risk stratification and suggest that arterial stiffness may be a key mechanistic pathway linking SDB with cardiovascular pathology.

Multi-Omics Sequencing and Mendelian Randomization Analysis Identifies Corticotropin-Releasing Hormone Receptors (GRHR) as a Potential Therapeutic Target for Obstructive Sleep Apnea

S. Zhang¹, Y. Wang¹, D. Lei¹

¹Qilu Hospital of Shandong University, Department of Otorhinolaryngology, NHC Key Laboratory of Otorhinolaryngology, JiNan, China

Introduction: Obstructive sleep apnea (OSA) is a multifactorial sleep-related breathing disorder characterized by recurrent upper airway obstruction during sleep, resulting in intermittent hypoxia, sleep fragmentation, and excessive daytime sleepiness. Although mechanical interventions such as positive airway pressure and surgery are effective, pharmacological options remain lacking. This is partly due to limited knowledge of the neurobiological circuits and molecular pathways regulating upper airway motor control. The hypoglossal motor nucleus (HMN), which innervates the genioglossus muscle, plays a central role in maintaining upper airway patency. Here, we aimed to identify novel therapeutic targets for OSA through a combination of brainstem and peripheral tissue multi-omics profiling, and human genetic analyses.

Materials and methods: A rat model of OSA was established via chronic intermittent hypoxia (CIH) exposure. We performed single-cell RNA sequencing (scRNA-seq) and spatial transcriptomics on the HMN and genioglossus muscle to characterize cellular heterogeneity and spatial gene expression dynamics under hypoxic stress. Targeted neurotransmitter-focused metabolomic profiling was conducted on serum samples of human and rat model to evaluate systemic and local neuroendocrine alterations.

To translate these findings to human populations, we integrated data from the UK Biobank Pharma

Proteomics Project and conducted two-sample Mendelian randomization (MR) analysis using cis-acting protein quantitative trait loci (pQTLs) to test for causal associations between circulating proteins and OSA risk. Sensitivity analyses included reverse MR and Bayesian colocalization to validate causal direction and genetic co-regulation.

Results: Multi-omics profiling revealed significant upregulation of corticotropin-releasing hormone receptor (CRHR) in the HMN and genioglossus muscle following CIH exposure. Spatial transcriptomics confirmed localized CRHR expression enrichment in motor regulatory nuclei. Metabolomic analyses indicated CRHR-linked dysregulation of neuroendocrine and energy metabolism pathways, potentially impairing upper airway neuromuscular responsiveness.

Mendelian randomization analysis identified a significant causal relationship between genetically predicted circulating CRHR levels and increased OSA susceptibility (inverse variance weighted odds ratio > 1.0, $p < 0.001$). Reverse MR analysis excluded reverse causality, and Bayesian colocalization supported a shared genomic architecture between CRHR-regulating variants and OSA-associated loci. Ongoing functional validation using central and peripheral CRHR agonists/antagonists in CIH-exposed rats further suggests a modulatory role of CRHR in genioglossus excitability and upper airway stability during sleep.

Conclusions: This study provides convergent evidence from central and peripheral transcriptomics, metabolomics, and human genetic analyses identifying CRHR as a mechanistically relevant and pharmacologically actionable target in OSA. By implicating CRHR in the regulation of hypoglossal motor outflow and upper airway dilator muscle tone, our findings lay the groundwork for future therapeutic strategies aimed at restoring neuromuscular control in sleep-disordered breathing.

Multi-Tier Evaluation for Obstructive Sleep Apneics undergoing Maxillomandibular Advancement

P.-F. Wang¹, C.-H. Lin²

¹Chang Gung University, Taoyuan, Taiwan, ²Chang Gung Memorial Hospital, Taoyuan, Taiwan

Introduction: Maxillomandibular advancement (MMA) has been the most effective surgical option in reducing AHI (apnea-hypopnea index). Despite the high success rate, the long-term and cure rates remain low. Pre-surgical evaluations of craniofacial anatomy, cephalometry, and nasopharyngoscopy may provide information on craniofacial structures and airway dimensions. Polysomnographic indices show the physiological presentation. However, the correlation between structure and physiological indices is scarce. In this study, we tried to find a clinically feasible model to conduct sophisticated and comprehensive pre-surgical evaluation by organizing a multi-tier pre-surgical evaluation for adult OSA patients. In addition to the gold standard of polysomnography, commonly used tools include clinical craniofacial evaluation, 2D/3D photo analysis, 2D/3D cephalometry and airway dimension measurements, computational fluid dynamics study, and drug-induced sleep (sedative) endoscopy. The purpose of this study was to identify the feasibility of multi-tier pre-surgical evaluation and its correlation to surgical simulation of MMA and the polysomnographic outcomes.

Materials and methods: A retrospective review was conducted on 30 OSA patients undergoing multi-tier pre-surgical evaluation, computer-aided surgical simulation and MMA. Craniofacial anatomical evaluation, cephalometric measurements from 2D/3D radiographs, and nasopharyngoscopic evaluation under local and general anesthesia were reviewed. Combining with polysomnographic indices, the correlation between the evaluation and surgical outcomes was tested.

Results: On average, the maxilla(at A point) and the mandible(at B point) were advanced 4.0 ± 2.9 mm and 13.2 ± 3.7 mm, respectively. After surgery, generally, SNA and SNB increased $3.7 \pm 3.2^\circ$ and $6.3 \pm 2.0^\circ$, respectively. Apnea-Hypopnea Index (AHI) was significantly reduced from $39.6 \pm 24.7/\text{hr}$ to $4.0 \pm 7.0/\text{hr}$. Surgical success was 100% for females and 93.2% for males. Intra-luminal obstruction leads to the priority of obstruction removal by intra- or extra-pharyngeal obstructive soft tissue resection. Pharyngeal airway dimensions observed during awake/sedative/anesthesia and sitting/supine were correlated with polysomnographic indices before and after surgery.

Conclusions: Through multi-tier pre-surgical evaluations, we may obtain a comprehensive assessment to connect anatomy to sleep physiology and build a rational treatment plan for individual patients.

Next-Generation Hypoglossal Nerve Stimulation Therapy for the Treatment of Obstructive Sleep Apnea

C. Cheong¹, S.T. Toh², A. Ng², P.R. Song², J. Teo², S. Binte Abdul Rahim², N. Binte Mohd Isa², S.H. Goh², S. Png², H. Bin Borhan¹, H. Firdaus Bin Abdul Haddy¹, M.A. Bin Ramlan¹, S. Loh²

¹National University Hospital, Singapore, Singapore, ²Singapore General Hospital, Singapore, Singapore

Introduction: Hypoglossal nerve stimulation (HGNS) is a proven therapy for moderate to severe OSA patients who struggle with CPAP. The next-generation Inspire HGNS System (Inspire V) is designed to simplify the procedure by including sensing technology within the IPG and eliminating the sense lead. It is also designed to provide enhanced patient comfort and more efficient patient management with new features including therapy ramp duration and smaller amplitude step sizes. This study includes implant and follow-up of the first worldwide implants of this new-generation HGNS technology.

Materials and methods: First implants and activations of this new technology occurred in a prospective, multicenter study of 44 patients in Singapore, who are being followed to 6 months post-therapy activation. Baseline and medical history were collected for all participants. Implant information including duration of implant (from first incision to last closure) was reported and compared to implant times from the previous generation (which included implantation of a sense lead). Inspiration Phase Overlap Percent (IPOP) was measured by in-lab PSG. The objective of this measure is to demonstrate non-inferiority of inspiratory overlap with Inspire V compared to previous generations of the Inspire system. Therapy use after activation of the therapy was reported at 3 months post-implant. Adverse events were also collected.

Results: A total of 44 participants (88.6% male; mean age: 55.68±10.24 yrs; baseline AHI: 36.97±15.23; baseline BMI: 26.91±2.75) were implanted with the Inspire V system between September 2024 and February 2025. No unexpected adverse effects have been reported at or after implant of the systems. Implant times decreased by 20.4% compared to implant of the previous HGNS system. At the 3 months' visit, ramp duration (5/10/15 min) was reportedly utilized in 25% of patients to provide support for comfort and/or insomnia. The smaller amplitude step size was reportedly utilized in 12% of patients, specifically to support comfort while the patient is acclimating to therapy. Results of IPOP are pending and will be available at the time of presentation. Mean therapy use at 3 months post-activation (n=30) is 6.0±1.67 h/nt.

Conclusions: The next-generation HGNS technology provides more efficient implantation as well as features that can be employed to increase patient comfort and utilization.

Acknowledgments: The Next Generation Study is sponsored by Inspire Medical Systems, Inc.

Niacin infusion suppresses free fatty acids in individuals with obstructive sleep apnea and prediabetes: Insights from an ongoing mechanistic study

B. Haugen¹, K. Wroblewski¹, B. Tucker¹, M. Jensen², E. Tasali¹

¹University of Chicago, Biological Sciences Division, Chicago, United States, ²Mayo Clinic, Rochester, United States

Introduction: Obstructive Sleep Apnea (OSA) has been strongly linked with impaired glucose metabolism independently of obesity, but underlying mechanisms remain to be elucidated. It is well recognized that increased adipose tissue lipolysis, i.e., excess free fatty acids (FFAs), can lead to insulin resistance and glucose intolerance. In OSA, FFAs have been reported to be elevated. We hypothesize that excess FFAs induced by OSA lead to insulin resistance and glucose intolerance. Here, we present findings from an ongoing mechanistic study in individuals with prediabetes and moderate-to-severe OSA studied under experimental sleep conditions. We use continuous niacin (i.e. vitamin B3) infusion as a tool to suppress lipolysis to interrogate the role of excess FFAs and downstream metabolic impairments in OSA.

Materials and methods: Individuals with OSA and prediabetes were studied under three in-lab conditions in random order using a within-subject crossover design with a 4-week washout period between study conditions: (a) untreated OSA (i.e., Baseline), (b) 5 nights of continuous positive airway pressure (i.e., CPAP) treatment of OSA, (c) continuous niacin infusion (i.e., Niacin) overnight through the end of metabolic testing on the following day. On the final day of each condition, all subjects underwent an isotope tracer-based oral glucose challenge with frequent blood sampling to assess insulin sensitivity and glucose dynamics. Post-challenge FFA suppression was calculated from the area-under-the-curve (AUC; trapezoidal rule) from glucose ingestion until the nadir FFA values. Plasma FFA

concentrations were measured via enzyme-based colorimetric Wako non-esterified fatty acid kits. Comparison across conditions was performed using linear mixed effect models with a Kenward-Roger small sample adjustment. In this preliminary analysis, no adjustment for multiple comparisons was made.

Results: Findings are reported from all available data in a total of 16 subjects (age: 48 ± 11 years, BMI: 34 ± 6 kg/m²). Mean fasting FFA levels (overall $p < 0.0001$) were suppressed with Niacin ($n = 11$) by ~58% compared to Baseline ($n = 13$) and by 54% compared to CPAP ($n = 14$) ($p < 0.0001$ for both), but CPAP did not differ from Baseline ($p = 0.298$). Post-challenge AUC FFA (overall $p < 0.0001$) was suppressed with Niacin by ~51% compared to Baseline ($p < 0.0001$) and by ~42% CPAP ($p = 0.001$). CPAP treatment reduced post-challenge AUC FFA by ~18% compared to Baseline ($p = 0.051$). Additional data analysis on glucose metabolism (e.g., insulin sensitivity) derived from isotope-tracer based minimal models is ongoing.

Conclusions: Niacin suppressed both fasting and post-challenge FFA levels in individuals with OSA and prediabetes. For the first time in OSA patients, these findings show that Niacin can be an effective tool to suppress lipolysis to interrogate the mechanistic role of FFAs in impaired glucose metabolism in OSA. The complete dataset from this study will provide mechanistic insights into how OSA can directly impair glucose metabolism and inform future treatment strategies.

Acknowledgments: Taryn Schnoor, Ariel Crenshaw, Adrian Vella, Giovanna Distefano, Lauren Sparks, Chiara Dalla Man, Roberto Visentin, Robert Wolfe, NIH 1R01HL146127, 5UL1TR002389, 5T32DK131958

Nicotine Use and Sleep Architecture in Postmenopausal Women with Obstructive Sleep Apnea

S.R. Yoo¹, B. Phung¹, S. Saretha¹, J.-Y. Wang¹, M. Varma¹

¹California University of Science and Medicine, Colton, United States

Introduction: Previous literature suggests that nicotine use and postmenopausal status contribute to decreased sleep quality and increased risk of sleep disorders, particularly obstructive sleep apnea (OSA). Hormonal changes during menopause are believed to influence fat distribution and respiratory stability during sleep, increasing susceptibility to obstructive sleep apnea (OSA). In addition to hormonal factors, lifestyle and physiological variables such as smoking and body mass index (BMI) have been identified as critical contributors to the onset and severity of sleep apnea in this population. However, there is little research on the combined effects of nicotine use and postmenopausal status on sleep architecture. This study seeks to explore whether nicotine affects sleep architecture among postmenopausal women with OSA. It also explores whether there is an interaction between nicotine exposure and body mass index (BMI) in influencing sleep.

Materials and methods: A retrospective cohort study was conducted on 32 postmenopausal women diagnosed with OSA with and without a history of smoking from a community clinic. Body mass index (BMI), history of diabetes, and smoking status and history were collected. Comprehensive sleep metrics were recorded for each participant through an overnight polysomnography, including time spent in bed, percentage of wakefulness, light sleep (% N1 and % N2), deep sleep (% N3), REM sleep, and total sleep time (TST).

A student t-test was used to compare sleep parameters between postmenopausal women with and without a history of smoking. Multiple linear regression analyses were performed to assess whether BMI modified the relationship between smoking and sleep outcomes.

Results: Although there were no statistically significant differences (all $p > 0.05$), there was a trend in which postmenopausal women with a history of smoking had shorter TST compared to those without a history of smoking. The smoking group had a mean TST of 6.38 ± 1.51 hours, whereas the non-smoking group averaged 7.11 ± 0.69 hours ($t(29) = -1.86$, $p = 0.0725$). The multiple linear regression analyses examining the effect of BMI and nicotine use on sleep parameters failed to demonstrate significance (all $p > 0.05$).

Conclusions: In this study, nicotine use and BMI was not significantly associated with changes in sleep architecture in postmenopausal women. There was a trend in which postmenopausal women with a history of smoking had a shorter TST, suggesting that there may be a subtle effect that could not be detected due to the small sample size which limited statistical power. Further research is warranted to

explore the association between nicotine use and sleep architecture in postmenopausal women across multiple geographic and clinical settings to increase generalizability.

Acknowledgments: The authors would like to thank Dr. Varma for her valuable feedback. We also acknowledge the community clinic in Southern California who provided us with polysomnography data. We thank CUSM as well.

Nighttime Light Exposure Predicts Higher Sleep Apnea Risk: A Prospective Study with Explainable Machine Learning

W. Wang^{1,2,3}, B. Lin^{1,4}, G. Zhang^{1,3,5}, X. Mei^{1,3}, Q. Huang^{1,2,3}, J. Zhang^{1,3}, H. Feng^{1,3}

¹Guangzhou Medical University, The Affiliated Brain Hospital, Center for Sleep and Circadian Medicine, Guangzhou, China, ²Guangzhou Medical University, School of Basic Medical Sciences, Guangzhou, China, ³Guangzhou Medical University, Key Laboratory of Neurogenetics and Channelopathies of Guangdong Province and the Ministry of Education of China, Guangzhou, China, ⁴Jinan University, The First Affiliated Hospital, Department of Neurology, Guangzhou, China, ⁵Guangzhou Medical University, School of Public Health, Guangzhou, China

Introduction: Nighttime artificial light is an increasingly prevalent environmental exposure that may affect sleep health. However, its role in the development of sleep apnea remains underexplored. We investigated the longitudinal association between objective nighttime light exposure and incident sleep apnea, and evaluated its relative contribution and independence using explainable machine learning.

Materials and methods: A total of 84,774 adults (62.43 ± 7.82 years; 55.0% female) without sleep apnea at baseline were included. Nighttime light exposure was derived from seven-day wrist-worn actigraphy recordings and categorized into quartiles. Incident sleep apnea was identified from hospital and primary care records. Cox proportional hazards models were used to estimate hazard ratios (HRs) with sequential adjustment for demographic, behavioral, and clinical covariates. An XGBoost-based survival model with SHapley Additive exPlanations (SHAP) was further used to assess the relative importance and interaction profile of each predictor.

Results: Over a median of 9.3 years (total 773,025 person-years), 802 participants were diagnosed with sleep apnea. Participants exposed to ≥ 32.5 lux at night (upper quartile) had a 36% higher risk of developing sleep apnea compared to those exposed to ≤ 1.4 lux (lowest quartile) (HR=1.36; 95% CI: 1.07–1.73; $p_{\text{adj}} = 0.032$). SHAP-based interpretation demonstrated that nighttime light exposure was among the predictors included in the cumulative 90% of total model importance, based on mean absolute SHAP values across all 23 covariates. Compared to other top predictors such as BMI category and physical activity, which exhibited stronger interaction patterns (maximum SHAP interaction strength = 0.05), nighttime light showed minimal interaction with other covariates (maximum = 0.02). Along with non-significant results from likelihood ratio tests for interaction terms with age, sex, chronotype, diet, and physical activity (all $p_{\text{adj}} > 0.05$, respectively), these findings support the independent and robust role of nighttime light exposure in predicting sleep apnea risk.

Conclusions: Nighttime light exposure is a robust and novel predictor of sleep apnea risk. Further studies are needed to determine whether nighttime light exposure can serve as a modifiable environmental target for sleep apnea prevention.

Non-contact On-device Detection of Obstructive Sleep Apnea from Infrared Video

Y.R. Choi¹, D. Park¹, H.K. Lee², S. Bae¹, S. Park¹, H.-S. Kim¹, H.-W. Shin²

¹Seoul National University, Graduate School of Data Science, Seoul, Korea, Republic of, ²Seoul National University College of Medicine, Seoul, Korea, Republic of

Introduction: Despite growing demand for accessible sleep monitoring, traditional polysomnography (PSG) remains limited by high cost, discomfort, and poor feasibility for long-term use. Alternative sensor-based and wearable solutions often suffer from compliance issues, noise sensitivity, and limited generalizability. In contrast, video-based methods offer a non-contact, user-friendly approach for assessing respiratory patterns and sleep position. However, existing methods require high computational resources, strict recording conditions, and lack validation on large-scale datasets. We propose **SIAction**, a non-contact, on-device system for continuous obstructive sleep apnea (OSA) monitoring using infrared video.

Materials and methods: *SIAction* captures the full sleep environment via a wall-mounted infrared camera and processes data locally to ensure privacy. The system was developed and evaluated using the **Korea Video Sleep Study (KVSS)** dataset, comprising 936 overnight recordings (over 5,000 hours) from three institutions. Each video is synchronized with PSG annotations, and facial regions are anonymized. Through analysis, we identified respiratory arousals (RAs)-brief cortical arousals following apnea or hypopnea episodes, typically accompanied by distinctive movements-as reliable visual markers of disordered breathing. *SIAction* detects RA events and sleep positions every 30 seconds using a unified four-class deep learning model. A regression model then estimates the apnea-hypopnea index (AHI), which is used to classify OSA severity (normal, mild, moderate, severe) and determine positional OSA (POSA) by comparing supine and non-supine AHI values.

Results: *SIAction* was trained on 70% of 475 recordings from Hospital A, with 15% used for validation and 15% for testing. It outperformed both video- and signal-based baselines across all tasks. For AHI estimation, it achieved a Spearman correlation of 0.91, mean absolute error of 9.31, and R^2 of 0.76. Based on the estimated AHI, the system achieved a macro F1 of 87.93 for OSA screening ($AHI > 15$) and 61.67 for severity classification. It reached 100% relaxed accuracy, where predictions within one adjacent severity level are considered correct. For POSA classification, macro F1 was 70.87. All processing is performed on-device. The system runs in real time on a \$120 Jetson Nano using only the CPU, processing each 30-second epoch in 16 seconds. Raw video is discarded after processing, retaining only diagnostic results to preserve privacy. The model trained on Hospital A generalized well to external test sets from Hospitals B (205 recordings) and C (110 recordings), confirming strong cross-institutional robustness.

Conclusions: *SIAction* demonstrates that RA-driven, position-aware video analysis enables accurate and efficient OSA monitoring without physical contact or cloud-based processing. Running in real time on a low-cost, on-device system, it ensures both privacy and scalability for home and clinical use. Trained on a large, diverse dataset and validated across institutions, *SIAction* offers a practical, generalizable alternative to PSG for long-term, non-intrusive sleep apnea assessment.

Nonlinear Associations Between AHI, Hypoxemia, and Cardiometabolic Risk: The Xiangya SDB Cohort study from mainland China

M. Zhang¹, M. He¹, S. Wang¹, J. Yan¹, B. Tang², M. Yi³, X. Su¹, Y. Zhang¹

¹Central South University, Department of Respiratory & Sleep Medicine, Xiangya Hospital, Changsha, China, ²Central South University, Department of Neurology, Xiangya Hospital, Changsha, China,

³Central South University, School of Life Sciences, Changsha, China

Introduction: Sleep-disordered breathing (SDB) has been associated with cardiovascular and metabolic diseases; however, limited research has explored the relationship between the severity of sleep apnea and comorbidities in individuals with a high apnea-hypopnea index (AHI), particularly when oxygen saturation-related parameters are considered.

Materials and methods: We include individuals from The Xiangya SDB Cohort Study(I) who completed sleep monitor at the Sleep Medicine Center of Xiangya Hospital of Central South University from January 1, 2016 to December 31, 2023. Also, related electronic medical records of demographic characteristics and relevant comorbidity diagnoses were extracted. The severity of OSA was evaluated

using the AHI and the percentage of total sleep time spent with oxygen saturation <90% (T90). Restricted cubic spline (RCS) analysis, logistic regression models, and k-means clustering were employed to assess the association between OSA severity and the prevalence of cardiometabolic comorbidities, including hypertension (HTN), coronary heart disease (CHD), heart failure (HF), atrial fibrillation (AF), cerebrovascular disease (CeVD), and diabetes mellitus (DM).

Results: A total of 7,631 individuals aged 18 years or older with suspected sleep apnea were selected from The Xiangya SDB Cohort Study, among whom 4,383 were suspected to have obstructive sleep apnea (including 3,816 with confirmed OSA and 567 without SDB). After adjusting for confounding factors, a nonlinear association was observed between AHI and the prevalence of HTN, CHD, and CeVD. Further analysis showed that when AHI <40, there was a positive association between AHI and HTN (OR: 1.012; 95% CI: 1.002–1.021). However, when AHI ≥40, AHI was negatively associated with HTN (OR: 0.992; 95% CI: 0.985–0.999), CHD (OR: 0.988; 95% CI: 0.979–0.997), AF (OR: 0.978; 95% CI: 0.963–0.993), and CeVD (OR: 0.989; 95% CI: 0.979–0.999). K-means clustering of suspected OSA patients using AHI and T90 identified three clusters: low-AHI, high-AHI/low-T90, and high-AHI/high-T90. In the high-AHI/low-T90 group, AHI remained negatively associated with HTN (OR: 0.987; 95% CI: 0.979–0.996), CHD (OR: 0.986; 95% CI: 0.976–0.997), AF (OR: 0.968; 95% CI: 0.951–0.984), and CeVD (OR: 0.989; 95% CI: 0.978–1.000). In contrast, within the high-AHI/high-T90 group, T90 showed a negative effect on comorbidities: HTN (OR: 0.988; 95% CI: 0.976–0.999), CHD (OR: 0.968; 95% CI: 0.949–0.988), and HF (OR: 0.966; 95% CI: 0.941–0.992). When using AHI of 40 and T90 of 25 as cutoff values to classify suspected OSA patients into low-AHI, high-AHI/low-T90, and high-AHI/high-T90 groups, the results were consistent with the cluster-based approach.

Conclusions: Our findings suggest a nonlinear association between AHI and the prevalence of OSA-related comorbidities. Among individuals with severe OSA (AHI ≥40), the severity of OSA exhibited a paradoxical inverse association with several comorbid conditions, and T90 of 25 may serve as a useful threshold for subgroup classification in this population. These results highlight the need for a more nuanced classification of patients with high AHI, beyond the conventional AHI-based stratification, to better identify those at elevated risk for cardiovascular and metabolic comorbidities in clinical settings.

Nrf2 Pathway Activation: A Neuroprotective Strategy Against ER Stress-Mediated Apoptosis in Obstructive Sleep Apnea

P. Zhong¹, X. Cai¹, X. Li¹

¹The Second Affiliated Hospital and Yuying Children's Hospital of Wenzhou Medical University, Department of Pediatrics, Wenzhou, China

Introduction: Chronic intermittent hypoxia (CIH), a hallmark of obstructive sleep apnea (OSA), is a major contributor to pediatric cognitive impairment, partly through endoplasmic reticulum stress (ERS)-mediated apoptotic pathways. While Nrf2 signaling is renowned for conferring neuroprotection in models of neurological disease, the involvement of this pathway in mitigating ERS-associated apoptosis and modulating antioxidant responses specifically in CIH-challenged prefrontal neurons requires further elucidation.

Materials and methods: This research examined the influence of Nrf2 on cognitive impairment and mechanistic pathways triggered by CIH, employing both cellular (PC12) and animal (4-week-old male C57BL/6 mice) models. Nrf2 signaling was modulated via specific activation and inhibition protocols to evaluate its function in CIH-mediated neuropathology. Y-maze testing assessed cognitive function. Morphological alterations indicative of damage were visualized by light and electron microscopy. Protein abundance was determined using Western blotting (WB) and immunofluorescence assays.

Results: In PC12 cells modeling OSA-related neuronal injury, chronic intermittent hypoxia (CIH) exposure significantly induced endoplasmic reticulum stress (ERS) and subsequent apoptosis. This was demonstrated by upregulation of ERS markers (p-PERK, ATF4, CHOP) and apoptotic markers (cleaved Caspase-3). Concurrently, CIH activated the antioxidant system via elevated expression of Nrf2, HO-1, and Gclc. Pharmacological activation of Nrf2 by sulforaphane (SFN) attenuated CIH-induced apoptosis through suppression of ERS signaling and enhanced HO-1 expression. Conversely, the Nrf2 inhibitor ML385 exacerbated these effects.

In a murine CIH model, 4-week exposure impaired spatial learning and memory in Y-maze tests. Histological analysis revealed increased neuronal apoptosis in the prefrontal cortex, marked by elevated cleaved Caspase-3 and Nrf2 pathway activation. SFN treatment mitigated cognitive deficits

and neuronal apoptosis by inhibiting ERS signaling and upregulating HO-1. In contrast, Nrf2 inhibition produced opposing outcomes.

Conclusions: Collectively, our data indicate that Nrf2 activation attenuates CIH-induced cognitive impairment by suppressing neuronal apoptosis through inhibition of the PERK-ATF4-CHOP pathway and upregulation of HO-1 expression.

Acknowledgments: Our sincere appreciation goes to the dedicated teams at the Department of Science and Research Center at The Second Affiliated Hospital and Yuying Children's Hospital of Wenzhou Medical University, as well as the Experimental Animal Center of Wenzhou University, for their unwavering and selfless assistance throughout this project.

Obstructive Sleep Apnea and Medical Comorbidities in the Asian Population: Evidence From a Nationwide Healthcare System Data in South Korea

S.C. Hong¹, Y.-C. Kim²

¹St. Vincent's Hospital, College of Medicine, The Catholic University of Korea, Department of Psychiatry, Suwon, Korea, Republic of, ²St. Vincent's Hospital, College of Medicine, The Catholic University of Korea, Suwon, Korea, Republic of

Introduction: Obstructive sleep apnea (OSA) is a breathing disorder characterized by recurrent airway obstruction during sleep. Previous western studies have investigated the link between medical disorders and the pathophysiology of OSA. The prevalence and comorbidity rates of OSA; however, vary across different countries and racial groups. This study aimed to delve into medical comorbidities in patients with OSA using a large nationwide healthcare database in Korea.

Materials and methods: This nationwide study used the Korean National Health Insurance claims database (2010-2019). The effect of OSA on the incidence of medical disorders was estimated using the Cox proportional hazard ratio (HR) model. The results were reported as crude and adjusted HRs with 95% confidence intervals (CI). Subgroup analysis was conducted by sex and age.

Results: In total, 103,785 patients with OSA and 207,570 patients without OSA were included. OSA group had significantly higher HRs for ischemic heart disease and stroke even after adjusting for hypertension, dyslipidemia, and diabetes. The OSA group also showed an increased risk of metabolic syndrome-related diseases, chronic kidney disease, and gastroesophageal reflux disease. Female patients with OSA exhibited notably higher rates of comorbid liver cirrhosis, chronic obstructive pulmonary disease, and asthma. The cardiovascular burden of patients increased in accordance with the patients' age.

Conclusions: Korean patients with OSA have a significantly increased risk of cardio-cerebrovascular diseases, which aligns with the previous studies conducted in the western countries. This result holds particular significance as it represents the first nationwide, population-based study conducted in Asia.

Obstructive Sleep Apnea and α -Synucleinopathies: Nationwide Analysis from South Korea's Healthcare Database

S.C. Hong¹, Y.-C. Kim¹

¹St. Vincent's Hospital, College of Medicine, The Catholic University of Korea, Suwon, Korea, Republic of

Introduction: Obstructive sleep apnea (OSA) is increasingly acknowledged for its correlation with systemic health issues, notably neurodegenerative diseases. This study assesses the association between OSA and α -synucleinopathies, focusing on Parkinson's disease (PD), Parkinson's disease dementia (PDD), and Dementia with Lewy Bodies (DLB), and highlights the influence of demographic factors.

Materials and methods: A retrospective cohort study on 103,785 OSA patients and matched controls was conducted using data from South Korea's National Health Insurance claims database from 2010 to 2019. We investigated the incidence of PD, PDD and DLB in OSA patients, applying chi-square tests, t-tests, and a multivariable logistic regression model to calculate adjusted odds ratios (AOR), with further subgroup analysis by sex and age.

Results: Analysis showed that OSA patients had significantly higher odds ratio for PD (AOR of 2.166, 95% CI: 1.84-2.549, $p < .0001$) and DLB (AOR of 4.001, 95% CI: 1.501-10.66, $p = 0.0056$). Subgroup analysis revealed a stronger association of PD and DLB with OSA in males, with an increased risk in those over 60 years of age.

Conclusions: The study indicates a significant association between OSA and an increased risk of PD and DLB, underscoring the critical role of demographic factors. These insights advocate for enhanced monitoring and tailored management of OSA, especially in patients at higher risk of neurodegenerative diseases, and pave the way for future research into the progression and therapeutic management of these conditions.

Obstructive sleep apnea in the general population - A very common, serious, but treatable chronic condition

E.H. Thorarinsdottir^{1,2}, B. Benediktsdottir², H.S. Palsdottir^{2,3}, J. Potts^{4,5}, A.F.S. Amaral^{4,5}, T. Gislason^{2,3}
¹Primary Health Care of the Capital Area, Reykjavik, Iceland, ²University of Iceland, Faculty of Medicine, Reykjavik, Iceland, ³Landspítali University Hospital, Department of Sleep, Reykjavik, Iceland, ⁴Imperial College, National Heart and Lung Institute, London, United Kingdom, ⁵NIHR Imperial Biomedical Research Centre, London, United Kingdom

Introduction: Obstructive sleep apnea (OSA) is a highly prevalent and multifactorial disorder, strongly associated with other chronic conditions. However, whether population-level screening and treatment of OSA is feasible remains uncertain. This study aimed to estimate the prevalence of moderate to severe OSA in a well-defined, middle-aged general population and to evaluate the feasibility of identifying and treating OSA through population-based screening.

Materials and methods: Icelandic participants in the multinational Burden of Obstructive Lung Disease (BOLD) study were invited to undergo home sleep apnea testing (HSAT). Participants with an apnea-hypopnea index (AHI) ≥ 15 events/hour were offered clinical evaluation. Those who were symptomatic and interested in treatment were referred for positive airway pressure (PAP) treatment.

Results: Of the 378 individuals invited to screening, only 18 declined. Another 26 had a prior OSA diagnosis. A total of 334 (55% male) completed a technically adequate HSAT. Among them, 132 (39.5%) had an AHI ≥ 15 events/hour. Of these, 126 underwent clinical evaluation, and 96 were referred for PAP treatment. Compared to the 30 individuals not referred, the PAP-treated group was younger, had higher mean AHI (30.2 vs. 20.2 events/hour), and a greater prevalence of cardiometabolic comorbidities. PAP initiation and follow-up adhered to standard clinical protocols, although some procedures were modified due to the COVID-19 pandemic. Eleven individuals discontinued PAP within the first three months, and according to hospital records, another 24 had quit by two years. At the two-year follow-up, all 96 were re-invited; 43 were no longer using PAP, while 53 remained long-term users. Among them, 24 had used PAP for more than four hours per night on average in the previous 30 days. Long-term PAP users were more likely to be male and had a higher mean BMI at baseline (32 vs. 30 kg/m²).

Conclusions: Undiagnosed OSA affects approximately one-third of the general middle-aged population. Most individuals identified through screening accepted clinical evaluation and found PAP treatment a feasible option. Long-term adherence to PAP therapy was comparable to routine clinical settings. These findings suggest that population-based OSA detection, clinical management and PAP treatment are achievable goals, with approximately half of those identified with OSA becoming long-term PAP users – corresponding to 15% of the general population.

Acknowledgments: To all participants of the BOLD II study. BOLD II was financially supported by Wellcome Trust grant 085790/Z/08/Z. The Icelandic BOLD was supported by The Icelandic Research Fund (IRF) (Iceland, Reykjavik) and Landspítali University Hospital Scientific Fund.

Obstructive sleep apnea is associated with sympathetic overactivation in non-elderly but not elderly

B. Chen¹, Y. Li¹

¹Shantou University Mental Health Center, Department of Sleep Medicine, Shantou, China

Introduction: Obstructive sleep apnea (OSA) has been noted to associate with sympathetic overactivation. Our previous studies have shown that OSA predicted increased risk of incident hypertension, but the strength of their association significantly decreases with age. We hypothesized that OSA was associated with sympathetic overactivation in non-elderly but not elderly.

Materials and methods: We consecutively recruited adults with OSA from the Sleep Disorders Clinic of Shantou University Mental Health Center. The elderly were defined as age>50 years. The sympathetic activity was assessed by 24-hour urinary norepinephrine. Blood pressure was measured manually in the evening prior to PSG and in the morning right after PSG, with their mean values used for statistical analyses. Interaction terms of age*Time under 90% of SpO₂ [T90], and subgroup of age were introduced to determine the different association between OSA and sympathetic overactivation among patients with different ages. Mediation effect models were used to explore the association between OSA, sympathetic overactivation, and blood pressure in patients with different ages.

Results: A total of 166 OSA patients were included with a mean age of 45.51±10.33 years. Each 1-hour increase in T90 was significantly associated with 4.76-μg increase in 24-hour urinary norepinephrine ($\beta=0.29$, 95%CI=2.30~1.21, $p<0.001$) with adjustment of age, sex, body mass index, hypertensive medication, and REM%. Interestingly, the interaction terms of T90*age and T90*elderly were significant ($p=0.002$ and 0.017). Among the non-elderly, each 1-hour increase in T90 was associated with 6.36-μg increase in 24-hour urinary norepinephrine ($\beta=0.37$, 95%CI=3.41~9.31 $p<0.001$), 3.43-mmHg increase in SBP ($\beta=0.39$, 95%CI=1.84~5.03, $p<0.001$) and 2.99-mmHg increase in DBP ($\beta=0.44$, 95%CI=1.80~4.20, $p<0.001$), whereas such associations were not evident among elderly (all $p\geq0.667$). Mediation effect models showed that the 24-hour urinary norepinephrine significantly mediated the association between T90 and SBP with mediation effect of 13.41%, as well as DBP with mediation effect of 7.67% among non-elderly but not elderly. Consistent findings were also observed in the sensitivity analyses with AHI as independent variable replacing T90.

Conclusions: OSA is associated with sympathetic overactivation in non-elderly but not elderly. Early assessment and intervention should be especially warranted in non-elderly OSA patients.

Acknowledgments: This study was supported by the National Natural Science Foundation of China (82270105 and 82300117), and Noncommunicable Chronic Diseases-National Science and Technology Major Project (2024ZD0529106).

Obstructive Sleep Apnea (OSA): Do symptoms correlate with severity?

K. Raghavachari Suresh¹, G. Dhamodaran¹, N. Namboodiripad Kakkattu Mana^{1,2}, N. Ramakrishnan¹

¹Nithra Institute of Sleep Sciences, Chennai, India, ²Sri Ramachandra Institute of Higher Education & Research, Chennai, India

Introduction: Obstructive Sleep Apnea (OSA) is a common sleep disorder characterized by recurrent partial or complete airway obstruction during sleep. The gold standard method for diagnosis of OSA remains polysomnography (PSG). Cost, limited certified personnel and availability of sleep labs necessitate alternate measures to diagnose OSA. Previous studies have shown a poor correlation between OSA severity and its classic symptoms, such as snoring, witnessed apneas (WA) excessive daytime sleepiness (EDS) and daytime fatigue (DF). This study aims to compare these symptoms across different OSA severities and examine any potential correlation in Indian ethnicity.

Materials and methods: This is a retrospective study involving patients diagnosed with OSA from a tertiary sleep center during the years 2023 and 2024. Data including demographic details, Apnea hypopnea index (AHI), and Epworth Sleepiness Scale (ESS) were collected. These patients were questioned regarding symptoms they experienced which included snoring, WA, EDS, DF. Responses to symptoms were recorded as "Yes", "No", or "Not recorded". Correlations between AHI severity and clinical parameters were done.

Results: Of the 1142 patients diagnosed with OSA, 888 were males (77.7%) and 254 were females (22.3%). There were 274 patients with Mild OSA, 299 patients with Moderate OSA, 569 patients with severe OSA. Snoring was reported by all patients regardless of OSA severity. Assessment of correlation of demographic features with severity of OSA revealed that age was significantly different between the groups except for moderate versus severe. BMI also showed significant correlation with severity of OSA, though there was no difference between mild and moderate OSA. Using logistic regression, EDS, DF, WA had a sensitivity of 90.6% and precision of 0.524 to predict the presence of Mild or Moderate OSA, a 99.8% sensitivity and 65.7% precision for predicting Moderate or Severe OSA, and 100%

sensitivity and 67.7% precision for predicting Mild or Severe OSA. However, ordinal regression showed that a model including all the four symptoms was not a good fit. ESS and WA were the only symptoms which remained significant when expecting likelihood of severity of OSA.

Conclusions: The study indicates that while there is not a uniform correlation between the severity of OSA and reported symptoms such as EDS, DF, and WA, there is a noticeable trend of increased symptom reporting amongst the severe OSA cohort. The findings suggest that older individuals and those with a higher body mass index (BMI) are more likely to experience more severe forms of OSA. The study also highlights the limited precision in the current methods used to assess OSA severity, re-emphasizing the need for more objective diagnostic tools, such as PSG, to provide more accurate and comprehensive diagnosis.

Obstructive sleep apnea (OSA) –The Iceberg In The Sea Of Comorbidities

R. Joseph K¹, S. Kumar²

¹International Sleep Research Training Program Mentee(Class of 2022), World Sleep Society , Aster CMI hospital, Department of Interventional Pulmonology, Bengaluru, India, ²Aster CMI Hospital, Department of Interventional Pulmonology, Bengaluru, India

Introduction: Obstructive Sleep Apnea (OSA) is the second most common sleep disorder, affecting nearly 1 billion adults worldwide.³ The AASM's recent campaign rightly emphasizes that *OSA is more than a snore!*⁴ OSA is often the hidden contributor to diabetes, hypertension, dyslipidemia, stroke, AF, insomnia, depression, GERD, asthma, cognitive decline, and RLS.

Materials and methods: Five life-changing OSA cases transformed by PAP therapy

- **Case 1 (ComOSAR; OSA + RLS/PLMS):** A 73-year-old overweight female with hypertension, Bronchial asthma, pulmonary hypertension, and depression exhibited persistent symptoms despite PAP therapy. Repeat PSG showed severe OSA (AHI 33.9/hr), poor sleep efficiency, PLM index 128/hr, and labs showed iron deficiency. This presentation aligns with *ComOSAR*⁵, observed in ~24% of OSA patients.
- **Case 2 (MS + OSA):** A 66-year-old obese female with stable multiple sclerosis and incidental MCA aneurysm presented with dyspnea; PSG revealed moderate OSA (AHI 21.7/hr). OSA commonly worsens MS symptomatology—including fatigue, cognition, and quality of life.
- **Case 3 (UARS):** A 35-year-old obese female with daytime somnolence, tachycardia, idiopathic intracranial hypertension, and empty-sella syndrome showed mild OSA on Level 1 PSG (AHI 13.3/hr) but a Level 3 study revealed 1,575 flow-limited breaths, diagnostic of *Upper Airway Resistance Syndrome (UARS)*—a condition producing significant sleep fragmentation and daytime dysfunction despite low AHI .
- **Case 4 (Fibromyalgia + Parasomnias):** A 60-year-old obese female with fibromyalgia, rhinitis, and parasomnias exhibited severe OSA (AHI 53/hr). BiPAP titration (IPAP 14/EPAP 10 cm H₂O) resolved sleep paralysis, hypnopompic hallucinations, and significantly reduced fibromyalgia fatigue within a month.
- **Case 5 (OSA-related AF):** A 41-year-old obese hypertensive surgeon with paroxysmal atrial fibrillation and severe OSA (AHI 32/hr) showed a reduction in arrhythmias from 73→24 events on CPAP and further to 12 on BiPAP (IPAP 17/EPAP 12 cm H₂O), with complete apnea resolution

Results: PAP therapy demonstrated profound, system-wide benefits:

1. **ComOSAR:** Resolution of PLMS and RLS symptoms, improved sleep efficiency and PAP adherence—critical as coexistence of OSA and RLS correlates with higher insomnia, cognitive, metabolic, and psychiatric comorbidity .
2. **MS + OSA:** Reduction in daytime fatigue and cognitive load, with enhanced quality of life.
3. **UARS:** Significant decreases in flow-limited breathing episodes and daytime dysfunction following targeted CPAP therapy.

4. **Chronic pain & parasomnias:** Rapid cessation of sleep disturbances and reduction in fibromyalgia-induced fatigue, paralleling research showing PAP benefits in chronic pain conditions.
5. **Cardiovascular:** Substantial reduction in atrial arrhythmias; literature supports a ~30–40% reduction in AF recurrence with PAP therapy, due to improved oxygenation, reduced sympathetic activity, and attenuation of atrial remodeling.

Conclusions: PAP therapy not only treats sleep-disordered breathing—it also mitigates neurophysiological disturbances, chronic pain, and cardiovascular comorbidities. Proactive screening and management of OSA is essential in populations with MS, ComOSAR, and AFib to enhance overall health and quality of life.

Obstructive sleep apnea prevalence and underlying mechanisms in young individuals with post-traumatic stress disorder symptoms

M. Schenker¹, A. White¹, D. Cherian¹, Y. Pan¹, G. Bruce¹, L. Zeng¹, J. Avraam¹, K. Felmingham¹, A. Jordan¹

¹University of Melbourne, Psychological Sciences, Parkville, Australia

Introduction: Obstructive sleep apnea (OSA) has been reported to occur in ~75% of people with PTSD. Most prior studies have assessed military populations who commonly have other OSA risk factors. The aims of this study were to determine whether 1) OSA is more common in individuals with PTSD symptoms exposed to non-military traumas as compared to individuals without PTSD symptoms; and 2) the ventilatory response to arousal from sleep - an OSA endotypic trait - differs according to PTSD symptoms.

Materials and methods: 61 individuals with a range of PTSD symptoms (PTSD symptom checklist for DSM-5, PCL-5) completed an overnight sleep study. OSA prevalence and the ventilatory response to arousal were compared between those with likely PTSD (PCL-5 >33 plus intrusions and Criterion A trauma exposure), sub-syndromal PTSD (PCL-5 = 15-33 plus intrusions and Criterion A trauma exposure) and No-PTSD (PCL-5 <15 and no intrusive symptoms).

Results: Data from 52 participants (36 female) have been analysed: 17 with likely PTSD, 12 sub-syndromal PTSD and 23 No-PTSD. The 3 groups were comparable in age (25±7 years), sex (69% women) and BMI (24.1±4.3 kg/m²). In total, 7 participants had OSA; 4 in the Likely PTSD group, 2 in the sub-syndromal group and 1 in the No-OSA group. The ventilatory response to arousal was assessed in the participants without OSA and found to be significantly larger in individuals with likely and sub-syndromal PTSD as compared to the No-PTSD group (Peak response = 178±17%, 193±23% and 124±8% respectively, ANOVA interaction $p < .001$).

Conclusions: The prevalence of OSA in a young mixed-trauma PTSD population is not as high as that observed in military populations. However, the ventilatory response to arousal is elevated in PTSD and sub-syndromal PTSD, which may predispose to OSA when other risk factors are present such as older age or elevated body mass.

Acknowledgments: We would like to acknowledge funding support from the Melbourne School of Psychological Sciences.

Obstructive Sleep Apnea Syndrome and Recurrent Vasovagal Syncope: Insights from a Multicentric Observational Study

V. Puel¹, I. Godard¹, G. Papaioannou², N. Zarqane³, S. Ibrahim⁴, N. Molinari⁴, F. Gagnadoux⁵, J.-L. Pépin⁶, A. Sabil⁷

³Centre Hospitalier Princesse Grace, Monaco, France, ⁴IDESP, INSERM, PreMedical INRIA, CHU

Montpellier, Montpellier, France, ⁵Angers University Hospital, Department of Respiratory and Sleep Medicine, Angers, France, ⁶University Grenoble Alpes, Inserm, CHU Grenoble Alpes, HP2, Grenoble, France, ⁷Cloud Sleep Lab, Clinical Validation, PARIS 12, France

Introduction: This study evaluates the impact of diagnosing and treating obstructive sleep apnea syndrome (OSA) on the frequency of recurrent vasovagal syncope (RVS) episodes in OSA patients with comorbid RVS.

Materials and methods: A multicentric interventional observational study was conducted in patients with both OSA and recurrent RVS. Patients underwent CPAP therapy for a minimum of 12 months. The frequency of RVS episodes (with (LC+) and without (LC-) loss of consciousness), quality of life, and polysomnographic parameters, during the 6 months prior to CPAP initiation and during the last 6 months before the follow up visit after CPAP, were assessed.

Results: A total of 27 patients (66.7% female; mean age 42.1 ± 12.8 years; mean BMI 25.6 ± 3.5 kg/m²; mean AHI 22.2 ± 12.1 events/hour) completed 12 months CPAP therapy. The frequency of RVS episodes significantly decreased following treatment. The LC+ declined from 25.7 ± 38.6 to 17.7 ± 40.3 ($p < 0.05$), and LC- dropped from 39.7 ± 78.6 to 9.3 ± 8.5 ($p < 0.05$). CPAP therapy was also associated with significant improvements in daytime sleepiness (Epworth Sleepiness Scale: 9.3 ± 6.5 to 3.9 ± 5.7 , $p < 0.01$), fatigue (Pichot Scale: 16.0 ± 9.8 to 3.9 ± 5.1 , $p < 0.001$), and percentage of patients with positive depression scores (35.3% to 9.1%, $p < 0.001$). No statistically significant changes were observed in heart rate variability or 24-hour blood pressure parameters.

Conclusions: CPAP therapy significantly reduces RVS recurrence in patients with OSA, suggesting that OSA is a modifiable risk factor for RVS. These findings highlight the importance of OSA screening in patients with unexplained syncope. Randomized controlled trials are required to mitigate potential bias of the results due to the observational study design.

Obstructive Sleep Apnea Treatment Regulates Monocyte Inflammatory Phenotype and Function

S.-D. Cho¹, S. Hong¹

¹Seoul National University College of Medicine, Boramae Medical Center, Department of Otorhinolaryngology-Head and Neck Surgery, Seoul, Korea, Republic of

Introduction: Obstructive sleep apnea (OSA) is associated with chronic intermittent hypoxia and systemic inflammation, contributing to vascular and metabolic complications. Monocytes, as key mediators of innate immunity, have been implicated in this inflammatory state. However, the effect of OSA treatment on monocyte function and inflammatory phenotype remains poorly understood.

Materials and methods: In this prospective cohort study, OSA patients were evaluated before and after 4 months of continuous positive airway pressure (CPAP) therapy. Circulating monocytes were isolated, and inflammatory cytokine production (TNF- α , IL-1 β , IL-6) was assessed at baseline and post-treatment, both at rest and after LPS stimulation. Monocyte subset distribution (M1/M2) was evaluated by flow cytometry. Clinical severity parameters such as the apnea-hypopnea index (AHI) and oxygen desaturation index (ODI) were correlated with immune changes.

Results: CPAP therapy significantly reduced serum levels of TNF- α and IL-1 β and attenuated LPS-induced cytokine responses. A shift in monocyte phenotype toward an anti-inflammatory M2 profile was observed. These changes were significantly associated with baseline ODI, but not with AHI. Patients with higher ODI showed greater reductions in cytokine levels and more pronounced monocyte reprogramming after CPAP treatment.

Conclusions: CPAP alleviates systemic inflammation in OSA by reducing hypoxic burden and reprogramming monocytes toward an anti-inflammatory phenotype. The magnitude of immune modulation was more closely linked to ODI than AHI, supporting the use of hypoxemia-based metrics for identifying inflammation-prone OSA endotypes and guiding personalized therapy.

Obstructive Sleep Apnoea (OSA) and Continuous Positive Airway Pressure (CPAP): Experience of Chinese Patients in Australia

X. Zhu¹, Y.S. Bin^{2,3}, L. Smith¹, P.A. Cistulli^{2,3}, J.M. Cheung^{1,2}

¹The University of Sydney, Sydney Pharmacy School, Faculty of Medicine and Health, Sydney, Australia, ²The University of Sydney, Sleep Research Group, Charles Perkins Centre, Sydney, Australia, ³The University of Sydney, Northern Clinical School, Faculty of Medicine and Health, Sydney, Australia

Introduction: People of Chinese ethnicity have physiological vulnerabilities for Obstructive Sleep Apnoea (OSA) resulting in high disease prevalence and increased burden of cardiometabolic consequences. While Continuous Positive Airway Pressure (CPAP) therapy is the treatment of choice, treatment engagement among Chinese patients is often suboptimal. Cultural and systemic influences may shape treatment experiences in this group, however, remain under-researched. As such, this study aims to explore the beliefs, experiences, and attitudes towards OSA management from the perspectives of patients of Chinese ethnicity.

Materials and methods: Semi-structured interviews were conducted in a convenience sample of Chinese Australian participants using CPAP treatment for OSA. Participants first completed an online questionnaire and were given an option to be interviewed about their illness and treatment experiences. The interviews were conducted in English or Mandarin depending on participant's preference, recorded, transcribed verbatim and analysed using the Framework Approach to identify emergent themes.

Results: Of 32 returned surveys, 26 participants (mean age 55.1, SD 13.4 years; range 36-81 years, 54% male) were eligible and completed interviews. Eighty-one percent were first-generation immigrants, and 23% of interviews were conducted in Mandarin. The mean duration of CPAP use was 7.7 years (SD 6.6 years), whilst mean duration from diagnosis was 8.9 years (SD 6.9 years). Preliminary analyses unveiled four key themes: disease recognition; help seeking; treatment initiation/acceptance, and ongoing management. Limited awareness of OSA as a medical condition, failure to associate common symptoms with the disease, and notable stigma surrounding OSA and CPAP therapy, were identified as prominent themes that may delay help seeking. Cultural norms such as the perception of snoring as normal, along with influences from family members and social networks, impacted treatment-related decision-making and behaviours. Sustained CPAP use was driven by perceived treatment benefits and fear-based motivation. Lack of systematic follow-up after CPAP initiation, lack of perceived need for follow-up, and uncertainty about appropriate contacts for follow-up were identified as challenges with ongoing disease management.

Conclusions: Findings highlight the need for culturally sensitive education to improve OSA awareness and reduce stigma within Chinese communities. Involving family members or social networks in treatment discussions and emphasising OSA comorbidities and treatment benefits may improve engagement. Scheduled follow-up and ongoing management may support long-term CPAP adherence and reduce attrition.

Opioid-related Central Sleep Apnea Not Detrimental to Key Respiratory and Sleep Parameters: Results from the OpSafe Multicentre Trial

D. Wang¹, B. Yee¹, J. Wu¹, C. Ryan², F. Chung³

¹The University of Sydney, Royal Prince Alfred Hospital, and Woolcock Institute of Medical Research, Sydney, Australia, ²University of Toronto, Toronto General Hospital, Toronto, Canada, ³University of Toronto, University Health Network, Toronto, Canada

Introduction: Opioid-related central sleep apnoea (CSA) is increasingly common, but its clinical implications are poorly understood. Without clear evidence of adverse outcomes, sleep physicians find it difficult to make treatment decisions regarding opioid-related CSA. We analyzed the "OpSafe" (Opioid Safety Program in Pain Clinics) cohort, a large prospective multicenter study of chronic opioid users, to investigate whether opioid-related CSA worsens key respiratory and sleep outcomes.

Materials and methods: Participants on a stable opioid dose for chronic pain were recruited from five university-affiliated tertiary care pain clinics. Measurements included resting daytime oxygen saturation (SpO₂), Epworth Sleepiness Scale (ESS), and overnight in-lab polysomnography (PSG). PSGs were analyzed for sleep-disordered breathing, oxygenation parameters, sleep architecture and quantitative electroencephalography (qEEG).

Results: A total of 160 participants were divided into three groups: 21 CSA, 66 obstructive sleep apnea (OSA), and 73 no-apnea. CSA participants had ~4 times higher opioid dose and exhibited a ~3% lower daytime SpO₂ than OSA and no-apnea participants (all $p < 0.001$). However, during sleep, oxygenation

measures were similar between CSA and OSA groups (all $p > 0.2$). Comparing daytime SpO_2 to sleep mean SpO_2 , OSA group decreased significantly (95.1 ± 1.9 vs $93.9 \pm 2.1\%$, $p = 0.001$), no-apnea group moderately dropped (95.9 ± 1.9 vs $95.1 \pm 2\%$, $p = 0.05$), whereas CSA group had no change in oxygen saturation (92.9 ± 3.4 vs $93.5 \pm 2\%$, $p = 0.66$). CSA event duration was significantly shorter than that of OSA (15.6 ± 4.1 vs 19.4 ± 6.8 seconds, $p = 0.005$). CSAs primarily occurred during non-rapid eye movement (NREM) sleep, with the REM CSA index being a third less than the NREM index [$7.9(1.7-13.9)$ vs $27.7(10-50.1)/hr$, $p < 0.001$]. Sleep architecture and arousal indices in CSA patients were normal except for a reduced REM sleep linked to higher opioid doses. During REM sleep, while CSA was rare, the CSA group exhibited significantly higher Sigma, Alpha and Theta power than the OSA and no-apnea groups. Conversely, during NREM sleep, where CSA predominantly occurred, none of those qEEG band powers significantly differed among the three groups. We also found positive correlations between higher opioid doses and increased Sigma, Alpha, and Theta power during REM sleep. Furthermore, CSA was not a significant predictor of daytime sleepiness, explaining only 1.5% of the variance of ESS. In contrast, opioid dose was a significant predictor of daytime sleepiness.

Conclusions: Our novel findings showed that opioid-related CSA did not worsen key respiratory and sleep outcomes. Instead, it may act as a compensatory response through an augmented hypoxic ventilatory responses/loop gain to counteract opioids' central depressant effects. Opioid-related CSA would diminish if the respiratory depression were resolved, usually through reducing the opioid dose. While a positive airway pressure therapy could potentially improve daytime sleepiness in some chronic opioid users by alleviating hypercapnia, hypoxia, and co-existing OSA, this mechanism is unlikely through treating CSA. While it is essential to mitigate respiratory depression, targeted therapies to reduce opioid-related CSA may be unnecessary.

Acknowledgments: The OpSafe project was funded by the Ontario Ministry of Health and Long-Term Care Innovation Fund. We would like to thank all OpSafe participating centers.

Opioids-Related Modulation of Nocturnal Cardiac Autonomic Responses to Apneas and Hypopneas

A. Assadi^{1,2}, M. Mulot-Hauriez^{1,2}, F. Chung^{1,3}, C. Ryan¹, A. Yadollahi^{2,1}

¹University of Toronto, Toronto, Canada, ²KITE-Toronto Rehabilitation Institute, Toronto, Canada,

³Toronto Western Hospital, University Health Network, Toronto, Canada

Introduction: Heart rate (HR) responses to sleep-related breathing interruptions, such as apneas and hypopneas, reflect autonomic arousal and are linked to cardiovascular risk. Opioids, commonly prescribed for chronic pain, may alter these responses, potentially increasing cardiovascular vulnerability. This study investigated the impact of chronic opioids therapy on heart rate responses to respiratory events during sleep and examined sex-specific differences.

Materials and methods: In this preliminary retrospective case-control study, we analyzed sleep electrocardiogram (ECG) recordings from 20 individuals (≥ 18 years, 10 female) receiving chronic opioids therapy for > 3 months with stable daily dosing for at least 4 weeks. For each opioids-treated participant, 2 matched controls were selected from the Sleep Heart Health Study database using Mahalanobis distance matching based on age, sex, and body mass index (BMI), excluding individuals with major comorbidities. Respiratory events were annotated by sleep physicians following the American Academy of Sleep Medicine guidelines. ECG segments spanning 10 seconds before the start and 10 seconds after the end of each respiratory event were preprocessed, and R-peaks were extracted. All peak detections were visually validated, and segments with unreliable peak detection were excluded. Two outcome measures were used to evaluate heart rate responses to respiratory events: 1) HR_{post} , defined as the average heart rate during the 10 seconds following the end of respiratory event, and 2) HR_{diff} , defined as the difference between HR_{post} and the average heart rate during the 10 seconds preceding the end of the respiratory event. A linear mixed-effects model was used to assess the effect of opioids use on HR responses (HR_{post} , HR_{diff}), accounting for multiple respiratory events per individual and adjusting for sex, age, and BMI. Additional sex-stratified analyses were performed to evaluate sex-specific effects. P-value of 0.05 was considered statistically significant.

Results: The study population had a mean age of 54.7 ± 8.4 years and BMI of 31.7 ± 6.9 kg/m² with no significant difference between individuals with and without opioids therapy (age: 53.5 ± 9.0 vs. 54.9 ± 7.7 years, $p = 0.582$; BMI: 31.9 ± 7.7 vs. 31.8 ± 6.6 kg/m², $p = 0.972$). The average daily opioids dose among treated participants was 201.4 ± 207.5 morphine milligram equivalents. Our results showed that opioids therapy and female sex were independently associated with significantly higher HR_{post} , with

increases of 6.0 bpm and 5.7 bpm, respectively (both $p = 0.014$). In sex-stratified analyses, HR_{post} increase was more pronounced among men (+9.1 bpm, $p = 0.005$), whereas among women the estimated increase was smaller (+3.1 bpm) and not statistically significant ($p = 0.386$). While HR_{diff} did not differ significantly in the overall sample, men using opioids exhibited a significantly greater HR change following respiratory events (+1.15 bpm, $p = 0.047$), in contrast to women, who showed a non-significant reduction (-0.93 bpm, $p = 0.178$).

Conclusions: Chronic opioids therapy is associated with elevated post-event heart rate during sleep, particularly among men, suggesting sex-specific modulation of autonomic cardiac responses to respiratory events. Characterizing these alterations may provide insight into mechanisms underlying opioids-related cardiovascular risk and inform safer clinical management strategies for individuals using opioids.

Oscillometric Lung Function and Its Association with Obstructive Sleep Apnea Risk

L. Soebroto¹, C.M.L. Pradhana²

¹Faculty of Medicine University Sebelas Maret, Surakarta, Indonesia, Pulmonology and Respiratory Medicine, Surakarta, Indonesia, ²Pulmonology resident, Faculty of Medicine University Sebelas Maret, Surakarta, Indonesia, Pulmonology and Respiratory Medicine, Surakarta, Indonesia

Introduction: Obstructive sleep apnea (OSA) is a sleep disorder characterized by repeated episodes of upper airway blockage during sleep, leading to apnea or hypopnea. An apnea is defined as a episode as a reduction in airflow of $\geq 90\%$ lasting at least 10 seconds. A hypopnea is defined as a reduction in airflow of $\geq 30\%$ lasting at least 10 seconds and associated with a $\geq 4\%$ decrease in pulse oxygenation. Collapse or narrowing of the upper airway during sleep is OSA patient can increase resistance airflow in the upper airway. Oscillometry provides a non-invasive comprehensive assessment of lung function by analyzing airway resistance, reactance, and compliance. This multi-dimensional approach allows for detecting abnormalities in the peripheral airways. Oscillometry is a method used to assess upper airway resistance by applying small pressure oscillations to the airway during normal breathing. It measures respiratory system impedance, which includes airway resistance (Rrs) and reactance (Xrs). In OSA patients, increased upper airway resistance, usually in the supine position, can be detected using oscillometry.

Materials and methods: A total of 262 subjects aged 40 years and older were included in this study. The risk of OSA was determined using the STOP-Bang questionnaire, which evaluates clinical parameters including snoring, tiredness during daytime, observed apnea, and high blood Pressure-body mass index, age, neck circumference, sex. Pulmonary function was assessed and evaluated using an oscillometry. Subjects were categorized into low-risk and high-risk groups for OSA. Statistical analyses were performed using independent t-tests and chi-square tests, with a p-value < 0.05 considered statistically significant.

Results: There was no significant difference in age between the groups. High-risk subjects for OSA were more likely to be male ($p = 0.02$), have a higher BMI ($p < 0.05$), and a larger neck circumference ($p < 0.05$). Smoking was also more common in the high-risk group ($p = 0.03$). Comorbidities such as diabetes, cardiovascular disease, and kidney disease were significantly more prevalent in the high-risk group. Oscillometry parameters and respiratory patterns showed no significant differences between the groups.

Conclusions: Individuals at high risk for OSA had significantly higher BMI, neck circumference, smoking prevalence, and comorbid conditions. However, oscillometry findings did not differ between the risk groups, suggesting that respiratory impedance may not be a sensitive marker for differentiating OSA risk.

Acknowledgments: The authors would like to from Universitas Sebelas Maret Hospital and all health workers who assisted and supported this research.

Oximetry-based devices in diagnosis of obstructive sleep apnea: a systematic review and meta-analysis

E. Dantas¹, F. Stelzer¹, W. Bernardo², A. Eckeli¹

¹University of São Paulo / Faculty of Medicine of Ribeirão Preto, Ribeirão Preto, Brazil, ²University of São Paulo / Faculty of Medicine of University of São Paulo (FMUSP), São Paulo, Brazil

Introduction: Obstructive sleep apnea (OSA) is a common disorder, associated with significant morbidity and mortality. Polysomnography (PSG) or a home sleep apnea test (HSAT) is required for OSA diagnosis. Recently, several oximetry-based devices have been developed to assist with diagnosing OSA. This study aims to evaluate the diagnostic performance of these oximetry-based devices compared to PSG.

Materials and methods: We performed research in MEDLINE, EMBASE, Google Scholar, and Lilacs databases. We included studies that evaluated oximetry-based devices in comparison to PSG for OSA diagnosis in adults. Selected studies were divided into two subgroups: consumer wearable devices and medical devices.

Results: A total of 18 studies were included in the analysis, with 4 studies in consumer wearable devices subgroup and 14 studies in medical devices subgroup). The overall sensitivity was 97% (95% Confidence Interval [CI]: 96 – 97%) and specificity was 63% (95% CI: 61 – 65) of oximetry-based devices for OSA diagnosis. In the consumer wearable devices subgroup, sensitivity was 93% (95% CI: 90 – 96) and specificity was 63% (95% CI: 53 – 71). In the medical devices subgroup, sensitivity was also high as 97% (95% CI: 96 – 97) with a specificity of 63% (95% CI: 61 – 65). The summary area under the curve was 0.90 and the estimated post-test probability was 90%.

Conclusions: Oximetry-based devices have high sensitivity and high post-test probability but low specificity in adults at high risk for OSA diagnosis. Further research is necessary to assess these devices, particularly wearable ones, especially in low-risk individuals and those with comorbidities.

PAP titration in patients with OSAS and depression: more difficult, more variable and more complex

A. Rodenbeck¹, J. Behnke¹, M. Dorudian¹, W. Koerber¹

¹Evangelisches Krankenhaus Goettingen-Weende, Pneumology, Respiratory Medicine & Sleep Laboratory, Goettingen, Germany

Introduction: It has been known for 20 years that 21% of adults with depression also suffer from OSAS. Jens Acker and colleagues showed in 2017 that of 322 patients with a polysomnographic AHI of > 9/hour, 21.5% also suffer from clinically significant depression. Conversely, 23.7% of psychiatric patients were found to have OSAS when measured polygraphically in German psychiatric clinics (Behr et al. 2018). The effects on PAP therapy have so far been based primarily on the clinical impression of a more difficult handling of depressed patients.

Materials and methods: We compared OSAS parameters and PAP therapy in 203 patients with OSAS and clinically relevant depression with 125 OSAS patients without psychological comorbidity. All patients underwent an adjustment night with manual PAP titration followed by a first control night with fixed pressure measurement. The entire procedure took place on the same day for the patients in the control group as for the respective patients in the depression group in order to avoid bias due to different practitioners (MTAs and physicians). Depression was considered clinically significant if at least one antidepressant was taken at clinically relevant doses. Antidepressants or antipsychotics in only sleep-improving doses (19.7%) are not considered as an antidepressant medication.

Results: The groups did not differ in terms of age (56.2 ± 11.9 vs 57.3 ± 11.2 years), gender, BMI (33.8 ± 7.8 vs 32.83 ± 5.9), ESS (8.4 ± 4.3 vs 7.6 ± 4.1), AHI (30.2 ± 19.9 vs 32.2 ± 22.1), desaturation index or other OSAS parameters before the start of treatment. Patients with comorbid depression reported significantly more frequent sleep onset difficulties (45.8 vs 23.2%) and took additional sleep medication more often (19.7 vs 3.2%); sleep maintenance difficulties were equally distributed.

PAP therapy was initiated in 90 (44.5%) of patients with depression and in 69 (54.4%) of control patients. Bilevel S titration was more frequent in patients with comorbid depression (41 vs 27 patients). Significantly more depressed patients discontinued treatment after the first night (8.5 vs 4.8%). There were also significantly more patients who underwent polysomnography to check their PAP pressure (e.g. drivers, n=67 vs 42) who were fitted with a bilevel S device (16.4 vs 7.1%). In cases of inadequate PAP therapy on the night of recruitment, 5 patients (4%) in the control group were mostly (80%) switched to bilevel ST/ASV or NIV. In patients with OSAS and depression (n=24, 11.8%), these switches were much more variable. For example, 37.5% switched to bilevel ST, 33.3% to bilevel ST/ASV or NIV and a further 25% switched back from bilevel ST to CPAP/APAP.

Conclusions: Sufficient PAP therapy is much more difficult to achieve in patients with comorbid depression than in patients without concomitant psychiatric illness. Switching to a different PAP modus after one night of measurement was three times as common. Depressed patients therefore require much more time and material resources in the sleep laboratory. A single night of adjustment is not sufficient. A second subsequent night with the possibility of a change in therapy modus including a new practice phase on the day before the second night is necessary.

Acknowledgments: none

Pathway for bariatric/metabolic surgery candidates with obstructive sleep apnea(OSA) at a private Hospital in Brazil

E.L. Brasil^{1,2,3}, H. Libanori^{1,4}, S. Lottenberg^{1,4,5}, E. Lottenberg Vago^{1,6}, S. Márcia Tavares¹

¹Hospital Israelita Albert Einstein, Medical Sleep Assistance Group, São Paulo, Brazil, ²Hospital Israelita Albert Einstein, Department of Critical Care Medicine, São Paulo, Brazil, ³Faculdade Israelita de Ciências da Saúde Albert Einstein, São Paulo, Brazil, ⁴Hospital Israelita Albert Einstein, Medical Obesity, Metabolic and Cardiovascular Risk Assistance Group, São Paulo, Brazil, ⁵University of São Paulo Medical School, Endocrinology, São Paulo, Brazil, ⁶Faculdade Israelita de Ciências da Saúde Albert Einstein, Dentistry, São Paulo, Brazil

Introduction: Obstructive sleep apnea (OSA) is highly prevalent among individuals undergoing bariatric or metabolic surgery (MBS). Studies estimate that over 85% of patients with class III obesity suffer from OSA, highlighting the importance of addressing this comorbidity to reduce surgical risks, particularly respiratory complications, and improve long-term health outcomes. Developing specialized management strategies that integrate care for both obesity and OSA is vital for enhancing patient prognosis. One effective strategy involves the use of Continuous Positive Airway Pressure (CPAP) during the immediate postoperative period to prevent respiratory issues. However, surgeons often avoid using positive pressure in patients undergoing anastomoses in the upper digestive tract due to the risk of air swallowing, which could exert pneumatic pressure on the sutures.

Materials and methods: OSA evaluation begins during the initial medical consultation when MBS is proposed. This evaluation can be conducted by the patient's clinician (such as an endocrinologist, cardiologist, or other specialist) or the bariatric surgeon. The process incorporates standard diagnostic tools as well as specific questionnaires, namely the STOP-BANG questionnaire and the Epworth Sleepiness Scale(EES). Patients identified as having moderate or high risk for OSA are referred for Polysomnography (PSG) or Peripheral Arterial Tonometry (PAT). Those diagnosed with moderate to severe OSA immediately begin a CPAP adaptation program, which educates and trains patients to breathe using CPAP.

The typical preoperative preparation period for MBS lasts at least one month. During this time, medical, nutritional, psychological evaluations, as well as laboratory and imaging tests, are conducted. CPAP adaptation is seamlessly integrated into this timeframe, ensuring it does not prolong the preoperative preparation period.

Results: Patients who successfully adapt to CPAP therapy prior to surgery are encouraged to continue its use postoperatively. This approach minimizes complications such as aerophagia while effectively managing OSA. Follow-up appointments to adjust CPAP use are scheduled to coincide with the surgeon's routine check-ups, occurring at one, three, and six months after surgery. A follow-up PSG/PAT is performed six months postoperatively to reassess OSA status.

Conclusions: The collaborative efforts of a multidisciplinary team—including physicians, physiotherapists, dentists, nutritionists, nurses, and psychologists—enabled the creation of a comprehensive care pathway at HIAE. This initiative significantly reduces the risks for patients with OSA who are candidates for bariatric/metabolic surgery, thereby improving surgical outcomes and enhancing overall patient care.

Acknowledgments: Medical Sleep Assistance Group Hospital Israelita Albert Einstein(HIAE)/ GMA Department of Critical Care Medicine (CPAP Clinic) Hospital Israelita Albert Einstein

PFKFB3 Drives Endothelial Glycolysis, Promoting Vascular Injury under Obstructive Sleep Apnea

S.Q. Li¹, Q.y. Li¹

¹Shanghai Jiao Tong University School of Medicine, Shanghai, China

Introduction: Metabolic-inflammatory crosstalk is a hallmark of cardiovascular pathogenesis. Obstructive sleep apnea (OSA), characterized by chronic intermittent hypoxia (CIH), is an independent risk factor for cardiovascular disease (CVD). While endothelial inflammation driven by CIH is pivotal in CVD progression, the metabolic drivers of this process remain elusive.

Materials and methods: The project included inflammatory and metabolic analyses of ECs under CIH exposure or plasma stimulation model, CIH mouse models, and bioinformatics.

Results: We identified phosphofructo-2-kinase/fructose-2,6-biphosphatase 3 (PFKFB3), a key glycolytic activator, was markedly upregulated in ECs exposed to CIH exposure or OSA plasma stimulation, correlating with a metabolic shift characterized by enhanced glycolysis, suppressed mitochondrial respiration, and amplified inflammatory responses. Endothelial-specific PFKFB3 deficiency or pharmacological suppression of PFKFB3 restored the glycolytic balance and attenuated inflammatory responses. Mechanistically, CIH enhanced the expression of hypoxia-inducible factor 1 α (HIF1 α), which directly stimulated PFKFB3 by binding to its promoter, while PFKFB3 overexpression further amplified HIF1 α levels. Targeting the HIF1 α -PFKFB3 axis alleviated the inflammatory and glycolytic signatures of ECs.

Conclusions: Collectively, our findings identified PFKFB3 as a critical driver of endothelial inflammation fueled by abnormal glycolysis under CIH, offering novel insights into the vascular pathophysiology of OSA-related cardiovascular diseases and potential intervention targets.

Acknowledgments: This work was supported by the National Natural Science Foundation of China (funding no. 82270100, 82070089, 82100102).

Phenotypic and Anatomical Predictors of OSA Severity: Insights from DISE procedure

N. Lichter¹, I. Shochat¹, T. Teitelbaum¹, I. Braverman¹

¹Hillel Yaffe, Otolaryngology, Head & Neck Surgery Unit, Hadera, Israel

Introduction: Obstructive sleep apnea (OSA) severity and treatment responsiveness may depend on the anatomical sites of upper airway collapse. Drug-induced sleep endoscopy (DISE), employing the VOTE classification (Velum, Oropharynx, Tongue base, Epiglottis), offers real-time visualization of these patterns. This study examined how VOTE-defined collapse correlates with apnea-hypopnea index (AHI), hypoxic burden, and clinical phenotypes.

Materials and methods: We retrospectively analyzed 186 adults with OSA who underwent DISE and polysomnography. Each VOTE site was scored from 0 (no collapse) to 2 (complete collapse). Multivariable linear and gamma regressions assessed predictors of AHI and hypoxic burden, with anatomical scores and body mass index (BMI) as covariates. Logistic regressions identified demographic predictors of high collapse (score ≥ 1). K-means clustering (k=5) categorized phenotypes based on anatomical and polysomnographic metrics. Jaw-thrust responses during DISE were assessed in 182 patients.

Results: Velum and oropharyngeal collapse were strongly associated with disease severity. Patients with complete velum collapse (V=2) spent approximately 25 minutes with SpO₂ <90%, compared to under 3 minutes for V ≤ 1 . Oropharyngeal collapse (O=2) was linked to a mean AHI of 42/h, compared to 23/h for O=0. In multivariable models, oropharyngeal collapse ($\beta=5.1$, $p=0.001$) and BMI ($\beta=0.83$, $p=0.003$) emerged as the strongest predictors of AHI ($R^2=0.38$). Velum and oropharyngeal scores significantly predicted hypoxic burden, with each point increase associated with a 25–32% longer desaturation duration ($p<0.01$). Age was a significant predictor of high velum and oropharyngeal collapse (OR 1.06–1.07/year), BMI predicted high velum collapse (OR 1.11), and male sex predicted tongue-base collapse (OR 1.9). Five phenotypic clusters were identified: mild velar, classic oropharyngeal, pan-collapse severe, epiglottic curious, and mixed. Jaw-thrust improved airway patency in 90% of patients. Tongue-base collapse was the only independent predictor of a successful jaw-thrust response (OR 1.69, $p=0.03$), although response rates were consistently high across all phenotypes.

Conclusions: This study demonstrates that anatomical sites of collapse distinctly influence OSA physiology: the oropharynx drives AHI severity, while velar collapse predominantly impacts oxygen desaturation. Demographics such as age, BMI, and sex shape anatomical vulnerability. DISE-based phenotyping highlights the heterogeneity of OSA and supports stratified treatment planning. Jaw-

thrust success, particularly in tongue-base collapse, reinforces the relevance of mandibular advancement simulations.

Acknowledgments: I Would like to thank Dr. Isaac Shochat of the ENT department in Hillel Yaffe medical center (Israel) for his invaluable assistance in this research.

Polycystic Ovary Syndrome is associated with Masked Hypertension in Reproductive-Aged Women: Role of Obstructive Sleep Apnea

H. Wang¹, F. Han², X. Dong³, F. Gao⁴, X. Chen⁴, H. Han⁴, Y. Wang⁴, H. Shen⁴

¹peking university, Beijing, China, ²peking university people's hospital, Division of Sleep Medicine, Beijing, China, ³Peking University Peoples' Hospital, Division of Sleep Medicine, Beijing, China,

⁴Reproductive Center of Peking University Peoples' Hospital, Beijing, China

Introduction: Women with polycystic ovary syndrome (PCOS) face increased cardiovascular disease risk earlier than others. This study aimed to identify abnormal blood pressure(BP) profile in patients with reproductive-aged PCOS compared to matched controls, and determine whether OSA contributes to elevated blood pressure and masked hypertension in patients with PCOS.

Materials and methods: The study finally included 176 reproductive-aged women who scheduled to receive firstly assisted reproductive technology (ART), including 111 patients with PCOS according to the Rotterdam criteria and 65 controls matched age and BMI, from reproductive center of Peking University People's Hospital between July 2023 and October 2024. All participants underwent standard office BP measurements, and overnight home sleep apnea test (HSAT) by NOX-T3 device before ART cycle, followed by 24-hour ambulatory blood pressure monitoring (ABPM) the next morning. ANCOVA and generalized linear models compared groups in 24-hour BP readings, multivariate linear regression examined links between OSA severity and BP measurements, and logistic regression assessed the relationship between OSA and masked hypertension and its component, all adjusting for confounders such as age, BMI, central obesity, HOMA-IR, and DM.

Results: Women with PCOS demonstrated higher rates of masked hypertension (daytime and 24-hour hypertension) compared to matched controls (3.1% vs. 18.0%, $P=0.018$; 4.6% vs. 17.1%, $P=0.044$), even after adjusting for HOMA-IR factor. This cardiovascular risk profile was accompanied by a markedly higher prevalence of OSA in the PCOS cohort (44.1% vs. 20.0%, $P<0.001$), with a mean AHI of 7 events/hour. Within the PCOS group, we observed a dose-response relationship between OSA severity and the prevalence of masked hypertension and its components (all $P<0.01$). Multivariate regression analysis confirmed that AHI was positively correlated with ambulatory BP measurements, including 24-hour, daytime, and nocturnal systolic/diastolic BP ($\beta = 0.56, 0.34, 0.49, 0.31, 0.77, 0.45$, respectively; all $P<0.001$), and it also as a significant risk indicator for masked hypertension in PCOS patients (adjusted $P<0.05$). Using the clinically relevant threshold of $AHI \geq 10$ events/hour, OSA was associated with substantially increased risks of masked hypertension, including daytime hypertension (aOR=8.20, 95% CI: 1.74-38.62, $P=0.008$), and 24-hour hypertension (aOR=6.33, 95% CI: 1.39-28.90, $P=0.017$). A similar trend was observed for nocturnal hypertension, though this did not reach statistical significance (aOR=3.31, 95% CI: 0.91-12.03, $P=0.069$). Importantly, differences in 24-hour BP profiles between PCOS and non-PCOS groups disappeared entirely when patients with OSA were excluded from the analysis.

Conclusions: Women with PCOS exhibit higher 24-hour BP levels and increased rates of masked hypertension compared to matched controls, primarily mediated by OSA. This finding strongly suggests that OSA may be a key contributor linking PCOS to abnormal blood pressure regulation and increased cardiovascular risk in reproductive-aged women.

Polysomnographic Diagnosis of Obstructive Sleep Apnea in Patients Presenting with Insomnia Symptoms: A Retrospective Observational Study

H. Errabelli¹, M. Chirutha², P. Boianapalli³

¹Sleep Therapeutics, Pulmonology, Hyderabad, India, ²Sleep Therapeutics, Pulmonology & Sleep Medicine, Hyderabad, India, ³Prathima Hospitals, Internal Medicine, Hyderabad, India

Introduction:

Insomnia and obstructive sleep apnea (OSA) frequently co-occur, and in some cases, OSA may be the underlying aetiology of insomnia. However, this overlap is often under-recognised, particularly when patients present primarily with difficulty initiating or maintaining sleep. Misdiagnosis or missed diagnosis may result in delayed or suboptimal treatment. This study aims to assess the prevalence of OSA in patients referred for insomnia symptoms and to evaluate the utility of overnight polysomnography (PSG) in this population.

Materials and methods:

We conducted a retrospective observational study at Sleep Therapeutics, an advanced sleep medicine center located in Hyderabad, Telangana, India. A total of 166 adult patients who underwent overnight PSG between July 2023 and June 2025 were included. All patients presented with primary complaints of sleeplessness either sleep onset issues or sleep maintenance issues or both. OSA was diagnosed using standard criteria with an apnea-hypopnea index (AHI) ≥ 5 . Gender-specific prevalence and other PSG parameters were analysed.

Results:

Of the 166 patients assessed, OSA was diagnosed in 66.2% of males and 33.8% of females. These findings demonstrate that a significant proportion of individuals presenting with insomnia symptoms had undiagnosed OSA, and they were treated as having insomnia for a long period. Additional parameters-including sleep latency, sleep efficiency, arousal index, respiratory disturbance index (RDI), oxygen desaturation index (ODI), and reasons for arousals-revealed notable disruptions in sleep architecture. These findings will be detailed in the accompanying poster.

Conclusions:

A substantial number of patients with insomnia symptoms were found to have underlying OSA on PSG. These results underscore the importance of considering OSA in the differential diagnosis of insomnia in cases who present with complaints of sleeplessness. PSG should be recommended not only in chronic or refractory insomnia cases but also during initial evaluations when patients report minimal improvement with conventional insomnia therapies.

Acknowledgments: I acknowledge the support of Sleep Therapeutics, Hyderabad, India, my team who support me everyday, and the patients whose participation made this study possible.

Positional Obstructive Sleep Apnoea: When and Why the Neck-based Vibrotactile Device Fails

M. Del Forno¹, A. Riglietti², M. Manconi²

¹ASL2 Abruzzo, Pulmonology Clinic, Vasto, Italy, ²Neurocenter of Southern Switzerland, Regional Hospital of Lugano, Sleep Medicine Unit, Lugano, Switzerland

Introduction:

The efficacy of positional therapy with a neck vibrotactile device for positional obstructive sleep apnoea (POSA) has been demonstrated, but its inefficacy in changing body position has not been equally explored. The primary aim of this study was to evaluate the failure rate of the neck vibrotactile positional therapy in POSA. Secondary aims were: to investigate the reliability of a single night sleep study for labelling a supine sleeper, any differences on supine time between the laboratory and the home environment, the impact of the device on snoring and the compliance.

Materials and methods: A retrospective observational study reviewed patients with a diagnosis of POSA according to Cartwright and who had received monitoring and/or treatment with a Night Shift™ (NS) Sleep Positioner neck device for 4 nights in Monitor or Therapy mode or both. The diagnosis of POSA was made on respiratory polygraphy or polysomnography and a minimum supine sleep time of 15% was required. A supine sleeper was defined if supine sleep time at home was $> 5\%$ at least in 2 nights of neck vibrotactile device in Monitor mode. Failure was defined as continuous vibration time ≥ 5 minutes and a supine time $> 5\%$ in at least 2 nights.

Results: Ninety two adult patients were enrolled. The failure rate, restricted to 74 patients who had received the neck vibrotactile device in Therapy mode for ≥ 2 nights, was 14.8%, with a compliance rate of 96%. Non-supine sleepers at home were 13/74 (17.5%). A significant reduction of supine sleep time at home was observed in comparison with the diagnostic sleep study (23.9% vs 51%, $p < 0.001$).

Snoring rate was significantly reduced while using the vibrotactile device in Therapy mode versus Monitor mode.

Conclusions: Considering the failure rate of the device in changing body position, and the rate of patients that at home spontaneously do not sleep in supine position, around 32% of positional therapy prescribed might be inappropriate. An adequate trial with the neck vibrotactile device, in diagnostic and therapeutic modality, might disclose these cases. Main reasons for inefficacy are: sedatives, chronic sleep deprivation, motor limitations and cognitive impairment.

Acknowledgments: The statistical analysis was performed by Prof Rossella Baldini.

The idea of the project comes from the collaboration with Prof. Mauro Manconi, Dr Alessia Riglietti and the Sleep Team in Lugano.

Potential Markers of Brain Impairment Secondary to Obstructive Sleep Apnea: The Brain Asymmetry

J. Liao¹, Y. Shi¹, Y. Li¹, D. Han¹

¹Beijing Tongren Hospital, Capital Medical University, Department of Sleep Medical Center, Beijing, China

Introduction: Obstructive sleep apnea (OSA) is one of the leading causes of sleep disorders and often exhibits psychological impairments. Brain asymmetry (BA) is an important marker of psychological traits. OSA is strongly associated with brain activity and psychological disorders. And BA alterations could be observed in people with psychological disorders and motivational abnormalities. Our previous studies have found that OSA exhibits elevated BA during both sleep and daytime, and is associated with psychological abnormalities. Unfortunately, there is no evidence to support whether BA is secondary change in respiratory events or individual heterogeneity. Therefore, this study aimed to explore BA patterns during peri-obstructive sleep apnea-hypopnea.

Materials and methods: A total of 71 subjects with symptoms of OSA, such as nocturnal snoring, frequent arousal, and daytime sleepiness, were recruited for polysomnography (PSG) at the Sleep Medicine Center of Beijing Tongren Hospital. Inclusion criteria included adults aged ≥ 18 years, while exclusion criteria included severe pulmonary, cardiovascular, or cerebrovascular diseases, history of metal implants in the head, pregnancy, or non-cooperation with the examination. PSG was conducted using the Grael device, and EEG signals were recorded from the frontal, central, and occipital regions. Respiratory events (apnea or hypopnea) lasting >15 seconds with intervals >20 seconds were extracted and analyzed for BA changes. Power spectral density (PSD) was calculated for delta (0.5-4 Hz), theta (4-8 Hz), alpha (8-14 Hz), beta (14-30 Hz), and gamma (30-100 Hz) bands. Statistical analyses were performed using R software, and BA was assessed using the formula $\ln[\text{right}] - \ln[\text{left}]$.

Results: A total of 6445 respiratory events were extracted from 71 subjects, with 1265 events in N1, 3655 in N2, 62 in N3, and 1463 in REM sleep stages. BA was significantly elevated during respiratory events in the frontal and central regions, with a uniform pattern across frequency bands ($P < 0.0001$). In the occipital region, BA decreased during respiratory events and rose abruptly at the end of the event ($P < 0.001$). Subgroup analyses indicated that alpha, beta, and gamma bands were the main contributors to BA fluctuations. Non-severe and severe OSA exhibited similar trends in BA changes.

Conclusions: The findings suggest that respiratory events in OSA patients trigger bilateral cerebral asymmetry, with alpha, beta, and gamma bands playing a significant role in BA fluctuations. This study provides evidence that BA may serve as a marker and characteristic phenotype of brain impairment secondary to OSA, highlighting the causal relationship between sleep disorders and psychological disorders. Further research is needed to explore the implications of BA in the context of OSA-related cognitive and emotional impairments.

Acknowledgments: We appreciate the active cooperation of the medical and technical staff of Beijing Tongren Hospital Sleep Medicine Centre in the study. Research data can be requested from corresponding authors and shared in a desensitized form after review and approval.

Precision Oral Appliance Therapy :The Leading Non-surgical Alternative to CPAP in the treatment of OSA

E. Sall¹

¹Crouse Irving Hospital, Otolaryngology, Syracuse, United States

Introduction: In 1981, Dr Colin Sullivan in a landmark paper in the Lancet introduced CPAP for the treatment of Obstructive Sleep Apnea (OSA). Despite being labeled as the "gold standard", compliance has not improved significantly over the last 44 years. Precision Oral Appliance therapy has now emerged as the leading non-surgical alternative to CPAP. The latest studies and research will be reviewed in detail in support the improved effectiveness in Precision Oral Appliance Therapy compared to Oral Appliance Therapy in the past.

Materials and methods: This oral scientific session will review 15 clinical studies that involved 1431 patients over multiple clinical sites. This review is from studies utilizing Precision Oral Appliance Therapy for the treatment of all levels of severity in the treatment of OSA. The studies were conducted in the US Army, Portugal, Belgium, England and multiple clinical sites in the US. Success criteria utilized was the standard criteria utilized in determining surgical success (Sher's Criteria: >50% reduction in the AHI and/or AHI <20).

Results: 15 clinical studies involving 1431 patients across multiple sites showed a Mean Efficacy and Median Efficacy of 85% when utilizing the Sher's Criteria for surgical success. Patient compliance averaged 90% and side effects including jaw pain, tooth movement and TMJ dysfunction were minimal.

Conclusions: Despite the high "efficacy" of CPAP in the treatment of OSA, its real world "effectiveness" is compromised by poor compliance or adherence. While Precision Oral Appliance Therapy has lower efficacy than CPAP in the treatment of OSA, its "effectiveness" may be equal to or greater than CPAP when compliance is taken into account. Since mean disease alleviation and health outcomes show little difference between CPAP and Precision Oral Appliance Therapy these studies support an alternative treatment paradigm. Precision Oral Appliance Therapy may be now considered non-inferior to CPAP in all levels of severity of OSA with the results presented in this scientific oral presentation.

Acknowledgments: ProSomnus Sleep Technologies supported these studies.

Preclinical Evaluation of a Dual Target Neurostimulator Implant System for Obstructive Sleep Apnea at 34 Weeks

E. Ottestad¹, J. McCabe², K. Meng², D. Herron², S. Russell², G. Raux², J. Sutor², T. Ciciarelli², P. Paspas², D. Potts², R. Capasso¹

¹Stanford University, Stanford, United States, ²Restera Sleep, Santa Clara, United States

Introduction: Neuromodulation for the treatment of obstructive sleep apnea (OSA) is an emerging alternative therapy to positive airway pressure. While hypoglossal nerve (HGN) stimulation solutions are commercially available, research into other nerve targets has identified the ansa cervicalis (AC) as a promising candidate for stimulation in combination with HGN stimulation. Recent acute human studies have demonstrated the ability to improve airway collapsibility when stimulating both targets independently and simultaneously. Here, we present chronic results up to 34 weeks (8.5 months) post-implant of an ongoing study to evaluate the stability of the Restera Dual Target Neurostimulator Implant System in a large animal model.

Materials and methods: One Yucatan minipig (male, 44 kg) was implanted with a prototype of the Restera Dual Target Neurostimulator Implant System (Restera, Inc., Santa Clara, CA, USA), comprising two leads tunneled to an implantable pulse generator (IPG). Both leads were percutaneously inserted under ultrasound guidance. Each lead had two stimulating electrodes and two sets of anchoring fins to provide mechanical stability at the distal end. The leads were deployed adjacent to the corresponding nerve target (either HGN or AC). Follow-up visits were performed under general anesthesia at 2, 4, 8, 11, 22, 26 and 34 weeks to assess stimulation thresholds based on airflow measurements using the SFM3300-D flow sensor (Sensirion AG, Stäfa, Switzerland). For each lead independently, the threshold was defined as the minimum current amplitude (in mA) required to induce contraction of the corresponding muscle (genioglossus or infrahyoid strap muscles) that restored airflow to eupneic levels. Starting from the 11-week visit, dual target stimulation at threshold values (or above) with duty cycle was continuously delivered in the absence of external flow support for about one hour to assess stability over extended periods of stimulation.

Results: Electrical stimulation delivered to electrodes of both leads successfully activated the target nerves. During implant surgery, 3-Hz stimulation led to observable twitching responses of the corresponding muscles, confirming appropriate electrode placement near the nerves. During implant

surgery and follow-up visits, 40-Hz tonic stimulation led to sustained muscle contraction and airflow improvement. Stimulation thresholds remained stable over a period of 34 weeks with values ranging between 1.5-3.5 mA at the HGN target and between 0.32-1.5 mA at the AC target. Extended dual target stimulation consistently resulted in sustained airflow improvement over the entire stimulation period at each follow-up visit.

Conclusions: The prototype system used in this ongoing study to stimulate HGN and AC nerve targets demonstrated appropriate stability for chronic therapy, evidenced by the sustained ability to improve anesthetized airflow through contractions of the genioglossus and infrahyoid strap muscles. Future clinical studies will investigate the applicability of the proposed therapy for human patients with OSA.

Acknowledgments: The study was approved by the Institutional Animal Care and Use Committee (IACUC) and supported by the veterinary staff of LabCorp.

Predictors of successful reduction in AHI after Yoga-based intervention for treatment of obstructive sleep apnea

A. Gupta¹, P. P S Bhat¹, J. Kaur², P. Lamo¹, U. Singh¹, G. Shukla³, B. Mohan⁴, G. Sharma^{1,5}

¹Center for Integrative Medicine and Research, All India Institute of Medical Sciences, New Delhi, India, ²All India Institute of Medical Sciences, New Delhi, Cardio-Neuro Center, New Delhi, India, ³Kingston Health Sciences Centre & Queen's University, Kingston, Canada, ⁴Dayanand Medical College and Hospital, Ludhiana, India, ⁵All India Institute of Medical Sciences, New Delhi, Department of Cardiology, New Delhi, India

Introduction: Non-pharmacological interventions have been shown to improve obstructive sleep apnea (OSA) and result in a 30-40% reduction in the apnea-hypopnea index (AHI). Recently, yoga has emerged as a potential intervention for treating OSA; however, treatment responses vary among patients. The study aims to identify the predictors of effectiveness of yoga in reducing apnea-hypopnea index (AHI).

Materials and methods: We have merged the patient data from two randomized controlled trials who underwent yoga-based intervention for treating OSA. Patients who reduced their AHI by 40% or more (Group 1) on 6-month follow-up after a yoga-based intervention were considered treatment-responsive, while those with less than a 40% reduction in AHI (Group 2) were considered non-responsive to treatment. All baseline clinical and polysomnography parameters were compared between the responsive and non-responsive patients.

Results: Baseline data of 19 patients aged 47.21 ± 10.1 years, and 13 (68.42 %) were male, nine were responsive, and 10 were non-responsive and were included in the analysis. Mean 49.1 and $9 \pm 0.12\%$ AHI reduction occurred in the responsive and non-responsive groups. REM AHI was significantly higher among responsive patients ($64.62, \pm 38.55$ vs $25.36, \pm 15.84657$, $p=.03$). The mean baseline BMI was higher among non-responsive patients. However, there was a lack of statistical significance. (30.74 ± 3.99 vs 35.07954 ± 5.490883 , $p=0.07$). The number of patients with NREM-dominant OSA were significantly more common in Group 2 (11% vs 70%, $p=0.02$).

Conclusions: Morbid obesity and NREM-dominant obstructive sleep apnea (OSA) are predictors of a poor treatment response, and the severity of REM sleep apnea is a predictor of the effectiveness of yoga intervention in reducing apnea-hypopnea index (AHI).

Acknowledgments: We thank all the staff at the Centre for Integrative Medicine and Research (CIMR) for providing administrative and logistical support. We also acknowledge the Ministry of Ayush, Government of India, for their support through the Centre of Excellence scheme to the CIMR, AIIMS, New Delhi, India. We also thank Mrs Jyoti Katoch for data entry and management, Sumit Kushuwaha and Pratap Biswas for polysomnography acquisition and scoring.

Predictors of surgical outcomes for limited palatal muscle resection in patients with obstructive sleep apnea

K.-S. Cho¹, H.-J. Park², S.J. Mun³

¹Pusan National University School of Medicine, Pusan National University Hospital, Department of Otorhinolaryngology, Busan, Korea, Republic of, ²Pusan National University Hospital, Department of

Otorhinolaryngology, Busan, Korea, Republic of, ³Pusan National University Yangsan Hospital, Department of Otorhinolaryngology-Head and Neck Surgery, Yangsan-si, Korea, Republic of

Introduction: Limited palatal muscle resection (LPMR) is a modified palatal surgical technique to correct retropalatal obstruction without complications. This study aims to determine the associated factors affecting the success and cure rate of LPMR in patients with obstructive sleep apnea (OSA), thus guiding patient selection and improving surgical outcome.

Materials and methods: Thirty-five OSA patients underwent LPMR were enrolled. All patients received routine physical examination, preoperative drug-induced sleep endoscopy (DISE), and polysomnography (PSG). Clinical, polysomnographic, cephalometric variables, and DISE findings were evaluated. These measurements were compared between the surgical success and failure group based on the results of preoperative and postoperative PSG. Furthermore, we compared the cured and non-cured groups in the surgical success group.

Results: Among 35 patients, the overall success rate was 57 % with a cure rate of 31.4 %. Patients with Friedman stage II had a significantly higher success rate ($p = 0.032$). According to DISE results, tongue base obstruction affected the surgical outcome ($p < 0.001$). The success rate was 100 % in the no tongue base obstruction during DISE, 72.2 % in the partial obstruction, and 9.1 % in the total obstruction. Tonsil size is also helpful in predicting surgical success rate ($p = 0.041$). Furthermore, patients with mild AHI were more likely to be surgical cures. when compared with patients with severe AHI ($p = 0.044$).

Conclusions: Patients with larger tonsil size and no tongue base obstruction during DISE may have a higher chance of surgical success with LPMR. The lower AHI may be predictors of surgical cure after LPMR.

Preliminary study of the effects of Nortriptyline on OSA indices and snoring intensity in patients with OSA: a pilot study

P. Adimi Naghan¹, F. Mohammadi Aniloo¹, J. Setare², Z. Naderpoor³, S. Shaabani¹, E. Sabokdel⁴
¹Shahid Beheshti Medical University, Masih daneshvari Hospital, Sleep Lab, Tehran, Iran, Islamic Republic of, ²Mazandaran Medical University, Tehran, Iran, Islamic Republic of, ³Tehran Medical University, Shariati Hospital, Tehran, Iran, Islamic Republic of, ⁴Dr.Abidipharmaceuticals member of Cobel group, Tehran, Iran, Islamic Republic of

Introduction: Obstructive Sleep Apnea (OSA) is a common breathing disorder with long-term neurocognitive and cardiovascular consequences. Despite CPAP being the gold standard, many patients are intolerant. This has led to the exploration of alternative pharmacological therapies that can reduce obstruction by modulating the activity of respiratory muscles and neurotransmitters. Tricyclic antidepressants (TCAs), by blocking the reuptake of serotonin and norepinephrine, are among the drugs used. Nortriptyline, from this drug class, has the least affinity for muscarinic and histaminic receptors and has fewer side effects and is better tolerated compared to other drugs in this class. This pilot study investigates the effect of Nortriptyline on key OSA indices.

Materials and methods: This single-arm, open-label pilot study will recruit adult patients diagnosed with obstructive sleep apnea (OSA) [AHI > 15 on polysomnography (PSG)] who report intolerance or refusal to use continuous positive airway pressure (CPAP). Participants will receive oral nortriptyline 25 mg once daily, 30 minutes before bedtime, for a duration of four weeks. Feasibility will be assessed by recruitment and retention rates. Safety and tolerability will be monitored through adverse event reporting using the PRISE questionnaire and clinical assessments.

Preliminary efficacy will be evaluated by comparing changes from baseline to the end of the four-week treatment period in key OSA parameters measured by PSG, including the Apnea-Hypopnea Index (AHI), Arousal Index (Arl), and minimum oxygen saturation. Snoring intensity will be assessed using a Visual Analog Scale (VAS). Descriptive statistics will summarize patient characteristics, feasibility, and safety outcomes. Paired statistical tests will be used to explore potential changes in respiratory parameters and snoring intensity following nortriptyline administration. A sample size of 12 participants will be targeted to provide initial data for future controlled trials.

Results: In this study on 12 patients, after one month of treatment period, the mean Apnea-Hypopnea Index (AHI) decreased from 37.25 to 30.83 ($p=0.0026$). The mean score on the Epworth Sleepiness

Scale (ESS) decreased from 12.5 to 8.33 ($p=0.0001$). Also, the mean Sleep Efficiency (SE) improved from 73.83% to 87.75% ($p=0.0047$), which is considered a statistically significant change. In addition, the mean snoring intensity improved from 8.9 to 3.5, and the mean minimum blood oxygen saturation (Min SpO₂) improved from 82.41% to 83.33%.

Conclusions: The intervention improved sleep efficiency, reduced daytime sleepiness, and decreased the severity of sleep apnea and snoring. However, due to the small sample size, findings should be interpreted cautiously. Further investigation in larger trials is necessary to explore the effects of this intervention and its applicability to a wider population.

Acknowledgments: We express our sincere gratitude to all the patients who participated in this study, as well as to the medical staff and research personnel for their invaluable contributions.

Pressure Pays Off: Reducing Healthcare Burden in Moderate OSA with PAP Therapy

K.L. Sterling¹, RB. Dexter², C. Woodford², W. McConnell¹, K.V. Cole¹

¹Resmed Science Center, San Diego, United States, ²Resmed Science Centre, Halifax, Canada

Introduction: Obstructive sleep apnea (OSA) is a sleep-breathing disorder that can negatively impact daytime functioning, cardiovascular and pulmonary health, and quality of life when left untreated. Generally, the severity of OSA is determined by the apnea hypopnea index (AHI) where an AHI of 5-14.9 events per hour (e/hr) is mild, 15-29.9 e/hr is moderate, and greater than 30 e/hr is severe. Positive airway pressure (PAP) therapy is often recognized as first line treatment for OSA, yet globally there are differing requirements for determining a patient's eligibility to receive PAP. The aim of this study was to test the hypothesis that increased PAP therapy usage would be associated with reduced healthcare resource use and costs in a population of patients with moderate OSA.

Materials and methods: This was a retrospective cohort study conducted among patients with a sleep test (ApneaLink, Resmed) that diagnosed moderate OSA and initiated PAP therapy between March 2015 and October 2021. The sleep test and PAP therapy data were linked to administrative claims data through tokenization. Patients were required to have 1 year of data available prior to PAP initiation (index) and 2 years post. PAP adherence over 2 years was defined as adherent, intermediate, or non-adherent based on US Medicare criteria. Healthcare resource use was defined as occurrence of emergency room (ER) visits and hospitalizations. Healthcare costs were defined as total or associated with ER visits or hospitalizations. Inverse probability of treatment weighting was used to balance PAP adherence groups on baseline covariates.

Results: 9,157 patients met inclusion criteria, 38% were female, had an average age 52.5y and average AHI of 21.2 e/hr. 54.1% of patients had comorbid hypertension, 50.6% hyperlipidemia, 25.1% gastroesophageal reflux disease, 21.3% anxiety, 19.5% depression, and 18.5% type 2 diabetes. 77% were at least intermediately adherent to PAP therapy over 2 years (35% adherent, 42% intermediate, 23% non-adherent). Over 1 year, relative to non-adherence, adherent patients had a 19% lower risk for an ER visit (risk ratio (RR): 0.81, 95% confidence interval (CI): 0.73-0.90), 35% lower risk for hospitalization (RR: 0.65, 95% CI: 0.52-0.82), and lower total (US\$8,203 vs. US\$8,563, $p=0.004$), ER visit (US\$304 vs. US\$342, $p<0.001$), and hospitalization (US\$899 vs. US\$1,405, $p<0.001$) costs. Similarly, over 2 years, relative to non-adherence, adherent patients had a 13% lower ER visit risk (RR: 0.87, 95% CI: 0.80-0.94), 26% lower hospitalization risk (RR: 0.74, 95% CI: 0.62-0.87), and lower total (US\$16,116 vs. US\$16,364, $p=0.013$), ER visit (US\$624 vs. US\$705, $p=0.001$), and hospitalization (US\$1,968 vs. US \$2,474, $p=0.003$) costs. Resource use and costs for intermediately adherent patients generally fell between that of adherent and non-adherent patients.

Conclusions: This analysis supports the usage of PAP therapy in patients with moderate OSA to reduce the risk of hospitalization and ER visits and lower healthcare costs in the first 2 years of therapy. These insights should be used to raise awareness of the importance of assessing for and treating OSA in patients with moderate severity.

Acknowledgments: This study was funded by Resmed.

Prevalence and characteristics of obstructive sleep apnea (OSA) comorbid with catathrenia (nocturnal groaning)

M. Yu¹, Y. Wen², Z. Hao³, L. Xu², F. Han², X. Gao¹

¹Peking University School and Hospital of Stomatology, Orthodontics, Beijing, China, ²Peking University People's Hospital, Sleep division, Beijing, China, ³Capital Medical University, Xuanwu Hospital, Stomatology, Beijing, China

Introduction: Catathrenia (nocturnal groaning) is a rare sleep-related breathing disorder, but the comorbidity of catathrenia with obstructive sleep apnea (OSA) is not uncommon. This study highlights the prevalence, clinical, polysomnographic, and craniofacial characteristics of this comorbidity to raise awareness in clinical practice.

Materials and methods: This study was conducted across two independent sleep centers, including 1,123 participants (741 males/382 females), with an average age of 46.3 ± 14.0 y. Patients were diagnosed using full-night video polysomnography (PSG) and acoustic analysis was conducted to classify snoring and groaning sounds using a deep convolutional neural network. The cluster analysis was conducted to analyze subgroups of catathrenia, and inter-group polysomnographic characteristics were investigated. Additionally, craniofacial cone-beam CT was performed to assess the upper airway and surrounding structures. Mandibular advancement devices (MAD) and positive airway pressure (PAP) were used as treatment, and their efficacy was evaluated using PSG.

Results: Among the 1,123 participants, 865 (77.03%) were diagnosed with OSA, with 78 (6.95%, 76 males/2 females) also having comorbid catathrenia. Conversely, only 10 (0.89%, 5 males/5 females) of participants were diagnosed with primary catathrenia. Acoustically, snoring and groaning sounds exhibited distinct characteristics: snoring displayed an irregular waveform, while groaning had a sinusoidal or sawtooth waveform with a discernible fundamental frequency. Cluster analysis revealed two distinct subgroups of catathrenia. Compared to normal references, patients with OSA presented with a retrusive mandible and narrow palatopharynx, whereas patients with catathrenia had a well-developed mandible, and broad palatopharynx, yet narrow hypopharynx. The groaning index decreased significantly from 5.8(2.7,14.3) to 2.8(1.3, 12.2) ($p=0.014$) with MAD treatment.

Conclusions: This study suggests that catathrenia may be more prevalent among patients with OSA and that those with comorbid catathrenia exhibit distinct characteristics, including differences in sex distribution, AHI, acoustic features, and upper airway anatomy. Groaning sounds might be active, vocal sounds to overcome obstructions in the hypopharynx.

Prevalence and Characteristics of Positional Obstructive Sleep Apnea in a Racially Diverse Pediatric Population: Preliminary Results from a Community-Based Study

C.T. Au¹, Z. Beidas¹, S. Waraich¹, G. Subramanian², P. Papneja², I. Narang¹

¹The Hospital for Sick Children, Translational Medicine, Toronto, Canada, ²Richmond Hill Sleep and Lung Institute, Richmond Hill, Canada

Introduction: Positional obstructive sleep apnea (POSA) is characterized by upper airway obstruction that worsens when individuals sleep in supine position. This OSA subtype is commonly seen in both adults and children. Currently, there is a lack of knowledge regarding the prevalence of POSA in otherwise healthy children who may benefit from personalized treatment, specifically positional therapy, as an alternative to surgical intervention and CPAP. The objective of this study is to determine the prevalence and characteristics of POSA and to evaluate its association with symptoms in racially diverse pediatric population.

Materials and methods: Otherwise healthy children aged 4–17 years undergoing clinically indicated overnight polysomnography at a community-based sleep laboratory were prospectively recruited. Data collected included body size measurements, tonsil size, and OSA symptoms assessed using the Pediatric Sleep Questionnaire (PSQ). A PSQ total score of greater than 0.33 indicates a high risk for OSA based on parent-reported symptoms. POSA was defined as: (1) obstructive apnea-hypopnea index (OAHI) ≥ 1.5 events/hour, (2) supine to nonsupine OAHI ratio ≥ 2 , and (3) at least 30 minutes of sleep in both supine and non-supine positions.

Results: Preliminary analysis included 100 children (mean age 8.5 ± 3.1 years; 67% male; 40% White). Based on overall OAHI, 17 had no OSA (OAHI < 1.5), 38 had mild OSA (1.5–5), 25 had moderate OSA (5–10), and 20 had severe OSA (≥ 10). Among 83 participants with OSA, 18 (22%) were classified as POSA, 60 (72%) as non-POSA, and 5 (6%) were unclassified due to insufficient time in supine or non-supine sleep.

Compared to the non-POSA group, children with POSA spent a significantly lower percentage of sleep

time in the supine position [27.7% (17.2–52.6) vs. 49.8% (31.0–62.1); $p = 0.029$]. They also exhibited a higher OAHl during supine sleep [17.5 (6.3–28.9) vs. 6.2 (3.9–12.0) events/hour; $p = 0.002$] and a lower OAHl during non-supine sleep [4.2 (2.2–6.4) vs. 7.5 (4.4–12.2) events/hour; $p = 0.003$]. Additionally, the POSA group had a higher prevalence of enlarged tonsils [53% vs. 22%, $p=0.030$]. Interestingly, a smaller proportion of the POSA group had a PSQ score greater than 0.33 (47% vs. 75%, $p=0.032$) compared to the non-POSA group. No significant differences were found in age, sex, body mass index, neck circumference, overall OAHl, oxygen desaturation index, and arousal index between the two groups.

Conclusions: In this diverse pediatric cohort, approximately one-fifth of children with OSA were identified as having POSA. POSA was associated with enlarged tonsils, but these children displayed a lower symptom burden according to PSQ scores. These findings suggest that POSA may represent a distinct OSA phenotype in children, potentially amenable to positional therapy. Further studies are warranted to investigate potential racial differences and to evaluate both the short- and long-term effects of positional therapy compared to adenotonsillectomy in children with POSA, especially in those with enlarged tonsils.

Acknowledgments: We appreciate all participants for their active participation and the staff at the Richmond Hill Sleep and Lung Institute for their contributions to the study.

Prevalence and identification of rapid eye movement-related obstructive sleep apnea in the Han Chinese adults

E. Zhou¹, W. Huang¹, H. Yi¹, S. Yin¹

¹Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Otorhinolaryngology Head and Neck Surgery, Shanghai, China

Introduction: This study investigated the demographic, clinical, genetic characteristics of REM-related OSA (REMrOSA) in the Han Chinese population.

Materials and methods: This is a large-scale cross-sectional study conducted from 2007 to 2022 in our sleep center. The REMrOSA and its subgroups were classified based on the ratio of apnea-hypopnea index during REM (AHI_{REM}) versus non-REM (AHI_{NREM}) with sufficient sleep time during REM and NREM. Anthropometric, physiological, and biochemical indexes were collected. Based on the established raw genetic database, a genome-wide association study for AHI_{REM} and REMrOSA phenotypes was analyzed among matched subjects.

Results: A total of 3,631 OSA subjects were included for REMrOSA analysis, and 3,793 subjects (3,317 OSA and 476 NOSA) were included for GWAS analysis. The prevalence of REMrOSA was 18.09% (95% confidence interval, 16.86% to 19.39%) in OSA, which occurred more in females with younger age, better glucolipid profiles, and milder sleeping parameters (Mann-Whitney U test, $P<0.05$). The GWAS analysis identified 36 and 4 single nucleotide polymorphisms significantly associated with AHI_{REM} and REMrOSA phenotypes, respectively. Common gene loci associated with both phenotypes including *TBXAS1*, *SLCO5A1*, *ABCA1* and *ZNF603P*.

Conclusions: More than 1/6 of Han Chinese subjects with OSA had REMrOSA with unique clinical characteristics. Four common genome-wide significant trait-associated loci were identified and might provide novel insight into the genetic architecture of REM sleep disorders.

Acknowledgments: All of the authors are grateful to the staff in our sleep center and all of the subjects.

Prevalence and Modulating Factors of Upper Airway Collapse Sites in OSA Patients Assessed by Drug-Induced Sleep Endoscopy: A Meta-Analysis

C.M. Sung¹, S.R. Park¹, H.C. Yang¹, S.C. Lim¹

¹Chonnam National University Medical School and Chonnam National University Hospital, Department of Otolaryngology-Head and Neck Surgery, Gwangju, Korea, Republic of

Introduction: Drug-induced sleep endoscopy (DISE) is an established diagnostic tool for dynamically evaluating upper airway obstruction sites in patients with obstructive sleep apnea (OSA). However, significant variability in reported prevalence rates of obstruction sites across studies has highlighted the critical need for a systematic and comprehensive analysis.

Materials and methods: This meta-analysis aimed to synthesize the prevalence rates of upper airway obstruction sites (velum, oropharynx, tongue base, and epiglottis) as assessed by DISE. We also sought to quantitatively evaluate the impact of sedative type, method of sedation assessment, and patient demographic characteristics (age, body mass index, apnea-hypopnea index, and male ratio) on both the prevalence of obstruction and inter-study heterogeneity. Methods A random-effects model-based meta-analysis was performed using the metaprop function in R. Prevalence rates were calculated for the four obstruction sites based on the VOTE classification system. Subgroup analyses were conducted according to the type of sedative used and the method of sedation assessment. Publication bias was evaluated using Egger's test and the Trim-and-Fill method. The effects of covariates were analyzed via meta-regression using the rma.glmm function from the metafor package.

Results: In an analysis comprising a total of 3,842 patients, velum obstruction was the most prevalent at 75% (95% CI: 0.67-0.82), followed by tongue base at 40% (95% CI: 0.33-0.48), oropharynx at 31% (95% CI: 0.25-0.37), and epiglottis at 24% (95% CI: 0.17-0.32). High heterogeneity ($I^2 > 80\%$) was observed across all sites. Significant publication bias ($p < 0.0001$, right asymmetry) was identified specifically for epiglottic obstruction. After applying the Trim-and-Fill method, the adjusted prevalence of epiglottic obstruction increased substantially to 0.4611 (95% CI: 0.3373-0.5898), suggesting an underreporting bias in studies that reported high prevalence rates. Multivariate meta-regression analysis revealed that the heterogeneity in velum obstruction ($I^2=37.40\%$) was largely explained by sedation-related variables and demographic factors. However, high residual heterogeneity persisted for other sites (oropharynx, tongue base, and epiglottis). Notably, Midazolam use and sedation assessment based on clinical signs were associated with higher obstruction prevalence in some areas. Age, BMI, AHI, and male ratio also acted as significant moderating variables for site-specific obstructions.

Conclusions: This DISE-based meta-analysis elucidated the multilevel nature and site-specific patterns of upper airway obstruction, reaffirming the velum as the most common obstruction site. Our findings highlight that the high variability in DISE outcomes is influenced by sedation protocols and patient characteristics. This underscores the necessity for standardizing sedation protocols and considering patient characteristics in future research, thereby advocating for personalized treatment approaches.

Prevalence and Risk Factors of Residual Excessive Sleepiness in Chinese Obstructive Sleep Apnea Patients

X. Feng^{1,2}, Y. Shi³, Z. Chen³, S. Guan³, L. Sun², X. Tang³

¹West China Hospital, Sichuan University, Department of Respiratory and Critical Care Medicine, Sleep Medicine Center, Mental Health Center, Chengdu, China, ²The First Affiliated Hospital, Jiangxi Medical College, Nanchang University, Department of Respiratory and Critical Care Medicine, Nanchang, China, ³West China Hospital, Sichuan University, Sleep Medicine Center, Department of Respiratory and Critical Care Medicine, Mental Health Center, Chengdu, China

Introduction: Some obstructive sleep apnea (OSA) patients continue to experience sleepiness despite receiving continuous positive airway pressure (CPAP) treatment, a condition referred to as residual excessive sleepiness (RES). At present, the prevalence and risk factors for RES among OSA patients in China remain unclear. This study seeks to examine the prevalence and predictors of RES in Chinese OSA patients.

Materials and methods: The study prospectively enrolled patients diagnosed with OSA at the Sleep Medicine Center, West China Hospital, Sichuan University, between January 2022 and September 2024. Patients were included if they had a baseline Epworth Sleepiness Scale (ESS) score greater than 10 and had received effective CPAP treatment (residual apnea hypopnea index [AHI] < 5) for at least 4 hours per day. Data collected included: ESS before and after treatment, demographic details, comorbidities, polysomnography and CPAP parameters. After at least 3 months of CPAP treatment, patients were categorized into two groups based on their post-treatment ESS: the non-RES group (ESS ≤ 10) and the RES group (ESS > 10).

Results: A total of 1058 OSA patients treated with effective and adequate CPAP were included. The average age was 42.98 ± 11.27 years, with a BMI of 26.72 ± 3.72 kg/m², 81.6% were males, and the average AHI was 48.80 ± 27.25 events/hour at baseline. After an average of 4.3 months of CPAP treatment (5.79 ± 0.80 h/day), 339 patients (32.04%) complained of RES. Multivariate logistic regression analysis identified several risk factors for RES: higher ESS (OR=1.307, 95%CI: 1.224-1.396, $p < 0.001$) and arousal index (OR=1.109, 95%CI: 1.083-1.137, $p < 0.001$), greater proportion of sleep in N1 stage

(OR=1.040, 95%CI: 1.023-1.056, $p<0.001$), and lower average blood oxygen saturation (OR=1.080, 95%CI: 1.026-1.136, $p=0.003$) before CPAP treatment. In contrast, lower AHI (OR=0.900, 95%CI: 0.883-0.917, $p<0.001$) and a higher proportion of sleep in N3 stage (OR=0.841, 95%CI: 0.744-0.952, $p=0.006$) were protective factors. Additionally, CPAP adherence (OR=0.702, 95%CI: 0.574-0.859, $p=0.001$) was linked to the development of RES. Receiver operating characteristic (ROC) analysis showed that the multivariate model for predicting RES had an area under the curve (AUC) of 0.841.

Conclusions: In China, over 32% of OSA patients receiving CPAP treatment report experiencing RES. The factors associated with RES include baseline severer sleepiness, reduced sleep stability, lower AHI, and worse CPAP adherence.

Prevalence of high risk for obstructive sleep apnea in Thai patients undergoing elective general surgery

W. Banhiran¹, P. Danwilai¹, S. Chumpathong², P. Kesko¹

¹Faculty of Medicine Siriraj Hospital/ Mahidol University, Otorhinolaryngology, Bangkok, Thailand,

²Faculty of Medicine Siriraj Hospital/ Mahidol University, Anesthesiology, Bangkok, Thailand

Introduction: Limited studies have shown that a high proportion of patients undergoing elective surgery under general anesthesia (GA) are at high risk for obstructive sleep apnea (OSA), with 80% remaining undiagnosed. This study aims to determine the prevalence of high-risk OSA in Thai patients undergoing elective general surgery under GA and to explore its association with surgical categories and perioperative complications based on STOP-Bang scores.

Materials and methods: This cross-sectional study was conducted between August 2020 and February 2021. The inclusion criteria were Thai patients ≥ 18 years admitted to Siriraj Hospital for elective general surgery under GA. Exclusion criteria included patients scheduled for bariatric, airway, or neck mass surgery, those whose surgeries were canceled or had anesthetic substituted, and patients unable to complete the questionnaires. Before surgery, all subjects completed the STOP-Bang and associated questionnaires, and relevant medical records, including anesthetic notes, were reviewed.

Results: Of the 300 participants, 162 patients (54%) were classified as being at high risk for OSA (STOP-Bang values of ≥ 3). Among surgical categories, urologic surgery had the highest prevalence (69%) while breast surgery had the lowest (25.7%). High-risk patients shared several characteristics compared to the low-risk group, including being predominantly male, having a larger neck circumference, older age, higher body mass index (BMI), underlying hypertension, cardiovascular diseases, and higher anesthetic risk. However, no significant association was found between the STOP-Bang scores and postoperative complications.

Conclusions: Up to 54% of Thai patients undergoing elective general surgery under GA were at high risk for OSA, with the highest prevalence seen in those undergoing urologic surgery. Increasing awareness of preoperative OSA screening could help prevent future adverse outcomes.

Prevalence of High Risk of Obstructive Sleep Apnea in Patients with Vertigo

P. Thawornpradit¹, N. Kasemsuk¹, S. Limviriyakul¹, S. Rungmanee², W. Banhiran¹

¹Siriraj Hospital, Mahidol University, Bangkok, Thailand, ²Siriraj Sleep Center, Siriraj Hospital, Bangkok, Thailand

Introduction: There is a noticeable absence of research focusing on the prevalence of OSA among Asian individuals experiencing vertigo. Our study aims to address this gap by assessing the prevalence

of high-risk OSA in patients with vertigo and examining the association between OSA risk, the severity of dizziness symptoms, and levels of daytime sleepiness.

Materials and methods: This cross-sectional study was conducted at the Faculty of Medicine Siriraj Hospital, Thailand. Inclusion criteria were patients over the age of 18 with vertigo disorders, such as Meniere's disease, benign paroxysmal positional vertigo (BPPV), vestibular neuritis, and vestibular migraine. Patients with history of psychiatric disorders, brain diseases, and those who regularly used central vestibular suppressants, were excluded. Data was collected using the STOP-Bang questionnaire (SBQ), Epworth sleepiness scale (ESS), and Dizziness Handicap Inventory (DHI) scores.

Results: A total of 190 vertigo patients (48 men, 142 women) with a mean age of 58.9 ± 12.6 years (range 19-88 years) and body mass index (BMI) of 24.7 ± 3.9 kg/m² were recruited. The most common subcategory of vertigo was BPPV (56.8%). Ninety-eight patients (51.6%) were categorized as high-risk for OSA; significant independent risk factors for this group included male gender and hypertension ($p = 0.001$). A higher DHI rating was associated with increased ESS scores, but not with SBQ scores.

Conclusions: The prevalence of high-risk OSA among vertigo patients was 51.6%, which is higher than that observed in the general population. There was a notable correlation between the severity of dizziness and sleepiness. . Thus, screening for high-risk OSA in vertigo patients should be encouraged to promote early detection and treatment.

Introduction:

Obstructive sleep apnea (OSA) is a common sleep disorder associated with significant comorbidities such as hypertension, cardiovascular disease, and daytime sleepiness. Although polysomnography is the diagnostic gold standard, the STOP-Bang questionnaire offers a cost-effective screening tool. Vertigo is also prevalent and affects quality of life, particularly in older adults. While both conditions may share overlapping symptoms, such as fatigue and poor sleep, the relationship between OSA and vertigo remains underexplored, especially in Asian populations. Previous studies have reported a higher prevalence of OSA symptoms among patients with dizziness, but data remain limited. This study aims to determine the prevalence of high-risk OSA among patients with vertigo and to examine the association between OSA risk, dizziness severity, and daytime sleepiness

Materials and methods: This cross-sectional study was conducted at the Faculty of Medicine Siriraj Hospital, Thailand. Inclusion criteria were patients over the age of 18 with vertigo disorders, such as Meniere's disease, benign paroxysmal positional vertigo (BPPV), vestibular neuritis, and vestibular migraine. Patients with history of psychiatric disorders, brain diseases, and those who regularly used central vestibular suppressants, were excluded. Data was collected using the STOP-Bang questionnaire (SBQ), Epworth sleepiness scale (ESS), and Dizziness Handicap Inventory (DHI) scores.

Results: A total of 190 vertigo patients (48 men, 142 women) with a mean age of 58.9 ± 12.6 years (range 19-88 years) and body mass index (BMI) of 24.7 ± 3.9 kg/m² were recruited. The most common subcategory of vertigo was BPPV (56.8%). Ninety-eight patients (51.6%) were categorized as high-risk for OSA; significant independent risk factors for this group included male gender and hypertension ($p = 0.001$). A higher DHI rating was associated with increased ESS scores, but not with SBQ scores.

Conclusions: The prevalence of high-risk OSA among vertigo patients was 51.6%, which is higher than that observed in the general population. There was a notable correlation between the severity of dizziness and sleepiness. . Thus, screening for high-risk OSA in vertigo patients should be encouraged to promote early detection and treatment.

Quantitative Analysis of Sleep Electroencephalogram in Patients with Interstitial Lung Disease and Obstructive Sleep Apnea

K. Venkatnarayan¹, F. Ayoob², A. Sasidharan³, R. Venugopal³, U.M. Krishnaswamy¹

¹St. John's National Academy of Health Sciences, Pulmonary Medicine, Bengaluru, India, ²St. John's National Academy of Health Sciences, Biostatistics, Bengaluru, India, ³National Institute of Mental Health and Neurosciences, Neurophysiology, Bengaluru, India

Introduction: Patients with interstitial lung diseases (ILD) often experience disrupted sleep architecture due to nocturnal desaturation and co-morbid obstructive sleep apnea (OSA) which negatively impact sleep quality and may worsen both conditions. Existing literature focuses on sleep macroarchitecture which has shown reduced REM and slow wave sleep, increased arousals, and fragmented sleep in these patients. Quantitative EEG (qEEG) analysis offers a deeper evaluation of sleep microarchitecture undetectable by traditional scoring methods. This could serve as a potential biomarker for phenotyping and prognosticating ILD-OSA patients, guiding future therapeutic approaches. We aimed to analyse sleep microarchitecture in patients with ILD-OSA and compare it with that of OSA patients matched for disease severity.

Materials and methods: This retrospective study analyzed EEG-derived sleep microarchitecture in ILD patients who underwent level I polysomnography (PSG). Three groups were analyzed: ILD-OSA, ILD without OSA, and non-ILD OSA patients matched for AHI. PSGs with <4 hours of sleep or excessive artifacts were excluded. EEG signals (sampled at 512 Hz) from central channels were pre-processed using Python toolboxes (MNE, YASA, pyprep, autoreject), and 3s cleaned epochs were used for spectral analysis and the indices obtained were compared across the three groups. For comparing indices between the groups (ILD-OSA and ILD without OSA; ILD-OSA and non-ILD OSA) independent t-test or Mann-Whitney U test was used based on the normality of data.

Results: Eighteen patients each with ILD-OSA, ILD without OSA, and non-ILD OSA (matched for AHI; $p=0.2$) were included. Patients with ILD-OSA had a lower mean BMI (26 ± 4.4) compared to those with non-ILD OSA (30.8 ± 6.4) ($p=0.001$) and were less sleepy with a lower mean ESS (8.2 ± 3.6 vs 11 ± 4.1 ; $p=0.03$). Sleep architecture showed decreased N3% ($p=0.009$) and increased wake after sleep onset ($p=0.006$) in ILD-OSA group. Microarchitecture analysis showed higher slow wave peak to peak (PTP) (111.3 ± 13.9 vs 103.5 ± 7.07 ; $p=0.03$), spindle root mean square (RMS) (43.2 ± 66.2 vs 8.8 ± 2.7 ; $p=0.003$), and absolute spindle power (2.13 ± 0.6 vs 1.66 ± 0.2 ; $p=0.003$) for both high and low frequency spindles in ILD-OSA group. Neuroloop gain for spindles was lower among ILD-OSA compared to non-ILD OSA (39.4 ± 14.7 vs 55.6 ± 15.8 ; $p=0.003$). Comparison between ILD-OSA and ILD without OSA did not show any significant difference in the sleep microarchitecture.

Conclusions: ILD patients with comorbid OSA (ILD-OSA) were less sleepy and had a lower BMI compared to disease severity matched OSA patients. They exhibit distinct alterations in sleep macro- and microarchitecture, including reduced deep sleep (N3%) and increased sleep fragmentation. Spindle metrics were however higher in ILD-OSA (higher spindle power, PTP, and RMS) compared to non-ILD OSA patients, suggesting better cortical synchronisation during spindle generation. Neuroloop gain for spindles was reduced in ILD-OSA, suggesting poorer spindle generation due to altered thalamocortical dynamics. However, no significant differences in sleep microarchitecture were found between ILD-OSA and ILD without OSA.

Reading Your Sleep: Learning SpO₂ Words and Sentences for OSA Detection and Subtyping

D. Xie^{1,2}, Q. Zhao³, J. Jin¹, J. Chen², W. Huang^{4,5,6}, H. Yi^{4,5,6}, Y. Zhou³, Y. Leng⁷, S. Hong^{1,8}

Head and Neck Surgery, Shanghai, China, ⁵Shanghai Key Laboratory of Sleep-Disordered Breathing, Shanghai, China, ⁶Otolaryngology Institute of Shanghai Jiao Tong University, Shanghai, China, ⁷University of California, San Francisco, Department of Psychiatry and Behavioral Sciences, San Francisco, United States, ⁸Peking University, Institute for Artificial Intelligence, Beijing, China

Introduction: Obstructive Sleep Apnea (OSA) is a prevalent and serious sleep-disordered breathing condition. However, the current gold standard for OSA diagnosis, polysomnography (PSG), is a complex and costly procedure that relies heavily on expert interpretation of multi-channel signals. These limitations severely hinder its application in early screening and large scale population monitoring. Therefore, developing an accessible, low-cost, and reliable automated diagnostic method is of paramount importance. To this end, our study pioneers a approach that translates continuous SpO₂ signals into discrete "physiological words" and "sentences." By learning to read this oximetry language, we aim to provide an efficient and scalable solution for widespread OSA screening, perfectly suited for home based monitoring via wearable devices.

Materials and methods: We propose a novel pipeline to lingualize SpO₂ time series data. Three large-scale clinical datasets—MrOS, SHHS, and MESA—comprising a total of 14,430 polysomnography recordings are utilized as the foundation for both tokenizer construction and model pre-training. To begin, we augmented overnight SpO₂ signal segments from these datasets to create a diverse and representative training pool. Using unsupervised clustering on this enhanced dataset, we constructed a vocabulary of SpO₂ words. Each patient's full-night SpO₂ time series was then tokenized into sequences of these discrete words, which were subsequently organized into physiological sentences. A Transformer-based architecture was pre-trained on these token sequences, with the objective of learning the underlying grammar and semantics of the oximetry language through masked token prediction. The model was then fine-tuned for patient-level OSA detection and evaluated on independent validation cohorts. In addition, we explored the model's potential for identifying OSA subtypes by analyzing its behavior on misclassified cases to uncover atypical physiological patterns.

Results: Our model demonstrated excellent performance on an internal test set from a Chinese cohort (n=848, from a 4,240-subject fine-tune dataset from Shanghai Sixth People's Hospital), achieving an AUC of 0.958. To assess generalizability, we conducted external validation on three independent, multi-ethnic cohorts: the CFS (n=730), WSC (n=2,568), and STAGES (n=1,820) datasets. The model exhibited robust performance across these external datasets, attaining AUCs of 0.900, 0.926, and 0.823, respectively. Further analysis of misclassified cases revealed a subset of atypical OSA patients who were prone to false negatives. These individuals exhibited only mild, transient, or morphologically irregular oxygen desaturation events, with overall higher SpO₂ levels. While their oximetry patterns reflected underlying respiratory instability, the absence of overt hypoxic features posed a challenge for accurate detection by conventional models.

Conclusions: This study successfully demonstrates that lingualizing single-channel SpO₂ signals and leveraging NLP pre-trained models offers a feasible and highly effective pathway for accurate, automated OSA detection, with its robust generalizability validated across multiple independent cohorts. Furthermore, our framework reveals a powerful analytical capability: by conducting in-depth analyses of cases misclassified by the model, we have identified a set of clinically atypical patterns of subtle or irregular oxygen desaturation. This demonstrates that our method is a potent tool capable of reading deeper into the nuances of sleep-disordered breathing, paving the way for the discovery and understanding of different OSA subtypes.

Real-World Evidence for Surgical and Nonsurgical Sleep Apnea Therapies: safety, Clinical Outcomes and Healthcare Utilization Patterns

R. Capasso¹

¹Stanford University, Otolaryngology, Stanford, United States

Introduction: Obstructive Sleep Apnea (OSA) is a prevalent condition with wide-ranging clinical and economic consequences. While continuous positive airway pressure (CPAP) is the gold standard therapy, its limited adherence has led to increased interest in alternative treatments, including soft tissue and skeletal surgeries and implantable devices like hypoglossal nerve stimulation (HGNS). Randomized controlled trials (RCTs) are limited in their scope to capture long-term systemic outcomes

and healthcare costs. Real-world evidence (RWE) using national claims data offers valuable insights into these broader dimensions of sleep care.

Materials and methods:

We conducted a series of retrospective cohort studies using large-scale insurance claims databases (Truven MarketScan and Arcadia) from 2007–2023. Patients aged 18–90 with a diagnosis of OSA who received either CPAP, soft tissue or skeletal surgery, or HGNS were identified. Primary outcomes included:

- Cardiovascular, endocrine, and neurological event rates
- Healthcare utilization (inpatient, outpatient, pharmaceutical expenditures)
- Chronic opioid use and its risk factors following sleep surgery

Analyses employed high-dimensional propensity score matching, logistic regression, and Kaplan-Meier survival estimates, with follow-up ranging from 2 to 8 years depending on the dataset.

Results: Results:

- **Clinical Outcomes:** Patients undergoing soft tissue surgery for OSA demonstrated significantly reduced risk of cardiovascular (HR 0.91), neurological (HR 0.67), and endocrine complications (HR 0.82) compared to matched CPAP users.
- **Hypoglossal Nerve Stimulation (HGNS):** HGNS was associated with lower long-term rates of arrhythmias, heart failure, and stroke compared to CPAP.
- **Healthcare Utilization:** Over a 2-year period, surgery was associated with significantly lower average monthly healthcare expenditures compared to CPAP or no treatment when the cost of the intervention was excluded (e.g., \$694 vs. \$837/month).
- **Opioid Risk:** Among 10,766 OSA surgery patients, 2.8% developed persistent opioid use. Multivariate analysis revealed perioperative opioid prescription (OR 37.8) and smoking (OR 1.95) as independent predictors of chronic use. Skeletal surgery had the lowest opioid exposure compared to soft tissue procedures.

Conclusions: These RWE studies demonstrate that surgical interventions for OSA—particularly soft tissue surgery and HGNS—are associated with lower systemic complication rates, reduced long-term healthcare expenditures, and nuanced opioid risk profiles compared to CPAP therapy. This body of work supports the integration of RWE in clinical decision-making, policy formulation, and patient-centered sleep care strategies.

Real-world Incremental Economic Burden of Fatigue among Patients with Obstructive Sleep Apnea in the Medicare Fee-for-Service Population

K.S. Yu¹, N.F. Watson², B. Cade³, J. Yee¹, B. Zeldow⁴, R. Farkas¹, J. Cronin¹, J. Zhao⁴, A. Tan⁴, S. Redline³
¹Apnimed, Inc., Cambridge, United States, ²University of Washington School of Medicine, Department of Neurology, Seattle, United States, ³Brigham and Women's Hospital, Harvard Medical School, Department of Medicine, Boston, United States, ⁴Genesis Research, Inc., Hoboken, United States

Introduction: Fatigue, distinct from sleepiness, is one of the most common obstructive sleep apnea (OSA) symptoms, and is associated with diminished quality of life, poor psychological and physical functioning and increased risk of occupational and motor vehicle accidents. The aim of this study was to estimate the incremental healthcare cost burden of fatigue among patients with OSA in the Medicare fee-for-service (FFS) population.

Materials and methods: Retrospective observational claims analysis was conducted comparing newly diagnosed OSA patients with fatigue to matched OSA patients without fatigue. Medical and pharmacy claims from the 2017–2022 Medicare FFS database were used to identify incident cases of fatigue

among newly diagnosed OSA patients who met the following criteria: ≥ 1 inpatient or ≥ 2 outpatient claims (with ≥ 7 days apart) with an ICD-10-CM diagnosis code of OSA (G47.33, G47.30, G47.39); ≥ 1 procedure code for polysomnography or home sleep apnea test in 12 months prior to OSA diagnosis index date; continuous insurance coverage ≥ 12 months before OSA diagnosis index (baseline period) and ≥ 12 months after fatigue index date (follow-up period). Fatigue cases had ≥ 1 claim for fatigue (R53.1, R53.81, R53.82, R53.83) after the OSA diagnosis index date. Controls had no diagnosis of fatigue and were propensity score matched to fatigue cases.

Results: A total of 71,710 newly diagnosed OSA patients met eligibility criteria, of whom $\sim 36\%$ had ≥ 1 diagnosis claim for fatigue. Mean (SD) age was 72.8 years (5.3), 51% male, and 88% White. After OSA diagnosis, mean all-cause healthcare costs were significantly higher (all $p < 0.001$) for patients with fatigue vs. matched controls: Per-patient-per-year (PPPY) all-cause hospitalization (\$7,457 vs \$1,598); outpatient visits (\$5,122 vs \$2,177); emergency department visits (\$846 vs \$237); other medical visits (\$10,628 vs \$4,201); and pharmacy costs (\$5,075 vs \$2,926). Overall, the mean PPPY all-cause total costs (\$29,128 vs \$11,140, $p < 0.001$) in OSA patients with fatigue were significantly higher than those without fatigue, indicating over a two-fold increase.

Conclusions: Fatigue is significantly associated with an increase in all-cause total healthcare costs in newly diagnosed OSA patients as compared with matched patients without fatigue. Addressing fatigue may be useful as part of OSA screening, diagnosis and treatment due to the incremental humanistic and economic burden.

Reduced N3 Sleep Is Associated with Cognitive Impairment in Elderly Patients with Obstructive Sleep Apnea

W. Yang¹, S. Li¹, H. Wang¹, X. Dong¹, F. Han¹

¹Peking University People's Hospital, (11)北京市, China

Introduction: This study aimed to identify the prevalence and severity of cognitive impairment in elderly patients with obstructive sleep apnea (OSA), and to explore the association between sleep structure and mild cognitive impairment in elderly patients with OSA.

Materials and methods: 207 elderly patients were diagnosed with OSA (AHI ≥ 5) were continuously enrolled this study from the Division of Sleep Medicine of Peking University People's Hospital between February 2023 to November 2024. Montreal Cognitive Assessment Scale (MoCA)-Beijing was used to assess the prevalence and severity of cognitive impairment. Overnight polysomnography (PSG) was used to evaluate the sleep structure respiratory event. The sleep structure respiratory event are manually scored by trained sleep technicians, and all the scores are carried out in accordance with the criteria of the AASM (American Academy of Sleep Medicine) Manual for the Scoring of Sleep and Associated Events, Version 3.0. The Spearman analysis was used to assess the correlation between sleep structure and MCI score. Multivariate logistic regression was applied to analyze the relationship between MCI and sleep structure after controlling for confounding variables.

Results: 45.8% elderly patients with OSA were diagnosed with MCI (MoCA ≥ 26). Compared to patients without MCI, elderly patients with OSA complicated by mild cognitive impairment had significantly reduced total sleep time, sleep efficiency, and the percentage of N3 sleep stage, while the increased percentage of N1 sleep stage. Multivariate analysis found that a reduction in N3 - stage sleep was correlated with total MCI ($P < 0.05$), a reduced in N3 - stage sleep is a risk factor for MCI in patients with OSA ($P < 0.05$), (OR = 0.95, 95% CI : 0.91, 1.00).

Conclusions: In elderly patients with OSA, The prevalence and severing of MCI is increasing. a reduction in N3 - stage sleep is associated with mild cognitive impairment.

Refining the Detection of Sleep-disordered Breathing Events: Improving Annotations in National Sleep Research Resource (NSRR) Polysomnography Data

S. Lim^{1,2}, H.K. Ahn¹, Y. Na^{1,2}, Y. Lee^{1,2}, H.-W. Shin^{1,3,2}

¹Seoul National University College of Medicine, Obstructive Upper airway Research Laboratory, the Department of Pharmacology, Seoul, Korea, Republic of, ²Seoul National University College of Medicine, Department of Biomedical Sciences, Seoul, Korea, Republic of, ³Seoul National University Hospital, Department of Otorhinolaryngology-Head and Neck Surgery, Seoul, Korea, Republic of

Introduction: The Sleep Heart Health Study (SHHS), the Osteoporotic Fractures in Men Study (MrOS), and the Multi-Ethnic Study of Atherosclerosis (MESA) are frequently used public sleep study datasets provided by the National Sleep Research Resource (NSRR). These datasets contain full overnight polysomnography recordings with annotated sleep events. However, apnea and hypopnea were labeled solely based on flow reduction, ignoring sleep stages, desaturation, or arousal as required by American Academy of Sleep Medicine (AASM) guidelines. This discrepancy could introduce considerable inconsistency and ambiguity in future studies. Here, we aim to develop a standardized process for analyzing respiratory event annotations from major NSRR datasets and provide updated labels.

Materials and methods: This retrospective study examined polysomnography annotations from SHHS1 (n=5,793), SHHS2 (n=2,651), MrOS1 (n=2,904), MrOS2 (n=1,026), and MESA (n=2,054). Dataset characteristics, including scoring methods and known issues, were analyzed. Then, we evaluated the discrepancy between the reported apnea-hypopnea index (AHI) and the AHI derived from raw annotations and the recalculated AHI adjusted for sleep stage, desaturation, and arousal based on AASM guidelines. Subsequently, we performed identical analysis on the Korea Image-based Sleep Study (KISS) dataset (n=7,745) for comparison.

Finally, we highlighted the importance of precise annotations by developing an electrocardiogram-based sleep-disordered breathing event detection model using original and adjusted annotations from SHHS1, SHHS2, and MESA and comparing sleep apnea (SA) severity classification (Normal, Mild to Moderate, Severe) performance.

Results: The raw labels consistently overestimated AHI across all cohorts, with the largest mean absolute error (MAE) in SHHS1 (23.55 events/hour). Other datasets showed moderate overestimations: SHHS2 (10.45), MrOS1 (11.16), MrOS2 (10.31), and MESA (13.09). After adjusting the annotations per AASM scoring criteria, MAEs were dramatically reduced across all datasets: SHHS1 improved to 1.29 events/hour, SHHS2 to 1.20 events/hour, MrOS1 to 1.03 events/hour, MrOS2 to 0.56 events/hour, and MESA to 0.78 events/hour. Notably, the KISS, which strictly followed the contemporary scoring guidelines in its raw annotations, demonstrated inherently high accuracy with a MAE of 0.6 events/hour, requiring no further processing. Lastly, SA severity classification significantly improved with our annotations compared to the original ones, with the F1 score rising from 0.35 to 0.66.

Conclusions: Annotations of SHHS, MrOS, and MESA require additional processing to accurately identify respiratory events consistent with AASM guidelines. Our updated labels will facilitate unambiguous annotation usage, promoting reproducibility and enabling comparisons in future studies, as shown by our deep learning experiment result. KISS offers the most reliable annotations among the datasets studied.

REI4% Compared to REI3% Leads to Missed OSA Diagnoses and/or Restricts Access to Care in >50% of Pregnancies In a Real-World Symptomatic Clinical Cohort Characterized by Advanced Maternal Age, Morbid Obesity and Chronic Hypertension

M. Bazalakova¹, A. Stanic-Kostic², K. Antony³

¹University of Wisconsin Madison, Neurology, Madison, United States, ²University of Wisconsin Madison, Obstetrics and Gynecology, Madison, United States, ³University of Auckland, Obstetrics and Gynecology, Auckland, New Zealand

Introduction: Evidence is rapidly accumulating that obstructive sleep apnea (OSA) can complicate healthy as well as high risk pregnancies. NuMom2b, the largest prospective study of gestational sleep apnea (gOSA), has demonstrated an increased risk of gestational diabetes, gestational hypertension and preeclampsia in otherwise healthy pregnant subjects with even "mild" OSA, defined as a respiratory event index (REI) 3% 5-15/hr. Although the REI, just like the apnea hypopnea index (AHI), has limited

predictive value for OSA morbidity and/or treatment outcomes, it is a cornerstone for "severity" designation and eligibility for treatment in US clinical practice. In other words, the REI, rather than clinical diagnostic and risk/benefit assessments, determine recommendations for and access to positive airway pressure (PAP) as the gold standard treatment for OSA. Specifically, PAP insurance coverage for REI 5-15/hr is contingent upon insurance pre-determined, inconsistent and largely non-validated metrics such as the Epworth score. Here we add pregnancy as a clinical population where REI4% compared to REI3% criteria lead to both missed diagnoses and "severity" estimation disparities, and also limit access to insurance-covered gold standard PAP therapy in a vulnerable population, despite evidence that PAP treated OSA is associated with reduced pregnancy morbidity.

Materials and methods: This is a retrospective analysis of 188 home sleep apnea tests (HSATs) completed in gravidae who screened as high risk for OSA using the 4-variable "Facco" questionnaire and were tested for OSA with the Respironics Alice PDx® HSAT. In this analysis, we only included data from HSATs which were reported using both AASM-recommended 3% (REI3%) and Medicare 4% desaturation criteria (REI4%).

Results: Cohort characteristics included average age at referral of 33 yo and average pre-pregnancy BMI of 42 kg/m²; 32% had chronic hypertension, 21% - asthma, 14% - type 2 diabetes and 15% - hypothyroidism; 10% were Black/African American, 7% Hispanic/Latinx, 3% Asian or Indian and 75% White/Caucasian; 61% had one or more living children. Finally, 71% and 65% reported frequent and/or loud snoring respectively, 18% endorsed witnessed apneas, and 65% endorsed being tired during the daytime.

56% of gravidae who received diagnosis of no OSA by 4% criteria (REI4% < 5/hr) were diagnosed with OSA by 3% criteria (REI3% ≥ 5/hr) (n=60/108). 58% of gravidae who were diagnosed with mild OSA by 4% criteria (REI4% 5-15/hr), were reclassified as moderate to severe OSA by 3% criteria (REI3% ≥ 15/hr) (n=34/59).

Conclusions: Our findings from a real world cohort demonstrate that using REI4% rather than REI3% criteria misses the diagnosis of OSA in 56% of pregnant women in our clinical pipeline and results in a change in "severity" from "moderate to severe" to "mild," thus restricting automatic eligibility and insurance coverage for gold standard PAP treatment in 58% of gravidae. Pregnancy complications are significant determinants of long-term adult health, so interventions that improve pregnancy health drive population-based outcomes. In this context, it is imperative to reassess the application of non-validated, restrictive, and non-physiological REI criteria to OSA "severity" classification and determination of access to PAP treatment during pregnancy.

Relationship between Framingham cardiovascular disease risk profile and pulse-oximetry derived measures of hypoxic burden and vascular reactivity in a sleep clinic cohort

G.M. Stewart^{1,2,3}, B.K. Tong^{1,2,3}, P. de Chazal^{1,4}, J. Flood^{1,2,3}, P.A. Cistulli^{1,2,3}

¹University of Sydney, Charles Perkins Centre, Sydney, Australia, ²University of Sydney, Sydney Medical School, Sydney, Australia, ³Royal North Shore Hospital, Department of Respiratory and Sleep Medicine, Sydney, Australia, ⁴University of Sydney, School of Biomedical Engineering, Sydney, Australia

Introduction: Pulse-oximetry derived measures of respiratory event related hypoxemia and autonomic vascular reactivity during an overnight sleep study – quantified by hypoxic burden (HB) and the pulse wave amplitude drop (PWAD) index – have recently been proposed as biomarkers of cardiovascular disease (CVD) outcomes in patients with obstructive sleep apnoea (OSA). This study examined the relationship between Framingham 10-year CVD risk profile and a range of HB and PWAD characteristics in patients attending a sleep clinic for suspected OSA.

Materials and methods: This study examined HB and PWAD characteristics (from photoplethysmography) in 725 individuals (38% Female; age [mean ± standard deviation]: 50±15y; body mass index: 29.9±7.4kg/m²) who underwent diagnostic polysomnography and had sufficient clinical data to determine history of CVD and calculate a Framingham 10-year CVD risk score. Individuals were categorised as either having an established CVD (CVD_{ESTABLISHED}, n=110) or a Framingham 10-year CVD risk score that was elevated (CVD_{ELEVATED}, n=407) or low (CVD_{LOW}, n=208). Standard polysomnography variables as well as respiratory event related HB (cumulative area of respiratory event related hypoxemia, %min/h) and PWAD characteristics including PWAD_{INDEX} (number

of drops in pulse wave amplitude of >30% from baseline per hour of sleep, events/h) and PWAD_{DURATION} (mean duration of PWAD events, seconds) were derived and compared between CVD groups.

Results: A significantly higher HB ($p < 0.01$) was observed in patients with CVD_{ESTABLISHED} (72.1 ± 93.7 %min/h) and CVD_{ELEVATED} (76.1 ± 121 %min/h) than in patients with CVD_{LOW} (26.7 ± 86.6 %min/h), while HB was similar between CVD_{ESTABLISHED} and CVD_{ELEVATED} ($p = 0.380$). A significantly lower PWAD_{INDEX} ($p < 0.01$) was observed in patients with CVD_{ESTABLISHED} (37.8 ± 19.1 events/h) and CVD_{ELEVATED} (42.2 ± 22.3 events/h) than in patients with CVD_{LOW} (50.6 ± 19.3 events/h), and PWAD_{INDEX} was significantly lower in CVD_{ESTABLISHED} than CVD_{ELEVATED} ($p < 0.01$). A significantly longer PWAD_{DURATION} ($p < 0.01$) was observed in patients with CVD_{ESTABLISHED} (11.6 ± 4.5 seconds) and CVD_{ELEVATED} (9.0 ± 2.1 seconds) than in patients with CVD_{LOW} (8.0 ± 1.4 seconds), and PWAD_{DURATION} was significantly longer in CVD_{ESTABLISHED} than CVD_{ELEVATED} ($p < 0.01$). Similar group differences were observed during REM and non-REM sleep, and group differences in HB, PWAD_{INDEX} and PWAD_{DURATION} remained statistically significant after adjusting for age, sex, body mass index and apnoea-hypopnea index.

Conclusions: These data indicate that a high HB, low PWAD_{INDEX} and longer PWAD_{DURATION} may provide a marker of worsening Framingham 10-year CVD risk score in sleep clinic patients, independent of the presence and severity of OSA (as measured by the apnoea-hypopnea index). The mechanistic link between altered nocturnal PWAD characteristics and CVD risk requires further study.

Acknowledgments: The authors thank the Sydney Sleep Biobank investigators for providing access to the data.

Residents, Fellows, and Advanced Practice Providers' Awareness of Clinical Practice Guidelines in Managing Perioperative Obstructive Sleep Apnea: A Multi-Institutional Survey

Introduction: Patients with obstructive sleep apnea (OSA) undergoing surgery are at significant risk for perioperative morbidity and mortality. Physicians-in-training (Residents, Fellows) and Advanced Practice Providers (APPs; Nurse Practitioners, Nurse Anesthetists, Nurse Midwives, Clinical Nurse

Specialists, and Physician Assistants) are increasingly frontline patient care providers in managing patients worldwide. They often may not receive sufficient education in their clinical training or practice regarding OSA and the associated perioperative risks.

Materials and methods: Electronic surveys were sent to providers in three clinical roles (Residents, Fellows, APPs), four major categories of practice, at nine major United States academic institutions between May 9-June 30, 2021. Chi-square and Fisher's exact tests assessed association between survey question responses and participant characteristics. False discovery rate (FDR) adjustment was used to account for multiple comparisons, with FDR threshold $q < 0.05$ for statistical significance. Cochran-Mantel-Haenszel (CMH) tests evaluated associations stratified by institution, with the homogeneity of odds ratios from CMH tests evaluated using Breslow-Day tests.

Results: 2236 of 6724 (33.3%) participants responded, including 40.6% Residents, 11% Fellows, and 48.4% APPs. The primary category of practice included 20.3% in Anesthesiology, 8.9% Family Medicine (FM), 34.1% Internal Medicine (IM)/subspecialties, 6.7% Obstetrics/Gynecology/Gynecologic Oncology (OB), 25.9% Surgery/subspecialties, and 4.1% Other.

Almost all (93.2%) felt OSA was a risk factor for perioperative complications, with no differences based on clinical roles or categories of practice. However, one-third of providers did not routinely ask elective surgery patients about OSA risk. Many institutions have a written policy outlining the approach to evaluating and managing perioperative patients with concerns for OSA. Most respondents (74.6%) stated they "do not know" if their institution had a written policy, 18.2% reported that their institutions did, and 7.1% reported they did not have written policies. By reference, 6 of 9 (66%) participating institutions did have a written policy regarding the perioperative management of OSA. This lack of knowledge of institutional policy included all clinical roles, with 71% of APPs, 79% of fellows, and 73% of residents reporting that they did not know. Importantly, 50% of participants in Anesthesiology, 70% of Surgery, 76% of OB/GYN, 85% of Internal Medicine and 78% of Family Medicine did not know if there was an institutional policy.

Interestingly, most (79.3%) respondents indicated that clinical practice guidelines would assist in the care of perioperative patients with concerns about OSA, while 18.7% responded, "I'm not sure."

Conclusions: We found that many providers are not aware of institutional policies regarding the approaches to perioperative OSA-risk assessment and management based on clinical roles and categories of practice. This represents a critical void where standardized education regarding OSA and perioperative management may present significant opportunity to improve provider understanding and patient care.

Respiratory Arousal Threshold and Clinical Features in patients with Isolated Obstructive Sleep Apnea and Comorbid Insomnia (COMISA)

T. Han¹, X. Zhang¹

¹China-Japan Friendship Hospital, Department of Pulmonary and Critical Care Medicine, Center of Respiratory Medicine, Beijing, China

Introduction: Comorbid insomnia and obstructive sleep apnea (COMISA) affects up to 40% of patients with either disorder, suggesting shared pathophysiological mechanisms. The respiratory arousal threshold (ArTH) – the respiratory effort required to trigger sleep arousal – in COMISA remains uncharacterized. We hypothesized that low ArTH and complications occur more frequently in COMISA than in OSA alone.

Materials and methods: Participants referred for OSA diagnosis underwent a polysomnography (PSG) and answered the Athens insomnia scale (AIS) and the Epworth sleepiness scale (ESS). Participants with an AIS score ≥ 7 were defined as having insomnia. OSA was defined as an apnea hypopnea index (AHI) ≥ 5 events/h. A low ArTH was determined by an ArTH score of 2 or above (one point for each:

apnoea–hypopnea index (AHI) < 30/h, nadir oxygen saturation (SaO₂) >82.5%, fractions of hypopnoeas > 58.3%).

Results: A total of 387 subjects (158 OSA only and 229 COMISA) were analysed. There was a significantly higher proportion of low ArTH patients with COMISA compared with OSA only (35.37% vs 25.32%, $P = 0.036$). After adjusting for confounding factors, including age, sex, BMI, low ArTH was still independently associated with COMISA (OR: 1.696, 95% CI 1.054–2.738, $P=0.030$). Comparing the individual components of the ArTH scoring criteria, there was significantly higher proportions of COMISA subjects who had a fraction of hypopnoeas > 58.3% (68.22% vs 54.65%, $P = 0.010$). There was a significantly higher proportion of EDS, anxiety and depression in patients with COMISA. To illustrate the correlation between phenotypes and cardiovascular responses in patients with OSA alone and COMISA, Spearman correlation analyses were conducted; 18 pair-wise correlations were assessed and statistically significant correlations are shown in Figure 2.

Conclusions: A low respiratory arousal threshold is a predominant phenotypic feature in individuals with COMISA and may exhibit a greater relative contribution to OSA pathogenesis in these patients. Complications, include anxiety, depression and EDS, occur more frequently in COMISA than in OSA alone.

Acknowledgments: We would like to thank the technicians and nurses, who helped us analyze sleep data (Boyun Xiang, Zelong Liu, Xinrui Guo, Lusi Mao, Xin Liu).

Respiratory-related motor unit activity in human strap muscles

M. Potter¹, V. Padhye¹, P. Catcheside¹, D. Eckert¹, A. Hudson¹

¹Flinders University, Bedford Park, Australia

Introduction: To maintain upper airway patency, neural drive must be coordinated across 24 pairs of skeletal muscles, including the largest airway dilator muscle, genioglossus, located at the base of the tongue and the strap muscles of the neck. Imprecise multiunit surface recordings of muscle activity suggest that the strap muscles have inspiratory modulation. However, the relative activity of the sternohyoid and sternothyroid muscles is not known. Similarly, the extent to which strap muscle activity changes with increases in respiratory drive is unknown. This study aimed to characterise the pattern and discharge rate of single motor units (SMU) of human strap muscles during quiet and stimulated breathing.

Materials and methods: To date, SMU activity was recorded during quiet breathing, increased CO₂ breathing and deep breaths in the supine position in 2 healthy males and 1 female participant. EMG activity was recorded from the right sternohyoid and sternothyroid (5-10 sites each) using a monopolar needle electrode probe inserted via ultrasound guidance. Genioglossus EMG was recorded using intramuscular wire electrodes. Airflow, mouth pressure and end-tidal CO₂ were recorded via nasal mask and pneumotachograph. SMUs were discriminated to determine their discharge pattern, the timing of activity relative to the respiratory cycle, and firing frequency.

Results: Data collection and analysis are on-going, but during quiet breathing, most sternothyroid SMUs have phasic activity during inspiration with a peak discharge rate of 10-20Hz. Some SMUs have tonic activity with inspiratory modulation. There was a variable response to increased CO₂ and deep voluntary breaths. The inspiratory discharge of some sternothyroid motor units responded to changes in end-expiratory lung volume and inspiratory flow. Thus far, very limited respiratory-related motor unit activity has been seen in sternohyoid.

Conclusions: This is the first comprehensive description of respiratory-related motor unit activity in human strap muscles. Respiratory-related motor unit behaviour is sensitive to changes in chemical and voluntary neural drive as well as lung volume changes which highlights the dynamic control of their output by the central nervous system. The findings of this study will underpin future studies on strap muscle activity in conditions in which upper airway patency is compromised, such as obstructive sleep apnoea. Importantly, this study informs emerging electrical stimulation approaches that target the strap muscles as a potential treatment for obstructive sleep apnoea.

Respiratory self-similarity is a sleep apnea endotype that predicts cardiovascular disease related mortality in community-dwelling subjects

Y. Ni¹, E. Oppersma², W. Ganglberger³, T. Nassi², B. Westover³, R. Thomas⁴

¹Sichuan University, Chengdu, China, ²University of Twente, Enschede, Netherlands, ³Massachusetts General Hospital, Boston, United States, ⁴Beth Israel Deaconess Medical Center, Boston, United States

Introduction: The effect of sleep apnea phenotypes on cardiovascular disease and mortality remains unclear. It is plausible that pathological respiratory chemoreflex activation (high loop gain) in sleep apnea may independently add to the risk of adverse outcomes. This study is going to determine if high loop gain of the respiratory control system during sleep, estimated by respiratory self-similarity (SS), and the related algorithm detected central respiratory event index (CREI), are related to new onset of cardiovascular disease (CVD) and CVD related mortality.

Materials and methods: A secondary analysis of The Sleep Heart Health Study (SHHS) and Multi-Ethnic Study of Atherosclerosis (MESA) was done, generating SS% and CREI, measured using chest and abdominal RIP signal. Cox regression and restricted cubic spline were done to explore the relationship between SS%, CREI and CVD, CVD-mortality and all caused mortality. The cumulative incidence function and a Fine-Gray subdistribution hazard model were used to evaluate this outcome accounting for competing risks.

Results: A subset of 4,871 SHHS participants and 2,049 MESA participants were included in the analysis of incident CVD. In SHHS, 1,147 new-onset CVD cases were identified, compared to 217 in MESA. After adjusting for confounders, both SS% and CREI demonstrated significant associations with incident CVD in both SHHS (SS%: OR 1.263, 95% CI 1.069-1.492, p:0.006; CREI: OR 1.286, 95% CI 1.099-1.506, p:0.002) and MESA (SS%: OR 1.666, 95% CI 1.193-2.327, p:0.003; CREI: OR 1.620, 95% CI 1.148-2.286, p:0.006). Among SHHS participants, 1,219 deaths were attributed to all causes, including 342 deaths due to CVD, whereas MESA recorded 89 all-cause deaths and 31 CVD-related deaths. A SS% > 9.3% was related with CVD-mortality (HR 1.439, 95% CI 1.127-1.838, p: 0.003) in SHHS and >7.0% with CVD mortality (HR 2.189 95% CI 0.991-4.834, p:0.053) in the MESA study. Male sex had a stronger relationship in all the analysis. In males, a significant initial increase in CVD mortality was observed up to an SS% of approximately 2.9%, followed by a decrease and subsequent linear increase beyond SS% 6.7% (HR 1.04, 95% CI 1.00-1.08) in the non-linear association analysis. Similar results were found for CREI. No significant linear relationship was found between SS% and CVD mortality in females.

Conclusions: An endotype of sleep apnea reflecting high loop gain is associated with CVD and CVD mortality, especially in males.

Rethinking Sleep Apnea Severity: Beyond AHI versus multidimensional Polysomnographic Indices

S. Meshram¹

¹Govt. Medical College Superspecialty Hospital, Nagpur, Pulmonary and Sleep Medicine, Nagpur, India

Introduction: Obstructive sleep apnea (OSA) is a clinically and pathophysiologically heterogeneous disorder. Standard metric AHI alone fails assess spectrum of disease severity or predict consequences such as metabolic dysfunction or neuropsychiatric impairment. Each OSA phenotypes, has physiological signatures on polysomnography. Metabolic phenotype: ODI, duration saturation below 90%, Dmax duration), sympathetic activity. Neurocognitive/psychiatric: arousal index, REM duration. Hypoxic burden-phenotype. Due to limitations of AHI other polysomnographic parameters to be incorporated . This study evaluates whether AHI-based severity grading aligns with key physiologic markers in patients undergoing diagnostic polysomnography.

Materials and methods: This observational study included adult patients who underwent diagnostic polysomnography at a tertiary care center. Of 150 enrolled, data from the first 30 patients were analyzed. Subjects were divided into two groups: Group 1 (mild to moderate OSA, AHI < 30; n = 17) and Group 2 (severe OSA, AHI ≥ 30; n = 13). Parameters compared included , REM sleep duration, arousal index, lowest oxygen saturation, time spent with SpO₂ < 90%, oxygen desaturation index (ODI), desaturation maximum (Dmax) duration, and heart rate metrics. Statistical comparisons were made using independent t-tests or Mann-Whitney U-tests, and correlations with AHI were explored using

Pearson/Spearman coefficients. Complete data from 130 analyzable patients will be presented at the conference.

Results: In Group I, 14 subjects had REM less than 5% of Total Sleep time(TST). No correlation between AHI and NREM Arousal Index. Heart rate greater than 100 observed in 11 subjects (64%) not correlation AHI values. Duration with below 90 percent saturation, 13 subjects(76%) spent less than 2 minutes, 2 with moderate and one mild AHI spent 30 to 40 minutes and one mild grade with Arousal index 2 spent 119 minutes. Lowest Oxygen saturation less than 70% overserved in 3 subjects of moderate AHI.

In Group II, 11 subjects had REM less than 5% of Total Sleep time(TST) and 4 had no REM sleep. 10 Subjects with NREM AI less than 5 had AHI of more than 40. All 13 subjects had arousal index values less than 50% their corresponding AHI values. All subjects with less AI value had & more sever grade AHI, statistically not correlated. 7 subjects(50%) had longest duration of obstructive apnea more than 60 seconds. Among 12 subjects (92%)Highest Heart rate greater than 100 observed not corelating with AHI values. Duration with below 90 percent saturation, 6 subjects(46%) spent more than 100 minutes one subject 410 minutes. Lowest Oxygen saturation less that 70% overserved in 8(60%) subjects. 5 subjects(38%) had less ODI value compared to corresponding AHI values while 8 (62%) had ODI values at least 20% more than their AHI values. No correlation between AHI, ODI and D max duration.

Conclusions: Early findings suggest that AHI-based severity grading does not consistently align with other key physiological indicators of OSA burden. Metrics such as REM percent, AI, HR variability, ODI, Dmax duration, and hypoxic load may better reflect disease severity and clinical risk. Full analysis of 130 patients will further clarify these relationships and support a multidimensional severity framework in OSA assessment.

Revealing the knowledge gap: Maxillomandibular Advancement for Obstructive Sleep Apnea in Skeletal Class III Patients

C.W. Yong^{1,2}, C.K.J. Lee³, J.K.L. Hor³, Y.L. Song³, C. Cheong^{4,5}, R.C.W. Wong⁶

¹National University of Singapore, Dentistry, Singapore, Singapore, ²National University Centre for Oral Health Singapore, Oral and Maxillofacial Surgery, Singapore, Singapore, ³National Dental Centre Singapore, Department of Orthodontics, Singapore, Singapore, ⁴National University Hospital Singapore, Otolaryngology, Singapore, Singapore, ⁵National University Hospital Singapore, Otolaryngology, head and neck surgery, Singapore, Singapore, ⁶National University of Singapore, Faculty of Dentistry, Singapore, Singapore

Introduction: Maxillomandibular advancement (MMA) is a well-established and effective surgical intervention for the treatment of obstructive sleep apnea (OSA). It involves surgical repositioning of the maxilla and mandible to a more forward position, usually with a greater focus on the latter. In addition to functional improvements, it has been commonly cited to improve facial aesthetics in Skeletal Class I and II patients, especially for patients with a smaller lower jaw profile. However, the same cannot be applied to Skeletal Class III patients. The prevalence of OSA in Skeletal Class III patients is 11.22%. These patients have a longer lower jaw profile relative to their upper jaw. Thus, the principles applied to the classic MMA may no longer apply. Unfortunately, the application of MMA in skeletal Class III patients with OSA is not well documented.

Materials and methods: The aim of this scoping review was to explore the variations and outcomes of MMA techniques in this unique subgroup. A comprehensive search of PubMed, Embase, and Cochrane databases was conducted for articles published up to May 2025. The Inclusion criteria were: (1) Primary research articles; (2) Patients with skeletal Class III deformities; (3) Use of MMA or skeletal advancement surgery, (4) Diagnosis of OSA . The exclusion criteria were (1) Review articles; (2) Absence of skeletal Class III patients with OSA; (3) Inability to isolate data specific to Class III patients, (4) No skeletal advancement or MMA performed; (5) Lack of full-text availability or; (6) Presence of craniofacial syndromes

Results: Seven studies and 25 patients met the inclusion criteria. Three main variations of MMA were identified: (1) Bimaxillary advancement. Apnea-hypopnea Index (AHI) reduced by an average of $85.24 \pm 10.84\%$ after this variation of MMA was performed. This variation provided the most significant airway enlargement across all pharyngeal regions but carries the highest risk of facial aesthetic distortion in skeletal class III patients; (2) Maxillary advancement with mandibular auto-

rotation. The AHI was reduced by 81.7%. This is a less invasive option but is only suited for patients with isolated maxillary retrusion and symmetrical mandibular anatomy; (3) Maxillary advancement with mandibular setback. Mean AHI reduction was 68.23%. While this variation, addresses aesthetic concerns in patients with mandibular excess, it may compromise oropharyngeal airway space. The extent to which maxillary advancement can compensate for this potential airway reduction remains unclear. Essentially, all variations were reported to be effective in treating OSA.

Conclusions: Three surgical variations—bimaxillary advancement, isolated maxillary advancement, and maxillary advancement with mandibular setback—were identified, offer differing benefits depending on facial structure, obstruction site, and aesthetic goals. Surgical planning for skeletal Class III patients with OSA cannot rely on standardized protocols but must instead be tailored to patient-specific anatomy and functional needs. Further research with larger samples and detailed reporting is needed to guide evidence-based practice in this underrepresented subgroup.

Risk of mild cognitive impairment in relation to sleep apnea parameters: an 8-year longitudinal study in a community-based cohort

H.J. Kim¹, J. Choi^{2,1}, H. Bae^{1,3}, A.T. Siddiquee², H. Park¹, S. Kim^{2,4,5}, N.H. Kim^{2,6,7}, S.K. Lee², C. Shin²

¹Asan Medical Center, Neurology, Seoul, Korea, Republic of, ²Korea University, Institute of Human Genomic Study, Seoul, Korea, Republic of, ³Korea University Guro Hospital, Neurology, Seoul, Korea, Republic of, ⁴Seowon University, Department of Paramedicine, Cheongju, Korea, Republic of, ⁵Kangwon National University, Department of Preventive Medicine, Chuncheon, Korea, Republic of, ⁶Korea University Ansan Hospital, Biomedical Research Center, Ansan-si, Korea, Republic of, ⁷Korea University Ansan Hospital, Department of Endocrinology, Ansan-si, Korea, Republic of

Introduction: obstructive sleep apnea (OSA), has been linked to cognitive impairment. However, few studies have examined how AHI severity over time relates to the development of mild cognitive impairment (MCI) in community populations.

Materials and methods: A total of 1,508 cognitively intact participants (K-MMSE ≥ 24) at baseline (2011–2014) who underwent in-home polysomnography (PSG) across three exam periods (baseline ~4-year intervals) were drawn from the Korean Genome and Epidemiology Study (KoGES) for this retrospective study. Sleep apnea parameters included overall and positional AHI, and REM and Non-REM AHI from PSG over 8 years. Participants were classified as cognitively unimpaired (CU) or Mild Cognitive Impairment (MCI) at the 2nd follow-up using the Seoul Neuropsychological Screening Battery-II (SNSB-II). Linear mixed regression estimated how 8-year trajectories of sleep parameters differed retrospectively by MCI status at the 2nd follow-up.

Results: Among the sleep apnea parameters assessed via PSG, although CU group has statistically insignificant change ($p=0.09$), the MCI group showed a slightly steeper increase in N1% of sleep duration from 2011–2014 to 2019–2022 (β [95% CI] = 0.57 [0.18, 0.95], $p = 0.004$). Also, the MCI group has marginally greater increase rate of supine AHI over 8-year periods from baseline (0.87 [0.002, 1.73], $p = 0.049$). Other sleep parameters, including overall AHI, non-supine AHI, REM AHI, and NREM AHI, did not show differential slopes between MCI groups; however, each group presented independent increases over time ($p < 0.05$).

In men, CU group showed a greater increasing rate in hypoxic burden index (HB) compared to MCI group (-2.64 [-5.19, -0.09], $p = 0.043$). Within-group analyses indicated significant increases in both groups over 8 years (5.45[4.12, 6.78], $p<0.001$ and 2.81[0.63, 4.99], $p=0.012$, respectively). In women, N1% of sleep duration differed significantly between groups, with the MCI group showing a greater 8-year increase (0.50 [0.04, 0.96], $p = 0.035$). Women with MCI also had a significantly steeper increase in REM AHI (1.36 [0.08, 2.64], $p = 0.037$). For sleep parameters without group–time interactions, overall AHI, supine AHI, and non-supine AHI increased independently in both CU and MCI groups ($p < 0.05$). Unlike men, women showed an additional independent increase in NREM AHI over time in both groups ($p < 0.001$), without group differences.

Conclusions: In this cohort, the MCI group showed modest increases in N1% of sleep duration and supine AHI, while men demonstrated no clear group differences aside from a rise in HB among CU participants. In women, however, MCI was associated with steeper increases in N1% of sleep duration and REM AHI. Given the established link between OSA and cognition, our findings suggest that rising REM AHI may contribute to elevated MCI risk, particularly in women. The significance of positional

parameters further highlights posture-related vulnerability. Overall, sleep parameters in future MCI cases may diverge years before diagnosis.

Screening prediction models using artificial intelligence for moderate-to-severe obstructive sleep apnea in patients with acute ischemic stroke

H.J. Lin¹, W.H. Ho²

¹Kaohsiung Medical University Hospital, Department of Neurology, Kaohsiung, Taiwan, ²Kaohsiung Medical University, Department of Healthcare Administration and Medical Informatics, Kaohsiung, Taiwan

Introduction: Obstructive sleep apnea (OSA) is common after stroke. Still, routine screening of OSA with polysomnography (PSG) is often unfeasible in clinical practice, primarily because of how limited resources are and the physical condition of patients. In this study, we used several artificial intelligence techniques to predict moderate-to-severe OSA and identify its features in patients with acute ischemic stroke.

Materials and methods: A total of 146 patients with acute ischemic stroke underwent PSG screening for OSA. Their baseline demographic characteristics, including age, sex, body mass index (BMI), Epworth Sleepiness Scale (ESS) score, and stroke risk factors, were recorded. Logistic regression analysis was conducted to identify significant features associated with moderate-to-severe OSA in patients with stroke. These significant features were used with six machine learning and ensemble learning algorithms, namely decision tree, support vector machine, random forest, extreme gradient boosting (XGBoost), adaptive boosting (AdaBoost), and gradient boosting, to compare the performance of several predictive models.

Results: Multivariate logistic regression analysis revealed that age, sex, BMI, neck circumference, and ESS score were significantly associated with the presence of moderate-to-severe OSA. According to the machine learning and ensemble learning results, the XGBoost model achieved the highest performance, with an area under the receiver operating characteristic curve of 0.89 and an accuracy and F1 score of 0.80.

Conclusions: This study identified key factors contributing to moderate-to-severe OSA in patients with ischemic stroke. The XGBoost model exhibited high predictive performance, indicating it has potential as a supporting tool for decision-making in health-care settings.

Acknowledgments: The authors thank all the study participants. The authors are grateful to Dr. Meng-Tsang Hsieh, Dr. Yi-Cheng Tai, Dr. Kang-Po Lee, and Dr Yu-Hsuan Liu from E-DA Hospital for their assistance in data collection.

Self-Administered Home Sleep Testing Model in Screening of OSA in Healthcare Workers – SOHEW Study: A National Multi-Centre Study in Vietnam

S. Duong-Quy¹, T. Nguyen-Duy¹, K. Bui-Diem¹, L. Nguyen-Thi-Hong¹, T. Tang-Thi-Thao¹, D. Nguyen-Thi-Hong¹, B. Nguyen-Trong¹, A. Nguyen-Tuan¹, H. Nguyen-Huu¹, Q. Vu-Tran-Thien¹, T. Nguyen-Van¹, T. ¹Vietnam Society of Sleep Medicine, Da Lat, Vietnam, ²World Sleep Society, Rochester, United States

Introduction: Sleep disorders, including snoring and obstructive sleep apnea (OSA), are significant health concerns. OSA affects an estimated 4 million individuals in Vietnam, with 2.3 million suffering from moderate-to-severe conditions. Despite the high prevalence, underdiagnosis and limited accessibility to sleep diagnostics remain challenges. This study aims to assess the feasibility and effectiveness of a guided, self-administered home sleep study using a Level-3 diagnostic model.

Materials and methods: A cross-sectional multicenter survey conducted from October 2023 to March 2024 included healthcare professionals (HCPs) across Vietnam. Participants completed questionnaires (Epworth Sleepiness Scale, STOP-BANG), and high-risk individuals underwent respiratory polygraphy

using ApneaLink Air devices. Standardized instructions and technical support were provided remotely by trained technicians.

Results: This study involved 1,721 participants recruited from 16 hospitals across 4 regions of Vietnam. Screening and respiratory polygraphy (RPG) identified obstructive sleep apnea (OSA) in 21.9% of the participants. Among 358 high-risk individuals who underwent RPG using ApneaLink Air devices, 61.2% were diagnosed with OSA. The severity distribution in this subgroup was 32.5% mild, 19.5% moderate, and 9.2% severe OSA, while 38.8% had no OSA. Common symptoms reported across the total sample included memory impairment (49.4%), excessive daytime sleepiness (40.7%), and insomnia (22.8%). Regarding technical feasibility, 27 out of 358 RPG recordings (7.5%) were unsuccessful due to device-related or operational issues.

Conclusions: A Level-3 home sleep study model is effective for large-scale OSA screening. Integrating such approaches into public health initiatives can enhance early diagnosis and treatment access, reducing OSA-related health and economic burdens.

Self-reported continuous positive airway pressure (CPAP) therapy use for patients located in metropolitan and regional areas across Australia

S. Evas¹, A. Sweetman^{2,1,3}, A. Vakulin^{1,3}, N. Lovato^{1,3}, N. Grivell^{1,3}, S. Appleton^{1,3}, B. Toson¹, D. McEvoy^{1,3}, R. Adams^{1,4,3}, C.L. Chai-Coetzer^{1,4,3}

¹Flinders University, Flinders Health and Medical Research Institute: Sleep Health, Adelaide, Australia, ²Australasian Sleep Association, Adelaide, Australia, ³Flinders University, National Centre for Sleep Health Services Research, Adelaide, Australia, ⁴Southern Adelaide Local Health Network, Respiratory, Sleep and Ventilation Services, Adelaide, Australia

Introduction: Obstructive sleep apnoea (OSA) is a prevalent and underdiagnosed sleep disorder for which continuous positive airway pressure (CPAP) is typically considered the first-line treatment. Due to the geographical expanse of Australia, many Australians live in regional locations and may experience difficulty accessing CPAP. Metropolitan and regional differences in OSA care pathways have been explored previously, however differences in CPAP adherence within that sample had not been evaluated. Emerging evidence suggests that greater remoteness may be associated with poorer CPAP adherence in an Australian setting.

Materials and methods: Data are from a nationwide online survey to investigate pathways to diagnosis and management, use of treatments and health status of Australian adults with a diagnosis of OSA. Data collection took place in 2021. Participants were recruited via email, phone alerts and advertisements. Metropolitan and regional residence was coded according to Australian Bureau of Statistics criteria. Univariate analyses (Chi-Squared and Fisher's Exact tests) were conducted examining associations between demographic variables and CPAP usage variables. Demographic variables included age (<50, 50-67, 68+ years of age), sex, location (regional, metropolitan). CPAP usage variables included ever using CPAP, currently using CPAP, CPAP adherence (defined as self-reported use ≥ 4 hours/night and ≥ 5 nights/week). A multivariable binomial logistic regression was run with CPAP adherence as the dependent variable, and age and location as independent variables.

Results: Of the 412 respondents, 354 (86%) were recommended CPAP therapy (44% female), 138 (39%) resided in regional areas and 216 (61%) in metropolitan areas. 190 (54%) reported receiving a diagnosis of OSA 5+ years prior to participating in the survey. 'Moderate' and 'severe' self-reported OSA occurred in 37%, and 42% of respondents, respectively. 213 (69%) respondents who have used CPAP purchased their machine privately. Geographical location showed no significant associations with ever using CPAP ($p=.909$), currently using CPAP therapy ($p=.218$) or self-reporting as CPAP adherent ($p=.104$). Age group was not significantly associated with ever using CPAP ($p=.635$) or current use ($p=.838$). Age was significantly associated with CPAP adherence (<50 years: 54%; 50-67 years: 94%; 68+ years: 98%; $\chi^2(2, 245)=64.84, p<.001$). Sex was not significantly associated with ever using CPAP ($p=.717$), current use ($p=.929$) or CPAP adherence ($p=.687$). Compared to those aged <50, participants aged 50-67 were 13.8 times more likely to be CPAP adherent (95% CI: 5.48-40, $p<.001$), with those aged 68 and over 36.1 times more likely to be CPAP adherent (95% CI: 9.97-233, $p<.001$).

Conclusions: CPAP adherence was high (86%) which may have been related to sample characteristics, including socioeconomic advantage, and highly motivated individuals undertaking a survey. CPAP adherence did not vary significantly as a function of geographical location of participants, which may be related to the high proportion of private purchases of CPAP machines. Older age groups were

associated with a higher odds of CPAP adherence, though the lowest adherence observed was 54% (<50 years old). Limitations include the lack of objective CPAP data and regional location including both regional and remote.

Sex differences in endocrine, metabolic and psychological disturbance in obese patients with OSA

X. Zhang¹

¹Department of Pulmonary and Critical Care Medicine, Center of Respiratory Medicine, China-Japan Friendship Hospital, National Clinical Research Center for Respiratory Diseases, Beijing, China, Beijing, China

Introduction: Obstructive sleep apnea (OSA) is associated with increased risks of glucolipid metabolic disruption, endocrine disturbances and psychological distress. There is scarce research regarding the influence of sex on these associations. The current study aimed to evaluate the effects of sex on metabolic, endocrine and psychological changes in patients with OSA.

Materials and methods: One hundred sixty-four young adult women and one hundred sixty-two age-matched men with OSA completed polysomnography assessments, questionnaires (including the Epworth Sleepiness Scale [ESS], Self-Reported Anxiety Scale [SAS], Self-Rating Depression Scale [SDS], and 12-Item Short-Form Health Survey [SF-12]) and biochemical analyses for glucolipid metabolism and endocrine function, including the pituitary-adrenal (PA), pituitary thyroid (PT), and pituitary-gonadal (PG) axes.

Results: Homeostasis model assessment of insulin resistance (HOMA-IR), thyroid hormone and midnight PA axis activity levels were greater in female patients with severe OSA compared to those with mild-to-moderate OSA, and these metabolic and endocrine changes were associated with nocturnal hypoxia only in female patients. Additionally, midnight cortisol was associated with HOMA-IR (independent of anthropometry and sleep disturbance parameters) in females ($\beta = 0.545$, $P = 0.012$, adjusted $R^2 = 0.217$). ESS was higher for male patients with severe OSA compared to females with the same level of OSA ($P = 0.003$), and ESS was associated with nocturnal hypoxia in males ($\beta = -0.494$, $P = 0.001$, adjusted $R^2 = 0.224$). SAS was higher for female patients with severe OSA compared to males with the same level of disease ($P = 0.001$).

Conclusions: The metabolic, endocrine and psychological consequences of OSA may differ across sexes. The associations of nocturnal hypoxia with glucose metabolic disturbance and the activation of the PA and PT axes were observed in females, whereas the association of nocturnal hypoxia with ESS was limited to males. This could indicate a distinct metabolic, endocrine and psychological phenotype for female patients with OSA, who may require different disease management strategies compared to males.

Simultaneous Polysomnography and Cardiotocography Reveal Temporal Correlation Between Maternal Obstructive Sleep Apnea and Fetal Hypoxia

J. Wang¹, F. Han²

¹Bing Zhou Medical University Hospital, Binzhou, China, ²Peking university, Beijing, China

Introduction: Obstructive sleep apnea syndrome (OSAS) during pregnancy is a prevalent complication that can negatively affect fetal outcomes. However, quantitative studies on the immediate effects of maternal hypoxia on fetal heart rate (FHR) changes are lacking, which could provide valuable clinical insights into the potential link between maternal OSAS and fetal hypoxia.

Materials and methods: Time-synchronized polysomnography (PSG) and cardiotocography (CTG) data from two prospective cohorts were used to analyze the temporal correlation between maternal hypoxic events and FHR changes (accelerations or decelerations). Maternal hypoxic event characteristics were analyzed using generalized linear modeling (GLM) to assess their associations with different FHR alteration. To accurately capture the dynamic fetal response, we employed a phase-specific analysis framework that explicitly divided each maternal hypoxic event into pre-, during-, and post-event

phases, enabling precise temporal mapping of FHR fluctuations in relation to maternal oxygenation changes.

Results: A total of 118 pregnant women were included, with 35 from Peking University People's Hospital and 83 from the Maternal Sleep in Pregnancy and the Fetus (MSP) dataset. Immediate FHR changes were significantly associated with maternal hypoxic events, primarily characterized by accelerations as a compensatory response. Notably, a longer hypoxic duration was strongly correlated with increased FHR accelerations ($P < 0.05$), while both prolonged hypoxia (Coef. = 0.012, $P < 0.001$) and greater SpO₂ drop value (Coef. = -0.151, $P = 0.046$) were significantly linked to FHR decelerations in the MSP dataset. Across both cohorts, maternal hypoxia induced a transient increase in FHR, which subsequently returned to baseline following the resolution of hypoxic episodes, reflecting dynamic and reversible fetal responses.

Conclusions: The immediate impact of maternal hypoxia on FHR changes highlights the link between maternal and fetal hypoxia, suggesting that maternal OSAS may contribute to fetal hypoxia. These findings underscore the risks of pregnancy-related OSAS and the importance of maternal-fetal interactions, providing a foundation for future research on interventions to improve fetal health.

Sleep and cardiovascular outcomes are worse in people with co-morbid obstructive sleep apnoea and chronic respiratory disease: insights from consumer data

M.-E. Day¹, B. Lechat¹, J. Manners¹, J. Fitton¹, L. Pinilla¹, T. Altree¹, S. Mukherjee¹, D. Eckert¹, A. Hudson¹

¹Flinders University, College of Medicine and Public Health, Adelaide, Australia

Introduction: Respiratory disease and obstructive sleep apnoea (OSA) are individually associated with increased risk of cardiovascular disease (CVD) and all-cause mortality. People with co-morbid respiratory disease and OSA (co-ROSA) may be at increased cardiovascular risk due to worse night-time hypoxemia which may be exacerbated by disrupted sleep. However, there is a lack of data assessing sleep and cardiovascular risk in co-ROSA.

Materials and methods: We used an international consumer sample of 321,307 nights of sleep data (Withings Sleep Analysers and Scan Watches) from 2573 people with a self-reported doctor diagnosis of respiratory disease (asthma, chronic obstructive pulmonary disease, emphysema) and/or OSA. The odds of self-reported CVD (heart attack, stroke, coronary heart disease, congestive heart failure) and sleep metrics were compared in co-ROSA, respiratory disease and OSA using logistic regression and ANCOVA, respectively, while controlling for age, sex, and BMI. It was hypothesised that people with co-ROSA would have poorer sleep (less total sleep time, higher sleep irregularity, and decreased sleep efficiency), and greater incidence of cardiovascular disease, than people with respiratory disease or OSA alone.

Results: Participants were middle-aged (53.2 ± 13.7 yrs, mean $\pm$ SD), predominantly male (73.2%), with high BMI (31.1 ± 6.5 kg/m²), and normal sleep duration (7.2 ± 1.2 hrs). People with co-ROSA had shorter sleep duration (7.07 hrs $\pm$ 82 minutes) than people with respiratory disease (7.41 hrs $\pm$ 65 minutes), as well as higher night to night variability (rmssd of sleep duration = 137.78 ± 93.41) compared to respiratory disease alone (122.89 ± 58.90), and poorer sleep efficiency ($85\% \pm 9.17$) than respiratory disease alone ($89\% \pm 7.33$). However, there were no differences between co-ROSA and OSA. Co-ROSA was associated with 53% increased odds of CVD compared to respiratory disease 95%CI [30, 92], $p=0.02$, but not OSA, OR 66%, 95%CI [42, 105], $p=0.08$.

Conclusions: Overall sleep quality was worse in co-ROSA than respiratory disease alone, with shorter sleep duration, greater night to night variability, and poorer sleep efficiency. In line with this finding, CVD is also more prevalent in co-ROSA than respiratory disease alone. OSA often goes undiagnosed in people with co-morbid respiratory disease as it can be more challenging to diagnose in this population. OSA diagnosis should be prioritised in people with respiratory disease to improve sleep outcomes and better identify CVD risk. The nearable and wearable technology utilised in this study is a promising new tool that could aid in the diagnosis and management of OSA in more challenging and under-diagnosed populations.

Sleep and hematological diseases

A. De Sanctis¹

¹Centre hospitalier de Versailles, Hôpital André Mignot, Sleep Unit, Le Chesnay, France

Introduction: Sleep is fundamental in global health and multidisciplinary is the key. We focussed on the link between hematologists and sleep specialists. In clinical practice patients are referred to Sleep Unit by the hemathologists to detect obstructive sleep apnea (OSA) in case of : Sickle cell disease (SCD) and erythrocytosis. The aim of this abstrct is to make a state of the art of data in Literature.

Materials and methods: A research on Pubmed was performed for "sickle cell disease and sleep disorders"; "sickle cell disease and OSA" , "erythrocytosis and OSA". For the 2 pathologies datas about epidemiology, prevalence, physiopathology, recommandations and treatment have been collected.

Results: Sickle cell disease is the most common genetic disease worldwide. Studies describe an higher prevalence of OSA in SCD (17-44%) than in general population (4-8%). That can be partially due to origin of patients (african more than caucasian), social profile (underprivileged population), increased attention to diagnosis as OSA can aggravate SCD. The mechanisms of this aggravation in OSA patients are: intermittent hypoxia that can trigger Hbs polymerisation and red blood cells (RBC) sickling; oxydative stress and inflammation; impaired vascular function and autonomic nervous system dysfunction that can generate venocclusive crisis. In Literature in the last 40 years few papers and only 3 clinical trials with small population have been published on this subject. They confirmed the strong association OSA and SCD.

OSA signs and symptoms in SCD patients are unusuals : patients are younger, with lower IMC, less sleepy, blood pressure is not higher, and at polygraphy there are more désaturations. More than 50% of patients are Insomniacs.

The complications in SCD seem to be associated to hypoxia on the contrary the apnea hypopnea index (AHI) doesn't seem to be a reliable marker of SCD crisis. There is still no evidence that treating OSA in adults reduces SCD complications.

Erythrocytosis is an abnormally elevated number of RBC and screening OSA is recommanded if a secondary erythrocytosis is suspected. Intermittent hypoxia in OSA is considered a potential trigger for erythropoietin production. Among the 171 papers analysed in the metalalysis publishd in 2022 (Martelli et al; HEMATOLOGY) the prevalence of erythrocytosis in OSA is 2% and in severe OSA 6.2%. The effects of CPAP were a reduction of 3.7- g/l of Hb and 1,1% of HCT.

Erythrocytosis in OSA can be also relative : due to nycturia if the blood test is done in the morning the hemoconcentration during sleep can be responsable of a higher HCT that will be normalised if the blood test is controlled in the afternoon (differences up to 7%).

Conclusions: Hematologists are concerned by OSA diagnosis in SCD and erythrocytosis. In both diseases the physiopathology of the association is well known but we still need studies to determine the threshold of AHI or hypoxic burden to propose treatment and the efficacy of CPAP in reducing crisis in SCD patients and reducing HCT in erythrocytosis

Studies about sleep and hematology are a good exemple of the multidisciplinary of sleep medicine

Sleep and Survival: A Low-Cost Home Ventilation Strategy for Children with Neuromuscular disease in Resource-Limited Settings

S. Suresh Shinde¹, I. Kinimi¹, R. Ramesh², N. Rao¹, A. Sahoo¹, A. Khemani¹, M. Maganthi³, A. Agnes Mathew²

¹Manipal Hospitals, Pediatric Pulmonology and Sleep Medicine, Bangalore, India, ²Baptist Hospital, Pediatric Neurology, Bangalore, India, ³Baptist Hospital, Pediatric Genetics, Bangalore, India

Introduction: Children with neuromuscular disorders are especially vulnerable to sleep-related breathing disturbances and chronic respiratory failure, which is a leading cause of death in these children. In many low- and middle-income countries, delivering comprehensive care is challenging due to high out-of-pocket costs and limited access to specialized equipment. This study presents real-world

data from a pediatric neuromuscular clinic in India, highlighting how low-cost, innovative strategies can support effective home ventilation and sleep care in resource-limited settings.

Materials and methods: This is a retrospective observational study. We included children with NMD up to 18 years of age who attended our tertiary pediatric neuromuscular clinic between January 2018 and February 2025. Clinical profiles, Level-1 Polysomnography (PSG) data when available, along with treatment and outcomes, were analysed.

Results: 415 children (63.6% male) diagnosed with NMD were included. The majority of our cohort had spinal muscular atrophy (SMA, n=213), followed by Duchenne muscular dystrophy (DMD, n=96), and the remaining had other NMD (n=106).

302/415 (72.2%) children had a PSG done with a median Apnea-Hypopnea Index (AHI) of 7.6 (0.3 to 78) per hour of total sleep time, with 64.14% of children having moderate to severe OSA.

HMV was initiated in 351/415 (84.5%) of children. 78/213 (36.6%) of children with SMA1 and SMA2 received DMT-like gene therapy (n=35), Risdiplam (n=22), and Spinraza (n=21). 18 children had a tracheostomy, 55 used mechanical insufflation-exsufflation (MI-E), 34 were on NG feeds, and 28 had a PEG tube with fundoplication done. Optimizing care in these children reduced recurrent hospital admissions in 74% of children. 25 children expired due to respiratory failure.

Among 351 children on HMV, 68% were remotely monitored via video and telephone consultations. A 24/7 emergency contact number along with technician support was provided to families, many of whom travel from across India and often lack access to specialized respiratory care locally. Smaller hospitals frequently hesitate to initiate BiPAP in acutely unwell children, making remote guidance and continuity of care essential.

To overcome the financial burden of out-of-pocket healthcare expenses in India, families utilize affordable Indian-manufactured BiPAP devices (costing <\$500 USD) or rent BiPAP and MI-E machines for \$40 and \$120/month, respectively. Additional support through crowdfunding has helped cover the cost of diagnostics and treatment, while the donation of 40 BiPAP units to our neuromuscular disease unit has further expanded access. Equally important has been the role of family WhatsApp groups, which have become a powerful tool for real-time support, shared learning, and fostering a sense of community among caregivers facing similar challenges and simultaneously raising awareness.

Conclusions: A low threshold for initiation of BiPAP when indicated without a PSG initially is a reasonable practical approach in resource-limited settings. Early initiation of cough assist and HMV helped reduce morbidity and mortality.

This model of care—combining remote monitoring, low-cost locally manufactured respiratory devices, rental options, and philanthropic support—demonstrates a sustainable approach to delivering HMV. Such strategies provide a practical framework for scalable and equitable chronic respiratory care in other low- and middle-income countries.

Sleep Apnea-Hypopnea Events Detection Using a Wireless Abdomen-Worn Sensor with SpO₂ Monitoring

T.H. Dang¹, H.-k. Min², N.-h. Sung², Y.-m. Huh², H. Yoon¹, B. Franklin¹

¹Ulsan National Institute of Science and Technology, Department of Electrical Engineering, Ulsan, Korea, Republic of, ²Ulsan National Institute of Science and Technology, SB solutions Inc, Ulsan, Korea, Republic of

Introduction: Obstructive sleep apnea (OSA) is traditionally diagnosed using polysomnography (PSG), a costly and inconvenient procedure requiring specialized facilities and long wait times. To address these challenges, wireless wearable devices have been explored as alternatives. However, most of these devices do not classify apnea and hypopnea events, which are essential for determining appropriate treatment for OSA. Detecting hypopnea is particularly challenging due to its subtle characteristics compared to apnea. This study presents a deep learning method for classifying apnea and hypopnea events using a wireless abdomen-worn sensor and SpO₂ monitoring.

Materials and methods: Two hundred participants suspected of OSA underwent overnight in-laboratory PSG, along with data collection from a wireless abdomen-worn sensor (sampling rate: 5 Hz). PSG data were manually scored by clinicians, classifying respiratory events as apnea or hypopnea. SpO₂ and pulse rate data were extracted from PSG and downsampled to 5 Hz. Capacitive and 3-axis accelerometer data from the abdomen-worn sensor were synchronized with the PSG data and preprocessed. Features such as normalized capacitance, local capacitive gap, sleep position, and the length of the acceleration vector were extracted from the capacitive and accelerometer data, serving as primary inputs for the classification model. The MLP-Mixer model was employed for automated classification, utilizing inputs that included the extracted features along with or without SpO₂ and pulse rate information. The apnea-hypopnea index (AHI) was computed as the total number of apnea and hypopnea events detected by the model divided by the recording time. Seven recordings were excluded due to poor data quality, leaving 100 subjects for training and 93 for testing. The area under the curve (AUC) metric was used to evaluate the model's performance in detecting apnea and hypopnea across three configurations: Model 1 (abdomen-worn data with SpO₂ and pulse rate), Model 2 (abdomen-worn data with SpO₂), and Model 3 (abdomen-worn data alone). The agreement between AHI measured by PSG (AHI-PSG) and the predicted AHI (AHI-Model) was assessed through Pearson correlation.

Results: On the test set, the hypopnea detection resulted in AUC values of 0.856, 0.8762, and 0.7571 for Model 1, Model 2, and Model 3, respectively. The apnea detection resulted in AUC values of 0.9483, 0.9511, and 0.9035 for Model 1, Model 2, and Model 3, respectively. The combined features of Soomirang and SpO₂ achieved a sensitivity of 0.7786 and specificity of 0.8082 for hypopnea detection, and a sensitivity of 0.9436 and specificity of 0.8015 for apnea detection. The correlation coefficient between AHI-PSG and AHI-Model2 was 0.9694.

Conclusions: This study highlights the effectiveness of using a wireless abdomen-worn sensor combined with SpO₂ data for accurately classifying apnea and hypopnea events. The results underscore the promise of a non-invasive, wireless, wearable solution for reliable OSA screening.

Acknowledgments: This work was supported by Innovative Human Resource Development for Local Intellectualization program through the Institute of Information & Communications Technology Planning & Evaluation (IITP) grant funded by the Korea government (MSIT)(IITP-2025-RS-2022-00156361).

Sleep apnea phenotypes based on multi-night assessment of sleep perception

J. Kuhn^{1,2}, L. Schiphorst^{1,2}, B. Wulterkens^{1,2}, J. Asin³, S. Overeem^{1,4}, M. van Gilst^{1,4}, P. Fonseca^{1,2}

¹Eindhoven University of Technology, Eindhoven, Netherlands, ²Philips Sleep and Respiratory Care, Eindhoven, Netherlands, ³Center for Sleep Medicine, Amphia Hospital, Breda, Netherlands, ⁴Sleep Medicine Center Kempenhaeghe, Heeze, Netherlands

Introduction: Sleep time misperception has been reported in obstructive sleep apnea (OSA) patients during polysomnography (PSG). However, little is known about multi-night sleep perception patterns in OSA patients' daily lives. We leveraged recent developments in wearable technology to identify OSA phenotypes based on patients' sleep perception patterns over multiple nights in their regular sleeping environment.

Materials and methods: The study included newly diagnosed OSA patients who were instructed to track their sleep for 14 days using objective and self-report metrics. Objective sleep parameters were calculated using a four-class sleep staging algorithm (distinguishing Wake, combined N1/N2, N3, and REM) that takes instantaneous heart rate and body movements acquired through a validated wrist-worn photoplethysmography and accelerometry device as input. A digital sleep diary was used to assess self-reported sleep parameters. All measurements were completed after diagnostic PSG and prior to starting OSA treatment. The perception of total sleep time (TST) was evaluated using the misperception index (MI), using the following formula: (objective TST – self-reported TST)/objective TST. K-means clustering was used to identify multi-night sleep perception patterns using two features: the median and the median absolute deviation of patients' MI values. Clusters were compared across several clinical characteristics and sleep parameters. For continuous parameters, the Kruskal-Wallis test (KW) was performed, with Dunn's post-hoc test (D) in case between-group comparisons were significant. For dichotomous variables, the chi-square test was performed, with pairwise Fisher Exact tests for post-hoc analysis.

Results: The study included 120 OSA patients, with 1605 recording nights in total (median=12.00, IQR=7.00). We identified four distinct sleep perception clusters: accurate estimation (n=64), underestimation (n=33), severe underestimation (n=6) and variable overestimation (n=17). Patients in the variable overestimation cluster were older (median age = 57.00) than patients in the accurate estimation cluster (median age = 46.50, $D p=0.005$), and had a higher apnea hypopnea index (AHI) than participants in all other clusters (KW $p=0.003$). Moreover, the sleep architecture of patients in this cluster was more disrupted compared to the other clusters, with a lower sleep efficiency than the accurate estimation cluster ($D p=0.007$), and a higher N1/N2% (KW $p=0.001$), a lower N3% (KW $p=0.044$) and a lower REM% (KW $p=0.024$) than the accurate and underestimation cluster. Both underestimation clusters had a higher prevalence of insomnia symptoms (Chi-square $p=0.001$), a lower self-reported sleep quality (KW $p<0.001$) as well as a higher Insomnia Severity Index (KW $p=0.001$), Pittsburgh Sleep Quality Index (KW $p<0.001$), and Pre-Sleep Arousal Scale (KW $p=0.013$) score than the other clusters. The severe underestimation cluster reported a particularly high pre-sleep cognitive arousal which significantly differed from the accurate estimation and variable overestimation clusters (KW $p=0.004$).

Conclusions: Distinct OSA phenotypes can be identified based on patients' multi-night sleep time perception patterns. Different phenotypes present with distinct clinical characteristics. For instance, they exhibited distinct profiles with regards to their AHI, insomnia symptom prevalence, as well as objective and self-reported sleep characteristics, highlighting the heterogeneity of the OSA population. These insights may facilitate more personalized treatment approaches.

Sleep Apnea-Specific Hypoxic Burden and Postoperative Outcomes Of Major Non-Cardiothoracic Surgery

Introduction: Obstructive sleep apnea (OSA) is a highly prevalent and heterogeneous condition that predisposes to postoperative complications. Adequate metrics of OSA severity to stratify postoperative risk in clinical setting are needed. This study evaluates whether quantifying OSA severity by the sleep apnea-specific hypoxic burden (SASHB) would predict postoperative cardiovascular (CV) complications and mortality among patients undergoing major non-cardiothoracic surgery.

Materials and methods: Multicenter clinic-based cohort linked with health administrative database, involving adult patients diagnosed with OSA between May 2007 and December 2018 who underwent major non-cardiothoracic surgery between OSA diagnosis and December 2021.

Exposure SASHB is defined as the area under the desaturation curve associated with sleep-related obstructive respiratory events.

The primary outcome was a composite of stroke, atrial fibrillation, heart failure, myocardial infarction, venous thrombo-embolism, and all-cause mortality within 30 days of surgery. The association of SASHB and other OSA severity metrics with the primary outcome was investigated using univariable and multivariable analyses.

Results: Among 1,962 patients with OSA (median [IQR] age of 58 [49-66] years; 64% men) who underwent major non-cardiothoracic surgery 3.5 [1.6-5.8] years after OSA diagnosis, the primary outcome occurred in 71 patients (3.6%) within 30 days of surgery. Compared with patients with SASHB<32%min/h, patients with higher SASHB at diagnosis exhibited increased odds for the primary outcome (adjusted OR [95%CI], 3.291 [1.407-7.699] and 4.217 [1.829-9.723] for SASHB 32 to <80%

and $\geq 80\%$ min/h respectively). A risk score based on age, history of CV diseases and SASHB was predictive of the primary outcome (area under receiver operating characteristic curve, 0.72 [95% CI, 0.68-0.79]).

Conclusions: Among OSA patients undergoing major non-cardiothoracic surgery, SASHB was significantly associated with the risk of 30-day postoperative mortality and CV complications. Further research is needed to determine whether interventions guided by SASHB scores can modify postoperative risk in patients with OSA.

Sleep Architecture and Quality of Life in Comorbid OSA and Depression: Cross-sectional analysis of the Sydney Sleep Biobank

D.E.C.Y. Chan¹, Y.S. Bin^{2,3}, K. Karaitis^{4,5,6}, B.J. Yee^{1,7,8}

¹Woolcock Institute of Medical Research, Macquarie Park, Australia, ²University of Sydney, Sleep Research Group, Charles Perkins Centre, Sydney, Australia, ³University of Sydney, Northern Clinical School, Faculty of Medicine and Health, Sydney, Australia, ⁴The Westmead Institute of Medical Research, Ludwig Engel Centre for Respiratory Research, Westmead, Australia, ⁵Westmead Hospital, Department of Respiratory and Sleep Medicine, Westmead, Australia, ⁶University of Sydney, Westmead Clinical School, Faculty of Medicine and Health, Westmead, Australia, ⁷Royal Prince Alfred Hospital, Department of Respiratory and Sleep Medicine, Camperdown, Australia, ⁸University of Sydney, Central Clinical School, Sydney Medical School, Sydney, Australia

Introduction: Obstructive sleep apnoea (OSA) and depression are individually associated with changes in sleep architecture and reduced quality of life. However, there are few studies which report on the joint impact of comorbid OSA and depression.

Materials and methods: 1217 participants from the Sydney Sleep Biobank database were assessed (38% female; age 49.5 ± 15.6). Participants were patients who were referred for and underwent an overnight sleep study on suspicion of sleep disordered breathing. Participants were divided into 4 groups based on the presence or absence of OSA and depression. Participants who were diagnosed with an alternate sleep disorder (i.e. central sleep apnoea, restless legs syndrome, insomnia, narcolepsy) were excluded. Criteria used to divide the groups were an apnoea-hypopnoea index greater than 5/hour ($AHI \geq 5$) and a depression subscore greater than 4 ($D > 4$) from the Lovibond and Lovibond Depression Anxiety Stress Scale-21; (1) no OSA-no depression ($AHI < 5$, $D \leq 4$), (2) OSA-only ($AHI \geq 5$, $D \leq 4$), (3) depression-only ($AHI < 5$, $D > 4$), (4) comorbid OSA and depression ($AHI \geq 5$, $D > 4$). Sleep architecture, quality of life (Epworth Sleepiness Scale, ESS and Functional Outcomes of Sleep, FOSQ-10), and cardiovascular comorbidities and cardiovascular risk as indicated by Framingham risk scores were compared between groups. Covariates considered included age, gender, body mass index, smoking, alcohol, and psychiatric medications.

Results: Data from 821 participants were included in the final analysis. Comorbid OSA and depression was associated with a longer REM latency (REML) than OSA-alone (141min vs 123min, $p=0.043$). However, further analysis excluding patients on psychiatric medications revealed that the prolonged REML was a medication effect. After psychiatric medications were accounted for, there were no other significant differences in sleep architecture between comorbid OSA and depression and OSA-alone. Depression groups had worse ESS and FOSQ-10 scores. There was no increase in cardiovascular risk or comorbidities with comorbid OSA and depression compared to OSA-alone.

Conclusions: Despite the lack of changes in sleep architecture, it is still important to identify comorbid OSA and depression as it can be associated with worse quality of life and this may affect treatment compliance.

Acknowledgments: We acknowledge the work of all those that have contributed to the Sydney Sleep Biobank (SSB) data collection. The authors would additionally like to thank all the SSB participants for contributing their data to this effort.

Sleep breathing impairment index predicts incident atrial fibrillation in obstructive sleep apnea: a prospective cohort study

L. Wang¹, X. Hui², W. Cao², R. Huang², Y. Xiao²

¹Peking Union Medical College Hospital, Department of Pulmonary and Critical Care Medicine, Beijing, China, ²Peking Union Medical College Hospital, Beijing, China

Introduction: Respiratory-event-associated hypoxia is crucial in cardiovascular comorbidities of obstructive sleep apnea (OSA). Intermittent hypoxia is an independent risk factor for atrial fibrillation (AF). The sleep breathing impairment index (SBII) is a novel metric that quantifies respiratory events and hypoxia, showing exceptional efficacy in predicting cardiovascular diseases. This study aims to evaluate the association between SBII and AF in OSA patients and compare the predictive performance of various OSA severity indices in predicting incident AF.

Materials and methods: This study included 1660 OSA patients without pre-existing AF from the Sleep Heart Health Study. Baseline SBII values were stratified into quartiles. Multivariate logistic regression analysis and restricted cubic spline analysis were conducted to explore the association between SBII and incident AF. Harrell's concordance statistic (C-statistic) was performed to compare the predictive value of SBII against other OSA severity indices.

Results: During a mean follow-up of 5.3 years, 190 (11.5%) OSA patients developed AF. SBII and hypoxic burden (HB) were associated with an increased risk of incident AF, with adjusted odds ratios of 1.87 (95%CI: 1.14, 3.11; $P=0.015$) and 2.01 (95%CI: 1.20, 3.41; $P=0.009$) for the third and fourth quartiles of SBII, respectively, and 1.70 (95%CI: 1.04, 2.81; $P=0.038$) for the fourth quartile of HB. Moreover, SBII had the largest C-statistic (0.75, 95% CI: 0.709, 0.782) compared with HB, AHI, and ODI.

Conclusions: This study demonstrated that elevated SBII and HB levels increased the risk of incident AF in OSA patients, with SBII outperforming other OSA severity indices in predicting AF.

Acknowledgments: The authors thank all the members of the Sleep Heart Health Study for their contributions.

Sleep-disordered breathing in children with Prader-Willi syndrome and the effect of growth hormone therapy

P. Tovichien^{1,2}, N. Simakajornboon², M.M. Hossain²

¹Faculty of Medicine Siriraj Hospital Mahidol University, Bangkok, Thailand, ²Cincinnati Children's Hospital Medical Center, Cincinnati, United States

Introduction: Growth hormone (GH) therapy may influence sleep-disordered breathing in children with Prader-Willi syndrome (PWS). This study analyzes polysomnographic data collected before and after GH initiation and compares longitudinal data on sleep-related respiratory parameters between children who received GH and those who did not.

Materials and methods: This retrospective study analyzed longitudinal polysomnographic data from children with PWS who underwent polysomnography at Cincinnati Children's Hospital between 2000 and 2024. Participants were categorized based on whether they received GH therapy. In the GH-treated group, pre- and post-treatment sleep parameters were compared using the Wilcoxon signed-rank test. Additionally, longitudinal polysomnographic data were compared between GH-treated and untreated children.

Results: A total of 49 children with PWS were included, with a median age of 1.3 years at their initial polysomnography. GH therapy was initiated in 32 of these children at a median age of 1.9 years. At baseline, the median obstructive apnea-hypopnea index (AHI) was 1.8 events/hour, with 25% of children exceeding 5.0 events/hour. Although the median obstructive AHI did not change significantly following GH therapy ($P = 0.639$), 56% of children showed an increase in obstructive events. In contrast, the median central AHI significantly decreases after GH therapy ($P = 0.014$). There were no significant differences in obstructive or central AHI between the GH-treated and untreated groups.

Conclusions: The rise in obstructive AHI among most children with PWS after GH therapy underscores the need for surveillance polysomnography to enable early detection and proper management.

Sleep-disordered breathing increases all-cause and cardiovascular mortality in patients with diabetes mellitus - SHHS study

J. Polak^{1,2}, K. Westlake¹, M. Petras³, T. Vichova^{1,4}, P. Waldauf⁵

¹Charles University, Third Faculty of Medicine, Department of Pathophysiology, Prague, Czech Republic, ²Thomayer University Hospital, Department of Internal Medicine, Prague, Czech Republic, ³Charles University, Third Faculty of Medicine, Department of Epidemiology and Biostatistics, Prague, Czech Republic, ⁴University Hospital Kralovske Vinohrady, Department of Cardiology, Prague, Czech Republic, ⁵Charles University, Third Faculty of Medicine, Department of Anaesthesia and Intensive Care Medicine, Prague, Czech Republic

Introduction: Sleep-disordered breathing (SDB) and diabetes mellitus (DM) frequently coexist; however, limited data are available on the effect of SDB on mortality in individuals with DM.

Materials and methods: The analysis included data from the Sleep Heart Health Study, a multicenter prospective observational study encompassing 5,780 participants with polysomnography and mortality data, among whom 453 had diabetes mellitus (DM). The study aimed to evaluate the influence of sleep-disordered breathing (SDB) variables and the presence of DM on all-cause, cardiovascular disease (CVD), and non-CVD-related mortality. Survival analysis and proportional hazard regression models were employed to determine adjusted hazard ratios (aHR) for mortality outcomes.

Results: Patients with diabetes mellitus (DM) who had an average SpO₂ greater than 91.4% demonstrated significantly lower risks of all-cause mortality (aHR 0.52, CI 0.34–0.80) and cardiovascular disease (CVD) mortality (aHR 0.44, CI 0.22–0.87) compared to those with SpO₂ below this threshold. In participants with DM receiving treatment, an apnea-hypopnea index above 31 (aHR 1.58, CI 1.10–2.28) and an oxygen desaturation index greater than 13.3 (aHR 1.58, CI 1.10–2.25) were linked to higher all-cause mortality. Sleep efficiency and the proportion of rapid-eye movement (REM) sleep did not affect mortality in patients with DM, differing notably from individuals without DM, where reduced sleep efficiency (<81.4%; aHR 0.77, CI 0.68–0.87) or lower REM sleep (<14.9%; aHR 0.78, CI 0.68–0.89) was associated with increased all-cause mortality.

Conclusions: Patients with diabetes undergoing treatment and moderate to severe sleep-disordered breathing face an elevated risk of all-cause mortality. Lower average oxygen saturation was a predictor of both all-cause and cardiovascular mortality in individuals with diabetes.

Sleep-disordered breathing is associated with adverse short - and long-term outcomes in acute ischemic stroke and TIA: Findings from the Bern Sleep-Stroke Registry

X. Yang^{1,1}, J. Lippert², S. Bauer-Gambelli², C. Horvath¹, S. Baillieul³, T. Meinel², T. Reichlin⁴, A.-K. Brill¹, C. Bernasconi², I. Filchenko², M.H. Schmidt², D.J. Seiffge², M. Arnold², U. Fischer², C.L.A. Bassetti²

¹Bern University Hospital (Inselspital) and University of Bern, Department of Neurology, Bern, Switzerland, ²Bern University Hospital (Inselspital) and University of Bern, Department of Pulmonary Medicine, Allergology and Clinical Immunology, Bern, Switzerland, ³Grenoble Alpes University, HP2 – Inserm U1300, CHU Grenoble Alpes, Grenoble, France, ⁴Bern University Hospital (Inselspital) and University of Bern, Department of Cardiology, Bern, Switzerland

Introduction: Sleep-disordered breathing (SDB) is prevalent after stroke and has been associated with poor outcomes; however, data from large cohorts following acute ischemic stroke remain limited. This study aimed to evaluate the impact of SDB on all-cause mortality, major adverse cardiovascular events (MACE), and functional outcomes.

Materials and methods: This retrospective cohort study included consecutive patients with acute ischemic stroke at the Stroke Center at Inselspital Bern who underwent respiratory polygraphy within 72 hours of admission. SDB severity was stratified by the apnea-hypopnea index (AHI) into mild (AHI ≥ 5 events/h), moderate (AHI ≥ 15 events/h), and severe (AHI ≥ 30 events/h). Outcomes included poor functional outcome (modified Rankin Scale [mRS] ≥ 3 at 3 months), all-cause mortality, and MACE. Associations were evaluated using multivariable Cox and logistic regression models, adjusted for age, sex, body mass index, hypertension, diabetes, dyslipidemia, atrial fibrillation, and initial stroke severity (NIHSS). Results were reported as adjusted hazard ratios (HR) or adjusted odds ratios (OR) with 95% confidence intervals (CI).

Results: A total of 1083 patients were included (678 males, 62.6%; mean age 66.0 ± 14.5 years; mean follow-up 84 months). SDB (AHI ≥ 5 /h) was present in 819 patients (75.6%), including 323 (29.8%) with mild, 248 (22.9%) with moderate, and 248 (22.9%) with severe SDB. Central sleep apnea was identified in 69 (6.4%) patients. Severe SDB was significantly associated with all-cause mortality (adjusted HR 2.77, 95% CI: 1.20–6.40). Moderate (adjusted HR 1.81, 95%CI: 1.18–2.79) and severe SDB (adjusted HR 1.55, 95%CI: 1.01–2.40) were linked to increased an increased risk of MACE, and severe SDB was associated with poor functional outcome (mRS ≥ 3) at 3 months (adjusted OR 2.50, 95%CI: 1.46–4.38). **Conclusions:** In this large cohort from the Bern Sleep-Stroke Registry, SDB was highly prevalent and independently associated with mortality, cardiovascular events, and impaired functional recovery, with risks increasing by severity. These findings support routine SDB screening and severity-based risk assessment in stroke care.

Sleep fragmentation during REM and NREM sleep and glucose metabolism in patients with obstructive sleep apnea

J. Guan¹, H. Xu², H. Yi², S. Yin²

¹Shanghai sixth people's hospital, Dept of Otolaryngology Head and Neck Surgery & Center of Sleep Medicine, Shanghai, China, ²Shanghai sixth people's hospital, Shanghai, China

Introduction: Although numerous studies have demonstrated the positive relationships between apnea-hypopnea index (AHI), micro-arousal index (MAI) and glucose metabolism, the associations between sleep fragmentation during REM-phase and NREM-phase and abnormal glucose metabolism is not clear yet.

Materials and methods: Subjects with initially suspected obstructive sleep apnea (OSA) in the Shanghai Sleep Health Study (SSHS) were selected. For each subject, MAI-REM and MAI-NREM data from overnight standard polysomnography; fasting plasma glucose and insulin (FINS) were also collected. The relationships between MAI and glucose metabolism in REM and NREM phases were assessed by logistic regression and multivariable linear regressions.

Results: A total of 4448 participants (mean age: 41.336 ± 12.374 years and mean BMI: $26.261 \pm 3.713 \text{ kg/m}^2$) were finally included in this study. Of all the subjects, the mean MAI-REM was 25.496 ± 19.279 events/h, and the mean MAI-NREM was 25.540 ± 18.204 events/h. Linear regression analyses revealed that MAI-NREM was independently associated with FINS ($\beta = 0.014$, $P = 0.011$). This association remained significant after sensitivity analyses excluding subjects with MAI-REM higher than the median ($\beta = 0.032$, $P = 0.026$). However, logistic regressions showed that no significant correlations were found between MAI-REM, MAI-NREM and hyperglycemia, hyperinsulinemia or insulin resistance (all $P > 0.05$), after adjustment for confounders including age, sex, BMI, smoking and alcohol consumption.

Conclusions: In OSA patients, a significant positive correlation was observed between MAI-NREM and FINS. Further prospective cohort studies are needed to determine such relationships.

Sleep quality and sleep symptom manifestation in patients with atrial fibrillation and sleep apnea

J. Kwon¹, X. Liu², P. Stafford³, H. Bonner³, Y. Cho⁴, Y. Kwon⁵

¹Stanford University, Palo Alto, United States, ²New York University, New York, United States, ³University of Virginia, Charlottesville, United States, ⁴Veterans Affairs Puget Sound Health Care, Seattle, United States, ⁵University of Washington, Seattle, United States

Introduction: Sleep apnea is highly prevalent in patients with atrial fibrillation (AF). Daytime sleepiness is an important consequence of sleep apnea, which can compromise quality of life. The current guidelines recommend screening for signs and symptoms of sleep apnea in patients with AF and considering treatment of sleep apnea to improve AF treatment outcomes. There have been suggestions that patients with AF tend to have poor quality of sleep but manifest less pronounced sleep symptoms. We investigated objective sleep quality and subjective daytime sleepiness in patients with AF.

Materials and methods: We included patients with and without (1:1 match) a history of AF who underwent clinically indicated in-lab sleep study at a single academic sleep center. Sleep apnea was defined by apnea-hypopnea index ≥ 15 . We compared sleep quality metrics (total sleep time, sleep efficiency, and deep sleep time [N3]) based on polysomnography by sleep apnea status. In patients with sleep apnea, we compared the subjective report of daytime sleepiness as measured by the Epworth sleepiness scale (ESS). We then examined whether excessive daytime sleepiness (EDS) ($ESS \geq 11$) is associated with sleep apnea in patients with AF, adjusting for sex, obesity, and age category by AF status.

Results: The cohort included 465 patients (AF 51%, male 57%, mean age 63). The prevalence of sleep apnea was similar between patients with and without AF (58 vs. 52%, $p=0.16$). While there was no difference in total sleep time (276 vs. 291 min, $p=0.18$), sleep efficiency (68 vs. 73%, $p=0.01$) was lower in patients with AF. The amount of deep sleep (N3) was similar between the two groups (10.6 vs. 11.6 min, $p=0.48$). In patients with sleep apnea, the reported degree of daytime sleepiness (ESS 10.1 vs. 10.7, $p=0.32$) and the prevalence of EDS (36 vs. 40%, $p=0.46$) were similar between the two groups. In multivariable analysis, EDS was associated with the risk of sleep apnea (odds ratio: 1.87 [1.1, 3.3], $p=0.03$). However, such an association was not found in patients with AF (odds ratio: 1.23 [0.71, 2.15], $p=0.46$).

Conclusions: Patients with AF had lower sleep efficiency but comparable total sleep time and deep sleep compared to patients without AF. In patients with sleep apnea, the subjective reporting of EDS was similar to that of patients without AF. In patients with AF, EDS was not predictive of sleep apnea. Thus, more rigorous sleep apnea screening beyond symptoms may be indicated in patients with AF.

Sleep Quality with EPAP Enhanced Novel Mandibular Advancement Device versus Continuous Positive Airway Pressure in Severe Obstructive Sleep Apnea

S. Sharma¹, A. Conflitti¹, H. Reiter¹, A. Sharma², G. Abraham³, H. Garg⁴

¹Centre for Sleep and Chronobiology, Toronto, Canada, ²University of Medicine and Health Sciences, Basseterre, Saint Kitts and Nevis, ³DentCare Dental Lab Pvt Ltd., Kerala, India, ⁴Sleep Care Solutions, Southport, Australia

Introduction: The study was performed to compare self-reported sleep quality, treatment compliance, and respiratory event index (REI) after 6 months of treatment with EPAP enhanced mandibular advancement device - O2Vent Optima+ExVent (EMAD) versus continuous positive airway pressure (CPAP) in severe obstructive sleep apnea (OSA). O2Vent Optima is a novel oral appliance that incorporates both mandibular advancement to reduce pharyngeal collapsibility and an air channel that allows airflow through the device to circumvent nasopharyngeal obstruction. The ExVent is an accessory to the novel oral appliance and provides oral Expiratory Positive Airway Pressure (EPAP) to support upper airway by passive dilatation of the airway, which reduces flow limitation.

Materials and methods: A total of 26 patients with severe OSA who either declined or failed CPAP were treated with EMAD. The comparison group was 26 severe OSA patients who were treated with CPAP therapy. Both groups were prospectively followed for 6 months. Data were collected through Level 1 polysomnographic sleep recordings, CPAP downloads, Epworth Sleepiness Scale (ESS), Stanford Sleepiness Scale (SSS) and Functional Outcomes of Sleep Questionnaire (FOSQ-10). Data was analyzed to assess compliance, ESS, SSS, FOSQ-10 scores and REI, respectively. Reliable change index (RCI) was used to evaluate change in FOSQ global score.

Results: More patients were compliant with EMAD treatment (89.5%) than CPAP treatment (67.9%) at 6-month follow-up ($P<0.01$). Both groups had improved ESS, SSS and FOSQ-10 scores: EMAD (ESS: 12.8 ± 3.6 to 7.9 ± 2.6 ; SSS: 3.4 ± 1.2 to 2.2 ± 0.7 FOSQ-10: 13.2 ± 2.9 to 17.3 ± 3.1 ; mean difference - 2.9, (95% CI -3.5 to -2.4); $P<0.001$) and CPAP (ESS: 13.2 ± 3.5 to 6.7 ± 3.4 , SSS: 3.3 ± 1.1 to 2.2 ± 0.9 ; FOSQ-10: 13.9 ± 2.5 to 17.8 ± 3.6 ; mean difference -3.1 (95% CI -3.2 to -2.4); $P<0.001$). Patients in both groups had improved FOSQ global score according to the RCI, EMAD group (38.6%) and CPAP

group (36.7%) ($P > 0.05$). Both treatments reduced REI to $< 10/\text{hr}$. similarly; EMAD (82%) and CPAP (94%) ($P > 0.05$).

Conclusions: Both EMAD and CPAP treatments improved self-reported sleep quality in patients with severe OSA. EMAD treatment was associated with better compliance; however, the improvement in sleep quality was similar with EMAD and CPAP, REI was reduced similarly with both the treatments. We conclude that EMAD treatment should be considered an effective therapeutic option for severe OSA patients who decline or fail CPAP therapy.

Acknowledgments: Funding for this research was provided by the Centre for Sleep and Chronobiology, Toronto, Canada.

Sleep-Related Tongue-Biting Events Associated with Obstructive Sleep Apnea: A Case Report

J. Wu¹, Y. Li¹

¹Mental Health Center of Shantou University, Department of Sleep Medicine, Shantou, China

Introduction: Obstructive sleep apnea (OSA) is a common sleep disorder, but it is very rare to be combined with sleep-related facial mandibular myoclonus (SRFMM). The relationship between OSA and SRFMM is not clear.

Materials and methods: This case reports the medical history, auxiliary examination, diagnosis and treatment, and prognosis of a patient with OSA complicated with SRFMM.

Results: A 69-year-old male presented with a 10-year history of nocturnal tongue biting and fragmented sleep. After video-polysomnography (v-PSG) examination, severe OSA was diagnosed, and epilepsy and sleep bruxism were excluded. v-PSG captured a tongue-biting episode triggered immediately after an obstructive respiratory event in REM sleep, featuring abrupt masseter/temporalis electromyography bursts without epileptiform activity. Continuous positive airway pressure (CPAP) initially failed due to poor adherence and persistent biting. Switching to bi-level positive airway pressure (BiPAP) eliminated tongue biting within 1 month. At 3-month and 6-month follow-ups, SRFMM remained fully controlled only with consistent BiPAP use. Cessation of BiPAP invariably triggered recurrence.

Conclusions: This case demonstrates severe SRFMM directly triggered by OSA-induced respiratory events and cortical arousals. BiPAP therapy, potentially by reducing respiratory effort and sleep instability more effectively than CPAP, achieved complete remission. SRFMM should be considered in OSA patients with unexplained nocturnal tongue injury.

Acknowledgments: The authors thank the sleep technicians and staff of Department of Sleep Medicine, Mental Health Center of Shantou University, for their support to this project. Patients are also thanked for their cooperation and consent to this report.

Sleep spindle characteristics in children with OSA and their associations with declarative memory function

M. Dong¹, Z. Xu²

¹Beijing Children's Hospital, Capital Medical University, Beijing, China, ²Respiratory Department, Beijing Children's Hospital, Capital Medical University, China National Clinical Research Center of Respiratory Diseases, National Center for Children's Health, Beijing, China

Introduction: Sleep spindles serve as one of the biological markers for cognitive function development in children, while children with Obstructive Sleep Apnea (OSA) exhibit varying degrees of cognitive impairment. This study systematically examined the spindle characteristics of children with OSA and explored the relationship between spindle parameters and declarative memory.

Materials and methods: Children aged 6 to 12 years old with snoring were included in this study, alongside age-matched healthy controls. Participants with OSA were divided into three distinct groups: primary snoring (PS), mild OSA (M OSA), and moderate-severe OSA (MS OSA) based on OAH1. All enrolled children completed a full-night polysomnography (PSG) and declarative memory task tests before and after sleep monitoring. During the N2 and N3 sleep stages recorded on the C3 channel, an advanced automatic detection of sleep spindles was implemented through a deep learning framework based on the BiLSTM-attention network. The characteristics of spindle activity were assessed using a

comprehensive set of parameters, including number, density, duration, intensity, amplitude, absolute power, relative power, center frequency, and the number of oscillations. Spindles were classified as fast spindles ($13 < f \leq 16$ Hz) and slow spindles ($11 \leq f \leq 13$ Hz) based on their central frequency, enabling the investigation of fast and slow spindle characteristics in OSA children and their correlations with declarative memory task performance.

Results: A total of 51 children were included: 15 PS, 13 M OSA, 13 MS OSA, and 10 healthy control. The results showed that the proportion of REM in children with MS OSA decreased, while N1 increased. Compared with children with M OSA, MS OSA had lower numbers, densities, durations, and intensities of total and slow spindles. In the assessment of declarative memory function, no significant differences were observed across varying degrees of OSA. Notably, the consolidation rate of recall demonstrated significant positive correlations with the absolute power of spindles, a pattern consistently observed across total, slow, and fast spindles.

Conclusions: Children with OSA, particularly those with MS OSA, exhibit sleep architecture disturbances and spindle activity impairments, which may underlie its cognitive dysfunction. The absolute power of sleep spindles could potentially serve as a more sensitive objective biomarker for assessing cognitive function in children.

Sleep-stage dynamics predicts current sleep-disordered-breathing and future cardiovascular risk

M. Bechny^{1,2}, Y. Tomita³, M. Scutari⁴, J. van der Meer⁵, M. Schmidt⁵, C. Bassetti⁵, A. Tzovara^{1,5}, A. Kishi^{*6}, F. Faraci^{*2}

¹University of Bern, Bern, Switzerland, ²SUPSI-MeDiTech, Lugano-Viganello, Switzerland, ³Sleep Center, Toranomon Hospital, Tokyo, Japan, ⁴Istituto Dalle Molle di Studi sull'Intelligenza Artificiale (IDSIA), Lugano-Viganello, Switzerland, ⁵Inselspital, Universitätsspital Bern, Bern, Switzerland, ⁶The University of Tokyo, Tokyo, Japan

Introduction: Sleep-disordered breathing (SDB) is a well-established contributor to cardiovascular morbidity and mortality, including hypertension, stroke, and heart failure^{1,2}. In addition to its respiratory effects, SDB disrupts sleep-macrostructure³ and, as emerging evidence suggests, alters sleep-stage dynamics⁴⁻⁶. This implies that both macrostructure and dynamics may be statistically linked with cardiovascular risk, as they can reflect downstream effects of SDB—thus enabling predictive modelling. Previous studies have primarily examined static macrostructural features, such as total-sleep-time (TST) or N3/REM durations, concerning cardiovascular outcomes⁷⁻⁹. However, the temporal organisation of sleep—specifically, transitions between stages—remains largely unexplored as a predictor of long-term cardiovascular risk. To address this gap, we present the first study evaluating whether sleep-stage dynamics can predict future cardiovascular outcomes in a large prospective cohort.

Materials and methods: We analyzed data from the Sleep Heart Health Study (SHHS)¹⁰, a prospective cohort of SDB-untreated individuals, examining the links between SDB and cardiovascular health. 5791 participants underwent baseline (SHHS1) in-home polysomnography (PSG); 2651 repeated it on-average 5 years later (SHHS2), and were followed for over 10 years. The PSG was scored into five stages (W, N1–3, REM), and apnea-hypopnea index (AHI) was calculated using the "recommended" definition, consistent with AASM guidelines (v2.2, 2015). We focused on 2581 SHHS1 participants without prior cardiovascular events or sleep-altering medications (e.g., antidepressants, diuretics, alpha/beta-blockers). The primary outcome was the first occurrence of a composite cardiovascular event: heart failure, stroke, myocardial infarction, angina, or cardiovascular surgical procedure since baseline. Predictors included: 25 (5x5) sleep-stage transition proportions, conventional sleep markers (e.g., TST), BMI, smoking status, and demographics. We used Random Forest (RF) for SDB detection and Random Survival Forest¹¹ (RSF) for cardiovascular risk prediction, both non-parametric methods robust to predictors' multicollinearity and non-linear effects.

Results: RF model for detecting moderate-to-severe SDB (AHI>15) achieved cross-validated ROC>75%, with stable performance across REM/NREM subtypes and strong generalization (ROC>70%) even to patients with medications or prior events, suggesting that SDB can be accurately predicted from sleep-stage features and demographics alone. RSF predicting future cardiovascular outcomes achieved concordance indices and time-dependent-ROC >75% across 1–10 year horizons, with significant log-rank separation ($p<0.05$, for high- vs. low-risk groups). Analysis of partial effects confirmed known risk factors like age and smoking, while revealing novel U-shaped risk profiles for many predictors—suggesting optimal ranges with increased risk at both extremes—including BMI (~25),

TST (~350 min), and sleep-stage continuities such as N1-to-N1 (~2%), N2-to-N2 (~40%), N3-to-N3 (~10–30%), and REM-to-REM (~20%). Specific atypical transitions, such as R-to-N3 and N3-to-N1, increased risk by >10% per single nightly occurrence; N3-to-REM and W-to-N3 were associated with ~5% increased risk when occurring ≥2 times per night.

Conclusions: Sleep-stage dynamics are sensitive markers for both SDB and long-term cardiovascular risk. Our findings, including confirmed effects of N3/REM^{7,*}, suggest novel risk markers based on sleep-stage transitions, providing deeper physiological insight than traditional macrostructure measures. While cardiovascular risk can be accurately predicted from sleep, further analysis is needed to design optimal treatment and sleep management interventions.

Sleep Surgery Symposium Proposal - "50 years of Sleep Surgery - Does it Work?"

K. Pang¹, R. Cheong², V. Agarawal³, S. Kishore⁴

¹Asia Sleep Centre, ORL, Singapore, Singapore, ²Royal National ENT, ORL, London, United Kingdom,

³Kandivali East, ORL, Mumbai, India, ⁴gachibowli hospital, ORL, Hyderabad, India

Introduction: Since 1970s, Sleep surgery has been part of the treatment of OSA. These past 50 years of sleep surgery has seen many changes and evolution of sleep surgery. Palate surgeries have evolved, Nasal surgeries have improved and become an integral part of OSA surgery. Tongue surgery has evolved from reduction to stimulation.

Materials and methods: Medical literature research on sleep surgery

Results: Sleep Surgery Symposium Proposal - "50 years of Sleep Surgery - Does it Work?"

Consisting of 4 oral presentations - by 4 renowned sleep surgeons, each discussing different aspects of sleep surgery over the past 50 years.

The different aspects of Sleep Diagnosis, Upper airway dynamics and Sleep surgery are discussed.

Conclusions: A strong conclusion of what works and what should be done to improve success rates.

Acknowledgments: Dr Kenny Pang, Dr Ryan Cheong, Dr Vikas, Dr Srivas Kishore

Small vessel disease in obstructive sleep apnea: a peak width of skeletonized mean diffusivity-based study

K.M. Park¹

¹Haeundae Paik Hospital, Neurology, Busan, Korea, Republic of

Introduction: Peak width of skeletonized mean diffusivity (PSMD) is a novel marker of small vessel disease in the brain. This study aimed to investigate the association between small vessel disease and obstructive sleep apnea (OSA) using PSMD.

Materials and methods: We enrolled patients with OSA and age- and sex-matched healthy controls, and performed diffusion tensor imaging (DTI) using a 3-tesla MRI scanner in them. We calculated the PSMD based on DTI in several steps, including preprocessing, skeletonization, application of a custom

mask, and histogram analysis using the FSL program. We compared the PSMD between patients with OSA and healthy controls and investigated the correlation between PSMD and clinical factors.

Results: Thirty-nine patients with OSA (apnea-hypopnea index > 5; mean = 20.5) and 48 healthy controls were enrolled. The PSMD was significantly higher in patients with OSA than that in the healthy controls (2.521 vs. 2.320×10^{-4} mm²/s, $p = 0.013$). In addition, PSMD positively correlated with age ($r = 0.512$, $p < 0.001$) and body mass index ($r = 0.472$, $p = 0.002$). However, PSMD was not associated with polysomnographic measurements.

Conclusions: The mean PSMD is higher in patients with OSA than that in healthy controls, indicating a white matter injury due to small-vessel disease in patients with OSA. Our study highlights the importance of actively diagnosing and treating OSA. In addition, PSMD can be used to determine the relationship between sleep disorders and small vessel disease.

Snoring Child with Central Apnea: Uncovering a Hidden Neurological Cause

M.Y. Seo¹, S.H. Lee¹

¹Korea University Ansan Hospital, Korea University College of Medicine, Otorhinolaryngology Head and Neck Surgery, Ansan city, Korea, Republic of

Introduction: Pediatric sleep apnea is a sleep-related breathing disorder characterized by partial or total obstruction of the upper airway, usually due to an obstructive cause such as enlarged tonsils in children. However, children can rarely present with central sleep apnea (CSA), which in some cases can be associated with various neurological conditions.

Materials and methods: A 7-year-old boy has presented with frequent snoring and morning headaches. Physical examination and PNS X-ray revealed no significant abnormalities in the paranasal sinuses, such as sinusitis, and no enlargement of tonsil and adenoid. Type 1 Polysomnography showed periodic breathing with central apnea and snoring, with minimal obstructive events. Further neurologic evaluation was performed to differentiate the cause of the central apnea, there is no abnormal finding on neurologic tests revealed any central nervous system problems.

Results: A subsequent brain MRI revealed a cerebellar tonsillar hernia extending below the foramen magnum, consistent with a Chiari 1 malformation.

Conclusions: This case highlights the importance of considering a central cause in pediatric patients presenting with snoring and abnormal central sleep apnea on sleep study findings. Early neuroimaging and appropriate management, when indicated, can result in clinical improvement and help prevent long-term complications.

Snoring index, not apnea-hypopnea index, associated with daytime dysfunction in elementary school children

Q. Zhu¹, H. Wada¹, Y. Ueda¹, M. Miyakawa¹, Y. Kameda¹, H. Nakano¹, T. Tanigawa¹

¹Juntendo University Graduate School of Medicine, Tokyo, Japan

Introduction:

This study aimed to investigate the independent effects of the Snoring Index, based on parent or guardian reports of snoring frequency and loudness, and the apnea-hypopnea index (AHI) on daytime dysfunction among elementary school children.

Materials and methods:

Two cross-sectional studies were conducted among elementary school children in Tokyo. Parents or guardians completed a questionnaire, and the children underwent overnight tracheal sound recordings. The Snoring Index was calculated as the mean of z-standardized parent/guardian ratings of snoring frequency and loudness. The AHI was estimated using a validated neural network algorithm based on the tracheal sound data. Daytime dysfunction was assessed using parent/guardian reports of hyperactivity/inattention, emotional symptoms, and daytime sleepiness. Generalized linear models

were employed to examine associations between the Snoring Index, AHI, and daytime dysfunction outcomes, adjusting for sex, age, BMI z-score, sleep duration, and nasal symptoms.

Results:

Analyses included 598 children from the Higasiyamato study (grades 1–2, mean age = 7.1 ± 0.7 years; 52.0% boys) and 240 children from the Musashimurayama study (grades 1–6, mean age = 9.3 ± 1.8 years; 58.2% boys). Higher Snoring Index scores were significantly associated with increased hyperactivity/inattention ($p < 0.05$) and daytime sleepiness ($p < 0.01$) in both cohorts. Emotional symptoms were significantly associated with the Snoring Index only in older children (Musashimurayama study; $p = 0.02$). In contrast, objectively measured AHI was not significantly associated with any daytime dysfunction outcomes (all $p > 0.1$).

Conclusions: Our findings indicate that the Snoring Index, which is based on parent or guardian reports of snoring frequency and loudness, was significantly associated with daytime dysfunction, particularly hyperactivity and daytime sleepiness, independently of AHI. These results underscore the importance of recognizing snoring as an independent contributor to cognitive and behavioral dysfunction in pediatric populations.

Sofia Scale: a female-specific screening tool for obstructive sleep apnea

Introduction: Sleep-Disordered Breathing (SDB) encompasses a spectrum of conditions, ranging from simple snoring to Obstructive Sleep Apnea (OSA), the most severe form of SDB. OSA is a highly prevalent disorder associated with significant cardiovascular morbidity, increased risk of occupational and traffic accidents, and a notable decline in health-related quality of life.

Classically, the hallmark symptoms of OSA include excessive daytime sleepiness (EDS), loud snoring, and witnessed apneas. However, there is increasing recognition that the clinical presentation of OSA in women frequently diverges from this typical phenotype. Women with OSA often report non-specific symptoms such as insomnia, fatigue, morning headaches, mood disturbances, or fragmented sleep, which may not be effectively captured by existing screening tools.

Current widely used questionnaires, such as STOP-BANG and the Epworth Sleepiness Scale, have demonstrated suboptimal performance in female populations, potentially contributing to underdiagnosis and undertreatment in this group.

Materials and methods: To address this gap, we developed the SOFIA scale (Screening Of Female-specific Indicators of Apnea), a novel screening instrument specifically designed to identify OSA in women.

The objective of this study was to validate the SOFIA scale and to compare its diagnostic performance with existing tools. We conducted a prospective study in which 100 women referred for suspected OSA underwent overnight sleep studies. Each participant completed the SOFIA scale, STOP-BANG questionnaire, and Epworth Sleepiness Scale prior to polysomnography or respiratory polygraphy. The primary outcome was to assess the predictive capacity of the SOFIA scale for the diagnosis of OSA, defined as an apnea-hypopnea index (AHI) >15 events/hour.

diagnosis of OSA, defined as an apnea-hypopnea index (AHI) >15 events/hour.

SCALE SOFIA: I feel tired during the day, I feel nervous during the day, I feel a lack of energy or

interest, I usually sleep poorly or have insomnia, I usually snore, headache, I feel that I do not rest properly when I sleep, Sensation of shortness of breath at night or have been told you breathe irregularly, Hormonal dysregulation, Overweight, age.

Results: The SOFIA scale comprises 26 items reflecting female-specific symptoms and risk factors for OSA. A total score above 16 was considered indicative of high risk for OSA.

The SOFIA scale demonstrated superior diagnostic accuracy compared to the STOP-BANG questionnaire, with an area under the receiver operating characteristic curve (AUC) of 0.745 versus 0.648, respectively.

For moderate-to-severe OSA (AHI >15), the SOFIA scale achieved a sensitivity of 71% and a specificity of 73.3%. The positive predictive value (PPV) was 82%, and the negative predictive value (NPV) was 58%. The kappa coefficient for agreement between SOFIA and sleep study diagnosis was 0.42, indicating moderate concordance.

Conclusions: The SOFIA scale represents a promising, female-specific screening tool for the identification of OSA in women. Its superior diagnostic performance compared to traditional questionnaires underscores its potential utility in clinical practice. Implementation of SOFIA could contribute to reducing the current underdiagnosis of OSA among women and support a more gender-sensitive, personalized approach to sleep medicine. Further studies in larger, diverse populations are warranted to confirm these findings and explore its integration into routine screening pathways.

'S score' - A novel computational algorithm for OSA severity assessment

G.B. Hosmane¹, R. Soori², N. Belur³, N. Bhushan⁴

¹K S Hegde Medical Academy, Pulmonary Medicine, Mangalore, India, ²K S Hegde Medical Academy, Anaesthesiology, Mangalore, India, ³L1-ID SOLUTIONS, Director, Bengaluru, India, ⁴Craffitti consulting pvt ltd, Founder director, Bengaluru, India

Introduction: Obstructive sleep apnea (OSA) is attaining pandemic proportion among non-communicable diseases with ever increasing lifestyle disorders. Assessing severity of OSA holds key in appropriate management this global health crisis. However currently widely accepted "AHI scale" for severity assessment has its own pitfalls. It assigns equal weightage to apnea and hypopnea. Current AHI system of severity grading do not factor in 'duration' of these events, technically events with prolonged duration will have more pronounced impact on physiological parameters like desaturation events and heartrate variability. To address these pitfalls and to provide comprehensive severity assessment tool, we have developed novel computational algorithm "S Score" for severity assessment in OSA . This study was done to validate effectiveness of "S score" in capturing physiological impact of apnea and hypopnea

Materials and methods: Novel computational algorithm "S Score" for severity assessment of OSA is used to assess severity of OSA in confirmed cases of OS following overnight level 1 polysomnography (PSG) were included [$S \text{ Score} = (0.73 (T^A - 10 N^A) + 0.27 (T^H - 10 N^H))/T$]. PSGs were recorded at a tertiary care hospital. Sleep study data including AHI, apnea frequency and duration, hypopnea frequency and duration, number of relative desaturations, mean SPO2 recorded in sleep, minimum SPO2 recorded in sleep, minimum, average and maximum heart rate in sleep, sleep onset, total sleep time, sleep efficiency were retrieved from the system. Logarithm transformed regression model was used for AHI and S score against mean SPO2, minimum SPO2, average HR and maximum HR.

Results: In our study we found that correlation coefficient between AHI and mean SPO2 in sleep is -0.4542 which is moderate correlation. Correlation between AHI and minimum SPO2 is -0.45577 which is also moderate correlation . However the correlation between S score and minimum SPO2 is -0.5940. The R² value of S score for highest heart rate is 0.0715 where as R² value of AHI for highest heart rate is only 0.0342. The R² value of S score for mean saturation is 0.3437 and for minimum saturation is 0.3724, however R² value of AHI for mean saturation is 0.2536 and for minimum saturation is 0.264. Our study objectively demonstrates that R² values for highest heart rate, mean and minimum saturation has better correlation with 'S score' than existing AHI for OSA severity assessment

Conclusions: 'S score' a novel severity assessment tool for OSA, captures the physiological consequences more precisely than existing AHI. S Score provides different weightages to apnea and hypopnea while also factoring in the 'duration' of events in totality. Whereas existing AHI is a mere summation of apnea and hypopnea without any reference to its physiological impact

Acknowledgments: Nil

Study of OSA biomarkers based on proteomics

W. Huang¹, J. Guan², H. Yi², S. Yin²

¹Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Department of Otorhinolaryngology, Head and Neck surgery, Shanghai, China, ²Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Department of Otorhinolaryngology Head and Neck Surgery, Shanghai, China

Introduction: Obstructive sleep apnea (OSA) is a complex and heterogeneous disease with great harm. The current diagnosis and treatment system of OSA still has great limitations. It is a hot topic in the field of sleep medicine to determine the risk of OSA and related multi-system injuries and to distinguish the subtypes of subjects most likely to benefit from OSA treatment. The study of OSA biomarkers can promote the development of precision sleep medicine. The purpose of this study is to explore the stage heterogeneity characteristics of biomarkers in OSA, so as to provide new methods for disease risk assessment, early injury warning and curative effect prediction.

Materials and methods: Through rigorous experimental design and research (including the discovery set of 90 samples, the internal validation set of 225 samples, the validation set with continuous positive airway pressure [CPAP] treatment cohort of 208 samples, and the external validation set of 150 samples as series validations). We combined the cross-sectional study with the cohort study. According to the proteomic test results of serum samples, bioinformatics analysis was used to explore the biomarkers of OSA. The diagnostic ability of biomarkers was confirmed in the training set and test set. The predictive ability of biomarkers on prognosis and efficacy was observed in intervention and non-intervention cohorts.

Results: In the proteomics study, we revealed that the distinctive protein combination and protein expression of OSA subjects were different at each severity stage and at each treatment stage of CPAP, namely stage heterogeneity characteristics. Biomarkers screened by proteomics had high accuracy in the diagnosis of OSA with different severity. At the same time, in non-intervention and intervention cohorts, molecular typing based on proteomic biomarkers was carried out, reflecting different susceptibility to OSA-related multi-system injury, blood pressure reactivity and mini-mental state examination improvement after CPAP treatment. These results have important implications for clinical identification of high-risk populations and prediction of treatment benefits, so as to explain the heterogeneity of disease. Growth and differentiation factor-associated serum protein 1 (GASP-1), as a key biomarker screened and verified, had a significant negative correlation with AHI and a significant positive correlation with genioglossal muscle compensatory response index reflecting genioglossal muscle function.

Conclusions: According to the proteomic results of serum samples, combined with bioinformatics analysis, the new combination of heterogeneous biomarkers in OSA stage was identified, and the heterogeneity characteristics of pathophysiology of the disease were further analyzed comprehensively from the molecular level. The combination of biomarkers can carry out disease diagnosis and risk identification with high accuracy. The molecular typing based on this provides a new method for disease risk assessment, early injury warning and curative effect prediction. At the same time, we preliminarily verified the potential biological function of factor GASP-1 found in proteomics research that is significantly related to the severity of OSA, and provided theoretical basis for further exploring the mechanism of biomarkers.

Acknowledgments: All of the authors are grateful to the staff in our sleep center and all of the subjects.

Study on gene single nucleotide polymorphisms in Han and Uyghur patients with OSA combined with hypertension

Z. He¹, X. Jiang¹, M. Han¹, F. Han², S. Ma¹, H. Yang¹, P. Thomas³

¹The Second Medical College of Xinjiang, sleep center of Kalamay central hospital, Karamay, China, ²Peking University People's Hospital, Department of Respiratory Sleep Medicine, Beijing, China, ³Charité University Medicine, Interdisciplinary Center of Sleep, Berlin, Germany

Introduction: The pathogenesis of obstructive sleep apnea (OSA) is complex, involving genetic and environmental factors. Some studies have found that certain genes are related to OSA. Therefore, studying the gene polymorphism of OSA patients is helpful for revealing its mechanism. Some study performed a comprehensive qualitative and quantitative analysis to estimate the contribution of variants from candidate genes to the risk of OSA, which associated with the risk of OSA, which also show ethnicity differences in East Asian and European subgroups. OSA is often accompanied by hypertension. It is very important to explore the related gene polymorphisms between the two diseases. This study to explore the differences in nucleotide sequences of 20 gene loci closely related to obstructive sleep apnea (OSA) in Han and Uyghur patients with hypertension.

Materials and methods: All patients were selected from a total of 433 OSA patients (both with and without hypertension) hospitalized in the respiratory sleep department of Karamay Central Hospital from January 2023 to September 2024. Additionally, 100 hypertensive individuals without OSA from the same period were included as the control group. The patients included 249 cases of OSA with hypertension, of whom 200 were Han and 29 were Uyghur, with an average age of (54.5 ± 12.1) years for Han and (52.2 ± 8.7) years for Uyghur. There were 134 males and 115 females. There were 172 cases of OSA without hypertension, including 138 Han and 34 Uyghur, with an average age of (49.8 ± 13.0) years for Han and (49.9 ± 10.0) years for Uyghur. There were 100 cases hypertension patients from the physical examination group, including 90 males and 10 females, with an average age of (50.6 ± 7.4) years. The genomic DNA was extracted using a Wizard Genomic DNA Purification Kit (Promega, Madison, Wisconsin, USA) as per the product instruction. A multiplex PCR-ligase detection reaction method was used for genotyping four SNPs. For each SNP, the alleles were distinguished by different fluorescent labels of allele specific oligonucleotide probe pairs. Different SNPs were further distinguished by different extended lengths at 3' end.

Results: By comparing the closely related to OSA among the groups (Han OSA with hypertension group, Uyghur OSA with hypertension group, Han OSA without hypertension group, Uyghur OSA without hypertension group, and physical examination hypertensive group), we found that the A/C/T Single-Nucleotide Polymorphism (SNP) in rs1137101 of the leptin receptor LEPR gene on chromosome 1, the G/A/T/C (SNP) in rs1143633 of the interleukin-1 receptor IL1B gene on chromosome 2, the C/G (SNP) in rs12511115 of the gamma-aminobutyric acid (GABA) A receptor GABRB1 gene on chromosome 4, and the C/G/T (SNP) in rs6313 of the 5-hydroxytryptamine receptor HTR2A gene on chromosome 13 showed significant differences between the Han and Uyghur OSA groups ($P < 0.05$).

Conclusions: The variations of the SNP in rs1137101 of the LEPR gene, the SNP in rs12511115 of the GABRB1 gene, the SNP in rs1143633 of the IL1B gene, and the SNP in rs6313 of the HTR2A gene may be related to OSA in different ethnic groups. The mechanisms need further study.

Study on the Effect of Chemogenetic Regulation of Neurons in the mPFC brain Region on Learning and Memory Impairment and Sleep Structure in Mice with Chronic Intermittent Hypoxia

G. Pei¹, R. Chen¹

¹Soochow University, The Second Affiliated Hospital, Suzhou, China

Introduction: Young and middle-aged patients with OSA often suffer from cognitive impairments in multiple cognitive functional domains such as attention, memory, and executive function. Chronic intermittent hypoxia (CIH) is one of the possible mechanisms leading to changes in electroencephalogram activity and cognitive dysfunction, but the current research results are controversial. Our preliminary research found that CIH significantly increased c-fos neuronal activity in the medial prefrontal cortex (mPFC) region of mice, suggesting that the mPFC is likely to be the key brain area involved in OSA-related cognitive impairment. Therefore, we intend to investigate the pathogenesis of learning and memory impairment in CIH mice from the perspective of neuronal regulation, aiming to provide new ideas and methods for clinical diagnosis and treatment.

Materials and methods: (1) Construction of an OSA mouse model

C57BL/6 mice aged 6-8 weeks were placed in a hypoxia chamber. Each cycle lasted 60 seconds, with the ambient oxygen concentration (FiO_2) decreasing from 21.0% to $6 \pm 0.5\%$ within the first 30 seconds, and then increasing back to 21% within the next 30 seconds.

(2) Chemogenetics regulates neuronal activity

Chemogenetic viruses were injected into the mPFC region of mice using stereotaxic techniques. The

viruses were allowed to fully express for 2-3 weeks. Half to one hour prior to the start of the experiment, clozapine-N-oxide (CNO) was injected intraperitoneally to activate the chemogenetic pathway.

(3) EEG/EMG recording

Mice were anesthetized and fixed using a stereotaxic apparatus. Electrodes were surgically implanted, with two electrodes for EEG signal recording and two flexible electrodes for EMG signal recording. EEG and EMG signals were amplified and filtered (EEG: 0.5-25 Hz; EMG: 20-200 Hz) and recorded using software.

(4) Cognitive-related behavioral tests

Behavioral tests such as the open field test, novel object recognition test, novel location recognition test, and water maze test were conducted to evaluate the cognitive abilities of mice.

(5) Immunofluorescence technique for observing changes in myelin and glial cells in CIH mice.

Results: 1. Compared to control mice, CIH-exposed mice exhibited increased c-fos expression in the mPFC-IL region.

2. Compared with the control group mice, CIH-exposed mice showed decreased learning and memory indices. However, chemogenetics can improve the learning and memory impairment of CIH mice.

3. Compared with the control group mice, CIH-exposed mice showed reduced myelin basic protein levels in the corpus callosum and decreased numbers of oligodendrocytes and OPCs across all hippocampal regions. Chemogenetics can improve the myelin injury and the decline in the number of oligodendrocytes and precursor cells in CIH mice.

4. Compared with the control group mice, CIH-exposed mice exhibited reduced REM sleep and an increased number of sleep-wake transitions, and chemogenetic regulation could not improve the disruption of sleep structure in CIH mice.

Conclusions: The mPFC brain region is a critical brain region for learning and memory impairment in CIH-exposed mice. Chemogenetic regulation of neurons in the mPFC brain region can improve learning and memory impairment by reducing myelin damage and increasing the number of oligodendrocytes and precursor cells. However, this intervention does not alleviate the disruption of sleep architecture in CIH mice.

Success rate of Portable Polysomnography in Snoring and Obstructive Sleep Apnea Patients in ENT Clinic Srinagarind Hospital, Khon Kaen University

S. Laohasiriwong¹, A. Pintapakung¹, A. So-ngern², P. Vatanasapt¹, W. Teeramatwanich¹

¹Khon Kaen University, Otorhinolaryngology, Khon Kaen, Thailand, ²Khon Kaen University, Medicine, Khon Kaen, Thailand

Introduction: Study objectives: To study the success rate of portable PSG, used in diagnosis and treatment monitoring in the snoring and sleep disorders clinic, Department of Otorhinolaryngology, Faculty of Medicine, Khon Kaen University, Thailand

Materials and methods: This study is a retrospective descriptive study in adult patients over 18 years old who received services at a snoring and sleep disorders clinic, Department of Otorhinolaryngology, Srinagarind Hospital from 2012 – 2019. Patient information was collected from Srinagarind Hospital's medical records. The collected data consisted of general patient information. Data based on the modified STOP BANG questionnaire, clinical data, physical examination, underlying diseases, portable PSG examination data results. All data were analyzed through percentage statistics and spearman correlation.

Results: There were 1,028 new patients, 110 were pediatric patients and 918 were patients over 18 years old. 58 patients were unable to retrieve data. The remaining 858 cases (93.5%) 550 were male (64.1%) and 308 female (35.9). Most of the cases, 256 patients (29.3%) aged between 50-60 years. 680 cases were diagnosed with OSA (79.2%) Most of the patients had modified STOP BANG at 4 points, 30%. There were 659 patients who tested PSG or 76.8%, divided into port PSG 599 cases, 69.8% of the patients were diagnosed with severe OSA 34.4% and moderate OSA 25.5%. There were 12 cases with re-test for PSG, or 1.8%. When studying the relationship between modified STOP BANG and the results of portable PSG, it was found that modified STOP BANG was greater than 2 and AHI with cut off value greater than 15 was found sensitivity 86.7% and specificity 26.4%. The Spearman correlation coefficient was 0.25 at P < 0.01 when comparing modified STOP BANG with portable PSG results. The majority of patients in the clinic 490 patients (57.1%) used CPAP, 83 cases (9.7%) were treated by

surgery and 13 cases(1.5%) used mandibular advancement devices . After treatment with additional life style modifications most of the patients' symptoms improved.

Conclusions: Portable polysomnography has the advantage of ease of use, better accessibility and lower cost. It can be utilized for diagnosis of OSA in areas in which in lab PSG is not yet fully accessible, with minimal data loss or inconclusive diagnoses.

Acknowledgments: This study was approved by Khon Kaen University Ethics Committee project no. HE641573. We thank you Mrs. Arunya Kotelong the clinic nurse for assistance in data collection.

Supplemental Low-Dose CO₂ Delivered by a Novel Device Abolishes Central Sleep Apnea at High Altitude

S. Liang¹, B. He¹, L. Wang¹, Q. Wei¹, Q. Zhu¹, A. Wellman², P. Catcheside³, M. Polkey⁴, A.R. Schwartz⁵, D.J. Eckert⁶, Y. Luo^{2,3,1}

¹Guangzhou Medical University, State Key Laboratory of Respiratory Disease, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China, ²Harvard Medical School, Division of Sleep and Circadian Disorders, Brigham and Women's Hospital, Boston, United States, ³Flinders University, AISH, Adelaide, Australia, ⁴Guy's and St. Thomas' NHS Foundation Trust London, London, United Kingdom, ⁵University of Pennsylvania Perelman School of Medicine, Philadelphia, United States, ⁶Flinders University, Adelaide, Australia

Introduction: Lowlanders ascending to high altitude often develop central sleep apnea secondary to hypocapnia. We designed a device that comfortably delivers a constant, low dose of CO₂. This study evaluated whether CO₂ supplementation could alleviate central sleep apnea and improve sleep quality in healthy adults at high altitude.

Materials and methods: Forty-six healthy lowlanders (mean age 25.2 ± 7.5 years; 26 men) were flown to 4,505 m. On their first night, participants were randomised 1:1 to inhale either 4.5% CO₂ or room air via a novel delivery device with virtually no functional dead space and negligible breathing resistance. Full overnight polysomnography was recorded.

Results: Compared with controls, the CO₂ group demonstrated a dramatically lower apnea-hypopnea index (4.0 ± 4.5 vs. 41.0 ± 49.8 events/h), higher mean SpO₂ (82.1% ± 4.0% vs. 65.1% ± 8.0%), and improved sleep efficiency (81.0% ± 8.5% vs. 65.2% ± 14.2%) (all P < 0.01).

Conclusions: Inhalation of low-dose CO₂ via our novel device effectively abolishes central sleep apnea, attenuates hypoxemia, and enhances sleep quality in healthy adults at high altitude.

Acknowledgments: This study was supported by Guangzhou Municipal Health Commission Major Technical Project Grant 2023C-GX02 and the Clinical and Epidemiological Research Project of State Key Laboratory of Respiratory Disease SKLRD-L-202401.

Surface electromyography of masticatory muscles in adults with obstructive sleep apnea

G. Aparecida Folha¹, A. Luiz Eckeli², F. Cardoso Pereira Valera³, C. Maria de Felício³

¹University of San Paulo, Health Sciences, Ribeirão Preto, Brazil, ²University of San Paulo, Department of Neuroscience and Behavioral Sciences, Ribeirão Preto, Brazil, ³University of San Paulo, Department of Ophthalmology, Otorhinolaryngology and Head and Neck Surgery, Ribeirão Preto, Brazil

Introduction: Obstructive sleep apnea (OSA) is a sleep-related breathing disorder with potential neuromuscular implications for orofacial structures during sleep and possibly during wakefulness. Therefore, the aim of this study was to compare the bilateral electrical activity of the temporalis and masseter muscles in adults with and without OSA using surface electromyography (sEMG) while awake.

Materials and methods: Study approved by the Human Research Ethics Committee of HCFMRP-USP (protocol no. 12634/2010). Fifty-four adults with OSA and fifteen healthy controls, diagnosed via polysomnographic evaluation, underwent bilateral sEMG of the anterior temporalis and masseter muscles while awake. The following indices were analyzed: percentage overlapping coefficient (POC) of temporalis and masseter muscles, torsion index (TORS), occlusal barycenter (BAR), absolute asymmetry index (Asim), and absolute activity index (Ativ). Between-group comparisons were performed using the Mann-Whitney U test. Correlations between the Apnea-Hypopnea Index (AHI) and sEMG values were analyzed using Spearman's correlation coefficient (p < 0.05).

Results: A moderate and significant negative correlation was observed between AHI and POC values of both temporalis and masseter muscles ($p < 0.001$), as well as with BMI and ATiv ($p = 0.03$). No significant correlations were found with age or other sEMG variables. The OSA group showed significantly lower COT values for both temporalis and masseter muscles ($p < 0.001$), indicating reduced muscle activation during clenching. No significant differences between groups were observed for POC, TORS, BAR, Asim, or Ativ indices.

Conclusions: Adults with OSA demonstrated reduced sEMG activation of masticatory muscles compared to healthy individuals. These findings support the hypothesis of orofacial myofunctional adaptations or impairments in OSA and highlight the potential value of muscle function assessment and rehabilitation in the clinical management of these patients.

Surgically assisted transverse jaw expansion in adult OSA patients

W.Y. Ng¹, H.Y.T. Lo¹, S.C. Fung¹, V. Abdullah¹, W.S. Choi¹, L.I. Ho¹

¹United Christian Hospital, Hospital Authority, Dentistry and Maxillofacial Surgery, Hong Kong, Hong Kong, SAR of China

Introduction: Obstructive Sleep Apnea (OSA) is a prevalent condition that significantly impacts the quality of life and overall health. This study evaluates the outcomes of surgically assisted transverse jaw expansion in adult OSA patients in Hong Kong.

Materials and methods: A retrospective analysis was conducted on OSA patients who underwent surgically assisted maxillomandibular expansion (MME) or maxillary expansion (MxE) between 2012 and 2025 at Department of Dentistry and Maxillofacial Surgery, United Christian Hospital, Hospital Authority, Hong Kong. Inclusion criteria included pre-operative Apnea-Hypopnea Index (AHI) ≥ 5 and age at surgery ≥ 16 . Objective outcomes measures included AHI and Lowest Oxygen Saturation (LSAT) pre- and post-operatively. Statistical analysis was performed with SPSS.

Results: A total of 10 subjects underwent surgical assisted transverse jaw expansion surgery (MME:6; MxE: 4). The median age of patients at surgery was 23.5 (IQR: 20-32). The median AHI significantly improved from 20.8 (IQR: 13.9-32.7) pre-operatively to 6.5 (IQR: 5.4 -26.8) post-operatively ($p = 0.022$). LSAT also showed improvement, increasing from a median of 85.5% (IQR: 78-89%) to 87.5% (IQR: 83-90%), although this change was not statistically significant ($p=0.153$).

Conclusions: This study demonstrates that surgically assisted transverse jaw expansion leads to a significant reduction in AHI and some improvement in LSAT in adult OSA patients. The findings suggest this surgical intervention may be effective to adult OSA patients; further study is warranted to confirm the result.

Acknowledgments: The authors would like to thank ENT colleagues Dr. Zion To and Dr. Bonnie Lam, orthodontist Dr. Frank Wong for their valuable contributions, as well as Mr. Alex Sum for his expert support with polysomnography, and Mr. Thomas Hui for his assistance with statistical analysis.

Tailored palatal surgery for obstructive sleep apnea patients with lateral pharyngeal wall collapse based on DISE phenotyping

H.J. Kim¹, D. Kim¹, S. Jin¹, S.D. Cho¹

¹Seoul national university hospital, Department of otorhinolaryngology, Seoul, Korea, Republic of

Introduction: Obstructive Sleep Apnea (OSA) is a heterogeneous disorder caused by a combination of anatomical and physiological factors that lead to upper airway collapse during sleep. Drug-Induced Sleep Endoscopy (DISE) provides real-time visualization of dynamic upper airway obstruction and has emerged as a valuable tool for individualized surgical planning. Among the various sites of collapse, the lateral pharyngeal wall has been increasingly recognized as a key contributor to airway obstruction in OSA. The aim of this study was to evaluate the utility of DISE in guiding the selection of palatal surgical techniques and to assess their clinical efficacy in OSA patients with lateral pharyngeal wall collapse.

Materials and methods: Patients with moderate to severe OSA underwent DISE to determine their patterns of upper airway obstruction. DISE phenotyping revealed a high prevalence of lateral pharyngeal wall collapse in this population. Surgical interventions were selected based on the severity and pattern of collapse observed.

Results: Patients were stratified to undergo soft palate webbing flap pharyngoplasty, relocation pharyngoplasty, or expansion sphincter pharyngoplasty according to their DISE findings. Uvuloplasty (e.g., soft palate webbing flap) was recommended for patients with mild to moderate OSA and minimal lateral wall collapse (< grade I) in DISE findings. Relocation pharyngoplasty was performed in patients with moderate lateral wall collapse (> grade II) and tonsillar hypertrophy (over grade 2 tonsil hypertrophy). Expansion sphincter pharyngoplasty was indicated for those with severe circumferential narrowing and significant lateral pharyngeal wall involvement (> grade III) in DISE findings and over grade 2 bilateral tonsil hypertrophy. Clinical outcomes showed that soft palate webbing flap pharyngoplasty achieved a 40.1% success rate, with mean apnea-hypopnea index (AHI) decreasing from 25.7 to 15.1 in selected cases of primary snoring and mild to moderate OSA. Relocation pharyngoplasty resulted in a 52.9% success rate and a 65.8% response rate in patients with moderate lateral wall collapse and enlarged tonsils. Expansion sphincter pharyngoplasty yielded favorable outcomes in severe OSA cases, with marked improvements in AHI and retropalatal patency.

Conclusions:

DISE-directed surgical planning allows for phenotype-based stratification and targeted correction of airway collapse in OSA. Tailoring palatal surgery according to specific collapse patterns—particularly those involving the lateral pharyngeal wall—leads to improved clinical outcomes and reduced surgical failure. This individualized approach represents a significant advancement in the personalized management of sleep-disordered breathing.

The application of hypoxic burden in evaluating systemic consequences associated with obstructive sleep apnea

Z. Hengyang¹, G. Shu²

¹Sichuan University, West China School of Medicine, Chengdu, China, ²West China Hospital, Nursing Department, Chengdu, China

Introduction: Obstructive sleep apnea (OSA) is a common sleep disorder primarily characterized by recurrent episodes of apnea and hypopnea during the sleep period, leading to intermittent hypoxemia, hypercapnia, and fragmented sleep. The prevalence of OSA has been steadily increasing. In recent years, the hypoxic burden (HB) has attracted considerable attention as an index that quantifies the cumulative effects of OSA-associated desaturation events by measuring the area under the curve of the decline in blood oxygen saturation (SpO₂). Compared to the conventional diagnostic metric, the apnea-hypopnea index (AHI), hypoxic burden shows significant promise in predicting the risk of OSA-related comorbidities and treatment outcomes, particularly in the realms of cardiovascular and metabolic diseases as well as cognitive dysfunction, thereby making it a more forward-looking tool for assessing the risk of complications associated with OSA.

Materials and methods: This study systematically reviews the definition, calculation methods, differences from other hypoxic indices, and the clinical utility of hypoxic burden in evaluating systemic damage caused by OSA.

Results: In this review, we provide a summary of the following aspects: the definition and calculation methods of hypoxic burden, comparisons between hypoxic burden and other hypoxia-related indices, the clinical value of hypoxic burden in the diagnosis and treatment of obstructive sleep apnea (OSA) and its associated diseases, and the application of hypoxic burden in OSA-related comorbidities.

Conclusions: As a highly promising metric, HB plays a significant role in the diagnosis and management of OSA, as well as in predicting OSA-related comorbidities. By accounting for the heterogeneity of OSA, it enables diagnosis, stratification according to severity, reflection of hypoxia-induced pathophysiological changes, and prediction of potential complications. Current evidence further suggests that HB provides superior prognostic value compared with the traditional apnea-hypopnea index (AHI). Nevertheless, HB remains an emerging metric, and its prognostic value for OSA-related comorbidities requires further validation. Methodological challenges, particularly the lack of

standardized computational procedures and clear baseline definitions, continue to limit its widespread adoption in clinical practice. Future research should validate HB in diverse populations, establish unified calculation standards, and explore integration with artificial intelligence-based analytic approaches. Collectively, these efforts may establish HB as a robust biomarker to advance precision medicine in OSA management.

Acknowledgments: This work was supported by the National Natural Science Foundation of China (Grant No.2024NSFC0621). We thank Prof. Gong Shu for her invaluable guidance.

The Association between Obstructive Sleep Apnea and Frailty Traits: A Bidirectional Mendelian Randomization Study

J. Huang^{1,2}, X. Zhu^{1,2}, H. Xu^{2,1}, J. Guan^{1,2}, H. Yi^{1,2}, S. Yin^{1,2}

¹Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Department of Otolaryngology Head and Neck Surgery, Shanghai, China, ²Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai Key Laboratory of Sleep Disordered Breathing, Shanghai, China

Introduction: Despite sharing similar risk factors and characteristics, the relationship between obstructive sleep apnea (OSA) and frailty remains unclear due to the predominance of observational researches. This study aimed to explore the genetic association between OSA and frailty traits using a bidirectional two-sample Mendelian randomization (MR) analysis.

Materials and methods: Utilizing summary data from large-scale genome-wide association studies (GWAS) obtained from FinnGen and MRC-IEU on European individuals, we designed a bidirectional two-sample MR analysis to comprehensively assess the genetic-level link between OSA and frailty traits, including frailty index, appendicular lean mass (ALM), grip strength and walking pace. Effect estimates were primarily evaluated using Inverse-variance weighted (IVW), with MR-Egger, weighted median (WM), simple mode, and weighted mode analyses serving as complementary methods. A series of sensitivity analyses, including outlier detection, heterogeneity analysis, and horizontal pleiotropy assessment, was applied to ensure the robustness of the results.

Results: IVW models showed that genetically predicted OSA had no significant effect on frailty index, ALM, grip strength, or walking pace. However, the reverse MR analysis suggested that a higher genetically predicted frailty index increased OSA risk (IVW: OR=1.777, 95% CI: 1.137--2.777, p=0.012) with 14 single nucleotide polymorphisms (SNPs), while a faster genetically predicted walking pace was identified as a protective factor for OSA (IVW: OR=0.204, 95% CI: 0.104--0.399, p=3.39E-06; WM: OR=0.368, 95% CI: 0.193--0.703, p=0.003) with 56 SNPs. MR-Egger indicated no evidence of genetic pleiotropy. Although heterogeneity among the instrumental variable was observed in the reverse MR analysis, the results could be considered robust based on the IVW analysis and other supplementary sensitivity analyses.

Conclusions: The two-sample MR study found genetic evidence supporting OSA causally associated by frailty traits in reverse MR analysis, with frailty index and walking pace as risk and protective factors, respectively. The forward MR analysis did not find significant association between OSA and frailty traits.

The Association of Obstructive Sleep Apnea with Serum and Cerebrospinal Fluid Biomarkers of Alzheimer's Dementia - A Systematic Review and Meta-Analysis

B.S.Y. Yeo¹, J.H. Koh¹, A.C.W. Ng², S.R.H. Loh², A.X. See², D.C.C. Seow³, S.T. Toh²

¹Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore, ²Singapore General Hospital, Department of Otorhinolaryngology-Head and Neck Surgery, Singapore, Singapore, ³Singapore General Hospital, Department of Geriatric Medicine, Singapore, Singapore

Introduction: The association between Obstructive Sleep Apnea (OSA) and dementia has been well-documented. Alzheimer's Disease (AD), the most prevalent form of dementia, is marked by the accumulation of extracellular amyloid-beta and the intracellular hyperphosphorylation of tau proteins. Consequently, it is hypothesized that OSA may be linked to elevated levels of AD-related biomarkers. This study seeks to perform a systematic review and meta-analysis to evaluate the relationship

between OSA and concentrations of Alzheimer's Disease biomarkers in both serum and cerebrospinal fluid.

Materials and methods: PubMed, Embase, and Cochrane Library were systematically searched to identify studies that compared serum and cerebrospinal fluid levels of dementia-related biomarkers between individuals with OSA and healthy control subjects. Two independent authors screened articles for eligibility, extracted relevant data into a structured template, and evaluated the risk of bias of included studies using the Risk of Bias of Non-Randomized Studies of Interventions (ROBINS-I) scale. Various meta-analyses of the standardized mean difference were conducted using random-effects models. Further subgroup, sensitivity, meta-regression and publication bias analyses were conducted. **Results:** From 17 studies with 2804 patients, meta-analysis found that cerebrospinal fluid amyloid beta-40 (SMD:-1.13, 95%CI:-1.65 to -0.60) serum total amyloid beta (SMD:0.68, 95%CI: 0.40 to 0.96), serum amyloid beta-40 (SMD:0.60, 95%CI: 0.35 to 0.85), serum amyloid beta-42 (SMD:0.80, 95%CI: 0.38 to 1.23) and serum t-tau (SMD:1.07, 95%CI: 0.27 to 1.88) were significantly higher in OSA patients compared with healthy controls. These results remained robust to various subgroup, sensitivity and meta-regression analyses, and publication bias was absent.

Conclusions: OSA is linked to elevated levels of certain AD biomarkers, and serum biomarkers may help quantify the severity of OSA. Further studies with larger cohort sizes and follow-up periods may offer deeper insights into the association between OSA and neurodegenerative biomarkers.

The combined effect of acetazolamide and oxygen (ACZO₂) on OSA severity and endotypes

S. Landry¹, S. Joosten², J. Collet¹, L. Thomson¹, C. Beatty¹, T. Emperado¹, D. Mann³, A.-M. Wong¹, A. Turton², S. Sands⁴, G. Hamilton², B. Edwards¹

¹Monash University, Melbourne, Australia, ²Monash Health, Melbourne, Australia, ³University of Queensland, Brisbane, Australia, ⁴Harvard University, Boston, United States

Introduction: Elevated loop gain contributes of OSA pathogenesis in at least one third of patients. Both acetazolamide (ACZ) and supplemental oxygen (O₂) have been demonstrated to reduce loop gain (via different mechanisms) and the apnoea-hypopnoea-index (AHI). This trial assessed the efficacy of combining both ACZ and O₂ (ACZ+O₂) to maximally lower loop gain.

Materials and methods: In a randomised single-blind cross-over trial, participants were first randomised to take ACZ (500mg orally) or placebo for 7 days. During each treatment period, participants undertook two polysomnograms (PSGs) during which they slept with supplemental oxygen (3L/min) or sham (medical air, 3L/min). PSGs were scored by a technologist blinded to intervention. In addition to standard scoring, respiratory events were scored excluding SpO₂ or arousal information to calculate a 'flow-based AHI' (fAHI). OSA endotypes (including loop gain, collapsibility, muscle compensation and arousal threshold) were quantified from PSG signals.

Results: In twenty participants (7 females, Age= 50.3 ± 10.3, BMI= 32.3 ± 4.6, AHI_{baseline}= 51.5 ± 23.6, loop gain_{baseline} = 0.69 ± 0.19), loop gain was significantly reduced by both ACZ (Δ LG = -0.16 [CI₉₅:-0.06, -0.27], p<0.001) and O₂ (-0.14, [-0.04, -0.25], p=0.003). Very large reductions in loop gain were observed for the combination ACZ+O₂ (-0.25, [-0.14, -0.35], p<0.001) relative to the placebo-sham-air condition. All participants achieved a low loop gain (defined by LG<0.7) on ACZ+O₂. Upper airway collapsibility was significantly improved by ACZ relative to both placebo/sham (+13.4 %Veupnea [2.7, 24.2], p = 0.009) and O₂ (+11.6 %Veupnea [0.8, 22.4], p = 0.030). The improved collapsibility effect appeared diminished in the ACZ+O₂ condition which was not different to placebo/sham (+7.5 %Veupnea, p = 0.269) or O₂ (+5.6 %Veupnea, p= 0.523) conditions. OSA severity, as quantified by fAHI, was significantly reduced by all three treatments compared to placebo; ACZ (-20.3 /hr [-13.5, -27.0]), p<0.001, O₂ (-14.5 /hr [-7.9, -21.1], p<0.001) and ACZ+O₂ (-23.5 /hr [-16.8, -30.2], p<0.001). While fAHI was significantly lower on ACZ+O₂ compared with O₂ (-9.0 /hr, p=0.004), the difference between ACZ+O₂ and ACZ was not significant (-5.8/hr, p=0.12). ACZ+O₂ induced a >50% reduction in fAHI in 11/20 participants and 7/20 participants achieved a fAHI<15.

Conclusions: These data demonstrate that the combination of both acetazolamide and oxygen can strongly reduce loop gain in unselected patients, and this effect appears borne out by reductions in fAHI. Future work is required to determine whether reductions in loop gain and OSA severity are larger in patients with high loop gain at baseline.

The correlation between snoring and sleep related breathing disorders using an under-mattress sleep monitoring device

J. Wanchaitanawong¹, A. Cotton-Clay², S. Baron², L. Fava², V. Easwar², A. Kinsolving², J. Zitser³, Y. Leng⁴, P. Kahn², C. Kushida¹

¹Stanford university, Division of Sleep Medicine, Stanford, United States, ²Fullpower Technologies, Inc., Santa Cruz, United States, ³Tel Aviv Sourasky Medical Center, Movement and Sleep Disorders Unit. Neurology Department, Tel aviv, Israel, ⁴University of California San Francisco, Department of Psychiatry and Behavioral Sciences, San Francisco, United States

Introduction: Snoring, often misunderstood as a sign of good sleep in some cultures, is a common but overlooked symptom of sleep-related breathing disorders (SRBD), which are linked to cardiovascular and metabolic complications. This study was conducted to evaluate the correlation between snoring and SRBD, particularly obstructive sleep apnea (OSA), using an under-mattress sleep study device (Sleeptracker-AI). Additionally, we aimed to investigate the differences in this correlation across age groups and between sexes.

Materials and methods: The validated Sleeptracker-AI Monitor (Fullpower Technologies Inc., CA, USA), which passively detects sleep-disordered breathing via piezoelectric sensors was used in the study. We reviewed de-identified data collected between August 15, 2023, and June 30, 2024.

Results: A total of 155,441 participants (84,183 men, and 71,258 women) with mean age 47.9 ± 12.7 years contributed 27,708,834 recorded nights of data. Predicted apnea prevalence increased from 7% for subjects with little snoring (snoring percentage 3%, 25th percentile) to 15% in those moderate to heavy snorers (snoring 22% of the night, 75th percentile) and 48% in heavy snorers (snoring percentage 55%, 95th percentile). The odds ratios for apnea ($AHI \geq 5$) associated with each 10-percentage-point increase in snoring, expressed as a percentage of total sleep time. Age modified this interaction ($p < 0.0001$), with odds ratios of 1.77 [1.73, 1.81], 1.61 [1.59, 1.63], and 1.45 [1.42, 1.47] at ages 30, 50, 70. Interaction with sex was insignificant ($p=0.54$).

Conclusions: A large-scale analysis revealed a significant age-dependent association between snoring percentage of total sleep time and OSA prevalence across snoring severity. Each 10% increase in snoring elevated apnea odds with a stronger effect in younger individuals. Sex did not significantly modify this relationship.

The different characteristics of polysomnography between stroke and TIA patients

N. Wongkanjana¹, C. Pimolsri¹, W. Chotinawattarakul¹, J. Srikajon¹

¹Faculty of Medicine, Siriraj Hospital, Mahidol University, Siriraj Sleep Center, Bangkok, Thailand

Introduction: Obstructive sleep apnea is the most common sleep related breathing disorders. The association between cerebrovascular disease and obstructive sleep apnea is bidirectional. However, studies involving polysomnographic data in stroke and TIA patients compared to general population have shown inconsistency results. Data on different effects of OSA on stroke comparing to TIA were scarce

Materials and methods: Patients age over 18 years were recruited from Siriraj Hospital medical records between 2016 and 2023. All patients underwent sleep studies at the Siriraj Sleep Center before the diagnosis of stroke or TIA. Demographic data, stroke and TIA disease characteristics, and polysomnographic data were collected and compared through statistical analysis.

Results: The study aimed to recruit 198 patients in total. We collected 206 patients. Polysomnography were done prior cerebrovascular event 66 months. One hundred fifty patients had hypertension and dyslipidemia, mainly. 102 patients were ischemic stroke and 104 patients were TIA. 161 (78.16%) patients had supratentorial pathologies and 118 (57.28%) patients has cerebrovascular disease from small vessel disease. Mean AHI in stroke and TIA patients were 38.22 ± 24.41 /hr and 36.21 ± 26.22 /hr, respectively (p -value = 0.571). Minimum oxygenation were $82.55 \pm 7.83\%$ and 81.76 ± 11.27 in stroke and TIA patients, serially (p -value = 0.561). There was significant difference in cumulative time with oxygen saturation below 90% in total sleep time (T90) between stroke and TIA patients (10.21 ± 19.41 in stroke patients and 5.22 ± 13.52 in TIA patients with p -value of 0.034). Mixed apnea events were also significantly higher in stroke patients (5.65 ± 14.81) compared to TIA patients (0.26 ± 0.86), with a p -

value of 0.033. Other polysomnographic data were not significantly different between stroke and TIA patients.

Conclusions: Severe OSA is common in patients developing cerebrovascular attacks. Duration of desaturation is significantly affected severity of cerebrovascular diseases. Difference of mixed apneas percentage may underline the different OSA pathogenesis of stroke and TIA.

The Effectiveness of a Smart Sleep Apnoea Self-Management Support Program (4S) in Improving Cardiovascular Risk and Quality of Life in Subjects with Moderate to Severe Obstructive Sleep Apnea: A Randomized Controlled Trial

A.Y.-k. Lai¹, M.P.-k. Lit², M.M.-S. Lui³, A. Choi⁴, S.K.-y. Tsang¹, W.-m. Chan², M.S.-m. Ip⁵

¹Hong Kong Metropolitan University, School of Nursing and Health Sciences, Hong Kong, Hong Kong, SAR of China, ²Queen Elizabeth Hospital, Medicine, Hong Kong, Hong Kong, SAR of China, ³Queen Mary Hospital, Medicine, Hong Kong, Hong Kong, SAR of China, ⁴University College London, Institute of Education, London, United Kingdom, ⁵The University of Hong Kong, Clinical Medicine, Hong Kong, Hong Kong, SAR of China

Introduction: Obstructive Sleep Apnea (OSA) affects 9% to 38% of the global population, contributing to cardiovascular diseases and a reduced quality of life. Self-management strategies, including increased physical activity, weight control, and regular monitoring, can help reduce symptoms and lower the risk of complications. This study assessed the effectiveness of the 1-year Smart Sleep Apnea Self-Management Support Program (4S) in improving cardiovascular health risks.

Materials and methods: This was a two-arm randomized controlled trial. Eligible patients had moderate to severe OSA, a BMI >23, and engaged in less than 150 minutes of moderate physical activity per week. Participants were recruited from two hospitals and randomly allocated to either the 4S intervention group or the General Hygiene Information (GHI) control group.

The 4S intervention included: (i) Two 30-minute brief motivational interviewing sessions, (ii) Scheduled theory- and theme-based instant messages and phone calls, (iii) Personalized chat-based coaching, and (iv) An e-platform for goal setting and self-monitoring.

The GHI control group received general health information at similar frequencies and in a comparable format. Quantitative assessments were conducted at baseline, 4 months, and 12 months. A linear mixed model was used to compare changes in cardiovascular risk factors between the 4S intervention group and the GHI control group.

Results: A total of 123 participants (73.2% male, mean age 60 years, BMI 30 kg/m²) with moderate to severe OSA were recruited. Baseline characteristics did not differ between the two groups. The intervention group showed increases in Positive Airway Pressure (PAP) use and engagement in moderate physical activity. There was a significantly greater increase in PAP use in the intervention group compared to the control group. However, the difference in changes in engagement in moderate physical activity was not statistically significant between the two groups. The intervention group showed significant reductions in body weight, waist circumference, systolic blood pressure, and triglyceride levels compared to baseline. These reductions were significantly greater in the intervention group compared to the control group.

Conclusions: The 4S program demonstrated significant improvements in cardiovascular health risk factors among physically inactive, overweight individuals with moderate to severe OSA. By promoting self-management and sustainable health behaviors, the program may provide an effective approach to improving outcomes for individuals with OSA.

The Effect of Bariatric Surgery on Obstructive Sleep Apnea Remission and Outcomes

J. Ngeyvijit^{1,2,3}, R. Meesart³, N. Chirakalwasan^{1,2}

¹Faculty of Medicine, Chulalongkorn University, Division of Pulmonary and Critical Care Medicine, Department of Medicine, Bangkok, Thailand, ²King Chulalongkorn Memorial Hospital, Thai Red Cross

Society, Excellence Center for Sleep Disorders, Bangkok, Thailand, ³Chaophraya Abhaibubejhr Hospital, Department of Medicine, Prachinburi, Thailand

Introduction: Obesity is a major global health concern with a steadily rising prevalence. It shares several adverse health consequences with obstructive sleep apnea (OSA). Bariatric surgery is an effective treatment for morbid obesity, offering substantial weight loss. However, its specific impact on OSA such as remission, symptom improvement, and reduced CPAP requirements remains underexplored. This study aimed to assess the effect of bariatric surgery on OSA remission and improvements in clinical and polysomnographic parameters.

Materials and methods: A retrospective cohort study was conducted on patients who underwent bariatric surgery between January 1, 2005, and February 28, 2025, and had both preoperative and postoperative polysomnography (PSG). Relevant clinical and polysomnographic data were collected and analyzed.

Results: A total of 638 patients underwent bariatric surgery, of whom 48 met the inclusion criteria and were included in the study. The mean duration of follow-up PSG after surgery was 3.36 ± 2.5 years. Significant reductions were observed in BMI, AHI, and ESS. BMI decreased from 50.2 ± 13.1 to 33.8 ± 9.9 kg/m² ($p < 0.001$), AHI decreased from 52.8 (IQR 29.4, 121.4) to 27.2 (IQR 13.3, 43.8) ($p < 0.001$), and ESS decreased from 11.4 ± 5.7 to 6.8 ± 4.4 ($p < 0.001$). Other polysomnographic parameters were also significantly improved including sleep efficiency increased from $80.9 \pm 12.3\%$ to $86.6 \pm 9.7\%$ ($p < 0.001$), mean oxygen saturation improved from $87.3 \pm 12.2\%$ to $95.5 \pm 2.2\%$ ($p < 0.001$) and nadir oxygen saturation improved from $71.9 \pm 17.1\%$ to $84.6 \pm 11.2\%$ ($p < 0.001$). Three patients (6.3%) achieved OSA remission. The proportion of mild OSA increased from 4.2% to 22.9%, moderate OSA increased from 20.8% to 25%, and severe OSA decreased from 75% to 45.8% ($p < 0.001$). Postoperative CPAP independence (AHI < 5 /hr or AHI 5-15/hr with ESS < 10) was observed in 25% of patients. Preoperative parameters including ESS < 10 , REM latency < 120 mins, WASO < 30 mins, and arousal index > 15 /hr were significantly associated with postoperative PAP independence. Bariatric surgical procedures, including Roux-en-Y gastric bypass and sleeve gastrectomy resulted in non-significant difference in BMI and AHI reductions.

Conclusions: Bariatric surgery resulted in significant reduction in AHI and BMI along with improvements in sleep parameters from PSG. Although the overall remission rate of OSA remained low, nearly half of the patients with moderate to severe OSA experienced an improvement in disease severity following surgery. Additionally, one-quarter achieved CPAP independence. These findings support bariatric surgery as a potential strategy for OSA management in patients with morbid obesity.

Acknowledgments: The authors thank the staff of the Excellence Center for Sleep Disorders, King Chulalongkorn Memorial Hospital, for their support. We also thank Dr. Suthep, Dr. Patchaya, and Dr. Primproy from the Chula BMI Clinic for their consultation and contributions regarding bariatric surgery in this study.

The effect of positive airway pressure therapy on cardiac remodelling and cardiovascular risk factors in patients with the chronic obstructive pulmonary disease and obstructive sleep apnoea overlap syndrome: The REMAPS study

B. Nguyen^{1,2,3,4}, R. Puranik^{3,5}, K. Wong^{2,3,4}, E. Lau^{2,3}, A. Piper^{2,3}, C. Menadue^{2,3}, C. Phillips^{4,6}, G. Gauthier², C. Hockings², F. Lowrie^{2,3,4}, G. Cho^{4,6}, B. Yee^{2,3,4}

¹St Vincent's Hospital, Sydney, Thoracic Medicine, Sydney, Australia, ²Royal Prince Alfred Hospital, Respiratory & Sleep Medicine, Sydney, Australia, ³University of Sydney, Faculty of Medicine, Sydney, Australia, ⁴Woolcock Institute of Medical Research, Sydney, Australia, ⁵Royal Prince Alfred Hospital, Cardiology, Sydney, Australia, ⁶Macquarie University, North Ryde, Australia

Introduction: Patients with chronic obstructive pulmonary disease (COPD) and obstructive sleep apnoea (OSA) are classified as overlap syndrome (OVS). OVS is associated with increased cardiovascular comorbidities and mortality compared to patients with COPD alone. The study aims were to assess changes in cardiac structure and function using cardiac magnetic resonance imaging (CMRI) following treatment of sleep disordered breathing with positive airway pressure (PAP) therapy in patients with OVS. The effects of PAP therapy were also assessed on cardiac biomarkers (high-sensitivity troponin, high sensitivity C-reactive protein, brain natriuretic peptide); arterial stiffness; and 6-minute walk distance (6MWD).

Materials and methods: We evaluated 10 patients with COPD (GOLD criteria) and severe OSA (apnoea-hypopnoea index (AHI) >30 events/hour by polysomnography). All participants underwent CMRI, pathology testing for cardiac biomarkers, pulse wave velocity (PWV) assessment and 6-minute walk test. After 3 months of CPAP therapy, these investigations were repeated.

Results: Participants were 90% male, median age 69 (IQR 60.5-71.8) years, AHI 55.2/hr (IQR 43.8-77). Median FEV1% predicted was 58% (IQR 45.3-67.3). Overall, there was no significant change in cardiac dimensions or cardiac function after CPAP therapy. However, there was a significant increase in left ventricular end diastolic volume (LV EDV) in patients without late gadolinium enhancement (LGE) compared to patients with LGE (mean difference 42.4±11 mL, p=0.005, 95% CI 17.1-67.7). There were no significant differences in cardiac biomarkers, PWV or 6MWD after CPAP treatment. The median CPAP compliance was 5.2 hrs/night (IQR 4.6-6) and treatment AHI was 1.4/hr (IQR 0.6-2.4).

Conclusions: The preliminary results from this pilot study demonstrated that CPAP treatment significantly increased LV EDV in patients without LGE compared to patients with LGE, reflecting possibly improved LV diastolic function. These results suggest that PAP therapy may have the greatest cardiac benefits in OVS patients without existing damaged myocardium.

The Effect of Resveratrol on Insulin Resistance in 3T3-L1 Adipocytes Exposed to Intermittent Hypoxia

S. Fradkov¹, N. Lopiansky¹, H. Masury², E. Engal¹, A. Gileles-Hillel^{2,1}

¹Hebrew University of Jerusalem, Faculty of Medicine, Jerusalem, Israel, ²Hadassah Medical Center, Pediatric Pulmonology and Sleep, Jerusalem, Israel

Introduction: Obstructive sleep apnea (OSA) is the most common sleep-related breathing disorder, characterized by repetitive upper airway narrowing or collapse during sleep that leads to intermittent hypoxia (IH). OSA has been associated with insulin resistance, increased risk of metabolic syndrome, and type 2 diabetes, potentially due to IH. One of the key mechanisms underlying this phenomenon is the generation of reactive oxygen species (ROS), which impairs insulin signaling. Our previous studies have indicated that oxidative stress is one of the key drivers of adipocyte insulin resistance under IH. Since oxidative stress contributes to insulin resistance, antioxidants such as Resveratrol have been explored as potential means to mitigate its effects. Resveratrol, a natural polyphenol found in grapes, berries, red wine, and other fruits and nuts, is known for its antioxidant, anti-obesogenic, and anti-diabetic properties. It modulates insulin signaling in adipose tissue by activating Nrf2-mediated transcription of antioxidant enzymes, such as the Heme-oxygenase 1 (HO-1), which in turn reduce mitochondrial ROS. The present study aimed to examine whether Resveratrol treatment may reduce insulin resistance induced by IH.

Materials and methods: We used 3T3-L1 cells, an established model of adipocytes, with significant similarities to primary human adipose tissues. 3T3-L1 cells were exposed to room air (RA) or IH (2%-17% O₂ 30-min cycles, 8 hrs on / 16 off) for 48 hours with or without Resveratrol (25mM). Western Blot was used to evaluate AKT phosphorylation rates in response to insulin, and mRNA expression of relevant genes [antioxidant capacity (HO-1, GPX2, SOD2) and glucose processing (Glut4)] was measured by RT-PCR.

Results: IH-exposed adipocytes demonstrated reduced pAKT/tAKT ratios in the presence of insulin, indicating impaired insulin signaling. IH exposure led to elevated mRNA expression of the antioxidant enzyme GPX2, suggesting a compensatory response to IH-induced ROS production. Resveratrol treatment, but not IH exposure, increased mRNA levels of HO-1, a direct transcriptional target of the antioxidant regulator NRF2. Glut4 expression remained unchanged. Functionally, Resveratrol treatment led to an improvement in insulin signaling in RA-exposed cells, but did not fully reverse IH-induced insulin resistance.

Conclusions: Collectively, these findings suggest that Resveratrol enhances insulin sensitivity primarily by attenuating oxidative stress, evidenced by an increased pAKT/tAKT ratio, rather than by modulating Glut4 expression. IH-induced insulin resistance may be only partially responsive to antioxidant interventions.

The Effect of Telemedicine-Based CPAP Management on 24-Hour Ambulatory Blood Pressure in Patients with Obstructive Sleep Apnea: A Randomized, Controlled, Non-Inferiority Trial

H. Yi¹, L. Xu¹, Z. Li², X. Dong¹, F. Han¹

¹Peking University People's Hospital, Sleep Medicine, Beijing, China, ²Peking University People's Hospital, Emergency surgery, Beijing, China

Introduction: Previous studies have demonstrated feasibility and availability of telemedicine management of Obstructive Sleep Apnea (OSA) in China, but further evaluation is needed to determine whether these telemedicine approaches can lower 24-Hour Ambulatory Blood Pressure (AMBP), which is one of the intermediary mechanisms leading to increased cardiovascular morbidity. This study aimed at evaluating the effects of telemedicine-based CPAP management on 24h AMBP reductions in OSA patients.

Materials and methods: 344 adult (18-75 years old) OSA patients (AHI $\geq$ 5 events/h) were randomized to either telemedicine management (TM) (web-based questionnaires, self-administered home sleep apnea testing (HSAT), automatic positive airway pressure (APAP) and video-conference for visits) (n=172) or in-person management (IP) (paper questionnaires, in-person HSAT set-up, APAP and face-to-face visits) (n=172) for three months. The primary outcome was the change in 24-Hour mean arterial BP (MAP) from baseline to three months. Secondary outcomes included APAP adherence, depressive symptoms, daytime sleepiness, sleep quality, and serum liver enzyme levels.

Results: A total of 127 and 129 patients in the TM and IP groups, respectively, completed APAP treatment and underwent follow-up 24h ABPM monitoring. Significant reductions in 24-Hour mean arterial pressure (MAP) were observed in both groups: 2.94 mmHg in the TM group (P = 0.016) and 2.98 mmHg in the IP group (P = 0.015). The between-group difference was 0.78 mmHg (95% CI: -2.88 to 1.32; P=0.467), with the upper bound of the confidence interval below the pre-specified non-inferiority margin of 1.5 mmHg. Both groups also showed significant improvements in 24-hour systolic and diastolic BP. Daytime sleepiness, sleep quality, and depressive mood significantly improved in both groups after three months of APAP therapy (all P<0.05), with no significant between-group differences (P=0.48, P=0.50, and P=0.86, respectively). Serum alanine aminotransferase (ALT) levels significantly decreased in both the TM group (38.9 to 30.5 U/L, P=0.001) and the IP group (38.6 to 32.9 U/L, P=0.01), with no significant difference between groups (P=0.40). Aspartate aminotransferase (AST) levels showed a decreasing trend, but the change was not statistically significant.

Conclusions: Comprehensive telemedicine-based CPAP management is non-inferior to conventional in-person management in reducing 24h MAP among patients with OSA. Both groups experienced comparable improvements in sleep-related symptoms and quality of life. Serum liver enzymes, particularly ALT, also decreased following three months of APAP therapy.

The Effect of Zolpidem on CPAP Acclimatization in Patients with OSA: A Crossover, Randomized, Double-blinded, Placebo-controlled Trial

P. Pisalnoradej¹, W. Banhiran¹, N. Kasemsuk¹

¹Department of Otorhinolaryngology, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand, Bangkok, Thailand

Introduction: One factor contributing to the failure of CPAP therapy is difficulty sleeping. Hypnotic medications, particularly eszopiclone, were shown to be beneficial in CPAP adaptation. However, research on zolpidem is limited.

This study aims to evaluate the effect of zolpidem on CPAP compliance in OSA patients compared to a placebo.

Materials and methods: This cross-over, RCT enrolled OSA patients indicated for CPAP therapy but naïve for the device usage. The enrolled participants were randomly allocated into 2 groups with different therapeutic sequences: group (1) 10-milligrams-zolpidem, and group (2) placebo in identical capsules 30 minutes before bedtime for 1-week. In the second week, the participants alternatively received either placebo or zolpidem. The wash-out period was 24 hours.

Results: The endpoint cohort included 28 participants (57.1% male) with an average age of 54.54 ± 13.70 years. The average CPAP usage per night (MD 0.18; 95% CI -0.39 to 0.75) and the percentage of the day utilized CPAP ≥ 4 hours (2.60; -5.65 to 10.87) did not differ significantly between the zolpidem and placebo groups, and treatment sequences had no significant effect ($p=0.87$). Subgroup analysis for gender, disease severity, and arousal index demonstrated no significant effects of zolpidem. No serious adverse events according to zolpidem usage were reported. The most common minor adverse event was dizziness (7.14%).

Conclusions: This article highlights the value of employing various CPAP acclimatization approaches during the CPAP introduction period instead of focusing on the regular use of zolpidem. Further studies with larger sample sizes and long-term follow-up are recommended.

The efficacy and safety of acupuncture for allergic rhinitis: a systematic review of randomised controlled trials

L. Chan¹

¹TMJ & Sleep Therapy Centre of Sydney, Sydney, Australia

Introduction: Allergic rhinitis (AR), affecting up to 40% of the global population, causes nasal symptoms and reduces quality of life. Conventional treatments (antihistamines, immunotherapy) often have side effects or require long-term commitment. This systematic review evaluates acupuncture as a safer, cost-effective alternative for AR management, focusing on recent RCTs (2015–2020).

Materials and methods: [https://drive.google.com/file/d/1kgwVqsohlo6ruOWn -MfUHe6T1uG0tp/view?usp=sharing](https://drive.google.com/file/d/1kgwVqsohlo6ruOWn-MfUHe6T1uG0tp/view?usp=sharing)

- **Search Strategy:** Databases (PubMed, Cochrane) were searched for English-language RCTs (2015–2020) using terms like "rhinitis," "acupuncture," and "randomized controlled trial."
- **Inclusion Criteria:** RCTs evaluating manual acupuncture in adults with moderate-to-severe AR (seasonal/perennial). Sham acupuncture, waiting lists, or conventional therapies served as controls.
- **Data Analysis:** Meta-analysis of nasal symptom scores (TNSS) and quality-of-life metrics (RQLQ) using RevMan 5.3. Heterogeneity was assessed via I^2 statistics.
- **Risk of Bias:** Evaluated using Cochrane criteria.

Results: [https://drive.google.com/file/d/1kgwVqsohlo6ruOWn -MfUHe6T1uG0tp/view?usp=sharing](https://drive.google.com/file/d/1kgwVqsohlo6ruOWn-MfUHe6T1uG0tp/view?usp=sharing)
Results

- **Included Studies:** Three RCTs (total 235 participants) from Australia and China met inclusion criteria.
- **Efficacy:**
 - **TNSS:** Acupuncture significantly reduced nasal symptoms post-treatment (SMD: -0.80; 95% CI: -1.54 to -0.05) and at follow-up (SMD: -0.51; 95% CI: -0.79 to -0.22).
 - **RQLQ:** Quality of life improved significantly at follow-up (SMD: -0.54; 95% CI: -0.82 to -0.25).
- **Safety:** Minor adverse effects (e.g., bruising, pain) occurred in 10.8% of patients (McDonald et al., 2016); no serious events were reported.
- **Heterogeneity:** High post-treatment heterogeneity ($I^2=84\%$ for TNSS, 79% for RQLQ) but resolved by follow-up.

Conclusions: This systematic review of recent RCTs assessing the efficacy and safety of acupuncture on the treatment of AR supports the previously performed reviews, suggesting that acupuncture is a safe and beneficial treatment modality for AR and may provide a low-cost non-invasive alternative for conventional treatment options. Further research, including high-quality integrative medicine RCTs will help in providing further objective support and establishing clinical guidelines.

Acknowledgments: CONTRIBUTION OF AUTHORS

LC, MA and SO performed the literature search, applied inclusion criteria and extracted data.

SO reviewed and combined extracted data and risk of bias. LC and MA performed the meta-analysis. First draft of the review was written jointly by the authors. All authors read and approved the final manuscript.

The Efficacy and Safety of Intraoral Negative Air Pressure Device in Obstructive Sleep Apnea Patients: A Systematic Review and Meta-analysis

N. Kasemsuk¹, C. Puvatanond¹, W. Banhiran¹

¹Siriraj Hospital, Mahidol University, Otorhinolaryngology Department, Bangkok, Thailand

Introduction: Oral pressure therapy (OPT) and intraoral negative air pressure (INAP) devices are recent innovations that have emerged as potential treatment options for individuals who cannot tolerate CPAP and are seeking alternatives. These devices alleviate airway blockage during sleep by periodically applying negative pressure to the oral cavity, which moves the tongue and soft palate forward, increasing the cross-sectional areas behind the palate and tongue. Given the recent surge in research, this updated systematic review and meta-analysis aims to investigate the safety and effectiveness of OPT and INAP therapy for OSA patients, based on the latest evidence.

Materials and methods: A systematic search of the Ovid Medline, Embase, and Scopus databases was conducted, without language restrictions, to identify all original studies on the effects of INAP devices in adult OSA patients that reported the apnea-hypopnea index (AHI). Final update was done on December 7, 2024. The risk-of-bias assessment tool for nonrandomized studies (RoBANS) was applied for quality assessments. RevMan was used to conduct the statistical analyses.

Results: From the 72 initially retrieved articles, 9 studies involving a total of 445 individuals were included. Meta-analysis of the pooled data showed that, following INAP treatment, the participants had a significant improvement of mean AHI with mean difference (MD) of 12.4 (95%CI, 7.5 to 17.3), minimum oxygen saturation with MD of -3.6 (95%CI, -5.3 to -1.8), Epworth sleepiness scale with MD of 2.64 (95% CI, 0.23 to 5.05), and oxygen desaturation index (ODI) with MD of 10.8 (95%CI, 7.2 to 14.3). The participants also had a trend of improvement in percentages of time spent with oxygen saturation $\geq 90\%$ after treatment but did not reach statistical significance. The most common device-related adverse events were oral tissue discomfort and irritation, but no serious adverse events were reported.

Conclusions: INAP devices significantly improved AHI and ODI after treatment. No serious device-related adverse events were reported. Based on the current evidence, INAP may be a suitable treatment option for OSA in selected patients.

Acknowledgments: The authors gratefully appreciate the kind contributions of all staff members of the Department of Otorhinolaryngology and the Siriraj Sleep Center who were involved in this project.

The Hyoid Bone's Role in Mandibular Advancement Therapy for OSA: Do Position and Mobility Affect Upper Airway Patency?

W. Saab^{1,2}, J. Ghafari^{2,3}, J. Amatoury^{4,1}

¹American University of Beirut, Sleep and Upper Airway Research Group (SUARG), Beirut, Lebanon,

²American University of Beirut Medical Centre, Department of Dentofacial Medicine, Beirut, Lebanon,

³University of Pennsylvania, Department of Orthodontics, Philadelphia, United States, ⁴American University of Beirut, Biomedical Engineering Program, Maroun Semaan Faculty of Engineering and Architecture, Beirut, Lebanon

Introduction: Mandibular advancement is a common treatment for obstructive sleep apnea (OSA), but its success rate is variable, and the reasons for treatment failure remain unclear. The mandible and mobile hyoid bone serve as anchor points for key upper airway muscles - some of which directly connect the two - and play essential roles in maintaining airway patency. Accordingly, the hyoid bone may play a significant role in mandibular advancement effectiveness, though this relationship remains underexplored. This study aimed to investigate how hyoid bone position and mobility affect the ability of mandibular advancement to improve upper airway patency. We hypothesized that a lower (more caudal) natural baseline hyoid position and restricted mobility would reduce mandibular advancement

effectiveness, while anterior surgical repositioning of the hyoid would enhance it, regardless of baseline hyoid position.

Materials and methods: A previously validated 2D mid-sagittal finite element model of the rabbit upper airway was used to simulate mandibular advancement under different conditions, alone and combined: (1) baseline hyoid positions at increasingly caudal levels, (2) hyoid either free to move or fixed, and (3) anterior surgical repositioning of the hyoid. For each case, upper airway collapsibility (closing pressure, P_{close}) and cross-sectional area were assessed.

Results: Mandibular advancement decreased P_{close} (indicating reduced airway collapsibility) and enlarged the upper airway at the original baseline hyoid position. In comparison, a more caudal hyoid increased P_{close} and reduced mandibular advancement efficacy, regardless of mobility. Fixing the hyoid also increased P_{close} and produced smaller airway enlargement than when the hyoid was free. Anterior surgical hyoid repositioning consistently reduced P_{close} and enlarged the airway, mitigating the negative effects of a lower hyoid position.

Conclusions: Hyoid bone position and mobility substantially modulate the effectiveness of mandibular advancement in improving upper airway patency. A lower hyoid position - commonly observed in individuals with OSA - diminishes the efficacy of mandibular advancement, while limited hyoid mobility further impairs its benefits. Anterior surgical hyoid repositioning, on the other hand, helps restore and even enhance mandibular advancement outcomes. These findings underscore the potential for individualized OSA therapies by incorporating hyoid mechanics into treatment planning and suggest a complementary role for hyoid repositioning in improving mandibular advancement outcomes.

The impact of body mass index on severity of sleep related breathing disorders in adults with class 3 obesity

R. Yang¹, L. Laks², P. Acosta-Reyes³, K. Grudzinskas¹, N. Kormas^{2,1}, M. Piya^{3,1}

¹Campbelltown Hospital, Sydney, Australia, ²Concord Repatriation General Hospital, Sydney, Australia,

³Western Sydney University, Sydney, Australia

Introduction: Obesity is a well-established risk factor for sleep related breathing disorders (SRBD) and the relationship between the two is multifaceted, although the influence of increasing body mass index (BMI) on the severity of SRBD in adults with class 3 obesity ($BMI \geq 40 \text{ kg/m}^2$) have not been conclusively explored. This study aimed to investigate the effect of BMI on SRBD severity in adults with class 3 obesity enrolled in a multidisciplinary weight management program.

Materials and methods: Adult patients (≥ 18 years) with class 3 obesity enrolled in a multidisciplinary weight management program in Sydney, Australia who underwent polysomnography between January 2020 and December 2024 were included in this retrospective study. Demographic details, anthropometric variables, clinical data, STOP-BANG score, Epworth sleepiness scale (ESS) score, and polysomnography parameters including sleep duration, respiratory indices, and oximetry were collected. Severity of SRBD was classified according to the respiratory disturbance index (RDI). Continuous variables were expressed as mean $\pm$ standard deviation (SD) and categorical variables were expressed as percentages (%). Independent T-tests were used to compare group means. Univariate and multivariate regression analyses were employed to assess associations between BMI and SRBD severity measures using SPSS v29.

Results: A total of 172 patients were included with mean age 42.9 ± 12.5 years and mean BMI $52.9 \pm 9.7 \text{ kg/m}^2$. The cohort was predominantly female (76.2%) and Caucasian (74.5%). The mean STOP-BANG and ESS scores were 4.7 ± 1.3 and 9.1 ± 5.0 , respectively. Majority of the cohort had severe SRBD (70.3%) defined by total sleep time (TST) RDI > 30 events/hour. The mean TST RDI was 54.2 ± 38.5 events/hour with mean hypopnoea index (HI) of 40.0 ± 26.2 events/hour and mean obstructive apnoea index (OAI) of 11.0 ± 22.4 events/hour. Key oximetry findings included mean nadir oxygen saturation (nSO_2) $77.3 \pm 11.6\%$, and mean proportion of total sleep with oxygen saturation $< 90\%$ ($pS < 90\%$) $16.5 \pm 25.7\%$. On univariate and multivariate regression analyses adjusted for age, sex and ethnicity, BMI was significantly associated with TST RDI (β 1.36, $p < 0.001$ univariate, $p < 0.001$ multivariate), nSO_2 (β -0.33, $p < 0.001$ univariate, $p < 0.001$ multivariate), and log transformed $pS < 90\%$ (β 0.055, $p = 0.002$ univariate, $p < 0.001$ multivariate). Patients with BMI $> 60 \text{ kg/m}^2$ ($n = 40$), compared to patients with BMI $40\text{--}49.9 \text{ kg/m}^2$ ($n = 68$), had significantly higher TST RDI (71.3 ± 42.6 events/hour vs 42.8 ± 31.5 events/hour, $p < 0.001$) and significantly lower nSO_2 ($72.4 \pm 13.8\%$ vs $79.6 \pm 9.0\%$, $p = 0.005$) with no

difference in STOP-BANG or ESS scores. Interestingly, 11% of the cohort had TST RDI <15 events/hour and 7.5% of the cohort with BMI >60 kg/m² had TST RDI <15 events/hour.

Conclusions: While there was a high prevalence of severe SRBD in adults with class 3 obesity, increasing BMI was associated with increasing severity of SRBD, as reflected by worsening RDI and greater burden of hypoxia during sleep but not worsening symptoms of SRBD. The relationship of weight loss in this group to improvement in SRBD needs further investigation. Additionally, a small proportion had normal to mild SRBD with RDI <15 events/hour despite having class 3 obesity and further investigation may reveal protective characteristics in this cohort.

The Impact of Early Intensive Nursing Interventions via Telemetric Monitoring on Long-Term Continuous positive airway pressure (CPAP) Adherence in Obstructive Sleep Apnea (OSA)- A single-centre experience in Hong Kong

P.H. Chiu¹, W.T. Tang¹, P.Y. Tse¹, K.L. Ip¹, H.L. Yu¹, K.Y. Ng¹, T.L. Choi¹, K.M. Wong¹, M.C. Chow¹, C.C.J. Wong¹, C. Wong¹, H.S. Cheng¹, C.W. Tong¹, P.L. Miu¹

¹Pamela Youde Nethersole Eastern Hospital, Medicine, Hong Kong, Hong Kong, SAR of China

Introduction: Long-term adherence to CPAP remains a significant challenge in the treatment of OSA. It has been shown that suboptimal initial CPAP experiences negatively impact patient compliance. Conventional in-laboratory CPAP titration, often limited to a single-night assessment, may fail to address patient adaptation challenges. To enhance early patient support while optimizing resource allocation, our center introduced a home-based CPAP titration protocol incorporating telemonitoring and nursing interventions. We conducted a retrospective comparative analysis to evaluate the efficacy of home-based versus in-laboratory titration.

Materials and methods: Patients with newly diagnosed pure OSA who were naïve to CPAP treatment and underwent either home-based (home group) or in-laboratory titration (in-lab group) between January and September 2024 were included in the analysis.

Both groups participated in an OSA and CPAP education session, followed by a daytime CPAP trial in the sleep center prior to titration. The in-lab group received standard single-night attended CPAP titration, whereas the home group used an auto-adjusting CPAP device with integrated telemonitoring (ResMed AirSense 10 AutoSet for Her) for one week. In home group, telemonitoring was performed via a cloud-based platform, supplemented by phone consultations by trained nurses to assess adherence. Based on patient-reported feedback and objective usage data, personalized guidance was provided to address side effects and troubleshoot issues. Remote CPAP setting adjustments were made when necessary. In both groups, data was reviewed by physician to determine the final PAP prescription. After titration, both groups received an educational pamphlet with written and video instructions on PAP use and troubleshooting.

The following outcomes were compared:

- Titration success rate (the ability to derive prescribed PAP settings from the test)
- CPAP uptake (patient procurement of a CPAP device post-titration)
- CPAP adherence at 3 months (usage ≥4 hours per night for ≥70% of days)

Results: A total of 332 patients were included (110 in-lab, 222 home). The mean age (in-lab: 60.2 years, home: 57.3 years; p=0.08) and pre-treatment apnea-hypopnea index (AHI) (in-lab: 38.8/ hour, home: 36.5/ hour; p=0.18) were similar among both groups. Although titration success rate was higher in the in-lab group (in-lab: 97.3%, home: 89.1%; p=0.01), CPAP uptake rate was similar among both groups (in-lab: 51.8%, home: 59%; p=0.25). Although majority of patients who procured PAP device chose auto-CPAP (in-lab 84.5%; Home 90%; p=0.25), those who had underwent home CPAP titration still demonstrated significantly better adherence at 3 months (in-lab: 19.6%, home: 36.3%, p=0.0002) (Figure 5). Neither pre-treatment AHI ≥30/ hour (p=0.65) nor pre-treatment ESS scores ≥ 11 (p= 0.59) showed significant relationship with good adherence rate.

Conclusions: While auto-CPAP offers a convenient approach to initiating therapy, early identification and management of CPAP-related challenges remain crucial for optimizing long-term adherence. Our findings demonstrate that home-based CPAP titration with telemonitoring and nursing support not only improves adherence but also enables sleep centers to reserve in-laboratory resources for patients with complex sleep conditions.

Acknowledgments: I would like to express my gratitude towards all staff in Hong Kong East Cluster Integrated Sleep Service Centre and Respiratory team of Pamela Youde Nethersole Eastern Hospital for their support.

The Impact of Exercise Training on the Obstructive Sleep Apnea Endotypes

C. Beatty¹, S. Landry¹, D. Mann², S. Joosten³, J. Collet¹, R. Ferreira-Silva⁴, L. Ueno-Pardi⁴, P. Genta⁴, G. Hamilton³, B. Edwards¹

¹Monash University, Physiology, Melbourne, Australia, ²University of Queensland, School of Electrical Engineering and Computer Science, Brisbane, Australia, ³Monash Medical Centre, Monash Health, Melbourne, Australia, ⁴Universidade de Sao Paulo, Sao Paulo, Brazil

Introduction: Weight loss interventions such as exercise are often recommended to manage both obstructive sleep apnea (OSA) and the cardio-metabolic complications associated with obesity. Interestingly, exercise can modestly improve OSA severity even without significant changes in body weight. However, the mechanisms underlying the improvements in OSA severity, separate from those observed with weight loss, are currently unknown. We aimed to assess how exercise affects the OSA pathophysiological endotypes (upper airway collapsibility, loop gain, arousal threshold and upper airway muscle compensation) and to identify individuals most likely to improve their OSA with exercise.

Materials and methods: We retrospectively analyzed data from OSA patients who underwent a 6-month exercise intervention (n=22). OSA endotypes were calculated from routine polysomnographic recordings before and following the intervention. Paired t-tests were used to compare the OSA endotypes before and after the exercise intervention. Correlation analysis was used to assess whether the baseline OSA endotype(s) predict change in OSA severity.

Results: Following 72 sessions of supervised exercise training, there was an improvement in the AHI (37.2[17.1, 57.4] to 27.9[15.9, 48.8] events/hr, p=0.046) but no significant change in body weight. Overall, there was no change in OSA endotypes; however, improvements in AHI were associated with improvements in upper airway muscle compensation ($\rho = -0.54$, p=0.011). Furthermore, poor upper airway muscle compensation at baseline predicted greater reductions in OSA severity ($\rho = 0.51$, p=0.017).

Conclusions: Exercise may improve OSA by strengthening the upper airway muscles. As such, regular exercise may be helpful to improve OSA in those with poor upper airway muscle function.

The Impact of Laparoscopic Sleeve Gastrectomy on Upper Airway Function and Sleep-disordered Breathing

Introduction: Obstructive Sleep Apnea (OSA) is a global health crisis, strongly associated with obesity, increasing cardiovascular and metabolic risks. Continuous Positive Airway Pressure (CPAP) is the primary treatment but requires lifelong adherence and is not always well-tolerated. Metabolic Bariatric Surgery (MBS) has emerged as a promising intervention by reducing excess weight and improving

upper airway anatomy. Laparoscopic sleeve gastrectomy (LSG) has become the most common form of MBS performed worldwide due to its excellent results and limited complications. This study evaluates the impact of LSG on OSA using Magnetic Resonance Imaging (MRI) and polysomnography to assess structural changes and clinical outcomes.

Materials and methods: This prospective study was conducted on OSA patients referred to bariatric surgical department, in Medical Research Institute Alexandria University during the period between May 2023 and January 2024.

Ethical approval was obtained from the institutional review board (IRB) of the Faculty of Medicine of Alexandria University (No. --0306534-). Informed consent was obtained from the patients. All methods were performed in accordance with the relevant guidelines and regulations. This prospective study included 40 patients aged 18–65 years with BMI >30 kg/m² and confirmed OSA (apnea-hypopnea index (AHI) ≥5). Pre- and post-operative assessments included MRI of the upper airway, polysomnography, and the Arabic version of the Epworth Sleepiness Scale (ArESS) for daytime sleepiness. Statistical analyses, including Generalized Estimating Equations (GEE) and correlation tests, were performed using R software to evaluate changes in weight, BMI, AHI, ODI, and airway dimensions.

Results: The ESS showed an average reduction from 17.0 ± 0.5 to 5.4 ± 0.2 . Regarding polysomnography, there was a dramatic decrease in the AHI from 38.1 ± 2.5 events per hour, the nocturnal oximetry and the ODI was significantly reduced from 30.7 ± 2.2 to 5.2 ± 0.5 events per hour. The need for CPAP decreased dramatically from 80% of patients to 22.5% post-surgery as well as the average CPAP pressure required.

Metabolic parameters showed significant improvements; average reductions in fasting glucose and HbA1c were 15.4 mg/dL and 0.6%, respectively. In addition to the Lipid profiles with average reductions in triglycerides (-44.0 mg/dL), LDL cholesterol (-17.4 mg/dL), and overall cholesterol levels (-26.8 mg/dL).

After surgery diabetes and hypertension were resolved in all cases ($p = 0.023$ and $p = 0.008$, respectively). Hypothyroidism and dyslipidemia improved in 85.7% of cases but did not reach statistical significance ($p = 0.077$ and $p = 0.480$, respectively). Osteoarthritis did not resolve in any patient but showed improvement in all cases (100%), while cardiac conditions improved in 33.3% of cases and resolved in 66.7%, neither reaching statistical significance ($p = 0.480$ for both).

Greater %TWL correlated significantly with improvements in ESS, AHI, and ODI when outliers were excluded.

Conclusions: LSG significantly improves OSA severity, upper airway anatomy, and reducing CPAP dependency. These findings highlight LSG as an effective intervention for OSA patients with obesity, emphasizing the need for long-term research.

The Menopause Effects in Obstructive Sleep Apnoea (OSA) and the use of STOP-BANG score in Hong Kong (MENOSAS-HK)

A.E. Le¹, S.M. Wong², C.Z.S. Tseng¹

¹Wong Tai Sin Hospital, Department of Tuberculosis and Chest Unit, Kowloon, Hong Kong, SAR of China, ²Private practice, Hong Kong, Hong Kong, SAR of China

Introduction: The median age of menopause in Hong Kong is 51 year-old⁽¹⁾.

In a recent review on OSA and menopause, the reduction in oestrogen and progesterone hormones might cause instability in the ventilatory control system, leading to an overall increased risk for OSA⁽²⁾. This study aimed to assess difference in sleep characteristics and polysomnographic patterns in menopause patients compared to male counterpart in Hong Kong.

Materials and methods: Patients referred for sleep studies were recruited from 15/09/2022 to 28/02/2023. OSA were defined as apnoea-hypopnea index ≥ 5 events/hour⁽³⁾. Menopause was defined as patients > 51 year-old⁽¹⁾. STOP-BANG has been validated in Hong Kong for screening of OSA⁽⁴⁾.

Results: A total of 263 patients were recruited, amongst them 59 patients were menopause (22.4%). Menopausal patients were older than male patients (62.24 ± 7.02 vs 58.40 ± 10.96 years ($p < 0.05$)). BMI, AHI and ESS were similar. Menopausal patients have more snoring (15.67 ± 18.54 vs 8.18 ± 11.58 ($p < 0.05$)) and more hypopnoea (27.98 ± 19.50 vs 21.22 ± 14.58 ($p < 0.05$)). While male subjects present

with more central apnoea (1.46 ± 2.34 vs 5.54 ± 7.49 ($p < 0.05$)).

There was 1 unit difference in STOP-BANG score between menopause and male patients ($p < 0.05$).

Conclusions: Despite the same BMI, AHI and ESS, there was 1 unit difference in STOP-BANG score between menopausal and male patients, reflecting the gender component, while the lack of oestrogen/progesterone in menopausal patients do not confer protection against OSA. Hence, the use of STOP-BANG as screening may underestimate OSA in menopausal patients.

Acknowledgments: All authors declare that they have no conflicts of interest.

The nonlinear endotypic characteristics and unique endotypic subtypes in Obstructive sleep apnea

X. Wang¹, W. Huang², H. Yi², S. Yin²

¹Department of Otolaryngology, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China, ²Department of Otorhinolaryngology Head and Neck Surgery, Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China

Introduction: The pathology mechanisms of obstructive sleep apnea (OSA) include high loop gain, low arousal threshold, more collapsible upper airway, and poor pharyngeal muscle responsiveness. Our research aimed to evaluate the dose-effect relationship between OSA endotypes and apnea hypopnea index (AHI), identify OSA endotypic clusters, and compare the cardiovascular disease (CVD) risk in different endotypic clusters.

Materials and methods: Individuals underwent polysomnography (PSG) were recruited. Endotypes were calculated with PSG-derived methods, including LG, ArTH, pharyngeal collapsibility (Vpassive), and muscle compensation (Vcomp). Restricted cubic spline (RCS) analysis was used to assess the non-linear relationship between variables. Latent profile analysis (LPA) was conducted to identify OSA clusters.

Results: This cross-sectional trial included 3616 OSA participants, fully adjusted model indicated loop gain, arousal threshold and upper airway collapsibility were non-linearly related to AHI; muscle compensation was linearly related to AHI. Latent profile analyses identified three OSA endotypic clusters, including high loop gain and upper airway collapsibility cluster, low arousal threshold cluster, low muscle compensation cluster. The high loop gain and upper airway collapsibility cluster had the highest CVD risk, while the low muscle compensation cluster had the lowest CVD risk.

Conclusions: In Chinese OSA participants, endotypes (except for Vcomp) were nonlinearly related to AHI. LPA identified the high LG and low Vpassive cluster, low ArTH cluster, and low Vcomp cluster.

The oral and gut microbiota dysbiosis in OSA

J. Gu¹, R. Zhao¹, M. Peng¹, J. Xue¹, Y. Chen¹, M. Sun¹, J. Li¹, L. Zhao¹, B. Zhou¹, X. Zhang¹, F. Han¹, X. Dong¹

¹Peking University People's Hospital, Beijing, China

Introduction: This study based on high-throughput sequencing technology to investigate the characteristics of oral-gut microecological communities in OSA and potential association with oral-gut microbiota and intermittent hypoxia.

Materials and methods: Adult subjects were enrolled from the department of sleep medicine, Peking University People's Hospital. All participants completed overnight PSG, collected fecal and oral pharyngeal swab sampling. 16s rRNA sequencing technology was used to analyze the microbiota structure and functional characteristics of OSA with different severity and healthy volunteers without snoring and apnea.

Results: (1) The alpha diversity of the gut microbiota in the OSA group was changed, the abundance of mild OSA and moderate-to-severe OSA(MSevOSA) group was greater than that of healthy control, but the species uniformity and microbiota diversity (Shannon index and Simpson index) were lower than those of healthy control. Linear discriminant analysis Effect Size analysis(LEfSe) found that *Ruminococcus_torques_group* and *Escherichia-Shigella* were significantly enriched in the gut of the MSevOSA group, and were positively correlated with cumulative time at $SpO_2 < 90\%$ (CT90) and cumulative percentage of sleep time spent with $SpO_2 < 90\%$ (CT90%), and significantly negatively correlated with lowest oxygen saturation(LSpO2). RDA analysis and Envfit test found the

environmental factors with the greatest impact on the gut microbiome were mean oxygen saturation(MSpO₂), CT90, LSpO₂, CT90%, BMI and ODI (r^2 was 0.804, 0.539, 0.525, 0.519, 0.307 and 0.272, respectively, $p < 0.005$), in which AHI had the lowest contribution to the difference in microbiota abundance ($r^2=0.216$, $p=0.006$). BugBase annotation showed that the aerobic phenotype of gut microbiota in MSevOSA group decreased significantly compared with the healthy control group [0.01(0.00-0.02) in the MSevOSA vs 0.02(0.01-0.02) in the healthy control group, $p=0.019$].

(2) The alpha diversity was demonstrated no difference in oropharyngeal microbiome, but there was a significant difference in beta diversity between healthy control and MSevOSA (Adonis test, $R^2=0.042$, adjusted $p=0.017$). In terms of microbial composition, Bacteroides, Lachnospirillum and Porphyromonas endodontalis were enriched in MSevOSA group. Among them, the differential genera Porphyromonas endodontalis, Bacteroides, and Lachnospirillum were positively correlated with AHI ($r=0.470$, 0.366 and 0.362 , respectively, $p<0.01$). RDA analysis and Envfit test showed that CT90% and AHI contributed the highest to the difference in the abundance of oropharyngeal microbiota ($r^2= 0.289$ and 0.254 respectively, $p < 0.01$).

Conclusions: Chronic intermittent hypoxia caused by OSA had a potential effect on the dysbiosis of the human oral-gut microbiota. The abundance of gut microbiome was high in patients with different degrees of OSA, but there was obvious heterogeneity in species evenness and diversity. The Ruminococcus_torques_group and Escherichia-Shigella were characteristic genera in the gut microbiota of MSevOSA, and were significantly correlated with the severity and duration of nocturnal hypoxia, but not AHI. Bacteroides and Lachnospirillum were enriched in oropharyngeal microbiome structure of MSevOSA, which is closely related to AHI and nocturnal hypoxia severity.

The Overlooked component: Proportion of Central Hypopnea in Obstructive Sleep Apnea Patients

K. Rawat¹, L.K. Saini¹, R. Gupta², K.S. Kumar¹

¹All India Institute of Medical Sciences Rishikesh, Respiratory Medicine, Rishikesh, India, ²All India Institute of Medical Sciences Rishikesh, Psychiatry and Sleep Medicine, Rishikesh, India

Introduction: Nearly 1 billion people globally are affected by Obstructive sleep apnea (OSA), with 425 million adults aged 30–69 having moderate to severe disease.

OSA involves repeated airflow reduction or cessation due to upper airway narrowing during sleep, causing hypoxia, arousals, and autonomic dysfunction.

These changes contribute to metabolic syndrome, hypertension, cardiovascular diseases, and cognitive decline.

Despite its prevalence, OSA remains underdiagnosed and untreated, and may coexist with central events. Central sleep apnea (CSA) results from impaired respiratory rhythm and is influenced by sleep stage, position, and gas exchange.

Differentiating OSA from CSA is essential, as both require distinct diagnostic and therapeutic approaches.

Materials and methods: This was a prospective cross-sectional single-center study consisting of 172 patients who fulfilled inclusion and exclusion criteria. A structured proforma was used to record demographics, symptoms, comorbidities, family history, and physical exam findings. All patients underwent Level-1 polysomnography.

For those diagnosed with OSA, hypopneas were manually classified as central or obstructive.

Central hypopnea proportion and revised Apnea-Hypopnea Index (excluding central events) were calculated.

The association between central hypopneas and clinical characteristics was then analyzed.

Results:

- 367 patients of OSA, who were diagnosed by level 1 polysomnography laboratory were screened for eligibility, and 172 patients were enrolled in the study. The proportion of central hypopnea in our study population was 7.35% (2.02% -18.95%). When analysed by OSA severity, the median proportion of central hypopnea was highest in mild OSA (22.97%), followed by moderate (11.04%) and severe (3.07%). The differences among groups were statistically significant. Central hypopnea had weak negative correlation with age and Body-mass index (BMI). Central hypopnea was lesser in type-2 diabetes and hypertensive patients.

Excluding central hypopneas from AHI calculation reclassified 23.1% of mild OSA patients as no OSA, 20.9% of moderate as mild with 2.3% as no OSA, and 6.7% of severe as moderate. When central hypopneas were counted as a part of central events, 3 out of 172 patients i.e. 1.7% could be labelled as central sleep apnea.

Conclusions:

- The study was conducted with the thought that although scoring hypopnea into obstructive and central is optional according to AASM scoring manual version-3, it is important to score central and obstructive hypopnea separately. Our study shows that central hypopnea is found in significant proportions in patients of OSA and may have diagnostic and therapeutic implications.

Abbreviations: OSA – obstructive sleep apnea, AHI – Apnea- Hypopnea Index, CPAP- Continuous positive airway pressure

The Prevalence of Obstructive Sleep Apnea among Patients with Secondary Polycythemia in Sultan Qaboos University Hospital

A. Al-Siyabi¹, M. Al-Abri², B. Al-Rawahi³, M. Al-Khabori³

¹Sultan Qaboos University, Muscat, Oman, ²Sultan Qaboos University, Physiology, Muscat, Oman,

³Sultan Qaboos University Hospital, Hematology, Muscat, Oman

Introduction: Obstructive sleep apnea (OSA) is a common sleep disorder in the general population. It is usually considered one of the causes of secondary polycythemia. The relationship between OSA and secondary polycythemia is controversial. Multiple studies reported a higher prevalence of secondary polycythemia among patients with OSA, while others did not show any significant relationship. This study aimed to investigate the prevalence of obstructive sleep apnea (OSA) among patients with secondary polycythemia.

Materials and methods: A retrospective cross-sectional study was conducted at Sultan Qaboos University Hospital (SQUH). This study included all patients admitted to the hematology clinic in SQUH with secondary polycythemia and a sleep study was done for them. Study population data was collected from Trackcare and entered into SPSS, and Descriptive Statistics (mean and frequency) were obtained.

Results: The data of 44 patients was collected (male/female). All the study subjects had OSA at different severity; 52% of patients were found to have severe OSA. The mean apnea-hypopnea index (AHI) was 33.27 event/h and the desaturation index of 20.28 event/h. The male population was more likely to develop polycythemia. Polycythemia is more common in the middle-aged population, with a mean value of 40 years old, and it is more common in obese people whose body mass index is more than 30 Kg/m².

Conclusions: Severe OSA is found to be common in patients with secondary polycythemia, and it is more prevalent among patients with obesity and male sex.

The Prognostic Significance of Severe Obstructive Sleep Apnea in Patients Undergoing Surgical Repair for Acute Type A Aortic Dissection

J. Mei¹, X. Xi², H. Zhang², J. Wang³, R. Li³, C. Li³, J. Zhu³, Y. Ge¹, J. Xie²

¹Capital Medical University, Department of Cardiovascular Surgery, Beijing Aortic Disease Center, Beijing Anzhen Hospital, Beijing, China, ²Capital Medical University, Beijing Anzhen Hospital Centre for Sleep Medicine and Science, Beijing, China, ³Capital Medical University, Department of Cardiovascular Surgery, Beijing Aortic Disease Center, Beijing Anzhen Hospital, Beijing, China

Introduction: Obstructive sleep apnea (OSA) is prevalent in patients with aortic dissection, yet its long-term effect on prognosis, particularly in those with acute type A aortic dissection (ATAAD), remains inadequately understood.

Materials and methods: This study conducted sleep test for 86 ATAAD patients within 90 days after total aortic arch replacement between January 2018 and December 2018. Severe OSA was defined as an apnea and hypopnea index ≥ 30 events/hour. Multivariable Cox regression analysis was used to evaluate the relationship between severe OSA and major adverse events (MAEs), including all-cause mortality and surgical reintervention.

Results: Over a median follow-up period of seven years, patients with severe OSA ($n = 22$) experienced a significantly higher incidence of MAEs (6 [27.3%] vs. 5 [7.8%], $P = 0.047$) and lower long-term survival rates (81.8% vs. 97.4%, $P = 0.003$) compared to patients without severe OSA ($n = 64$). Cox regression analysis revealed that severe OSA was a significant predictor of MAEs (HR = 3.9; 95% CI: 1.2–12.9; $P = 0.025$), with the association remaining significant after adjusting for age (HR = 3.7; 95% CI: 1.1–12.4; $P = 0.032$). Additionally, partial thrombosis of the false lumen was more frequently observed in patients with severe OSA compared to controls (9 [40.9%] vs. 9 [14.1%], $P = 0.028$).

Conclusions: Severe OSA is associated with poorer outcomes in patients undergoing surgical repair for ATAAD, underscoring the importance of identifying and managing OSA effectively, even following standard surgical intervention.

The relationship between obstructive sleep apnea and visual hallucinations in PD patients--a MRI and PSG study

L. Zhang¹, J. Zhu¹

¹Nanjing Brain Hospital Affiliated to Nanjing Medical University, Nanjing, China

Introduction: Parkinson's disease (PD) patients frequently experience visual hallucinations (VHs) and obstructive sleep apnea (OSA). The aim of this study was to describe the prevalence and clinical correlates of VHs and OSAS in the Chinese population with PD. Using magnetic resonance to measure upper airway parameters and explore their relationship with sleep apnea and visual hallucinations in Parkinson's disease.

Materials and methods: A sample of 489 PD patients was recruited for the present study. Patients were categorized as having formed VHs (FVHs) or minor VHs (MVHs) or as non-hallucinators (NVHs) according to the Unified Parkinson's Disease Rating Scale (UPDRS) and an initial questionnaire. Polysomnography (PSG) was used for objective assessment of sleep. Using color Doppler ultrasound to examine the thickness of the genioglossus muscle, the thickness of the tongue, the left-right diameter of the oropharyngeal airway at the end of deep inhalation, and the left-right diameter of the oropharyngeal airway at the end of deep exhalation in patients with OSA. Using MRI to reconstruct the upper airway of OSA patients, measure the volume of oropharynx, glossopharynx, laryngopharynx and nasopharynx.

Results: VHs were observed in 143 (29.2%) patients. Among them, 75 of the hallucinators experienced MVHs, and 68 experienced FVHs. The disease duration, UPDRS Part III score, Hoehn and Yahr (H-Y) stage, Pittsburgh Sleep Quality Index (PSQI) score and rapid eye movement (REM) sleep behavior disorder (RBD) score of hallucinators were significantly greater than those of non-hallucinators ($P < 0.05$). We also observed OSAS in 38.7, 54.7, and 63.3% of the NVHs, MVHs, and FVHs groups, respectively. PSG showed that the VH groups had a lower total sleep time, lower sleep efficiency, higher arousal index, lower sleep latency, lower N1%, higher apnea-hypopnea index (AHI), higher average duration of apnea, higher respiratory-related arousal (RRA), and lower values of the lowest O_2 and mean O_2 . The forward binary logistic regression model showed that AHI, N1%, RRA and lowest O_2 were independently associated with VHs in PD patients. MRI examination indicates that there are abnormalities in the bony structure of the upper airway in patients with OSA. Ultrasonic examination indicates that patients with OSA have a higher degree of airway collapse. CPAP treatment can significantly improve non motor symptoms such as motor symptoms, cognition, and VHs in patients.

Conclusions: Our results confirm the high prevalence of VHs and OSAS as well as their relationship in patients with PD. Emphasizing the treatment of patients with PD combined with OSAS is beneficial for improving the overall symptoms of PD.

The Role of Mouth Tape for CPAP Users in OSA Patients with Mouth Breathing

A. Meksukree¹, S. Pitipanyakul², W. Laohavinij³, B. Chaitusaney², N. Chirakalwasan^{2,4}, P. Hirunwiwatkul^{1,2}, N. Charakorn^{1,2}

¹Faculty of Medicine, Chulalongkorn University, Department of Otolaryngology, Bangkok, Thailand,

²King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Excellence Center for Sleep Disorders, Bangkok, Thailand, ³King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Department of Preventive and Social Medicine, Bangkok, Thailand, ⁴Faculty of Medicine, Chulalongkorn University, Division of Pulmonary and Critical Care Medicine, Bangkok, Thailand

Introduction: Continuous positive airway pressure (CPAP) is the standard treatment for obstructive sleep apnea (OSA), but its effectiveness depends on patient adherence. Mouth breathing during CPAP therapy is common among patients with OSA and is associated with reduced adherence. Current strategies to address this issue include the use of a chin strap with a nasal mask or switching to an oronasal mask. Mouth taping has recently emerged as a potential intervention; however, its impact on CPAP adherence remains unstudied. This study aims to evaluate whether mouth tape improves CPAP adherence in patients with OSA. Secondary outcomes include daytime sleepiness (Epworth Sleepiness Scale [ESS]), snoring (visual analog scale [VAS]), night awakenings, mouth/throat dryness, air leakage, and adverse effects.

Materials and methods: This randomized crossover study compared CPAP adherence with and without silicone hypoallergenic mouth tape in participants who exhibited mouth breathing during CPAP therapy. Participants received CPAP therapy with or without mouth tape for 30 days, then crossed over to the other intervention for another 30 days, with a 7-day washout period between phases. After each period, CPAP data (adherence, apnea-hypopnea index [AHI], and leakage) and questionnaires were collected. Tape application involved cutting silicone hypoallergenic tape to 2–4 cm based on facial structure and applying it vertically over the philtrum to seal both the upper and lower lips.

Results: Sixty-two patients with OSA (36 males; AHI [mean $\pm$ standard deviation], 45.8 ± 22.2 events/h; age, 57.7 ± 17.6 years; BMI, 27.9 ± 7.1 kg/m²) were randomized. Participants using mouth tape, compared to without mouth tape, showed higher CPAP adherence: average use increased by 51.8 minutes/day (95% CI, 33.1–70.4) and by 41.4 minutes/used day (95% CI, 27.9–55.0). Frequency of use increased by 14.2% (95% CI, 9.3–19.0), with 17.6% more days reaching ≥ 4 hours/night (95% CI, 12.7–22.6). Good adherence increased with an odds ratio of 4.5 ($p < 0.001$). Mouth tape significantly improved ESS, snoring VAS, mouth/throat dryness, and night awakenings ($p < 0.05$). Adverse effects were reported.

Conclusions:

Using mouth tape in patients with mouth breathing during CPAP improved CPAP adherence in both duration and frequency. Unfavorable symptoms related to OSA, or CPAP were alleviated, leading to better sleep quality.

Acknowledgments:

The authors thank the staff of the Excellence Center for Sleep Disorders at King Chulalongkorn Memorial Hospital for their support in conducting this study.

The Role of TREM-1 in Mediating Atherosclerosis Induced by Obstructive Sleep Apnea Syndrome: Insights into Mechanisms and Therapeutic Implications

X. Gao¹

¹The Second Hospital of Shanxi Medical University, Department of Respiratory Medicine, Taiyuan, China

Introduction: To investigate the role of TREM-1 in atherosclerosis (AS) development triggered by obstructive sleep apnea syndrome (OSAS) and understand the underlying mechanisms.

Materials and methods: Mendelian randomization (MR) analysis was conducted using genome-wide association study (GWAS) summary data to assess the causal relationship between OSAS and AS (Finngen R10). Single-cell RNA sequencing (scRNA-seq) analysis was performed to examine the impact of OSAS on cellular transcriptional status in lung tissue (GSE145435) and peripheral blood (GSE214865) at the single-cell resolution. Additionally, single-cell transcriptional landscapes of aortic AS (GSE155512) were constructed to explore the involvement of macrophages in AS pathology. A chronic intermittent hypoxia (CIH) mouse model was established to evaluate atherosclerosis of aorta

formation, polarization of macrophage, and expression level of TREM-1. In vitro experiments utilizing lentiviral RNA were conducted to silence TREM-1 and assess its effect on macrophage polarization.

Results: MR analysis demonstrated a significant association between OSAS and the progression of coronary AS ($P<0.001$), as well as atherosclerosis in other arterial territories ($P=0.003$). ScRNA-seq analysis revealed that OSAS-induced hypoxia did not significantly alter the cellular composition of lung tissue ($P>0.05$), whilst OSAS patients exhibited enhanced immune activity of CD14⁺ monocytes in peripheral blood. Macrophage subpopulations in AS tissues of non-OSAS patients showed elevated immune crosstalk with smooth muscle cells, with relatively low TREM-1 expression. In contrast, CIH mice exhibited significantly increased AS plaque area, accompanied by upregulated TREM-1 expression ($P<0.05$). Infiltrating macrophages in AS under CIH displayed a predominance of the M1 subpopulation. In vitro experiments using macrophages exposed to CIH showed elevated levels of IL-6, TNF- α , and TREM-1, as well as decreased IL-10 and VEGF ($P<0.05$). Silencing TREM-1 significantly reduced TNF- α expression and increased IL-10 and VEGF expression ($P<0.05$).

Conclusions: OSAS is genetically linked to aortic atherosclerosis. TREM-1 is involved in OSAS-related AS by influencing macrophage polarization towards M1 and may serve as a potential therapeutic target. OSAS can lead to more TREM-1⁺ monocytes in the blood, contributing to AS development. Targeting TREM-1 could be a promising approach for treating atherosclerosis.

The Safety of Oral Appliances for OSA: Ten Years of FDA Adverse Event Reports

L. Liptak¹, E. Sall¹, E. Mosca¹

¹ProSomnus Sleep Technologies, Pleasanton, United States

Introduction: Oral appliances (“OA’s”) are a leading treatment for OSA. Clinical practice guidelines advise on the risks of dental side effects, but do dental side effects result in adverse events? With the availability of pharmaceutical and surgical treatments for OSA, new learnings about CPAP, and the emergence of OAs, properly informing patients on the safety of treatment options is increasingly important.

Materials and methods: This investigation characterizes the safety profile for OA’s, based on adverse event reports submitted to the FDA over a 10-year period. The FDA MAUDE database was accessed on June 6, 2025.

The FDA MAUDE database documents serious adverse event reports, defined as undesirable medical device experiences when the patient outcome is: death, life-threatening, hospitalization, disability, permanent damage, requires a subsequent intervention, or other consequence that endangers the patient. The investigators searched for FDA product codes LRK (Anti-Snoring), PLC (Sleep Appliances with Patient Monitoring) and LQZ (Jaw Repositioning Devices).

OA’s were classified into three categories for post-hoc analysis: non-custom, semi-custom and precision-custom. Non-custom OA’s are prefabricated. Semi-custom OA’s are made from oral records but include prefabricated items. Precision-custom OA’s are 100% made from oral records for each patient without prefabricated components or modifications. This assessment was made by reviewing relevant device labelling.

Results: Our search queries for the three product codes returned 853 unique adverse event reports, after elimination of duplicates.

59% of records were categorized as OA device malfunctions. 41% as patient injuries.

Semi-custom, non-custom and custom precision OA’s accounted for 86%, 13% and 1% of records, respectively.

The ten most frequently cited patient problems comprise 87% of records. They are: No Clinical Signs (281), Hypersensitivity/Allergic Reaction (125), No Known Consequence (51), Insufficient Information (25), Pain (24) Reaction (20) No Information (14) Discomfort (12) Erythema (11) Inflammation (11) Swelling (11).

2% indicate dental related serious-adverse events. They are: Tooth Fracture (6), Sensitivity of Teeth (3),

Joint Dislocation (2), Break (1), Dry Mouth (1), Joint Disorder (1) and Lacerations (1).

The ten most frequently cited device problems comprise 90% of records. They are: Break (169), Detachment of Device Component (153), No Identified Problem (141), Insufficient Information (38), Biocompatibility (29), Fracture (29), Interaction Problem (14), Patient Incompatibility (13), Material Integrity Problem (12).

Conclusions: This investigation indicates that OA's are a relatively safe for OSA treatment. Applying conservative estimates for US OA prescriptions, adverse events remain well under 0.1% of total OA treatments.

Custom-precision OA's are associated with fewer adverse events than non-custom and semi-custom OA's, resulting in better health and safety, fewer emergency interventions, less time out of treatment for OA repairs and adjustments, and more efficiency for the healthcare provider and payers.

Stakeholders might be better served focusing on OA materials and design which account for the more frequently reported adverse events: Allergic Reactions, Biocompatibility, Inflammation, Swelling, and OA Component failures. Although patients should continue to be advised of dental side effects, the FDA MAUDE database results suggest that dental side effects rarely result in a serious adverse event.

The SHINE Survey: Uncovering Gender Differences in Psychosocial Burden of Obstructive Sleep Apnea

M. Mallampalli¹, A. Mendoza², E. Cooksey³, J. Yee², E. Brouwer⁴, L. Bloudek⁴, R. Wu⁴, K.S. Yu²

¹Alliance of Sleep Apnea Partners, Ellicott City, United States, ²Apnimed, Inc., Cambridge, United States, ³Project Sleep, Los Angeles, United States, ⁴Curta, Inc., Seattle, United States

Introduction: Obstructive sleep apnea (OSA) is a serious, chronic sleep-related breathing disease in which the airway is obstructed during sleep causing disrupted breathing, sleep fragmentation, and reduced oxygenation. OSA may present differently by gender, potentially causing differential underdiagnosis and disease experience. The objective of this study was to assess the psychological and social impact of OSA by gender in U.S. adults with diagnosed OSA.

Materials and methods: The SHINE online patient survey, developed in consultation with patient advocates and OSA experts, was administered to 1,500 OSA patients in the U.S. Results were assessed via generalized linear models with binomial distribution and logit link function, adjusted for age group, BMI category, race, region, income level, comorbidities, and time since diagnosis. Outcomes of interest were whether patients experienced ≥ 2 negative OSA symptoms in the past 30 days, experienced ≥ 2 negative feelings with OSA in the past 30 days and agreed (6 or 7 on a 7-point Likert scale) with ≥ 2 statements of OSA negatively affecting relationships.

Results: Of 1,500 respondents, 755 were men and 745 were women, with mean ages (SD) 50.7 (14.5) and 41.2 (14.4) years, respectively. Of seven listed OSA symptoms (daytime sleepiness, fatigue, irritability, mood changes, loud snoring, morning headaches, inability to concentrate), women were 1.52 times more likely than men to report ≥ 2 symptoms in the past 30 days ($p=0.04$). When asked whether OSA negatively affected relationships (overall impact, impact on care for family/friends, ability to be present, and social engagement), women were 1.42 times more likely than men of agreeing with ≥ 2 of 5 statements ($p=0.01$). Of 13 listed negative feelings (hopeless, depressed, frustrated, misunderstood, anxious, irritable, angry, not dependable, isolated, ashamed, embarrassed, scared, and low self-esteem), women were 1.61 times more likely than men to experience ≥ 2 feelings in the past 30 days ($p=0.01$).

Conclusions: It is known that OSA manifests differently in women compared to men. Our study further supports gender differences in patient reported outcomes, with women experiencing a higher psychosocial burden and more severe lived experiences, even after adjusting for baseline characteristics. These findings underscore the critical need for gender-specific approaches in the screening, diagnosis and treatment of OSA.

The theranostic value of gene signatures and molecular mechanisms between obstructive sleep apnea and heart failure derived by machine learning

T. Zhou¹, E. Zhou¹, W. Huang¹, J. Zhang¹, C. Li¹, H. Yi¹

¹Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China

Introduction: A bidirectional relationship has been established between obstructive sleep apnea (OSA) and hear failure (HF). Considering that HF is a progressive and irreversible condition, it is crucial to identify potential biomarkers and elucidate the underlying mechanisms linking OSA and HF to facilitate early-stage personalized interventions.

Materials and methods: Training and validation datasets of OSA and HF were retrieved from the GEO database. The raw data was integrated to find common differentially expressed genes (DEGs). Three machine learning algorithms (RF, LASSO logistic regression, and SVM-RFE) were employed to screen candidate biomarkers from common genes. The enrichment analyses were conducted to elucidate the biological functions and pathways. The validation and diagnostic performance of candidate biomarkers was evaluated using nomogram model and receiver operating characteristic (ROC) curve analysis. Additionally, consensus clustering analysis and immune infiltration analysis were processed to identify molecular subtypes and uncover potential mechanism underlying OSA-related HF.

Results: A total of 19 DEGs were identified as overlapping between OSA and HF. Enrichment analysis indicated that these genes were predominantly enriched in pathways related to immune and inflammatory response. Utilizing three machine learning algorithms, nine core genes (BTN3A2, MAPK10, STEAP4, FCER1G, CD109, SAMHD1, LUM, SFRP4 and FRZB) were selected as candidate biomarkers, and a nomogram was developed. ROC analysis showed that the nomogram achieved an AUC exceeding 0.80 in both training and validation datasets. Furthermore, immune infiltration analysis explored that these core genes are significantly associated with several immunocytes and immune checkpoint, which potentially regulate metabolic dysfunction and cardiac remodelling in OSA-related HF.

Conclusions: OSA is a risk factor implicated in the pathogenesis and progression of HF. Our machine learning analysis investigated the potential mechanism underlying HF secondary to OSA, and identified novel candidate genes that may serve as diagnostic biomarkers and potential therapeutic targets.

The 'USA' System: A Novel Classification for Hypoglossal Nerve Stimulation Therapy Outcomes

R. Soose¹, T. Kaffenberger^{1,2}, B. McCarty¹, L. Magana¹, M. Lundeen³, A. Bader³, I. Byrd³, K. Lee³, R. Whelan¹, P. Strollo^{4,2}, R. Patel^{5,3}

¹University of Pittsburgh, Otolaryngology, Pittsburgh, United States, ²Veterans Affairs Pittsburgh Healthcare Systems, Pittsburgh, United States, ³Inspire Medical Systems, Minneapolis, United States, ⁴University of Pittsburgh, Pulmonary, Allergy, Critical Care, and Sleep Medicine, Pittsburgh, United States, ⁵The Insomnia and Sleep Institute of Arizona, Scottsdale, United States

Introduction: Treatment effectiveness for obstructive sleep apnea (OSA) device therapy is traditionally defined by a binary (responder versus non-responder) assessment of the apnea-hypopnea index (AHI) and overlooks usage and symptom response. We sought to define a novel outcomes classification system within hypoglossal nerve stimulation (HGNS) patients to better capture the various multidimensional outcomes in clinical practice and to better guide therapy optimization efforts. The USA system combines metrics of therapy Usage (U), Symptom response (S), and reduction in Apnea burden (A); and is adaptable over time as novel metrics in these categories continue to evolve.

Materials and methods: The USA system was applied to the ADHERE registry, an international database of HGNS patients. Adequate *usage* (U) was defined as mean nightly use >4 h/night, *symptom* response (S) by a reduction of >2 in the Epworth Sleepiness Scale (ESS) or maintaining a baseline ESS <10 without postoperative increase, and adequate *apnea* burden reduction defined as a full-night treatment AHI <15 events/hour. USA Class I patients were successful in all three categories. Class II was characterized by favorable usage and variations of partial response. Class III had suboptimal therapy usage.

Results: We analyzed 1453 patients with complete data in all three categories. USA Class I patients met success criteria in all three outcome measures and comprised 45.5% of patients. USA Class II comprised 35.9%, also had favorable therapy usage, and were further categorized as IIA (symptom

control but residual AHI elevation, 25.1%), IIB (effective AHI reduction but residual symptoms, 5.6%), and IIC (residual AHI and symptoms, 5.2%). USA Class III comprised 18.7% of the group and were characterized by suboptimal usage.

Conclusions: Over 80% of HGNS patients are using therapy well with the majority of those (76.2%) meeting success criteria based on AHI or ESS or both. Almost half of the analyzed HGNS population met success criteria in all three dimensions. Targeted troubleshooting efforts for the other half could strengthen long-term HGNS outcomes. Compared to binary assessments of one metric, the USA classification system better captures the multidimensional outcomes of HGNS therapy and may focus future research efforts and guide therapy optimization strategies.

Three-Year Results of Positive Airway Pressure Adherence in Children with Sleep Apnea Compared to Adults

H.-J. Park¹, D.-H. Park², K.-S. Cho¹, S.J. Mun²

¹Pusan National University Hospital, Department of Otorhinolaryngology-Head and Neck Surgery, Busan, Korea, Republic of, ²Pusan National University Yangsan Hospital, Department of Otorhinolaryngology-Head and Neck Surgery, Yangsan, Korea, Republic of

Introduction: Most pediatric patients with obstructive sleep apnea (OSA) are known to be treated with adenotonsillectomy (AT). However, in some of them, positive airway pressure (PAP) can be used for underlying diseases or in case of AT failure. However, studies on PAP adherence for children are relatively fewer than adults as PAP is less commonly used in children. Thus, 3-year PAP adherence and compliance were compared in pediatric OSA to adult OSA.

Materials and methods: A retrospective study was conducted on 17 children and 167 adults who had performed polysomnography (PSG) and were prescribed PAP and followed up for more than 3 months from July 2018 to January 2023. Adherence was defined as the percentage of patients continuing to use PAP after prescription and compliance was defined as an average of more than 4 hours per night usage of 70% of the monitoring days. A patient's underlying disease, PSG results, as well as PAP adherence and compliance for the 1st, 3rd, 6th, 9th, 12th, 18th, and 36th months were evaluated.

Results: There were 11 males (64.7%) in pediatric and 141 males (84.4%) in adult patients. The mean age was 8.0 years (6.50-12.50) in pediatric and 50.0 years (41.00-58.00) in adult patients. The mean body mass index showed significant differences in the pediatric and adult groups (17.86 vs 27.7) ($p=0.001$). The mean apnea hypopnea index (AHI) (37.0 vs 50.7) and Lowest O₂ saturation (79.4% vs 75.5%) did not show any differences in the 2 groups. Longest apnea showed considerable differences (25.9 sec vs 50.8 sec) ($p=0.000$). After 36 months of PAP usage, AHI dropped from 37.0 to 5.1 vs 50.7 to 2.6, adherence decreased from 94.1% to 41.2% vs 90.4% to 38.9% ($p=0.944$), compliance reduced from 64.7% to 28.9% vs 67.0% vs 29.3% ($p=0.268$) in pediatric and adults groups.

Conclusions: There were no significant differences in adherence and compliance with PAP in children compared to adults. Adherence and compliance decreased the most between 3 months and 6 months in children similar to adults. PAP was tolerated in 2/3 at 3rd month, and less than one third at three years in children.

Time with increased intrathoracic pressure and nocturnal hypoxemia are independent predictors of mortality in patients with suspected obstructive sleep apnea

H. Hrubos-Strøm¹, H. Nahoui², G. Einvik³, H. Schirmer²

¹Akershus University Hospital, Otorhinolaryngology, Lørenskog, Norway, ²Akershus University Hospital, Cardiology, Lørenskog, Norway, ³Akershus University Hospital, Pneumology, Lørenskog, Norway

Introduction: Severe obstructive sleep apnea, defined by an apnea/hypopnea index (AHI) >30, is associated with cardiovascular disease and high mortality rates. Exaggerated negative intrathoracic pressure and hypoxemia during obstructive apnea episodes represent important pathophysiological

mechanisms.

Hypothesis: Negative esophageal pressure (PES) and nocturnal mean oxygen saturation (mSpO₂) are separate independent predictors of mortality, and increased PES is associated with comorbid heart failure.

Materials and methods: Patients referred with suspected sleep apnea between 2003 and 2016 were examined by respiratory polygraphy including esophageal pressure measurement. We extracted time in bed (TiB), a surrogate for sleep time, with PES above 10 and above 60 cmH₂O, mSpO₂, AHI and body mass index from polygraphy recordings, and age, sex and comorbidities from medical records. Mortality status was retrieved from the Norwegian Death Registry up to June 2024 and analyzed with multivariable Cox regression models.

Results: We included 16,476 patients, of which 4,356 (26%) were females, and mean± SD age of 48±12 years. Median AHI was 9.7 (IQR 4.3–21.1) and 2,652 (16%) had AHI >30. Median mSpO₂ was 94% and median TiB was 239 minutes for PES above 10 cmH₂O and 0.8 minutes for PES above 60 cmH₂O. During a mean 14.7±3.7 years follow-up, 1,546 (9.4%) patients died. None-survivors were older and more frequently males. Compared to survivors, non-survivors had also higher AHI 16.3 (7.3–31) vs 9.3 (4.1–20), longer TiB-PES10 271 min (171–335) vs 235 (127–321), TiB-PES60 1.5 min (0.4–4) vs 0.8 (0.2–2.7), and lower mSpO₂ 93% (91%–94%) vs 94 (93%–95%). In a fully adjusted model with mSpO₂, log_TiB-PES60 and log AHI, there was no association between higher AHI values and increased risk of mortality (HR 0.99, 95% CI: 0.93–1.06, p=0.85), while higher levels of TiB-PES10 (HR 1.11, 95% CI: 1.05–1.17, p<0.001), and lower levels of mSpO₂ (HR 0.90, 95% CI: 0.88–0.91, p<0.001) was significantly associated with increased mortality risk. There was a significant association between TiB with increased PES and comorbid heart failure (OR 1.096, [95% CI: 1.029–1.167], p=0.004) for PES> 10 cmH₂O.

Conclusions: Lower mSpO₂ and prolonged TiB with increased PES, but not AHI, were independent predictors of mortality in patients with suspected OSA. AHI, as a treatment criterion for patients with sleep apnea, may not be the optimal metric to identify high-risk individuals. A potential link between sleep time with increased PES and heart failure should be further investigated.

Tongue Function in Young Populations at High Risk for SDB: Age-Stratified Associations and Interaction Analysis

T. Jagomägi¹, D.A. Hoang^{1,2}, T.M. Nguyen³, T.A. Hoang⁴, D.T.N. Nguyen²

¹University of Tartu, Institute of Dentistry, Tartu, Estonia, ²Hue University of Medicine and Pharmacy, Faculty of Odonto-stomatology, Hue, Vietnam, ³Hue University of Medicine and Pharmacy, Department of Family Medicine, Hue, Vietnam, ⁴Hue University of Medicine and Pharmacy, Department of Internal Medicine, Hue, Vietnam

Introduction: Sleep-disordered breathing (SDB) is increasingly recognized in both pediatric and adult populations. The tongue, as a primary pharyngeal dilator muscle, maintains upper airway patency and contributes to SDB. Few studies have simultaneously evaluated tongue function and stratified SDB risk across age groups. This study is to evaluate age-specific associations between tongue function traits and the risk of SDB in children and young adults using multivariate and interaction models.

Materials and methods: A cross-sectional study was conducted among 1,244 healthy participants, comprising 462 children aged 7.5 years (47.2% female) and 782 adults aged 21.0 years (67.4% female). Participants were defined as at risk for SDB as meeting any one of the following criteria: for children, Pediatric Sleep Questionnaire (PSQ ≥ 8), Epworth Sleepiness Scale (ESS > 10), or Snoring Severity Scale (SSS ≥ 7); for adults, Berlin Questionnaire (≥2 positive categories), ESS > 10, or SSS ≥ 7. Tongue function was assessed through resting posture (the Friedman tongue position), mobility (tongue range of motion ratio—TRMR), strength (measured via the Iowa Oral Performance Instrument), and the Orofacial Myofunctional Evaluation with Scores (OMES). Mouth opening during sleep (reflecting impaired tongue-palate contact and oral seal) and tonsillar hypertrophy (as a tongue-base-related anatomical constraint) were also evaluated. Logistic regression models were performed on the entire sample and stratified by age group. The final model included all variables retained at the last step, along with potential interaction terms. Statistical significance was set at p < .05.

Results: High-risk SDB was found in 26.8% of children, 12.0% of adults, and 17.5% overall. In children, improper tongue rest (OR = 1.69, p = .047) and regular mouth opening during sleep (OR = 2.69, p =

.033) increased the odds of SDB; anterior mobility showed a marginal association (OR = 1.69, $p = .063$). In adults, higher OMES score (OR = 0.80, $p = .020$) and posterior tongue strength (OR = 0.98, $p = .026$) were protective. In the total sample, older age (OR = 6.52, $p < .001$), reduced anterior mobility (OR = 0.98, $p = .014$), restricted posterior mobility (OR = 2.66, $p = .025$), tonsillar hypertrophy (OR = 3.51, $p = .02$), and regular mouth opening during sleep (OR = 2.52, $p = .046$) were significant. Interactions revealed that normal posterior mobility reduced the impact of tonsillar hypertrophy on SDB (OR = 0.53, $p = .010$), while the effect was stronger in children (OR = 2.06, $p = .005$). There were no significant interactions in age-stratified models.

Conclusions: Tongue function traits were differentially associated with SDB risk across age groups. Regular mouth opening during sleep (in children) vs restricted posterior tongue mobility and better general orofacial myofunction (in adults) were independently associated with higher odds of SDB. Older age, restricted mobility, tonsillar hypertrophy, and open mouth posture increased the odds across the entire sample. Age-specific patterns and anatomical–functional interactions should be considered in tongue function and SDB risk assessment strategies.

Toward Understanding How R-Oxybutynin Influences Upper Airway Muscle Tone in sleep apnea: Focus on the Genioglossus in Anesthetized Rats

Y. Takahara¹, S. Fujita¹, Y. Ichihashi², N. Umeda³, K. Ogawa¹, E. Kasai¹, S. Yoneda¹

¹Shionogi & Co., Ltd., Laboratory for Drug Discovery and Disease Research, Toyonaka-shi, Japan,

²Shionogi & Co., Ltd., Laboratory for Medicinal Chemistry Research, Toyonaka-shi, Japan, ³Shionogi TechnoAdvance Research Co., Ltd., Toyonaka-shi, Japan

Introduction: Obstructive sleep apnea syndrome (OSA) is characterized by recurrent episodes of apnea and hypopnea due to upper airway collapse during sleep. Despite extensive research, no effective pharmacotherapy exists for this disease. While continuous positive airway pressure (CPAP) remains the standard treatment, its low adherence underscores the need for alternative oral medications. Reduced upper airway muscle tone and responsiveness play a central role in OSA pathophysiology, and a recent study (MARIPOSA study, [Am J Respir Crit Care Med, 2019](#)) reported that a combination of R-oxybutynin and atomoxetine improved these deficits. R-oxybutynin acts as a non-selective muscarinic receptor antagonist, but the specific subtype responsible for enhancing muscle activity remains unclear. This study aimed to develop a preclinical evaluation system for genioglossus (GG) muscle activity in rats and to identify the receptor subtype primarily responsible for the pharmacological effects of R-oxybutynin.

Materials and methods: Male rats were anesthetized with urethane (1.5 g/kg, i.p.), underwent bilateral vagotomy, and electromyogram (EMG) electrodes were implanted into the GG muscle. EMG signals were recorded using LabChart™ (ADInstruments), and phasic (peak), tonic (background), and integrated (total) GG activities were quantified. Baseline activity was calculated as the average over 5 minutes prior to drug administration. Rats received either vehicle (saline), R-oxybutynin (reference drug), non-selective antagonist scopolamine, or M2-selective antagonist compound A via subcutaneous injection. Drug effects were assessed by comparing the normalized average GG activity at 30 minutes after administration for R-oxybutynin and compound A, and at 15 minutes for scopolamine.

Results: R-oxybutynin showed dose-dependent enhancement of GG activity, specifically in tonic amplitude. Given known side effects linked to M1 and M3 receptor subtypes, compound A was designed as a selective antagonist for M2 receptor, with sufficient CNS exposure confirmed in rats. However, compound A failed to enhance either tonic or phasic GG activity. Similarly, scopolamine exhibited potentiation in GG activity at high doses, but not at lower doses. Analysis of free drug concentrations in the medulla and plasma suggested that neither selective M2 inhibition nor combined inhibition of M1, M2, and M3 receptors produced a significant increase in GG muscle activity.

Conclusions: These findings suggest that targeting the M2 receptor alone is insufficient to enhance GG muscle activity. Moreover, even broad muscarinic inhibition (M1 + M2 + M3) did not replicate the efficacy of R-oxybutynin, indicating the involvement of additional receptor subtypes or the need for a more balanced receptor profile. The specific muscarinic receptor subtype through which R-oxybutynin exerts its pharmacological effects could not be identified. Further investigation is necessary to elucidate the mechanisms underlying muscarinic modulation of upper airway motor tone.

Transforming Rural Sleep Health Care: Establishing a Rural Sleep-Disordered Breathing Service in East Malaysia

K. Raman¹

¹University Putra Malaysia, Otorhinolaryngology Department, Serdang, Malaysia

Introduction: Obstructive sleep apnea (OSA) remains a prevalent but underdiagnosed condition in rural Malaysia, where access to diagnostic and therapeutic services is often limited. In 2022, the Department of Otorhinolaryngology at Hospital Labuan—a rural secondary referral center—initiated a dedicated sleep service to improve the identification and management of sleep-disordered breathing (SDB).

Materials and methods: Between March 2022 and April 2024, 86 patients were evaluated through the newly established sleep clinic. Among them, 44 were diagnosed with severe OSA, 15 with moderate OSA, and 19 with mild OSA, based on AHI criteria and clinical findings. Most patients presented with moderate to severe OSA, with a high prevalence of comorbidities such as obesity, hypertension, and ischemic heart disease. Despite resource limitations, diagnostic PSGs were successfully conducted. Management was tailored to individual needs and preferences: 24 patients were initiated on CPAP therapy, while 11 patients underwent upper airway surgical interventions. The remaining patients were either managed conservatively or declined intervention.

Results: Between March 2022 and April 2024, 86 patients were evaluated through the newly established sleep clinic. Among them, 44 were diagnosed with severe OSA, 15 with moderate OSA, and 19 with mild OSA, based on AHI criteria and clinical findings. Most patients presented with moderate to severe OSA, with a high prevalence of comorbidities such as obesity, hypertension, and ischemic heart disease. Despite resource limitations, diagnostic PSGs were successfully conducted. Management was tailored to individual needs and preferences: 24 patients were initiated on CPAP therapy, while 11 patients underwent upper airway surgical interventions. The remaining patients were either managed conservatively or declined intervention.

Conclusions: Key challenges included limited patient awareness, delayed referrals, and issues with CPAP adherence, particularly among patients with lower health literacy or financial constraints. Nonetheless, early data show promising outcomes: patients with >70% compliance reported significant symptomatic relief, with mean AHI reduction to <5 events/hour. Customized education, follow-up, and equipment subsidies played a crucial role in improving adherence. This experience demonstrates that with structured planning, multidisciplinary coordination, and patient-centered care, effective sleep services can be successfully implemented even in rural settings. The Hospital Labuan model provides a replicable framework for other underserved regions aiming to address the growing burden of sleep disorders.

Trends and Associated Factors for Signs and Symptoms of Sleep-disordered Breathing in Children with Down Syndrome

H. Sawatari¹, A. Chishaki², Y. Yoshioka³, S.-i. Ando⁴

¹Hiroshima University, Department of Perioperative and Critical Care Management, Graduate School of Biomedical and Health Sciences, Hiroshima, Japan, ²Fukuoka Nursing College, Faculty of Nursing, Fukuoka, Japan, ³Saiseikai Futsukaichi Hospital, Fukuoka, Japan, ⁴Saiseikai Futsukaichi Hospital, Cardiovascular Division and Sleep Medicine Center, Fukuoka, Japan

Introduction: Sleep-disordered breathing (SDB) is a prevalent disease in people with Down syndrome (DS). SDB is characterized by not only frequent mid-night arousal, fragmented sleep, and repetitive hypoxemia but also hypertension and daytime sleepiness. These might lead to cognitive impairment, impaired attention, and attention-deficit/hyperactivity disorder like behaviors, which are common in people with DS. Furthermore, snoring or choking are strongly associated with SDB and can be considered as “signs and symptoms of SDB”. Although such signs and symptoms would be important markers in management of SDB, their temporal trends and associated factors for “signs and symptoms of SDB” in children with DS are still unknown. This study, thus, sought age and sex-dependent changes or trends of “signs and symptoms of SDB” and associated factors for them in children with DS.

Materials and methods: This cross-sectional questionnaire-based study included the children with DS aged 1-5 years who were belonging to Japan Down Syndrome Society. This survey was answered by the children's caregivers. The questionnaire included demographic data (sex, age, body height and

weight), self-reported sleep time, and witnessed signs and symptoms of SDB (snore and apnea). The data was analyzed in each age level. The estimated SDB was defined as presence of witnessed frequent snoring (defined as ≥ 5 times/week) or apnea.

Results: In 212 children with DS, their body height and weight increased as they grew ($p < 0.001$; all), while the body mass index (BMI) did not significantly change not only with growing but also between boys and girls ($p = 0.95$ and $p = 0.55$, respectively). The mean subjective sleeping time in boys and girls of 1 year old were 9.8 ± 0.7 and 10.2 ± 0.8 hour, respectively. The self-reported sleeping time significantly decreased with growing in girls ($p = 0.04$) but only a tendency in boys ($p = 0.07$). The presence of snoring and apnea significantly increased with growing in boys ($p = 0.001$ and $p = 0.04$, respectively), but not in girls ($p = 0.39$ and $p = 0.52$, respectively). The age depending changes of the frequency of snore was not observed in both sexes, but the estimated SDB suggested by frequent snore and/or apnea increased only in boys ($p = 0.04$) not in girls ($p = 0.47$). Growing was a significant associated factor for presence of snore, apnea, and estimated SDB, only in boys and high BMI was only a significant associated factor for presence of snoring in girls.

Conclusions: This study shows that the age dependent trends and predictors for estimated SDB and its' signs and symptoms are different between boys and girls with DS. In the low age generation, development or growing related anatomical changes might be more associated with SDB related signs and symptoms in boys than girls. Especially increase in body weight might be more related to SDB related signs and symptoms in girls. We should keep in mind this sexually different trends for management and follow up of SDB in the children with DS.

Ultrasound-Guided Tongue Base Thickness as a Screening Tool for Assessing Severity among patients with symptoms of Obstructive Sleep Apnea (OSA) at the Lung Center of the Philippines

M.E. De Vera¹, V. De Los Reyes¹

¹Lung Center of the Philippines, Quezon City, Philippines

Introduction: Obstructive Sleep Apnea is a sleep-related breathing disorder causing cessation of breathing for short periods of time and radiographic modalities such as ultrasound have been applied to assess the upper airway anatomy in OSA patients. This study aimed to determine if ultrasound-guided tongue base thickness can be used as a screening tool for assessing severity in patients who presented with symptoms of obstructive sleep apnea.

Materials and methods: This research was a single-center, analytical study conducted at the Lung Center of the Philippines. Study subjects included patients seen at the Sleep lab and Sleep disorders clinic from March to May 2024. Data was gathered from patients with sleep-related symptoms and tongue base thickness was measured via ultrasound. Subsequently, gold-standard polysomnography was done and subjects were classified according to apnea-hypopnea index (AHI) and OSA severity

Results: Of 143 patients who took part of the study, 98 were included in this study, 13 patients classified as non-severe OSA (mild and moderate OSA), and 85 patients as severe OSA. Those with severe OSA were found to be predominantly male, significantly increased weight and BMI, had a lower baseline awake oxygen saturation, higher STOP-BANG score of 5, lower oxygen saturation nadir during the sleep study, and higher Apnea-Hypopnea Index (AHI). Ultrasound guided tongue base thickness was significantly increased in the severe OSA group. After multivariate analysis, oxygen saturation of $\leq 97\%$ (OR 5.996 CI 1.23-29.13), and tongue-base thickness of $\geq 5.75\text{cm}$ (OR 7.7529 CI 1.68-35.8) was associated with an increased likelihood of having severe OSA. On the other hand, having a symptom of difficulty falling asleep (OR 0.0859 CI 0.02-0.43) was less likely to have severe OSA. Ultrasound guided tongue-base thickness was positively correlated with the apnea-hypopnea index on PSG ($r = 0.4683$). Area Under the Receiver Operating Characteristics (ROC) curve of tongue-base thickness to discriminate severe OSA was at 0.77 which means that there is 77% chance that ultrasound-guided tongue base thickness can correctly classify patients with severe OSA. This is corroborated by the measured sensitivity (70.59%) and specificity (69.23%) of ultrasound guided tongue-base thickness. After considering a cut-off tongue-base thickness of $\geq 5.75\text{cm}$, the probability of having severe OSA increases to 93.75% (PPV 93.75%). On the other hand, tongue-base thickness of $< 5.75\text{cm}$ lowers the probability of having severe OSA to 26.47% (NPV 26.47%). The accuracy of ultrasound guided tongue-base thickness was 70.41% which represents the overall proportion of patients who were correctly classified as severe and non-severe OSA based on our study.

Conclusions: Those with severe OSA were predominantly male, obese, had lower baseline awake oxygen saturation, higher STOP-BANG score, lower oxygen saturation nadir during the sleep study, higher Apnea-Hypopnea Index (AHI), and higher ultrasound guided tongue base thickness measurement. After multivariate analysis, oxygen saturation of $\leq 97\%$ and tongue-base thickness of $\geq 5.75\text{cm}$ was independently associated with severe OSA. Tongue-base thickness was positively correlated to the apnea-hypopnea index (AHI) with severe OSA cut-off at $\geq 5.75\text{cm}$. This is a good screening test for classifying severe OSA and can be utilized in combination with existing screening tools used by clinicians.

Ultrasound Tongue Tracking for Intraoperative Assessment of Neurostimulation Implant Placement for Obstructive Sleep Apnea

T. Ilyas¹, K. Meng², J. McCabe², D. Herron², D. Mehta¹, Z. Ge¹

¹Monash University, Clayton, Australia, ²Restera Sleep, Santa Clara, United States

Introduction: Hypoglossal nerve (HGN) stimulation is a treatment option for obstructive sleep apnea (OSA). Recently, percutaneous electrode placement near distal arborizing branches of the nerve under ultrasound guidance has been developed to reduce surgical invasiveness. To confirm optimal placement in the absence of airflow measurements, nasoendoscopy and nerve integrity monitor (NIM) systems can be used to assess upper airway responses to stimulation. Here, we propose that an ultrasound-based method to track and quantify tongue morphology can improve intraoperative decision-making for HGN stimulation devices.

Materials and methods: A deep learning model, comprising a segmentation network (encoder-decoder) and a discriminator network, was developed to track anatomical features from midsagittal ultrasound views of the tongue. A selection of 1,574 midsagittal ultrasound tongue images was extracted from UltraSuite, an open repository of ultrasound datasets for speech disorders. Selected images included a wide distribution of tongue morphologies from 25 subjects performing various speech tasks. Images were acquired using different curvilinear probes with a field of view of 90-140 degrees, a frequency of 3-5 MHz, and a depth of 70-90 mm. Images were annotated with 14 anatomical landmarks, including 11 points along the tongue surface, 1 point on the hyoid bone, and 2 points on the mandible (base and insertion point of genioglossus muscle fibers). To address the challenge of heterogeneous datasets, unsupervised domain adaptation was incorporated into the deep learning framework to enable alignment of feature distributions between labeled source domains (open speech data) and unlabeled target domains (clinical sleep data).

Results: The model achieved a mean sum of distances of 0.443 pixels and a mean intersection over union of 53.64%, indicating robust tongue surface tracking and hyoid-mandible detection. It can also be used to output real-time predictions from a continuous stream of ultrasound images used as inputs. In addition, modified components of the Dorsum Excursion Index (DEI) and Tongue Constraint Position Index (TCPI), two measures used in speech pathology research, were identified as possible correlates of airway patency. These new measures quantify the spatial relationship between the predicted tongue surface and the predicted positions of the hyoid bone and mandible.

Conclusions: The proposed method remains to be clinically validated in future studies involving HGN stimulation devices for patients with OSA. If validated as a reliable complement or alternative to nasoendoscopy and NIM systems, it has the potential to reduce procedure risks, while simplify operating room setup and minimizing personnel needs, thereby lowering costs. It could also be used for therapy optimization at the physician's office or in sleep laboratories to provide a quick assessment of the effectiveness of different stimulation strategies.

Acknowledgments: This project was facilitated by the Australian Postgraduate Research Intern (APR.Intern) program.

Unmasking Obstructive Sleep Apnea: Estimated Prevalence and Impact in the United States

I. Sönmez¹, A. Vo Dupuy¹, K.S. Yu², J. Cronin², J. Yee², A. Azarbarzin³

¹Clarivate Analytics, London, United Kingdom, ²Apnimed, Inc., Cambridge, United States, ³Brigham and Women's Hospital and Harvard Medical School, Division of Sleep and Circadian Disorders, Boston, United States

Introduction: Obstructive sleep apnea (OSA) is a serious, chronic sleep-related breathing disease, characterized by repeated upper airway obstructions during sleep, leading to episodes of disrupted breathing, sleep fragmentation, and reduced oxygen saturation. Adjusting for obesity as a major risk factor, we aimed to estimate the up-to-date prevalence of OSA in United States (US) adults in 2024.

Materials and methods: We conducted a literature-based analysis to identify studies of OSA prevalence in the general or community adult population, using the AHI₄ criteria (all apneas plus hypopneas with $\geq 4\%$ oxygen desaturation) from polysomnography or home sleep apnea test. OSA was defined as having an AHI₄ ≥ 5 events/hour. For the total prevalence, we estimated age- and gender-specific rates based on eligible studies and extrapolated missing data (e.g., age-group) from studies where data were available. The base-year estimation for 2004 was calculated by averaging age-specific total OSA prevalence data from these studies, accounting for methodological and population differences, to establish a foundational baseline for further adjustments. We calculated the obesity population attributable fraction (PAF) which was applied to base year estimates to project OSA prevalence in year 2024 adjusting for obesity and extrapolated to the US Census population data. The AHI distribution of mild (5 – <15), moderate (15 – <30) and severe (≥ 30 events/h) were also estimated.

Results: Total of 80.6 million individuals were estimated to be living with OSA in the US in 2024, of whom 47,623,848 (59%) were males and 32,967,117 (41%) females. This translates to 32.2% overall prevalence in the US among adults aged 20 years and older, with 39% males and 25.8% females, adjusting for obesity. The AHI severity distribution was estimated to be 61% mild, 24% moderate, and 15% severe.

Conclusions: Our findings indicate that OSA is highly prevalent among US adults. Despite its substantial prevalence, OSA remains largely undiagnosed, highlighting the urgent need for improved screening and diagnosis as well as greater awareness about the chronic and serious complications of untreated OSA.

Unmasking OSA: Predisposing Factors in Asian and Non-Caucasian Populations in Australia

S. Agwan¹, M. Bolger¹, B. Dyer², S. Beck³, A. Tay³, E. Kanno¹, P. Rankmore⁴, N. Sharma¹, G. Tay^{1,5,6}

¹Gold Coast University Hospital, Sleep Disorders Centre, Southport, Australia, ²Griffith University, Griffith Biostatistics Unit, Gold Coast, Australia, ³MySleep, Upper Mount Gravatt, Australia, ⁴Gold Coast University Hospital, Aboriginal and Torres Strait Island Health Service, Southport, Australia, ⁵The Prince Charles Hospital, Chermside, Australia, ⁶University of Queensland, Faculty of Medicine, Herston, Australia

Introduction: Obstructive sleep apnoea (OSA) is a common condition associated with obesity, excessive daytime sleepiness, cardiovascular disease, type 2 diabetes (T2DM), and increased risk of accidents. Understanding whether traditional OSA risk factors differ between Caucasian and non-Caucasian populations is critical for equitable clinical care. However, data on non-Caucasian Australians (including the Asian and Australian First Nation populations) remains limited, despite known disparities in cardiometabolic health. Importantly, emerging evidence suggests that OSA pathophysiology in this group may involve factors beyond obesity alone. This study compares conventional OSA predictors and their clinical relevance in Caucasian and non-Caucasians within our local health service, aiming to inform more tailored screening and intervention strategies.

Materials and methods: We undertook a retrospective analysis of medical records of all adults (≥ 18 years) undergoing a diagnostic sleep study in 2022-2023 at Gold Coast Hospital and Health Service (Queensland, Australia) and MySleep Upper Mount Gravatt (Queensland, Australia). Medical records were evaluated to compile data set. Linear regression was used to determine the association between traditional OSA predictors and AHI (Apnoea-Hypopnoea Index). BMI (body mass index) thresholds for moderate-to-severe OSA in Caucasians and non-Caucasians were estimated using Youden's Indices.

Results: A total of 2,181 patients were included in the study, of which 77% (n=1866) had OSA. Amongst these, 31% had mild, 23% moderate, and 32% severe OSA. The median age was 50 (IQR 39-61) years, with 60% being males. BMI was a significant predictor of OSA in both Caucasian and non-Caucasian groups ($p < 0.001$), with data suggesting trend towards strongest association between BMI and AHI in the Asian subgroup (1.8 AHI units per BMI point; $p < 0.001$). The BMI threshold for moderate-to-severe OSA was relatively lower in non-Caucasians (28kg/m²). Whereas a greater

proportion of patients with moderate-to-severe OSA were obese in the Caucasian group (76%) compared to the Asian subgroup (38%). Neck circumference, independent of BMI, was also a significant predictor of OSA in Caucasian, non-Caucasian, and Asian populations ($p < 0.001$). Male gender and hypertension were also linked to higher AHI in both Caucasian and non-Caucasian groups ($p < 0.001$), with a trend suggestive of gender having a greater impact on AHI in the non-Caucasian cohort.

Conclusions: OSA screening tools are derived from data that is predominantly taken from the Caucasian population. Our findings underscore the importance of considering ethnic variability in OSA risk profiling. Specifically, a lower BMI threshold may be warranted for OSA screening in the Asian population, which may be more sensitive to BMI increases. Male gender and hypertension also appear to be stronger predictors of OSA severity in non-Caucasians. Our results highlight potential ethnic differences in OSA burden and BMI sensitivity, reinforcing the need for ethnicity-specific screening and risk assessment strategies to improve early detection and targeted management of OSA. Future research should evaluate the performance of tools like STOP-BANG and Epworth Sleepiness Scale in Asian population to improve diagnostic accuracy and equity of OSA screening.

Unveiling Predictive Factors for CPAP Adherence: A Pilot Cohort Study on Real-World Use in OSA

Y. Sun^{1,2}, C.Y. Lee¹, J.J. Chen¹

¹En Chu Kong Hospital, Neurology, New Taipei City, Taiwan, ²Medical College, National Taiwan University, Neurology, Taipei, Taiwan

Introduction: Obstructive sleep apnea (OSA) is a modifiable risk factor for cardiovascular and cerebrovascular diseases. Continuous positive airway pressure (CPAP) remains the first-line treatment; however, adherence is often suboptimal. This study aimed to explore clinical and polysomnographic factors associated with CPAP adherence in a real-world setting.

Materials and methods: We conducted a prospective cohort study enrolling 10 participants diagnosed with OSA by in-lab polysomnography (PSG). All underwent overnight CPAP titration and were then offered home CPAP use for 30 or 90 days at their discretion, without a required minimum usage, to reflect natural adherence. We collected: 1. Demographics (age, sex, BMI, Epworth Sleepiness Scale score), 2. Baseline PSG data (AHI, minimum SpO₂, arousal index [AI], sleep efficiency [SE]), 3. CPAP titration data (residual AHI, SpO₂, AI, SE, optimal pressure), 4. Differences between baseline and titration parameters, 5. Daily CPAP usage metrics (residual AHI, pressure, and leak).

Good CPAP adherence was defined as using CPAP for more than 50% of total days at home, with both mean and median nightly usage ≥ 6 hours. Collinearity was assessed using Pearson correlation matrices. Group comparisons, univariate logistic regression, and multivariate regression were performed.

Results: The mean age was 50.2 ± 10.4 years, BMI 29.4 ± 5.7 , and baseline AHI 49.4 ± 24.3 . Older age was correlated with lower baseline sleep efficiency ($r = -0.82$). Higher baseline AHI was associated with a higher arousal index ($r = 0.79$), but also with greater improvement in arousal index ($r = 0.73$) and AHI ($r = 0.99$) during titration. Higher AHI was also associated with the need for higher daily pressure ($r = 0.72$).

Participants with good adherence had significantly lower optimal titration pressure (6.6 vs. 11.8 cmH₂O, $p = 0.03$), lower residual AHI during titration (2.7 vs. 8.1, $p = 0.04$), and lower daily CPAP pressure (7.5 vs. 9.3 cmH₂O, $p = 0.04$). These associations were statistically significant in univariate analysis. However, in multivariate analysis including these predictors, none remained statistical significance due to small sample size and co-linearity among pressure-related variables.

Conclusions: This pilot study suggests that individuals with higher AHI not only exhibit more disrupted sleep but also derive greater benefit from CPAP in terms of AHI and arousal reduction. Importantly, lower pressure requirements, both during titration and in daily use, along with effective titration (lower residual AHI), were associated with better CPAP adherence. Although significance was not retained in multivariate analysis, consistent trends support the importance of optimizing pressure settings for comfort and effectiveness. Larger studies are warranted to confirm these findings and to inform pressure adjustment strategies that promote long-term adherence.

Unveiling the circHDAC9/miR-138-5p/SIRT1 Axis: A Novel Mechanism Linking Obstructive Sleep Apnea-Hypopnea Syndrome to Cognitive Impairment through Senescence-Associated Neuronal Autophagy

W. Wei^{1,2}, H. Huang^{1,3}, Y. Wen^{1,4}, Q. Zhong^{1,5,6}, Y. Lu^{1,5,6}, L. Qin^{1,5,6}, M. Zhao^{1,5,6}

¹The People's Hospital of Guangxi Zhuang Autonomous Region, Department of Sleep Medicine, Nanning, China, ²Guangxi University of Chinese Medicine, Graduate School, Nanning, China, ³Guilin Medical University, Graduate School, Guilin, China, ⁴Guangxi Medical University, Graduate School, Nanning, China, ⁵The People's Hospital of Guangxi Zhuang Autonomous Region, Guangxi Clinical Research Center for Sleep Medicine, Nanning, China, ⁶The People's Hospital of Guangxi Zhuang Autonomous Region, Guangxi Sleep Respiratory Disease Diagnosis and Treatment Center, Nanning, China

Introduction: To investigate the circHDAC9/miR-138-5p/SIRT1 pathway in Intermittent Hypoxia (IH)-induced cognitive impairment for Obstructive Sleep Apnea-Hypopnea Syndrome (OSAHS) complication diagnosis and therapies.

Materials and methods: Ten 3-month-old male C57 mice were randomly divided into a control group (normoxic environment) and a model group (IH: 4.6-4.8% O₂ for 60 seconds followed by 20% O₂ for 30 seconds cyclically, 8 h/day). Cognitive function was assessed using the Morris water maze test. Hippocampal tissues were analyzed for histopathology, apoptosis, senescence, autophagy, mitochondrial structure, protein expression, and gene/protein levels via HE staining, TUNEL staining, β -gal staining, transmission electron microscopy, immunofluorescence, and Real Time PCR/Western blotting. In vitro experiments used HEK293T cells to validate miR-138-5p targeting SIRT1 and circHDAC9 via dual luciferase assays, and HT22 cells to confirm circHDAC9 expression and its interaction with SIRT1 using FISH and RIP.

Results: Model group mice exhibited significantly impaired cognitive function ($p < 0.05$), increased hippocampal neuron aging, apoptosis, and autophagy ($p < 0.0001$), upregulated miR-138-5p, and downregulated circHDAC9 and SIRT1 ($p < 0.001$). Aging-related molecules and autophagy-related proteins were upregulated ($p < 0.001$), pro-apoptotic Bax increased, anti-apoptotic Bcl2 decreased ($p < 0.001$), and telomere length shortened ($p < 0.0001$). Cell experiments confirmed miR-138-5p directly targets SIRT1 and circHDAC9, reducing luciferase activity ($p < 0.0001$), and revealed an interaction between circHDAC9 and SIRT1.

Conclusions: OSAHS triggers cognitive decline through a "senescence-autophagy-apoptosis" cycle via circHDAC9/miR-138-5p/SIRT1 axis disruption. CircHDAC9's dual regulation (sponging miR-138-5p and interacting with SIRT1) reveals therapeutic targets.

Validation of Ambulatory Polysomnography for Measuring Sleep and Detecting Obstructive Sleep Apnea in Patients with Rapid Eye Movement Sleep Behaviour Disorder

K.W. Chan¹, M.Q. Zhou¹, N.Y. Chan¹, C.K.W. Ho¹, Y. Xu², B. Huang¹, Y.K. Wing¹

¹The Chinese University Of Hong Kong, Psychiatry, Hong Kong, Hong Kong, SAR of China, ²Hangzhou Seventh People's Hospital, Hangzhou, China

Introduction: Rapid eye movement sleep behaviour disorder (RBD) is often associated with obstructive sleep apnea (OSA). The standard method for assessing sleep disorders is in-laboratory polysomnography (lab PSG). However, ambulatory polysomnography conducted in home setting (home PSG) has become increasingly utilised in clinical settings due to its convenience and ease of administration. Despite this, the agreement between home PSG and lab PSG in evaluating OSA in RBD patients remains insufficiently validated. This study aimed to compare the consistency of home PSG and lab PSG in measuring the key sleep structure parameters (such as sleep latency, sleep efficiency, etc.) as well as the OSA severity.

Materials and methods: This study included 35 patients (mean age 66.7 years, 25.7% female) who were diagnosed as suffering from RBD with standard attended lab v-PSG. Each participant underwent both home and standard PSG, with a mean time interval of 63.7 days (range 12 to 113 days). AHI thresholds of ≥ 5 , ≥ 15 , and ≥ 30 , and ODI thresholds of ≥ 5 and ≥ 15 were applied, and the sensitivity, specificity,

positive predictive value (PPV), negative predictive value (NPV), and accuracy of home PSG in detecting OSA were calculated for both AHI and ODI. The correlation between home PSG and lab PSG in various sleep parameters, including AHI, ODI, sleep latency, sleep efficiency, wake after sleep onset (WASO), REM latency, stages percentages, and arousal index, was compared using correlation analysis.

Results: There was a strong correlation between home PSG and lab PSG for most sleep parameters, with the highest correlation coefficients being for ODI ($r = 0.85$), followed by AHI ($r = 0.81$) and N3 sleep ($r = 0.78$). However, the correlation for REM sleep ($r = 0.24$) and arousal index ($r = -0.02$) was low. Regarding the OSA severity and diagnosis, 23% of the patients ($N = 8$) had $AHI \geq 15$ as diagnosed by lab PSG. The sensitivity of home PSG was 0.75, specificity was 1.00, PPV was 1.00, NPV was 0.93, and accuracy was 0.94. In contrast, the sensitivity in the $AHI \geq 5$ group ($N = 17$, 48.5%) was lower (0.53), while for severe OSA ($AHI \geq 30$; $N = 4$, 11.4%), despite a specificity and PPV of 1.00, the sensitivity was only 0.25. For ODI, in the $ODI \geq 5$ group ($N = 10$), home PSG had a sensitivity of 0.60, specificity of 0.88, PPV of 0.67, NPV of 0.85, and accuracy of 0.80. In comparison, for the $ODI \geq 15$ group ($N = 3$), sensitivity improved to 1.00, with higher specificity (0.94) and accuracy (0.94), but lower PPV (0.60).

Conclusions: Home PSG shows good diagnostic agreement with lab PSG in assessing OSA severity, particularly for $AHI \geq 15$ and $ODI \geq 15$ in RBD patients. However, home PSG has lower sensitivity in detecting mild OSA, leading to a potential risk of underdiagnosis. Nevertheless, home PSG can serve as an effective screening tool especially when lab PSG is not feasible.

Vasomotor Intracranial Blood Vessels in Obstructive Sleep Apnea Patients

C.A. Suhendra¹, A. Budikayanti², T. Mesiano², F. Fardizza³

¹Universitas Indonesia, Neurology, Central Jakarta, Indonesia, ²Dr. Cipto Mangunkusumo National General Hospital, Neurology, Central Jakarta, Indonesia, ³Dr. Cipto Mangunkusumo National General Hospital, Ear, Nose and Throat, Central Jakarta, Indonesia

Introduction: Obstructive Sleep Apnea (OSA) is characterized by episodes of complete or partial airway collapse accompanied by decreased oxygen saturation or awakening from sleep. OSA is an independent factor for stroke. The initial sign of vascular abnormalities in OSA is vascular endothelial dysfunction. Cerebral vascular endothelial dysfunctions in OSA can be detected by Transcranial Doppler (TCD) examination by assessing cerebral vasomotor reactivity (RVS). Assessing RVS can be done through the Breath Holding test procedure by assessing the Breath Holding Index (BHI). Currently, there are no specific assessments objectively to predict stroke in OSA patients, so this study is expected to be the basis for objective initial screening in assessing stroke risk.

Materials and methods: In this study, OSA patients were screened using a STOP-BANG questionnaire of more than 1 point. Then, 46 subjects were grouped into non-OSA ($N = 8$) and OSA ($N = 38$) based on the results of the polysomnography (PSG) examination. Mean flow velocity (MFV) and BHI were measured in the middle cerebral artery (MCA) using a TCD device. BHI values above 0.69 are considered normal and MFV MCA values less than 120 cm/sec are considered normal. Screening for comorbidities and other risk stroke (smoking, physical activity) was evaluated.

Results: In this study, there was a significant difference in BHI score values between the OSA and non-OSA groups (0.76 ± 0.62 vs 1.27 ± 0.70 ; $p = 0.04$) and a higher trend in MFV MCA values in the OSA group. There was a negative correlation between AHI and BHI values ($r = -0.381$, $p = 0.009$). There was a correlation between smoking and BHI values ($p = 0.115$). Then continued into multivariate linear regression analysis, but only the AHI value was significant ($p = 0.029$).

Conclusions: As the degree of OSA increases, the vasomotor function of intracranial blood vessels is disrupted. This shows that the more severe the degree of OSA, the more cerebral endothelial dysfunction has occurred.

Acknowledgments: A grant from the BIMA Ministry of Education, Culture, Research, and Technology Indonesia supported this study.

Sleep Health

A comparison of coblation and modified monopolar tonsillectomy in adults

Z. Lou¹, Z. Lou²

¹Wenzhou medical university affiliated Yiwu Hospital, Yiwu, China, ²Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Department of Otolaryngology Head and Neck Surgery, Shanghai, China

Introduction: Objective: To compare the intraoperative records and postoperative clinical outcomes of adults who underwent coblation and modified monopolar tonsillectomy tonsillectomies.

Materials and methods: Material and Methods: Adult patients with tonsillectomy were randomly divided into the coblation and modified monopolar tonsillectomy groups. The estimated blood loss, postoperative pain score, operation time, post-tonsillectomy hemorrhage (PTH), and cost of disposable equipment were compared.

Results: Results: Pain intensity in the coblation and monopolar groups was similar on postoperative days 3 and 7. However, the mean maximum pain score in the monopolar group was significantly higher compared to the coblation group on postoperative days 1 ($P < 0.01$) and 2 ($P < 0.05$). Secondary PTH occurred in 7.1% (23/326) of patients in the coblation group and 2.8% (9/327) of patients in the monopolar group ($P < 0.05$).

Conclusions: Conclusion: Although pain was significantly increased on postoperative days 1 and 2 in the modified monopolar tonsillectomy group, the operation time, secondary PTH, and medical costs were significantly decreased compared to the coblation technique group.

Adult Attachment, Sleep Hygiene and Sleep Quality, a Cross-Sectional Mediation Analysis

J. Samii¹, M. Banissy¹, A. Rowe¹

¹University of Bristol, School of Psychological Science, Bristol, United Kingdom

Introduction: Insecure attachment dimensions have been associated with decreased sleep quality and reduced health behaviors. The current study aimed to expand the literature by testing whether sleep hygiene might mediate the relationship between adult attachment dimensions and sleep quality.

Materials and methods: Adult participants from an international sample ($N = 221$) were recruited through opportunity sampling using an online participant platform and were asked to fill in a online questionnaire containing sections on attachment dimensions, sleep quality, mood, fatigue, and sleep hygiene. Multiple regressions were conducted to determine the associations between attachment dimensions (anxious and avoidant) and sleep hygiene, as well as to assess whether sleep hygiene mediated the relationship between attachment dimensions and sleep quality, while controlling for age, gender, mood, and fatigue.

Results: The mediation diagrams indicate a partial mediation effect of sleep hygiene; individuals scoring higher on both insecure attachment scales also reported lower sleep hygiene scores and poorer sleep quality.

Conclusions: Previous literature has revealed relationships between insecure attachment styles and decreased sleep quality. Our results suggest that sleep hygiene may be contributing to this relationship through partial mediation as insecure attachment appears to have a negative effect on sleep hygiene which in turn appears associated with decreased sleep quality. Future sleep interventions should consider incorporating attachment based strategies as individuals' may benefit from an interpersonal approach in terms of their sleep hygiene and sleep quality.

An 8-week mindfulness programme for sleep and well-being among informal caregivers of children with neurodevelopmental disorders: a mixed-methods feasibility case series

H.F. Sit¹, M.H. Lo¹, T. Chao², H.L. Lam¹, L.C. Lee¹, S.X. Li^{1,3}

¹The University of Hong Kong, Sleep Research Clinic & Laboratory, Department of Psychology, Hong Kong, Hong Kong, SAR of China, ²University of Macau, Department of Psychology, Macau, Macao, SAR

of China, ³The University of Hong Kong, The State Key Laboratory of Brain and Cognitive Sciences, Hong Kong, Hong Kong, SAR of China

Introduction: Poor sleep and mental health are common among parents of children with neurodevelopmental disorders, including autism spectrum disorder (ASD) and attention deficit hyperactivity disorder (ADHD). However, the existing options and evidence regarding psychosocial mental health interventions for this specific group remain limited. Mindfulness-based interventions have shown promise in improving mental health outcomes across different populations, including those with subclinical conditions and busy schedules. The unique practical challenges faced by parents of children with neurodevelopmental disorders highlight the importance of adapting psychological interventions to meet their specific needs. The objective of this mixed-methods feasibility case series study was to evaluate the feasibility and acceptability of a mindfulness-based programme with an abridged adaptation in informal caregivers of children with neurodevelopmental disorders.

Materials and methods: Parents of children with neurodevelopmental disorders were recruited via a local non-governmental organisation (NGO) in Hong Kong and were invited to participate in an 8-week mindfulness programme. Participating parents first underwent a clinical interview and were subsequently asked to complete a set of questionnaires that assessed depression, anxiety, insomnia, stress, and mindfulness before and after the programme. Additionally, participants' experiences in the intervention were evaluated by a post-programme survey and an individual qualitative interview.

Results: Seven participants were recruited (mean age: 47 years, range 35 - 53 years; 86% female; 71% married; and 29% in full-time employment). Two participants dropped out by session 4 and did not complete the follow-up assessment because of their family commitments. The mean number of attended sessions in the follow-up sample was 7 sessions (5 - 8 sessions). Of the completed participants (n=5), 4 reported reduced depression, 2 reported reduced anxiety, 3 reported reduced insomnia symptoms, 4 reported reduced perceived stress, and 2 reported improved mindfulness. Qualitative findings revealed four key themes. Firstly, participants expressed expectations for the programme (e.g., learning mindfulness, improving well-being). Secondly, positive intervention experiences were highlighted, such as good quality of teaching and guidance, as well as reported improvements in sleep and daily functioning. Third, negative intervention experiences were also identified, such as distractions during practice, a lack of energy, and challenges related to travel time. Lastly, participants offered some suggestions for improvement (e.g., adopting a hybrid format to facilitate participation).

Conclusions: The preliminary findings showed that an 8-week mindfulness programme is feasible and well-accepted by parents of children with neurodevelopmental disorders to improve their psychological well-being and sleep. There is a need to explore ways to address the barriers reported by the participants to improve their engagement in the future implementation of the programme in this population.

Anaerobic Airborne Bacteria Dominate Bedroom Environments of Individuals with High Sleep Apnea Risk

H. Amin¹, H. Thorarinsdottir², C. Janson³, T. Gislason⁴, R.J. Bertelsen¹

¹University of Bergen, Department of Clinical Science, Bergen, Norway, ²Landspítali University Hospital, Department of Anesthesia and Intensive Care, Reykjavik, Iceland, ³Uppsala University, Department of Medical Sciences: Respiratory, Allergy, Sleep Research, Uppsala, Sweden, ⁴University of Iceland, Faculty of Medicine, Reykjavik, Iceland

Introduction: Sleep disorders such as obstructive sleep apnea (OSA) may be influenced by environmental exposures like air pollution, temperature, humidity and season. The role of indoor microbial communities and endotoxins, especially in bedroom, remains poorly understood. Our aim was to examine the association between the composition and the load of indoor airborne bacteria and endotoxins in bedroom and a clinical indicator of OSA risk in a well-defined general population sample from five Nordic centers.

Materials and methods: Participants in five Nordic centers (Aarhus, Bergen, Uppsala, Reykjavik and Tartu) in the ECRHS III study (<https://www.ecrhs.org>) were asked to collect dust samples for two weeks from their bedrooms (For details see: PMID: 37523308). They used electrostatic dust fall collectors (EDCs) and the extracted dust was later analysed for bacterial and endotoxin load (qPCR, LAL

assay) and bacterial community composition (16S rRNA sequencing). While these microbial data have previously been used to characterize environmental determinants of indoor bacterial exposures, this study is the first to assess their relationship with sleep health.

The multivariable apnoea prediction (MAP) index (sensitivity 88% and specificity 55%) was used to identify subjects with a high risk of OSA using scores above 0.5 and 0.7 to determine a high risk of OSA. We assessed the relationship between bedroom microbial exposures and the MAP index using both continuous scores and clinically relevant categorical cutoffs (MAP > 0.5 and >0.7). Linear regression models were adjusted for centre, window opening, pets in the bedroom, number of residents, house age, season, and cleaning frequency.

Results: Altogether 801 (M 362, F 439) participants mean age (SD) 50 years (± 7) returned usable EDCs after two weeks. In total 127 (15.8%) had MAP index <0.5. Majority was males (110). Bacterial composition differed significantly between MAP risk groups at both 0.5 and 0.7 thresholds (ANOSIM R = 0.085–0.116, $p < 0.05$). Participants with MAP > 0.7 had significantly higher bedroom bacterial load ($p = 0.016$). In total, 35 bacterial genera were significantly associated with MAP index scores. Genera positively associated with higher MAP scores were predominantly anaerobic and human-associated (oral or gut), such as *Blautia*, *Porphyromonas*, and *Murdochella*. In contrast, genera negatively associated with MAP were primarily aerobic and environmental, including *Marmoricola* and *Nakamurella*.

Conclusions: Participants with high risk for OSA in a multi-center epidemiological study on general populations showed bedroom airborne bacterial exposures with a microbial profile dominated by human-associated anaerobic taxa. These findings indicate a relevance of the bedroom microbiome in sleep-related conditions and indicate the importance of further studies to evaluate environmental indicators of sleep health risk.

Acknowledgments: This research was supported by the European Research Council (ERC) through the European Union's Horizon 2020 research and innovation program (Grant Agreement No. 804199).

Analysis of the Characteristics and Influencing Factors of Working Memory Impairment in Middle-aged and Young Patients with Obstructive Sleep Apnea-Hypopnea Complicated by Nocturia

T. Su^{1,2}, C. Cheng³, M. Wu⁴, Z. Wang¹, R. Chen¹

¹The Second Affiliated Hospital of Soochow University, Suzhou, China, ²Loujiang New city Hospital of Taicang city (Ruijin Taicang Branch), Taicang, China, ³The First People's Hospital of Wuhu, Wuhu, China, ⁴The First People's Hospital of Zigong, Zigong, China

Introduction: Lower urinary tract symptoms are a major public health issue worldwide that affect patients' quality of life. Among these, nocturia is evaluated as the most common condition associated with various diseases, such as sleep disorders and/or obstructive sleep apnea syndrome (OSAS). Although the long-recognized association between nocturia and OSAS exists, cognitive impairment in patients with OSAS complicated by nocturia has yet to be explored. This study investigates the incidence of nocturia in middle-aged and young patients with obstructive sleep apnea-hypopnea and examines the characteristics of their working memory impairment.

Materials and methods: This study recruited patients diagnosed with OSA due to snoring at the Sleep Center of The Second Affiliated Hospital of Soochow University from September 2021 to September 2022. According to inclusion and exclusion criteria, a total of 102 patients were enrolled. Cognitive function was thoroughly assessed, and all patients' clinical data and polysomnography (PSG) parameters were collected. Based on whether patients woke to urinate due to the urge at night ≥ 2 times, they were divided into the OSA group and the OSA + nocturia group. Collected indicators were compared between the two groups, and characteristics of cognitive impairment in OSA patients with nocturia were analyzed. Additionally, partial correlation analysis was used to explore factors influencing working memory impairment in these patients.

Results:

1. Among the 102 OSA patients included in the study, 44.12% (45/102) had nocturia. Compared with the OSA group, the OSA + nocturia group had higher age, Epworth Sleepiness Scale scores, a higher proportion of nocturnal awakenings due to urgency, a higher prevalence of hypertension, and higher arousal index (Arl) (all $P < 0.05$); no statistically significant differences were found in other aspects (all $P > 0.05$).

2. There was no statistically significant difference in overall cognitive function between the OSA group and the OSA + nocturia group. However, in terms of working memory, the OSA + nocturia group had significantly lower correct rates of delayed paired associate recall (PRM) than the OSA group ($P < 0.05$).
3. After adjusting for age, BMI, and years of education by partial correlation analysis, the results showed that the correct rate of delayed PRM in OSA patients with nocturia was negatively correlated with the longest apnea duration ($P < 0.05$).

Conclusions: Among middle-aged and young patients with OSA, those with nocturia exhibited more significant working memory impairment than those without nocturia, characterized by decreased object working memory, and the degree of impairment was negatively correlated with the longest apnea duration.

A national study and public mandate for sleep health policy reform

E.L. Gale¹, P.D. Donnelly¹

¹University of St Andrews, School of Medicine, St Andrews, United Kingdom

Introduction: Unlike established campaigns on mental health, diet, and physical activity, Scotland lacks a public health sleep strategy, with sleep not formally recognized in national health frameworks. In 2023, the World Sleep Society identified sleep as a global public health concern. Countries such as Finland, Japan, and Australia have implemented national strategies including school education, workplace reform, and public campaigns. Scotland has yet to follow. The aim of this study was to examine sleep patterns in the Scottish population, explore public perceptions of sleep, identify barriers to healthy sleep, and assess support for integrating sleep into national policy.

Materials and methods: *Scotland Speaks* is a mixed-methods study, one component being a cross-sectional online national survey, launched on World Sleep Day. Adults (16+) in Scotland completed questions on sleep habits, insomnia symptoms, occupational and societal influences, and awareness of sleep-related policy. Caregivers reported children's sleep using the Children's Sleep Habits Questionnaire (CSHQ). Wearable users submitted weekly sleep duration and quality. Quantitative data were analyzed descriptively and statistically (ANOVA, correlation, linear regression), adjusting for age, gender, employment, sleep-aid use, and formal diagnosis. Open-text responses were thematically analyzed.

Results: Participants included 5,039 adults (53.2% male, most aged 25-44 (44.6%), employed full-time (67.1%)) from all 32 Scottish regions. Shorter sleep (<7 hours) was common on weekdays (77.4%) and weekends (35.6%), with women reporting significantly less than men ($p < 0.001$). Moderate-to-severe insomnia affected 46.8%, more prevalent in males ($p < 0.001$), yet only 10.8% reported a formal sleep disorder diagnosis. Over a third (36.0%) used sleep-aids; 41.5% of which used alcohol 3+ times a week. Participants felt sleep was less prioritized by government and employers than diet (75.2%), physical activity (76.4%), mental (71.5%), and physical health (72.8%). High support existed for identifying sleep as a core health pillar (96.8%) and embedding it in community programs (97.2%), workplace policies (91.3%), school education (92.0%), medical training (93.4%), and a national sleep strategy (87.4%). Among caregivers ($n=2,473$), 50.3% of children met the CSHQ threshold for sleep problems (mean= 31.0 ± 17.5). Primary barriers included inconsistent routines (90.1%), screens (84.4%), homework (81.4%), early school times (81.4%), and mental health (67.3%). Adjusted regression analyses indicated that poorer CSHQ scores were significantly associated with caregivers who were younger ($\beta = -2.46, CI[95\%] = -2.89, -2.04, p < .001$), had shorter sleep ($\beta = -2.73, CI[95\%] = -3.23, -2.24, p < .001$), had more severe insomnia ($\beta = .85, CI[95\%] = .77, .95, p < .001$), had a sleep disorder ($\beta = 10.99, CI[95\%] = 9.47, 12.52, p < .001$), or did not view sleep as a public health concern ($\beta = -1.42, CI[95\%] = -1.70, -1.14, p < .001$). Thematic analysis revealed public support for a societal approach to sleep health, prioritizing school-based education, expanded NHS services (sleep clinics, CBT-I), workplace reforms (flexible working, right to disconnect), addressing environmental barriers (noise, light pollution), and campaigns to shift cultural attitudes undervaluing sleep.

Conclusions: *Scotland Speaks* highlights widespread sleep disruption, limited policy awareness, and strong public demand for change. A disconnect exists between public recognition of sleep as essential and its absence in national strategy. With clear support for integrating sleep into schools, workplaces,

healthcare, and public health promotion, Scotland faces an urgent policy opportunity. The case for a national sleep strategy is not only evidence-based, but also publicly driven.

Acknowledgments: Supported by the University of St Andrews.

A peer-influence approach to reduce night-time use of interactive devices and social media among adolescents: CLOCK OFF intervention development and feasibility study

A. Martin¹, C. Ewart¹, C. Wu¹, C. Shore², B. Rigby³, H. Scott⁴, H. Cleland-Woods⁴, S. Good⁵, A. O'Brien⁶, S. Simpson¹

¹University of Glasgow, School of Health and Wellbeing, University of Glasgow, Glasgow, United Kingdom, ²Glasgow Caledonian University, Glasgow, United Kingdom, ³Newcastle University, Population Health Sciences Institute, Newcastle, United Kingdom, ⁴University of Glasgow, School of Psychology & Neuroscience, Glasgow, United Kingdom, ⁵Evidence to Impact, Cardiff, United Kingdom, ⁶Sleep Action, Edinburgh, United Kingdom

Introduction: Poor sleep among adolescents poses significant risks to their health and wellbeing. A key contributor to delayed bedtimes and disrupted sleep is prolonged night-time use of interactive electronic devices (IED), including social media use. The aim of this study was to develop and assess the feasibility and acceptability of CLOCK OFF, a 10-week school-based intervention combining teacher-led lessons and peer-nominated students trained as Peer Supporters (PS) to promote healthy sleep habits and reduce IED use.

Materials and methods: CLOCK OFF was implemented with all students in S1 (11-12 years) in four high schools across Scotland during 2024. Fifty-eight PS and sixteen teachers were trained by a sleep charity. Semi-structured interviews and focus groups were conducted with PS ($n = 18$), non-PS ($n = 9$), teachers ($n = 8$), parents ($n = 8$), and trainers ($n = 3$). Data underwent thematic analysis, with 50% independently double-coded.

Results: Key strengths of CLOCK OFF included the peer nomination process (representative, fair), engaging peer training and teacher-led lessons (useful and comprehensive, engaging materials and activities), benefits of the PS role (improved confidence, expanded social networks, improved sleep and wellbeing). Challenges included teacher time constraints (study set up, training, lesson delivery), perceived role of PS (sharing peer messages, gap in digital strategies, prevalence of IED use), engagement (training materials, parental involvement), researcher challenges (school coordination, obtaining consent).

Conclusions: CLOCK OFF is feasible and refinements for an effectiveness study will consider duration of teacher training, dose of PS training, session content and materials, inclusion of digital strategies, and parental engagement. Adaptions to theory of change will include increased focused on IED behaviour change and delivery to an older adolescent population (12 - 13 years). These modifications aim to enhance the impact and scalability of CLOCK OFF.

A Proposal on a Formula for Calculating Optimal Sleep Duration Based on Self-Reported Survey Data

J. Kohyama¹

¹Tokyo Bay Urayasu/Ichikawa Medical Center, Urayasu, Japan

Introduction: Many adolescents have sleep debt. Individuals who sleep for their optimal sleep duration (OSD) are expected to experience no sleepiness. Therefore, it is important to recognize one's OSD to reduce sleep debt. However, there is no simple method for determining individual OSD. Since body mass index (BMI) and sleep duration exhibit a U-shaped association, it is expected that person sleeping

for his/her OSD would show no marked deviation from the mean BMI value for the population. This study aimed to estimate individual OSD using self-reported sleepiness and BMI.

Materials and methods: Data from 2,540 students in grades 5–11 were used. Written informed consent from each pupil's parent was obtained. Students who reported no sleepiness during class and had a gender- and grade-standardized BMI within ± 1.5 were termed ideal students (id-St). The differences in sleep duration between id-St and non-id-St were added to the habitual sleep duration (HSD) of each non-id-St to obtain the assumed OSD. A multiple regression line to predict the assumed OSD was calculated using the least squares method. This cross-sectional study was approved by the Committee for Medical Research Ethics of author's institute.

Results: A total of 666 ideal students (id-St) were identified. Their average weekly sleep durations were higher than those of non-ideal students (non-id-St): 62.0 hours in elementary school (61.2 hours), 55.6 hours in junior high school (54.1 hours), and 50.1 hours in senior high school (48.6 hours), exceeding the 49 hours assumed appropriate for children aged 6 to 17 years by the National Sleep Foundation. Two key issues were confirmed: the sleep duration of id-St fell within the appropriate range, and id-St slept longer than non-id-St. Then, the habitual sleep duration (HSD) of each id-St was considered their "assumed daily OSD." The differences in average daily sleep duration between the id-St group (8.49 hours) and the 11 groups of non-id-St ranged from 0.04 hours to 1.92 hours. The "assumed daily OSD" for each non-id-St was then determined by adding these differences to the HSD of each non-id-St individual. Multiple regression analysis was conducted using bedtime (on schooldays and non-schooldays), wake time (on schooldays and non-schooldays), BMI, grade, gender, self-reported academic performance, after-school activity (hours/week), breakfast frequency score, defecation frequency score, physical activity (days/week), and screen time (on schooldays and non-schooldays) as independent variables, with "assumed OSD" as the dependent variable. A significant linear formula for estimating OSD was derived (adjusted $R^2 = 0.996$, $p < 0.001$): $23.375 - 0.710 * (\text{bedtime before schooldays}) - 0.286 * (\text{bedtime before non-schooldays}) + 0.714 * (\text{wake time on schooldays}) + 0.281 * (\text{wake time on non-schooldays}) + 0.513 * (\text{sleepiness score; from 1 = never to 4 = always}) + 0.009 * [\text{gender (male: 1; female: 2)}] + 0.003 * (\text{BMI})$. Times were measured in hours; Bedtimes (23:45 as 23.75, 3:15 as 27.25), Waking times (6:00 as 6.00, 11:30 as 11.5).

Conclusions: Although further studies are needed, this formula offers a simple method for estimating individual OSD based on easily obtainable parameters.

A Python-Based Analysis of Sleep-Related Projects Funded by the U.S. National Science Foundation

B. Shen¹, P. Fan², C. Gao¹, X. Wang², X. Zhang², Q. Zhai², C. Tu², S. Qin²

¹Shanghai Children's Medical Center, Department of Nursing, Shanghai, China, ²Shanghai Jiao Tong University, School of Nursing, Shanghai, China, ³Shanghai Jiao Tong University, School of Mechanical Engineering, Shanghai, China

Introduction: To analyze the funding status of sleep-related research projects supported by the U.S. National Science Foundation, in order to provide references for the advancement of sleep medicine in China.

Materials and methods: Python-based web scraping and the Latent Dirichlet Allocation (LDA) model were used to collect, preprocess, and analyze sleep-related project data from the U.S. National Science Foundation.

Results: A total of 193 sleep-related research projects funded by the U.S. National Science Foundation were included in this study. Covering the period from 1987 to 2024, both the number of projects and the overall funding amount demonstrated a steadily increasing trend. A total of 4,728 unique terms were extracted from the project data. Using the Latent Dirichlet Allocation (LDA) model, these projects were clustered into nine thematic areas: (1) sleep and technological development, (2) sleep and circadian health, (3) sleep and cognitive-emotional development, (4) sleep and circadian behavior, (5) circadian modeling and activity, (6) sleep environment and physical activity, (7) sleep deprivation and neural networks, (8) sleep and gene regulation, and (9) sleep-related respiratory monitoring and devices. These topics collectively reflect a broad and multi-dimensional research landscape in the field of sleep science, with each theme characterized by distinct high-frequency terms. The results highlight research progress and practical applications across multiple layers, including the influence of sleep on circadian rhythms and cognitive functions, the neural consequences of sleep deprivation, and

technological advancements in sleep monitoring and respiratory assessment. Together, the findings underscore the diverse directions of sleep-related research at the intersection of life sciences, technology, and public health.

Conclusions: By applying new data analysis techniques to explore research trends and methodologies in the field of nursing, researchers can further investigate the development prospects of nursing in China in light of the national context.

A Scoping Review of Sleep Patterns and Circadian Rhythm Disturbances in Critically Ill Pediatric Patients

B. Shen¹, P. Fan², X. Wang², Q. Zhai², X. Zhang², L. Li¹, S. Qin²

¹Shanghai Children's Medical Center, Department of Nursing, Shanghai, China, ²Shanghai Jiao Tong University, School of Nursing, Shanghai, China, ³Shanghai Jiao Tong University, School of Clinical Medicine, Shanghai, China

Introduction: To conduct a scoping review of research on sleep and circadian rhythms in critically ill children. The aim is to provide guidance for the early diagnosis, treatment, and intervention of sleep disorders in critically ill pediatric patients.

Materials and methods: Following the methodology of a scoping review, relevant literature on sleep and circadian rhythms in critically ill pediatric patients was retrieved from five English-language databases (PubMed, Embase, CINAHL, Ovid, and Web of Science) and three Chinese databases (CNKI, Wanfang, and VIP Information Services Platform). The search covered all available literature up to July 15, 2024. Two researchers independently screened the literature and extracted key study characteristics, including author, publication year, year of data collection, country of sample collection, study type, study objective, study population, sample size, assessment tools or methods, and main findings.

Results: A total of 1,801 articles were retrieved, and 42 studies were ultimately included. Among them, 32 were in English and 10 in Chinese, with publication years ranging from 2014 to 2024. The studies were mainly categorized into observational studies (n = 24) and interventional studies (n = 17), along with one consensus study. The analysis indicated that sleep disorders are common among critically ill children and are associated with significant adverse outcomes. A total of nine assessment tools or methods were identified, including seven structured questionnaires. Commonly used instruments included the Pittsburgh Sleep Quality Index (PSQI), Brief Infant Sleep Questionnaire (BISQ), Brief Infant Sleep Questionnaire-Revised-Short Form (BISQ-R-SF), Children's Sleep Habits Questionnaire (CSHQ), Sleep Disturbance Scale for Children (SDSC), Adolescent Sleep-Wake Scale (ASWS), and the Richards-Campbell Sleep Questionnaire (RCSQ). Factors influencing sleep disorders in critically ill children were grouped into three categories: sociodemographic factors, disease- and environment-related factors, and psychological and behavioral characteristics. Interventions for sleep disorders were classified into four types: pharmacological, physical, cognitive-behavioral, and nursing care interventions. However, existing studies on prevention and intervention remain limited.

Conclusions: Sleep disorders are highly prevalent among critically ill children and are associated with significant adverse outcomes. Current research demonstrates limited awareness and understanding of sleep disturbances in this population. The contributing factors to sleep disorders in critically ill children are complex and multifaceted.

Association between cyclic alternating pattern during sleep and incident dementia

X. Tan^{1,2}, Y. Zheng²

¹Karolinska Institutet, Clinical Neuroscience, Stockholm, Sweden, ²Zhejiang University School of Public Health, Big Data in Health Science, Hangzhou, China

Introduction: Cyclic Alternating Pattern (CAP) is a sleep physiological rhythm observed during non-rapid eye movement (NREM) stage, characterized by alternating phases of transient events (A1–A3 phase) and background activity (B phase). Particularly, subtype A1 is almost exclusively composed of slow waves, which promote cognitive processing, memory consolidation and the restoration of hippocampal learning. In addition, reduced slow-wave sleep has been linked to impaired clearance of

amyloid-beta, which is one of the most common pathogenesises of Alzheimer's dementia. However, the potential role of CAP for dementia remains unknown.

Materials and methods: We conducted a prospective cohort study involving 2,586 dementia-free participants from the Osteoporotic Fractures in Men Sleep Study (MrOS) who underwent overnight polysomnography (PSG) at baseline. A high-performance automated CAP detection system was applied for CAP scoring from electroencephalogram (EEG), and CAP rate, CAP index, A index subtypes, number of CAP sequences, and CAP sequence duration were calculated. Dementia was identified by self-reported physician-diagnosed dementia and dementia medication use during follow-up. Cox proportional hazard models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs).

Results: During 9.0 ± 3.1 years of follow-up, 175 participants developed incident dementia. Participants in the lowest tertile of A2 index exhibited an increased risk of developing dementia compared to those in the highest tertile (HR 2.04, 95% CI: 1.41, 2.96) after adjustment for age, ethnicity, education, BMI, smoking status, alcohol intake, prevalence of hypertension and diabetes, and total sleep time (TST). Further, a lower combined A2+A3 index and shorter CAP sequence duration were associated with higher risk of dementia in the fully adjusted model ($P < 0.05$).

Conclusions: These findings suggest that specific features of CAP may serve as useful markers to identify those at risk of dementia.

Acknowledgments: The Osteoporotic Fractures in Men (MrOS) Study is supported by National Institutes of Health funding. The following institutes provide support: the National Institute on Aging (NIA), the National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), and the National Center for Advancing Translational Sciences (NCATS) under the following grant numbers: U01 AG027810, U01 AG042124, U01 AG042139, U01 AG042140, U01 AG042143, U01 AG042145, U01 AG042168, U01 AR066160, R01 AG066671, and UL1 TR002369. The National Heart, Lung, and Blood Institute provided funding for the ancillary MrOS Sleep Study, "Outcomes of Sleep Disorders in Older Men," under the following grant numbers: R01 HL071194, R01 HL070848, R01 HL070847, R01 HL070842, R01 HL070841, R01 HL070837, R01 HL070838, and R01 HL070839. The National Sleep Research Resource was supported by the National Heart, Lung, and Blood Institute (R24 HL114473, 75N92019R002).

Association Between Daily Step Count and Sleep Health: Findings from a National Survey in China

X. Fu^{1,2}, W. Zhang^{1,2}, X. Liu³, X. Gao^{1,2,4}, Z. Huang^{4,5}

¹Peking University School and Hospital of Stomatology, Department of Orthodontics, Beijing, China,

²Peking University School and Hospital of Stomatology, Oral Center of Sleep Disordered Breathing, Beijing, China, ³HUAWEI Health Lab, Shenzhen, China, ⁴Chinese Sleep Research Society, Beijing, China,

⁵School of Basic Medical Sciences; State Key Laboratory of Medical Neurobiology and MOE Frontiers Centre for Brain Science, Institutes of Brain Science, Joint International Research Laboratory of Sleep, Shanghai Medical College, Fudan University, Shanghai, China

Introduction: Sleep health is closely linked to chronic disease prevention, cognitive function, and overall quality of life. With the growing use of wearable devices, daily step count has become a widely used measure of physical activity. Its relationship with sleep duration, sleep quality, insomnia, and obstructive sleep apnea (OSA) has gained increasing attention. This study, based on a large-scale 2024 national survey, aims to examine the association between daily step count and various sleep health indicators.

Materials and methods: Data were collected from 93,640 participants. Subsamples who completed the Pittsburgh Sleep Quality Index (PSQI), the Athens Insomnia Scale (AIS), and the Stop-Bang questionnaire were analysed after excluding those with missing data, extreme step counts ($> 50,000$), implausible sleep durations (< 3 or > 13 hours), or incomplete questionnaires. Mean sleep duration across multiple days was calculated. Associations between step count and sleep measures were assessed using Spearman correlation. Participants were grouped by average daily steps ($\leq 4k$, 4-8k, 8-12k, $> 12k$), and group differences were compared using Kruskal-Wallis H tests with post hoc analysis. Sleep quality (PSQI), insomnia risk (AIS), and OSA risk (Stop-Bang) were categorized, and group differences in these classifications were analyzed using Chi-square tests.

Results: Step count showed a weak negative correlation with sleep duration ($r = -0.117$, $P < 0.001$). The $> 12,000$ -step group had significantly shorter sleep duration (6.27 ± 1.44 hours) than the $\leq 4,000$ -

step group (6.81 ± 1.76 hours, $P < 0.001$). Higher step counts significantly associated with better sleep quality ($r = -0.141$, $P < 0.001$), with peak improvement around 8,000 steps/day; improvements plateaued thereafter ($P = 0.240$). Higher step counts were associated with a greater proportion of participants classified as having good sleep quality ($\chi^2 = 138.351$, $P < 0.001$). Step count was also inversely correlated with insomnia risk ($r = -0.109$, $P < 0.01$), with significant differences between the 4,000–8,000 and 8,000–12,000 step groups ($P = 0.014$). Participants with higher step counts were more likely to be in the non-insomnia group ($\chi^2 = 12.499$, $P = 0.006$). For OSA risk, the correlation was weak ($r = 0.044$, $P = 0.013$), and group differences based on Stop-Bang scores (>2 indicating high risk, ≤ 2 indicating low risk) were not statistically significant ($\chi^2 = 7.461$, $P = 0.059$).

Conclusions: Higher daily step count is significantly associated with improved sleep quality and reduced insomnia risk, with 8,000 steps/day representing a potential optimal threshold. The inverse association with sleep duration may suggest a complex relationship between physical activity and sleep health. Future longitudinal and objective sleep measurement studies are warranted to clarify causality. Moderate physical activity—such as walking 8,000 steps per day—is an potentially effective strategy for improving population sleep health.

Association Between Multidimensional Sleep Health and Psychological Distress in Japanese Community Residents

R. Furihata¹, Y. Tateyama^{2,3}, T. Shimamoto², N. Nishioka^{2,4}, Y. Takahashi⁵, K. Yamamoto⁶, H. Okada⁷, T. Nakayama⁸, T. Iwami²

¹Kyoto University, Agency for Student Support and Disability Resources, Kyoto, Japan, ²Kyoto University School of Public Health, Department of Preventive Services, Kyoto, Japan, ³Teikyo University Faculty of Pharmaceutical Sciences, Department of Environmental Health and Global Health, Tokyo, Japan, ⁴Kyorin University School of Medicine, Department of Nephrology and Rheumatology, Tokyo, Japan, ⁵Kyoto University School of Public Health, Department of Implementation Science in Public Health, Kyoto, Japan, ⁶Osaka Dental University, Translational Research Institute for Medical Innovation, Osaka, Japan, ⁷Wakayama Medical University, Pharmaceutical Sciences, Wakayama, Japan, ⁸Kyoto University School of Public Health, Department of Health Informatics, Kyoto, Japan

Introduction: To investigate the association between multidimensional sleep health (MDSH) and psychological distress among Japanese community residents.

Materials and methods: A self-administered questionnaire survey was conducted from December 2022 to February 2023 among Kyoto City residents aged 40 years or older. MDSH was assessed using the RU_SATED, which evaluates six sleep health dimensions (regularity, satisfaction, arousal, timing, efficiency, and sleep duration) and generates a total score. Psychological distress was measured using the Kessler 6 (K6) scale. This study was approved by the Ethics Committee of Kyoto University.

Results: Among 661 respondents (57.9% female, mean age 64.9 years, 68.4% urban residents), the prevalence of K6-5 distress, K6-13 distress was 28.9%, and 3.0%. Spearman correlation analysis showed that K6 scores were negatively correlated with total RU_SATED scores ($r_s = -0.25$, $P < 0.001$). Each 1-point increase in the RU_SATED score corresponded to a -0.325-point decrease in the K6 score. Multiple logistic regression analysis showed that K6-5 distress was associated with all six dimensions (odds ratio [OR] = 0.309–0.671), whereas K6-13 distress was associated with satisfaction (OR = 0.176).

Conclusions: This study found that total RU_SATED scores were negatively associated with psychological distress, with each sleep dimension showing a distinct relationship. Further research is needed to explore these relationships in diverse populations.

Association Between Ophthalmic Diseases and Sleep Duration: A Nationwide Cross-Sectional Study

Y.-C. Kim¹, J. Kim²

¹St. Vincent's Hospital, College of Medicine, The Catholic University of Korea, Department of Psychiatry, Suwon, Korea, Republic of, ²Seoul St. Mary's Hospital, Department of Internal medicine, Seoul, Korea, Republic of

Introduction: To investigate the relationship between specific ophthalmic diseases—diabetic retinopathy (DMR), age-related macular degeneration (AMD), epiretinal membrane (EM), and glaucoma—and sleep duration in a nationwide, population-based sample, focusing on whether individuals with these conditions experience altered sleep duration compared to those without.

Materials and methods: This cross-sectional study analyzed data from the 2019 and 2020 Korea National Health and Nutrition Examination Survey. Ophthalmic diseases were diagnosed through fundoscopy, and sleep duration on weekdays and weekends was self-reported. The study included 8,395 participants aged 40 and older who underwent fundoscopy. Multistage, stratified, clustered sampling ensured population-wide representation. Statistical models adjusted for demographic and clinical covariates, including age, sex, BMI, and comorbidities.

Results: Patients with DMR and EM experienced significantly reduced sleep duration, with reductions of 0.3 to 0.5 hours on both weekdays and weekends compared to individuals without these conditions. No significant differences in sleep duration were observed for AMD or glaucoma. After adjusting for covariates, the association between shorter sleep duration and DMR or EM remained significant, while no significant differences were found for AMD or glaucoma.

Conclusions: This study highlights that DMR and EM are associated with reduced sleep duration, while AMD and glaucoma do not show a significant impact. These findings emphasize the need for targeted sleep interventions for patients with certain ophthalmic conditions. Further research is warranted to elucidate the mechanisms linking ophthalmic diseases and sleep disturbances and to develop tailored clinical strategies.

Association Between Screen Time Exposure and Sleep Duration among U.S. Adolescents and Young Adults: An exploratory analysis of NHANES 2011–2016 cohorts

D. Bancovsky¹, A. Gileles-Hillel^{2,3}

¹Safran Children's Hospital - Sheba Medical Center, Pediatric Neurology Unit, Ramat Gan, Israel, ²The Hebrew University of Jerusalem, The Faculty of Medicine, Jerusalem, Israel, ³Hadassah Medical Center, Pediatric Pulmonology and Sleep Unit, Jerusalem, Israel

Introduction:

Digital addiction is an emerging public health concern associated with various comorbidities, mental health issues, sleep disturbances, and even mortality. Previous research has examined the impact of screen time exposure on sleep health, particularly sleep latency, continuity, and duration, with inconsistent findings. These were mainly observational studies, primarily conducted in adults and using unrepresentative samples, often without adequate adjustment for confounders.

In the present study, we aimed to explore the association between high daily screen exposure and sleep duration among youth, using pooled, nationally representative cross-sectional data.

Materials and methods: We analysed pooled cross-sectional data from the U.S. National Health and Nutrition Examination Survey (NHANES) cycles 2011–2016, including participants aged 16–20 years. Self-reported sleep duration served as the primary dependent variable, whereas screen exposure was the main independent variable. Sleep loss was defined as fewer than 7 hours of sleep per night. A univariate logistic regression analysis was conducted to assess the crude association between sleep loss and high screen time (≥ 3 hours/day). A multivariate logistic regression model was then adjusted for race/ethnicity, gender, age, body mass index (BMI), household poverty index, physical activity, depressive symptoms (assessed via the nine-item Patient Health Questionnaire, PHQ-9), and other health conditions.

Results:

The final sample included 2,227 participants. High screen time was significantly associated with increased odds of sleep loss (OR 1.40, 95% CI: 1.08–1.81, $p < 0.05$). After adjustment, the association remained significant (aOR 1.66, 95% CI: 1.13–2.46, $p < 0.05$). Other covariates independently associated with sleep loss in the final model included older age (aOR 1.22, 95% CI: 1.11–1.33, $p < 0.001$), non-Hispanic Black ethnicity (aOR 1.80, 95% CI: 1.26–2.56, $p < 0.01$), and severe depression (aOR 3.33, 95% CI: 1.15–9.66, $p < 0.05$).

Conclusions:

High daily screen exposure is independently associated with increased odds of sleep loss among U.S. adolescents and young adults, as demonstrated in a pooled 6-year nationally representative sample. Our findings, based on a large cohort and adjusted for key confounders, align with parts of the existing literature and a recent systematic review. Moreover, the significant associations between sleep loss, race/ethnicity, and mental health symptoms highlight the multifactorial nature of sleep health and reinforce the need for multidisciplinary approaches in clinical care. Prospective and controlled trials are warranted to determine safe thresholds for screen exposure duration and content in relation to sleep, given the growing relevance of this issue as a major public health concern in the digital age.

Association between Sleep Disturbances and Stages of Parkinson's Disease: A Cross-Sectional Study

T. Amalnerkar¹, M. Abdulrazzaq Jabbar², Y.Y. Tan³

¹Universiti Tunku Abdul Rahman, Department of Physiotherapy, MK Faculty of Medicine and Health Sciences, Cheras, Malaysia, ²College of Medicine, Gulf Medical University, Department of Community Medicine, Ajman, United Arab Emirates, ³Universiti Tunku Abdul Rahman (UTAR), Department of Physiotherapy, MK Faculty of Medicine and Health Sciences, Kajang, Malaysia

Introduction: Various studies and research show that People with Parkinson's Disease (PwPD), apart from motor issues also suffer with various non-motor symptoms such as sleep issues (insomnia, obstructive sleep apnea, circadian rhythm sleep disorders and so on) orthostatic hypotension, psychological difficulties and many more. Sleep disturbances are one of the most common and frequently encountered issues. These issues need further attention. Sleep disturbances have been associated with decreased quality of life (QOL) and can lead to many serious health issues. The objective of this study was to identify sleep disturbances among (PwP) and to investigate the association between sleep disturbances and stages of PD.

Materials and methods: A cross-sectional study design with convenient sampling method was used for this study. Study was conducted at the Malaysian Parkinson's Disease Association (MPDA), Malaysia. The Parkinson's Disease Sleep Scale 2 (PDSS-2) and Hoehn and Yahr scale were used in the study.

Results: A total of 33 (PwPD) participated in this study. Altogether 63.6% (n=21) of the participants were found to have some form of sleep disturbances. Nocturia, with a prevalence of 72.7%, has been found the most prevalent sleep disturbance, followed by psychosis, then issues with sleep refreshment and others. Prevalence of sleep disturbances among the patients in the later stages (stage 2- 81.8%, stage 3- 57.1%, stage 4- 100.0%, and stage 5- 100.0%) was higher than the prevalence of sleep disturbances in the lower stage (stage 1- 0.0%).

Conclusions: This study found that there is a considerably high prevalence of sleep disturbances among (PwPD) and an association was also found between sleep disturbances and stages Parkinson's disease. Larger sample size, with further subjective and objective assessment of sleep and confounding factors that may impact sleep should be assessed further. A physiotherapist can be instrumental in making an early diagnosis, methods such as positioning, inspiratory muscle training, oropharyngeal exercise and various intensity exercises can also help in managing a few of the issues. An awareness, knowledge and attitude towards the sleep problem can improve the quality of life of the (PwPD) and may prevent from consequences of poor sleep. Knowledge of the application of chronobiology in the context of timing of exercise with medication or standalone method can also be explored further in the management of circadian rhythms sleep disorders in (PwPD).

Acknowledgments: We would like to express our sincere thanks to Ms. Sara Lew, the president of the Malaysian Parkinson's Disease Association (MPDA), Malaysia, all the valued and respected participants. We also wish to convey our deep gratitude, Prof. K Ray Chaudhuri, Dr. Claudia Trenkwalder and Mapi Research Trust.

Association between Sleep Duration and Cancer-Specific Mortality among community-based population: A Systematic Review and Meta-Analysis

L. Yan¹, R. Wang¹, Y. Guan¹, Y. Kong¹, H. Zhao¹, J. Zhang¹, X. Yang², M. Yang¹

¹Zhengzhou University, School of Education, Zhengzhou, China, ²The First Affiliated Hospital of Zhengzhou university, Zhengzhou, China

Introduction: Cancer has emerged as a significant challenge in global public health, imposing a substantial burden on individuals, healthcare systems, and societies worldwide. Abnormal sleep duration may influence cancer mortality, but evidence for U-shaped/J-shaped relationships and daytime napping with cancer-specific mortality remains inconsistent. Thus, the current study aimed to conduct a systematic review and meta-analysis of the association between sleep duration (nighttime, 24-hour, daytime napping) and all-cancer and site-specific cancer mortality.

Materials and methods: We conducted a systematic search of PubMed, Embase, and the Cochrane Library databases up to March 19, 2025 without language restrictions, following PRISMA guidelines (PROSPERO: CRD420251009205). Observational studies reporting risk estimates for cancer-specific mortality associated with sleep duration in community-based populations were included. Data were extracted independently by two reviewers, and study quality was assessed using the Newcastle-Ottawa Scale (NOS). Random-effects models were used to pool relative risks (RRs) with 95% confidence intervals (CIs). Heterogeneity, publication bias, and sensitivity analyses were performed.

Results: Of the 7,326 screened studies, 32 studies (622,133 participants; 25,244 deaths) were included. All-cancer-specific mortality showed U-shaped associations: short sleep (RR=1.04, 95% CI 1.01–1.08; $I^2=23.4\%$) and long sleep (RR=1.13, 1.08–1.19; $I^2=51.1\%$) vs. 7–8h. Lung cancer-specific mortality increased with short (RR=1.14, 1.01–1.29) and long (RR=1.22, 1.02–1.45) sleep. No associations were found for digestive system, breast, or prostate cancers. Daytime napping slightly increased the risk of all-cancer-specific mortality (RR=1.06, 1.02–1.10). Subgroup analyses revealed 24-hour short sleep (RR=1.07, 1.03–1.12), but not nighttime short sleep (RR=1.01, 0.98–1.04), was significant. The association of long sleep was stronger in Asian populations and studies with ≤ 10 -year follow-up.

Conclusions: A U-shaped relationship exists between sleep duration and all-cancer-specific mortality in community-based populations, with both short and long sleep durations, as well as daytime napping, associated to increased risk.

Association between Sleep Problems and Social Frailty Among U.S. Older Adults

M. Thalil¹, S. Lee²

¹Pennsylvania State University, Human Development and Family Studies, University Park, United States, ²Pennsylvania State University, University Park, United States

Introduction: Sleep problems can negatively impact various aspects of social functioning, potentially increasing the risk of social frailty in older adults. While sleep quality and duration have been previously linked to social frailty, other dimensions of sleep remain understudied. This study examined the association between multidimensional sleep problems and social frailty among older adults, including differences by sex.

Materials and methods: We analyzed cross-sectional data from 2,318 community-dwelling adults aged 65 and older from the 2013–2014 waves of the National Health and Aging Trends Study. Sleep health was assessed across five dimensions (satisfaction, alertness, timing, efficiency, and duration) using the SATED framework. Social frailty was measured using the Makizako Index, classifying participants as socially robust (0 components), pre-frail (1), or frail (≥ 2). Multinomial logistic regression models examined associations between sleep problems and social frailty status, adjusting for socio-demographics, depressive symptoms, and chronic conditions including hypertension, diabetes, cardiovascular diseases, stroke, lung disease, arthritis, osteoporosis, dementia, and cancer.

Results: Older adults with sleep problems had a significantly higher risk of being socially pre-frail (RR = 1.15, 95% CI: 1.03–1.29) and socially frail (RR = 1.46, 95% CI: 1.27–1.67) after adjusting for covariates. The association between sleep problems and social frailty was more pronounced among older men compared to women (interaction $p < 0.05$). Among individual sleep domains, dissatisfaction with sleep (RR = 2.53, 95% CI: 1.74–3.69), poor daytime alertness (RR = 1.66, 95% CI: 1.15–2.37), and suboptimal sleep efficiency (RR = 2.53, 95% CI: 1.78–3.58) were significantly associated with increased risk of social frailty. No significant associations were observed for sleep timing or sleep duration.

Conclusions: Multidimensional sleep problems are associated with a higher risk of social frailty in older adults, particularly among men. Interventions that improve sleep health, especially targeting sleep satisfaction, alertness, and efficiency, may help reduce the burden of social frailty in this population.

Association between snoring and in vitro fertilization outcomes among infertile women

H. Wang¹, F. Han², X. Dong², F. Gao³, X. Chen³, H. Han³, Y. Wang³, H. Shen³

¹peking university, Beijing, China, ²peking university people's hospital, Division of Sleep Medicine, Beijing, China, ³Reproductive Center of Peking University Peoples' Hospital, Beijing, China

Introduction: Snoring is well known to increase risk of metabolic and cardiovascular consequences in general population, with limited attention to reproductive health. The study aim to explore the association between snoring and in vitro fertilization (IVF) outcomes in infertile women, focusing on embryological parameters and pregnancy outcomes.

Materials and methods: 632 infertile women, aged 24 to 45 years, undergoing their first IVF treatment, were continuously recruited at the Reproductive Center of Peking University People's Hospital from January 2018 to Nov 2021. All patients with their husbands' assistance completed a questionnaire including snoring status and frequency before ovulation induction (OI). Embryology parameters were observed during the first IVF cycle, with subsequent follow-up to assess pregnancy outcomes.

Results: Results: Of the 579 subjects, 33.5% reported occasional snoring, and 8.8% reported frequent snoring. A multiple linear regression model adjusted for confounding factors, indicated that frequent snorers had higher β -coefficients for the number of blastocysts and available embryos compared to non-snorers (both $P < 0.05$). Among 551 subjects who completed the first embryo transfer, 6.2% suffered biochemical pregnancy loss, Frequent snorers had a higher likelihood of biochemical pregnancy loss compared to non-snorers and occasional snorers (5.7% vs. 14.6%, $P = 0.033$; 4.8% vs. 14.6%, $P = 0.026$). Multivariable analysis revealed that frequent snoring (adjusted odds ratio, aOR: 2.95, 95% confidence interval, CI: 1.06-8.24, $P = 0.039$) was a risk factor for biochemical pregnancy loss, while high-density lipoprotein cholesterol (HDL-C) level (aOR: 0.21, 95% CI: 0.05-0.92, $P = 0.038$) was found to be a protective factor after IVF.

Conclusions: Frequent snoring is associated with a reduced number of available oocytes and is a risk factor for biochemical pregnancy loss after IVF. However, this observed association should be interpreted with caution, as the potential effects of undiagnosed obstructive sleep apnea (OSA) have not been excluded.

Acknowledgments: Thanks for every participants in this study, thanks for the support of Peking University People's Hospital, and thanks for the support of National Natural Science Foundations of China(32441101, 82341243 to HF; 82470092 to DXS), Natural Science Foundations of Beijing(2023YFE0118500 to HF) and funds of YC202301JS0025.

Association between Work Engagement and Psychomotor Vigilance among Physicians in a Japanese University Hospital: Stratified Analysis by Age Group and Medical Specialty

Y. Kameda¹, H. Wada², Y. Ueda², M. Miyakawa², M. Hosokawa³, Q. Zhu², Y. Kodama⁴, H. Nakano⁵, T. Tanigawa²

¹Juntendo University Graduate School of Medicine, Department of Public Health, Tokyo, Japan,

²Juntendo University Graduate School of Medicine, Department of Public Health, Tokyo, Japan,

³Juntendo University Graduate School of Medicine, Department of Epidemiology and Environmental Health, Tokyo, Japan, ⁴Juntendo University Graduate School of Medicine, Division of Respiratory Medicine, Tokyo, Japan, ⁵National Hospital Organization Fukuoka National Hospital, Sleep Disorders Center, Fukuoka, Japan

Introduction: Work engagement is a positive and fulfilling psychological state related to one's work, often considered the opposite of burnout. In clinical settings, higher work engagement among physicians has been associated with better patient care and lower turnover rates. Since the COVID-19 pandemic, there has been growing concern about the work environment and mental health of healthcare professionals. This study aimed to examine age- and specialty-related differences in work

engagement and its association with psychomotor vigilance, an objective indicator of sleep debt, among physicians at a Japanese university hospital.

Materials and methods: Among 836 physicians, 391 (response rate: 46.8%) completed a questionnaire and underwent a 3-minute brief Psychomotor Vigilance Test (PVT-B) after work. The total score of the Utrecht Work Engagement Scale (UWES-17) was used as the dependent variable. Independent variables included depressive symptoms (Center for Epidemiologic Studies Depression Scale: CES-D) and PVT performance (lapse355), with sex, BMI, age group (20s, 30s, 40s, ≥ 50 s), and sleep duration (< 5 h or ≥ 5 h) as covariates. Stratified analyses were performed by age group and by specialty (medical vs. surgical). Statistical significance was defined as $p < 0.05$. Statistical analyses were conducted by SAS version 9.4 software (SAS Institute Inc., Cary, NC).

Results: Stratified analyses were performed by age group and by specialty (medical vs. surgical). Statistical significance was defined as $p < 0.05$. UWES scores were significantly lower in the 20s ($\beta = -13.8$, $p < 0.01$) and 30s ($\beta = -10.1$, $p < 0.01$) compared to ≥ 50 s. Lapse355 was negatively associated with UWES ($\beta = -0.3$, $p < 0.01$), and CES-D showed a marginal association ($\beta = -3.9$, $p = 0.08$). In adjusted models that substituted objective PVT measures for subjective sleepiness, model fit improved ($\Delta R^2 = 0.018$, $\Delta F = 7.58$, $p < 0.01$). In age- and specialty stratified analyses, the association was more evident among physicians with a surgical specialty in their 20s.

Conclusions: The results from present study suggest that work engagement is associated with PVT performance, an objective indicator of sleep debt, especially among young physicians at a Japanese university hospital.

These findings highlight the need for early intervention in cognitive and mental fatigue among early-career physicians.

Association of Accelerometer-measured Daily Steps and Sleep Disorders: A Prospective Cohort Study

L. Zhang¹, J. Du¹, J. Wang¹, M. Liu¹, W. Zhang¹, Y. He^{1,2}, J. Zhang¹, Y.Y. Liang^{1,3}

¹The Affiliated Brain Hospital, Guangzhou Medical University, Center for Sleep and Circadian Medicine, Guangzhou, China, ²The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China, ³The Affiliated Brain Hospital, Guangzhou Medical University, Institute of Psycho-neuroscience, Guangzhou, China

Introduction: Sleep medicine is a vital component of psychiatry. As one of the most common mental disorders, sleep disorders have raised a global concern. Emerging evidence suggests that physical activity may help alleviate sleep disturbances. Tracking daily steps is a simple and popular way of physical activity, but its impact on sleep quality remains unclear.

Materials and methods: This prospective cohort study analyzed UK Biobank data collected from February 2013 to November 2021, with a median follow-up of 6.94 years. Several potential confounders were considered in this study, including demographic factors, socioeconomic indicators, lifestyle variables, health conditions, environmental exposure, medication history, accelerometer wearing season and duration. We employed Cox proportional hazards regression and restricted cubic spline analyses to examine the relationship between accelerator-measured step count and the incidence of sleep disorders.

Results: Among 83,578 participants with valid step measurements, 913 developed sleep disorders. An inverse dose-response relationship was observed between daily step count and intensity with the risk of developing sleep disorders. Risk reduction plateaued after 4,800 steps/day and 100 steps/min for purposeful steps and peak-30 cadence, respectively. Compared with low volume of total daily steps, moderate and high volumes of total daily steps were significantly associated with a 17% (HR = 0.83, 95%CI = 0.70-0.99) and 26% (HR = 0.74, 95%CI = 0.61-0.90) reduction in the risk of developing sleep disorders, respectively. For purposeful steps, only high daily steps were associated with 31% (HR = 0.69, 95%CI = 0.56-0.85) reduction in risk. Regarding peak-30 cadence, only moderate intensity was associated with a 25% (HR = 0.75, 95%CI = 0.62-0.89) reduction in risk of developing sleep disorders.

Conclusions: Higher step count and intensity, as measured by accelerometers, are associated with a lower risk of sleep disorders. These findings suggest that daily steps management could be a valuable strategy in public health interventions aimed at improving sleep quality.

Acknowledgments: This research was conducted using the UK Biobank Resource under application number 93604. We sincerely thank the participants and staff who contributed to the UK Biobank. Association of Longitudinal Changes in Rapid Eye Movement Sleep with Mortality in Older Men

Q. Wang¹, K. Stone², A. Azarbarzin³, Z. Lu⁴, B. Zhao⁵, Y. Bao⁶, L. Shi¹, L. Lu^{1,6,7}

¹Peking University Sixth Hospital, Peking University Institute of Mental Health, NHC Key Laboratory of Mental Health (Peking University), National Clinical Research Center for Mental Disorders (Peking University Sixth Hospital), Beijing, China, ²Department of Research Institute, California Pacific Medical Center, San Francisco, United States, ³Division of Sleep and Circadian Disorders, Brigham and Women's Hospital and Harvard Medical School, Boston, United States, ⁴Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden, ⁵Department of Statistics and Data Science, University of Pennsylvania, Philadelphia, United States, ⁶National Institute on Drug Dependence and Beijing Key Laboratory of Drug Dependence, Beijing, China, ⁷Peking-Tsinghua Center for Life Sciences and PKU-IDG/McGovern Institute for Brain Research, Beijing, China

Introduction: Decreased rapid eye movement (REM) sleep has been linked to an increased risk of mortality. However, existing research has focused on sleep stages at a single point in time, leaving a gap in understanding how longitudinal changes in REM sleep influence mortality. The aim of this study is to evaluate the relationship between longitudinal changes in REM sleep and mortality in older men.

Materials and methods: This study included 871 community-dwelling older men who participated in the first (2003-2005) and second (2009-2012) sleep ancillary study visits of the Osteoporotic Fractures in Men Study (MrOS). We utilized polysomnographic data from the two sleep visits, along with data on the occurrence and timing of mortality during the follow-up period. Participants who had two measures of REM sleep were included in the analysis. Participants showed a decline in mean REM sleep percentage from 19.83% at sleep visit 1 to 19.12% at sleep visit 2, corresponding to an annual reduction of 0.11% per year. Cox models were used to adjust for multiple sociodemographic and lifestyle factors, depression, comorbidities, and other clinical characteristics.

Results: During a median follow-up of 9.4 (interquartile range, 5.5-12.5) years, a total of 620 all-cause deaths, 243 cardiovascular disease (CVD) deaths, and 112 cancer deaths were recorded. After adjustment for multiple sociodemographic and lifestyle factors, depression, comorbidities, and other clinical characteristics, men with a more rapid decline (tertile 1) change in REM sleep had an elevated risk of all-cause (hazard ratio, 1.25; 95% CI, 1.02-1.54; P = 0.03) and CVD-specific mortality (hazard ratio, 1.50; 95% CI, 1.07-2.10; P = 0.02) as compared to those with an increased change (tertile 3) in REM sleep. However, no significant association was found between changes in REM sleep and the risk of cancer-specific mortality and other non-CVD/non-cancer mortality.

Conclusions: Our results suggested that reduction in REM sleep was associated with a greater risk of all-cause and cardiovascular disease-specific mortality. These findings may help identify older men at increased risk for mortality.

Acknowledgments: The Osteoporotic Fractures in Men (MrOS) Study is supported by National Institutes of Health funding. Association of Sleep Quality and Mental Health Among Students : A College Based Study From Bilaspur District of Himachal Pradesh (North India)

P. Verma¹, H. Jani¹, P. Bhandari¹, B. Patel¹, R. Parlewar¹

¹AIIMS Bilaspur HP, Physiology, Bilaspur, India

Introduction: Sleep is necessary for maintenance of physical and mental health. Sleep disorders among young adults have emerged as a significant global health issue, ranking as second most common mental health problem. Varying degree of environmental and academic challenges causes inappropriate sleep hygiene practice among young adults leading to circadian rhythm disturbances. Poor sleep quality can lead to host negative consequences, including physical Health Risks and mental health Issues like elevated risk of depression, anxiety, cognitive impairment and impaired academic achievements and absenteeism. Hence to better manage these problems in college students, it is important to determine prevalence poor sleep quality, and its potential risk factors. This study was conducted with objectives. 1. to assess the sleep hygiene practice (SHP), sleep quality (SQ) and mental health; 2. To determine prevalence of poor sleep quality and mental health problems among medical and non medical students; 3. To find association between these.

Materials and methods: The cross sectional observation study was conducted on 638 students (17-25 years of age) from medical institute and degree college of Bilaspur, HP. Data was collected using online questionnaire. Students having chronic disease, current or past history of neurological disorders, taking neuro-psychotic medications were excluded from study. Questionnaire consisted of items of Pittsburgh Sleep Quality Index (PSQI) & Sleep Hygiene practice and Awareness Scale (SHAPS) and Depression, Anxiety Stress Scale²¹(DASS 21). Time for distribution of questionnaire was chosen carefully paying attention to exams schedule of students such that they will not be having exam over one month before and after filling out questionnaire. After collecting data and eliminating defective questionnaires, properly completed questionnaires were scored as per the scale provided in questionnaires. Appropriate statistical analysis was performed using SPSS.

Results: Total of 638 students including medical 314(49.21%) and nonmedical (324(50.78%) students, participated in study . Mean age of all participants was 22.95 ±2.59. Median of PSQI score was 7.71 significantly higher among medical students (7.91). Males (7.24) were having significantly higher PSQI score than females (7.11). Total Median score of SHA and SHP were :21 and 11 respectively. Mild to moderate level depression, anxiety and stress was observed in 468 (73.35%) students with no significant difference between two groups.

Significant association was observed between SHP and sleep quality in both groups; between sleep quality and all three components of mental health. Poor SHP and Poor sleep quality have shown significant association with academic year in medical groups of students, being statistically higher among first and final year medical students.

Sleep efficiency, sleep latency, and daytime dysfunction were found as main predictor of these mental health problems.

Conclusions: Poor sleep quality and mental health problems are prevalent among students more in medical students. Study's findings emphasize the need for targeted interventions and given the potential negative impact of poor sleep on mental health of this vulnerable group, it's crucial to implement strategies to address this issue. Educational institutions should consider implementing sleep awareness programs and providing accessible mental health resources and creating a supportive learning environment that prioritizes student well-being.

Acknowledgments: Heartful thanks to All participants.

Associations between multidimensional sleep health domains and brain structure, cognition, emotion and body composition in middle-aged adults

J.S.X. Chong^{1,2}, V.H. Lew^{1,2}, S.H.F. Neo^{1,2}, X.Y. Chua^{1,2}, C.S. Soon^{1,2}, E.K.K. Ng^{1,2}, S. Qin^{1,2}, J.L. Ong^{1,2}, M.W.L. Chee^{1,2,3}, J.H. Zhou^{1,2,3,4}

⁴National University of Singapore, Department of Electrical and Computer Engineering, Singapore, Singapore

Introduction: Sleep health has been recognised as a multidimensional construct encompassing domains including duration, continuity, and regularity, which in turn relate to cognitive, physical and mental well-being. Midlife represents a pivotal period in the life course, during which health and well-being can shape later-life outcomes. To date, few studies have systematically examined how multiple sleep domains relate to diverse health outcomes in midlife. Our study addressed this gap by testing whether and how different sleep components differentially relate to brain structure, cognition, emotion, and body composition in community-dwelling middle-aged adults.

Materials and methods: We studied 140 healthy middle-aged adults (age=52.0±6.7 years, 51 males) who completed brain MRI, body composition, neurocognitive and emotion assessments. Participants additionally wore an Oura Ring and completed cognitive tasks (via the Z4IP app) daily for four weeks prior to MRI. Principal components analysis was performed on 22 Oura Ring-derived sleep measures (comprising means and standard deviations (SDs) of 11 metrics across the tracking period: efficiency, wake after sleep onset (WASO), wake after sleep offset (WASF), sleep fragmentation index (SFI), time-in-bed (TIB), total-sleep-time (TST), sleep onset latency (SOL), wake count, durations of light, rapid eye movement (REM) and deep sleep). We then conducted Pearson correlations between sleep component scores and various health outcomes (body composition, cognition, emotion and cortical thickness measures), after regressing out age, sex, education, handedness and total intracranial volumes (for cortical thickness).

Results: We identified three principal components corresponding to sleep continuity (high positive loadings in mean efficiency, high negative loadings in mean WASO and SFI), duration (high positive loadings in mean TIB, TST, SOL, light and REM sleep durations) and variability (high positive loadings in SD across most metrics), which exhibited differential associations with health outcomes in middle-aged adults. Specifically, sleep variability- and continuity-related components were both associated with body fat measures, with higher sleep variability-related component score linked to higher waist-hip ratio, and higher sleep continuity-related component score linked to lower body mass index, waist-hip ratio and visceral fat area ($r_s=0.188-0.227$, $p_{\text{false discovery rate (FDR)-adjusted}}<0.05$).

In contrast, higher sleep duration-related component score related to better performance in daily app-based cognitive assessments including faster reaction time in the symbol search task, better performance in the dot memory task, and less reaction time variability in the psychomotor vigilance task ($r_s=0.191-0.252$, $p_{\text{FDR-adjusted}}<0.05$).

Of the three components, only higher sleep continuity-related component score was associated with higher cortical thickness in specific regions including the left fusiform gyrus, left pars orbitalis, right entorhinal cortex and right precuneus ($r_s=0.265-0.341$, $p_{\text{FDR-adjusted}}<0.05$). No associations with emotion measures and neurocognitive assessment scores were found.

Conclusions: Our findings reveal distinct associations of sleep continuity-, variability- and duration-related components with cognitive, brain, and physical health in middle-aged adults. Our study underscores the importance of multidimensional sleep health for brain, cognitive, and metabolic vulnerability in midlife, and suggest that targeted sleep interventions may offer promising avenues for promoting healthy ageing.

Acknowledgments: The study was supported by the Singapore National Medical Research Council, A*STAR, Ministry of Education, and Yong Loo Lin School of Medicine, National University of Singapore.

Associations between obesity, a composite risk score for long COVID, and sleep problems in SARS-CoV-2 vaccinated individuals

Introduction: Preliminary data suggests that obesity might hasten the decline in mRNA vaccine-induced immunity against SARS-CoV-2. However, whether this renders individuals with obesity more susceptible to long COVID symptoms post-vaccination remains uncertain. Given sleep's critical role in immunity, exploring the associations between obesity, probable long COVID symptoms, and sleep disturbances is essential.

Materials and methods: We analyzed data from a survey of 5919 adults aged 18 to 89, all of whom received two SARS-CoV-2 mRNA vaccinations. Participants were categorized into normal weight, overweight, and obesity groups based on ethnicity-specific BMI cutoffs. The probability of long COVID was evaluated using the Post-Acute Sequelae of SARS-CoV-2 (PASC) score, as our survey did not permit confirmation of acute SARS-CoV-2 infection through methods such as antibody testing. Additionally, sleep patterns were assessed through questionnaires.

Results: Participants with obesity exhibited a significantly higher adjusted odds ratio (OR) of having a PASC score of 12 or higher, indicative of probable long COVID in our study, compared to those with normal weight (OR: 1.55, 95% CI: 1.05, 2.28). No significant difference was observed for overweight individuals (OR: 0.92 [95% CI: 0.63, 1.33]). Both obesity and probable long COVID were associated with increased odds of experiencing a heightened sleep burden, such as the presence of obstructive sleep apnea or insomnia ($P < 0.001$). However, no significant interaction between BMI and probable long COVID status was found.

Conclusions: Even post-vaccination, individuals with obesity may encounter a heightened risk of experiencing prolonged COVID-19 symptoms. However, confirming our observations necessitates comprehensive studies incorporating rigorous COVID infection testing, such as antibody assays - unavailable in our anonymous survey. Additionally, it is noteworthy that the correlation between probable long COVID and sleep disturbances appears to be independent of BMI.

Acknowledgments: We express our sincere gratitude to the anonymous participants who generously donated their data and dedicated their time to contribute to the success of this study. Without their valuable participation, this research would not have been possible.

Associations Between Sleep Health and Gut Microbiota: A Metagenomic Analysis in a Community-Based Sample in Hong Kong

S. Xie¹, C.X. Chen¹, S.W.H. Chau¹, B. Huang^{1,2}, J.W.Y. Chan¹, R.N.Y. Chan¹, Y.K. Wing^{1,2}

¹Li Chiu Kong Family Sleep Assessment Unit, The Chinese University of Hong Kong, Faculty of Medicine, Department of Psychiatry, Hong Kong, Hong Kong, SAR of China, ²Li Ka Shing Institute of Health Sciences, The Chinese University of Hong Kong, Faculty of Medicine, Hong Kong, Hong Kong, SAR of China

Introduction: The gut-brain axis plays a pivotal role in health and disease. Previous studies have shown that sleep problems disrupt gut microbiota composition, which have been linked to inflammation, metabolic dysregulation, and cognitive impairments. However, evidence of sleep-gut microbiota relationships in community-dwelling populations is limited, with most studies relying on subjective sleep assessments and 16S sequencing microbiome analyses. This study addresses these gaps by employing both validated subjective and objective actigraphy-based sleep assessments, combined with high-resolution shotgun metagenomic profiling with the aim to investigate the associations between gut microbiota diversity and composition with sleep health.

Materials and methods: This cross-sectional study recruited participants from community in Hong Kong. A total of 645 participants (mean age: 53 ± 14 years; 64% female) provided stool samples for shotgun metagenomic profiling and completed sleep questionnaires assessing sleep related parameters including sleep-wake pattern, insomnia severity index and excessive daytime sleepiness. Actigraphy

data (Actiwatch Spectrum PRO, Philips Respironics) was available for 567 participants meeting wear-time criteria (≥ 3 valid days with $< 33.3\%$ missing data/day). Sleep parameters included total sleep time (TST), sleep onset latency (SOL), wake after sleep onset (WASO), sleep efficiency (SE) and sleep fragmentation index (SFI) were generated from actigraphy. Multivariable linear models adjusted for age, sex, BMI, education, smoking and alcohol drinking habits, chronic disease history, depression and COVID-19 infection history were used to assess associations between gut microbiota diversity and sleep parameters. Species-level associations were identified using MaAsLin2, with false discovery rate correction.

Results: Gut microbiota alpha diversity indices were significantly reduced in individual with SE $< 80\%$ (adjusted beta [95% CI]: richness: -24.76 [-39.24, -10.28], $P < 0.001$; Shannon index: -0.13 [-0.23, -0.04], $P = 0.008$). PERMANOVA tests revealed that SE and SFI significantly influenced gut microbiota composition (SE $< 80\%$: $R^2 = 0.003$, $P = 0.018$; SFI: $R^2 = 0.003$, $P = 0.031$). In contrast, subjective sleep assessments were not associated with either alpha or beta diversity of the gut microbiota. MaAsLin2 identified 13 species significantly associated with SE $< 80\%$ and SFI. For example, *Coprobacillus cateniformis* and *Clostridium scindens* were positively associated with SFI (Coef = 0.0006, $P < 0.001$, $Q = 0.192$; Coef = 0.0002, $P = 0.007$, $Q = 0.322$). *Odoribacter splanchnicus* and *Phocaeicola plebeius* were reduced in individual with SE $< 80\%$ (Coef = -0.0002, $P = 0.008$, $Q = 0.348$; Coef = -0.004, $P = 0.024$, $Q = 0.469$). Elevated *P. plebeius* abundance was associated with increased TST (Coef = 0.004, $P = 0.028$, $Q = 0.517$). Increased *C. scindens* abundance was also associated with higher WASO (Coef = 0.0001, $P = 0.004$, $Q = 0.283$).

Conclusions: Our findings demonstrate that gut microbiota diversity and specific bacterial taxa are strongly associated with actigraphy-measured sleep parameters, particularly with sleep efficiency and fragmentation, in a community-based adult population. Notably, no significant associations were observed between gut microbiota and subjectively measured sleep parameters. These results highlight the potential for microbiota-targeted interventions to improve sleep health. Future studies are needed to confirm these findings, explore underlying mechanisms, and evaluate the causality in longitudinal and interventional studies.

Associations Between Sleep Quality, Sleep Duration, and Cognitive Function Among Older Adults in India: Evidence From the WHO-SAGE Study

M. Biswas¹

¹National Institute of TB and Respiratory Diseases, Department of Pediatrics, New Delhi, India

Introduction: Sleep is fundamental to human health and well-being, significantly influencing various cognitive functions such as attention, memory, and executive functioning. This study aimed to investigate the relationship between sleep quality, sleep duration, and cognitive performance among older adults in India.

Materials and methods: The data were drawn from the second wave of the World Health Organization's Study on Global AGEing and Adult Health (WHO-SAGE), conducted in 2015 across six selected states in India, representing different regions of the country. The sample consisted of 6,396 adults aged 50 years and older. Multivariable linear regression models were employed to assess the associations between sleep quality, sleep duration, and cognitive function separately for older men and women.

Results: Older men and women who experienced poor sleep quality or short sleep duration had lower average cognitive scores compared to their counterparts with good sleep quality and adequate sleep duration. Among older men, both poor sleep (adjusted coefficient [aCoef]: -5.09, 95% CI: -8.66 to -1.51) and short sleep duration (aCoef: -5.43, 95% CI: -7.77 to -3.10) were significantly associated with poorer cognitive functioning, and these associations remained significant even after adjusting for a wide range of socio-demographic, health, and behavioral factors (poor sleep aCoef: -2.39, 95% CI: -3.78 to -1.00; short sleep duration aCoef: -4.39, 95% CI: -6.46 to -2.31). Similarly, poor sleep (aCoef: -3.15, 95% CI: -5.79 to -0.52) and short sleep duration (aCoef: -2.72, 95% CI: -4.64 to -0.81) were associated with lower cognitive functioning among older women; however, these associations were not statistically significant after adjusting for potential confounders.

Conclusions: This study highlights a significant link between sleep health and cognitive functioning among older adults in India, particularly among older men, indicating that poor sleep quality and inadequate sleep duration may negatively impact cognitive health. It is recommended that healthcare

providers regularly assess sleep quality and ensure age-appropriate sleep duration in older patients, while also incorporating sex- and gender-sensitive sleep interventions into cognitive health management strategies.

Associations between thyroid hormone regulation and sleep phenotypes

M. He¹, Q. Fei², S. Wang¹, M. Yi³, Y. Zhang¹, X. Su¹

¹Central South University, Department of Respiratory & Sleep Medicine, Xiangya Hospital, Changsha, China, ²Central South University, Xiangya School of Medicine, Changsha, China, ³Central South University, School of Life Sciences, Changsha, China

Introduction: Our study aims to assess the causal relationships between thyroid hormone regulation (including thyroid stimulating hormone (TSH), free thyroxine (FT4) levels, hypothyroidism, and hyperthyroidism) and sleep traits such as Apnea-Hypopnea Index (AHI)/Respiratory event index (REI), obstructive sleep apnea (OSA), snoring, excessive daytime sleepiness (EDS), insomnia as well as sleep duration.

Materials and methods: We obtained summary statistics from published genome-wide association studies (GWAS) on thyroid hormone regulation and sleep traits. Subsequently, we performed bidirectional Mendelian Randomization (MR) analyses to estimate the causal directions and effects between them. The inverse variance weighting (IVW) approach was used as the primary method, with multiple methods serving as alternative sensitivity analyses.

Results: We revealed that insomnia has a negative causal influence on TSH levels ($\beta = -0.192$, 95%CI = [-0.383, -0.002], $p = 0.048$). We also observed that OSA has a positive causal influence on FT4 levels ($\beta = 0.098$, 95%CI = [0.022, 0.175], $p = 0.012$). Sleep duration was found to have a negative causal effect on FT4 levels ($\beta = -0.187$, 95%CI = [-0.314, -0.060], $p = 0.004$). Conversely, TSH levels showed a positive causal impact on OSA ($\beta = 0.079$, 95%CI = [0.025, 0.132], $p = 0.004$). Further validation analyses based on heterogeneity and pleiotropy status were consistent with the causal direction of the above initial results.

Conclusions: Our results indicated suggestive causations from insomnia to TSH levels, from OSA and sleep duration to FT4 levels as well as from TSH levels to OSA, providing valuable insights into clinical strategies for regulating thyroid function and preventing sleep problems.

Associations between waking activities and sleep, morning/evening preference and perceived barriers to sleep in first-year undergraduate students

A. Willoughby¹, Y. Lepcha¹, K. Chong¹, M. Chee¹

¹National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore

Introduction: Sleep is typically studied in isolation or in relation to bedtime routines; however, research shows that how we spend our waking hours influences our sleep. This holds true for both the broad structure of daily obligations (e.g., daytime class/work schedules) and individual activities with direct effects on sleep architecture (e.g., exercise influences NREM/REM ratio). In this study, we characterize incoming university students based on daily time use data to identify common patterns of waking activities and how they affect students' sleep and what are perceived as barriers to sleep.

Materials and methods: 505 incoming National University of Singapore undergraduate students provided daily 24-hour time use data for the first two weeks of term. Latent class analysis (LCA) was used to identify days sharing similar activity profiles. Fuzzy k-means clustering was then used to group participants based on the proportion of days belonging to each activity profile. These groups were then compared on objective measures of sleep (Oura ring), the Insomnia Severity Index (ISI), morning/evening preference and perceived barriers to sleep.

Results: Eight daily activity profiles were identified by LCA, and participants were grouped into six clusters. Each cluster was characterized by a particular combination of time use profiles. There were three Study clusters, comprising students who had a greater proportion of activity profiles involving studying. There was one Digital Leisure cluster, including students who engaged in more late-night digital leisure activities; and two hybrid Social clusters (Social and Digital Leisure, and Social and Co-Curricular Activities).

Objective sleep measures indicated earlier sleep timing and longer sleep duration for students in the Study clusters than the other clusters (mean Study bedtimes: 00:32, 01:03, 00:55; mean non-Study bedtimes: 02:49, 02:23, 01:59; mean Study sleep duration (hrs): 6:39, 6:26, 6:44; mean non-Study sleep duration (hrs): 6:14, 6:28, 6:10). ISI scores for the Study clusters were lower than those for the other groups, indicating fewer insomnia symptoms. Both the Digital Leisure and the Social and Digital Leisure groups, which displayed the latest sleep timing, reported a stronger evening preference.

The Digital Leisure and hybrid Social groups reported social activities and digital entertainment as more significant barriers to sleep than the Study groups. Study load and academic worries were rated similarly across most groups, although the Afternoon Study group perceived them as higher barriers.

Conclusions: In this study, we reveal underlying patterns of daily time use exhibited by incoming university students, and how they co-occur within individuals. Students who showed different combinations of daily time use profiles also showed different sleep patterns, morning/evening preference and perceived barriers to sleep. These results illustrate how waking activities influence sleep in concert with intrinsic sleep regulation mechanisms.

Associations Between Weather Variables and Sleep Architecture: A Large-Scale Analysis Using Consumer Sleep Data

M. Lee¹, H. Hong², S. Kim², E. Cho², D. Lee², J. Hong², D. Yoon², K.-Y. Jung³, J.H. Lee⁴, I.-Y. Yoon⁵

¹Soonchunhyang University Seoul Hospital, Department of Psychiatry, Seoul, Korea, Republic of, ²Asleep Inc., Seoul, Korea, Republic of, ³Seoul National University College of Medicine, Seoul National University Hospital, Department of Neurology, Seoul, Korea, Republic of, ⁴Dream Sleep Clinic, Seoul, Korea, Republic of, ⁵Seoul National University College of Medicine, Seoul National University Bundang Hospital, Department of Psychiatry, Seongnam, Korea, Republic of

Introduction: Environmental conditions such as temperature, humidity, and sunlight exposure have been shown to influence sleep, yet large-scale studies linking objective sleep data with weather patterns remain limited. This study aimed to examine the effects of daily weather variables on sleep architecture and assess how these associations vary depending on the severity of suspected sleep-disordered breathing.

Materials and methods: Sleep data were collected from 1,067 users in South Korea who used the SleepRoutine mobile application at least once monthly between December 1, 2023, and November 30, 2024. After applying exclusion criteria based on extreme or implausible values, 236,115 nights of data were included. Weather variables included daily mean temperature, humidity, and sunshine duration in Seoul, Korea.

Results: A total of 1,067 individuals used the app at least once per month, and 236,115 nights were included in the analysis. Higher temperature was significantly associated with reduced sleep efficiency (SE), total sleep time (TST), and deep sleep ratio (SE: $\beta = -0.041$, $p < 0.001$; TST: $\beta = -0.274$, $p < 0.001$; Deep: $\beta = -0.035$, $p < 0.001$), and with increased sleep latency (SL), wake after sleep onset (WASO) and light sleep ratio (SL: $\beta = 0.022$, $p = 0.008$; WASO: $\beta = 0.123$, $p < 0.001$; Light: $\beta = 0.008$, $p = 0.031$). Increased humidity was associated to decreased SE and light sleep ratio (SE: $\beta = -0.009$, $p < 0.001$; Light: $\beta = -0.006$, $p = 0.004$), and prolonged SL and WASO (SL: $\beta = 0.011$, $p = 0.018$; WASO: $\beta = 0.023$, $p = 0.002$). Longer sunshine duration was associated with decreased light sleep ratio ($\beta = -0.021$, $p = 0.001$) but increased TST and REM sleep ratio (TST: $\beta = 0.156$, $p < 0.001$; REM: $\beta = 0.020$, $p < 0.001$). Seasonal comparisons showed that summer was associated with poorer sleep quality than spring, while autumn and winter exhibited mixed effects on sleep parameters. Notably, interactions between weather variables and Apnea-Hypopnea Index (AHI) groups revealed that temperature and sunshine duration had differential effects on SE, SL, and WASO depending on AHI severity. Significant seasonal interactions with AHI group were also found sleep stages.

Conclusions: Daily weather conditions, particularly temperature, humidity, and sunshine duration, exert significant influence on sleep structure. These effects may be less pronounced in individuals with sleep-disordered breathing.

Associations of Lifestyle Habits with Sleep Quality

X. Fu^{1,2}, X. Liu³, X. Gao^{1,2,4}, Z. Huang^{4,5}

¹Peking University School and Hospital of Stomatology, Department of Orthodontics, Beijing, China, ²Peking University School and Hospital of Stomatology, Oral Center of Sleep Disordered Breathing, Beijing, China, ³HUAWEI Health Lab, Shenzhen, China, ⁴Chinese Sleep Research Society, Beijing, China, ⁵School of Basic Medical Sciences; State Key Laboratory of Medical Neurobiology and MOE Frontiers Centre for Brain Science, Institutes of Brain Science, Joint International Research Laboratory of Sleep, Shanghai Medical College, Fudan University, Shanghai, China

Introduction: Sleep is a fundamental biological process crucial for overall health and well-being. However, poor sleep quality is a widespread public health concern. Numerous factors are believed to influence sleep, with lifestyle habits playing a prominent role. While these associations are often discussed, a comprehensive understanding of their independent contributions to sleep quality remains essential for developing effective public health strategies. Therefore, this study aimed to investigate the relationship between these multiple lifestyle habits—smoking, alcohol consumption, daily mobile phone use duration, eating before bed, and caffeine intake—and sleep quality.

Materials and methods: Demographic information and lifestyle habit data were collected using questionnaires. Sleep quality was assessed with the Pittsburgh Sleep Quality Index (PSQI), where a total PSQI score greater than 5 was defined as poor sleep quality. We used a multivariate logistic regression model, adjusting for covariates such as demographic factors (e.g., body mass index (BMI), age, gender, marital status, education level, occupation type, region, area type, number of bed partners, income level) and the lifestyle habits under investigation (smoking, alcohol consumption, daily mobile phone use, eating before bed, caffeine intake). Data analysis was conducted using R statistical software (version 4.4.2), with statistical significance set at $P < 0.05$.

Results: From 19,680 collected data, 13,407 complete questionnaires were included after data cleaning. Drinking alcohol before bed was significantly associated with poorer sleep quality. Compared to non-drinkers, individuals who consumed alcohol before bed had an odds ratio (OR) of 2.100 (95% Confidence Interval [CI]: 1.277-3.700) for poor sleep quality. Compared to non-smokers, daily smokers had an OR of 1.521 (95% CI: 1.353-1.712) for poor sleep quality. Smoking fewer than 5 cigarettes daily showed no significant difference from non-smokers, but sleep quality significantly declined for those smoking 5 or more cigarettes daily. Individuals smoking more than 20 cigarettes daily had an OR of 1.793 (95% CI: 1.415-2.295). Compared to using a phone for less than 2 hours daily, the ORs for poor sleep quality were 1.225 (95% CI: 1.019-1.470) for 2-5 hours, 1.472 (95% CI: 1.219-1.776) for 5-8 hours, and 1.860 (95% CI: 1.521-2.263) for more than 8 hours of use. Compared to those who never ate before bed, the ORs for poor sleep quality were 1.417 (95% CI: 1.264-1.588) for occasional eaters, 2.023 (95% CI: 1.750-2.339) for sometimes eaters, and 2.270 (95% CI: 1.921-2.688) for frequent eaters before bed. Compared to those who never consumed caffeine, the ORs for poor sleep quality were 1.223 (95% CI: 1.112-1.345) for consuming caffeine less than 3 times per week, 1.383 (95% CI: 1.212-1.579) for 3-7 times per week, and 1.459 (95% CI: 1.239-1.721) for more than 7 times per week.

Conclusions: Drinking alcohol before bed, smoking, prolonged mobile phone use, eating before bed, and high-frequency caffeine intake are all significantly associated with poorer sleep quality. These findings underscore the importance of modifying these lifestyle habits to improve sleep health and provide a scientific basis for developing targeted health interventions.

Associations of microarousals-related ventricular repolarization lability during sleep with long-term cardiovascular disease and mortality

S. Ai¹, G. Li², F. Yu³, K. Stone⁴, Y.-K. Wing⁵, J. Zhang¹

¹The Affiliated Brain Hospital, Guangzhou Medical University, Center for Sleep and Circadian Medicine, Guangzhou, China, ²The Affiliated Brain Hospital, Guangzhou Medical University, Guangzhou, China, ³The First Affiliated Hospital of Xinxiang Medical University, Department of Cardiology, Heart Center, Weihui, China, ⁴University of California-San Francisco, Department of Epidemiology and Biostatistics, San Francisco, Armenia, ⁵The Chinese University of Hong Kong, Li Chiu Kong Family Sleep Assessment Unit, Department of Psychiatry, Faculty of Medicine, Hong Kong, China

Introduction: Sleep plays a critical role in regulating autonomic nervous system activity. Even brief arousals during sleep can significantly impact cardiac autonomic modulation, as reflected in changes of heart rate variability (HRV) after arousals. Microarousals (MAs) are defined as brief (3- to 15-s-long) wake intrusions during sleep, which are clinical markers for various sleep disorders. Previous studies have established a link between MAs and the incidence of cardiovascular diseases (CVD), but the underlying mechanisms remain unclear. Cardiac ventricular repolarization lability is a measure of the instability in the ventricular repolarization process, which can be quantified using various ECG-based metrics and is clinically significant for assessing CVD risk. However, whether MAs-associated changes in ventricular repolarization lability are associated with the risks of CVD and mortality remains unclear. We hypothesize that MAs-related cardiac ventricular repolarization lability could predict long-term CVD risk and mortality.

Materials and methods: We analyzed overnight polysomnography (PSG) data from two large independent cohorts, the Sleep Heart Health Study (SHHS) and Osteoporotic Fractures in Men (MrOS), comprising a total of 8,702 participants. A deep learning algorithm was developed to accurately detect the MAs for each subject. Cardiac ventricular repolarization lability was assessed by the short-term variability of the QT interval (STVQT) before and after these MAs. The importance of STVQT in predicting CVD risk was evaluated by the Cox regression model and the Shapley Additive Explanations (SHAP) method.

Results: During 11.0 ± 2.8 years of follow-up in SHHS, 729 participants had incident CVD and 192 participants died due to CVD. During 15.5 ± 4.4 years of follow-up in MrOS, 427 participants had incident CVD, and 391 died due to CVD. In multivariable Cox regression models, elevated STVQT during MAs was associated with an increased risk of chronic heart failure (SHHS: hazard ratios [HR]: 1.34; 95% confidence interval [CI]: 1.02 - 1.75; $p = 0.034$; MrOS: HR: 1.89; 95% CI: 1.15 - 3.10; $p = 0.012$), CVD (SHHS: HR: 1.33; 95% CI: 1.10 - 1.62; $p = 0.003$; MrOS: HR: 1.45; 95% CI: 1.14 - 1.86, $p = 0.003$), and CVD mortality (SHHS: HR: 1.67; 95% CI: 1.21 - 2.31; $p = 0.002$; MrOS: HR: 1.50; 95% CI: 1.13 - 1.98; $p = 0.005$) after adjusting for covariates. Additionally, SHAP_Values indicated that MAs-related STVQT was a more important predictor of CVD risk compared to conventional HRV metrics.

Conclusions: Our results suggest that MAs-related ventricular repolarization lability may be a useful metric to identify those at increased risk for CVD and CVD mortality.

Associations of Pre-Sleep Arousal and Dysfunctional Sleep Belief with Depression in Youths with Eveningness

D.D. Liao¹, J.A.H. Man¹, F.Y. Jin¹, F.T.W. Cheung^{1,2}, Y. Pan¹, H.F. Sit¹, J.W.-Y. Chan³, N.Y. Chan³, Y.-K. Wing^{3,4}, S.X. Li¹

¹Sleep Research Clinic & Laboratory, Department of Psychology, The University of Hong Kong, Hong Kong SAR, China, ²Nuffield Department of Clinical Neurosciences and Sir Jules Thorn Sleep & Circadian Neuroscience Institute, University of Oxford, Oxford, United Kingdom, ³Li Chiu Kong Family Sleep Assessment Unit, Department of Psychiatry, Faculty of Medicine, The Chinese University of Hong Kong, Hong Kong SAR, China, ⁴Li Ka Shing Institute of Health Sciences, Faculty of Medicine, The Chinese University of Hong Kong, Shatin, Hong Kong SAR, China

Introduction: Youths with eveningness are vulnerable to developing sleep disturbances and mood related psychopathology. Psychological and arousal related factors may contribute to both insomnia and depression. Although previous research has investigated the association between insomnia, chronotype and depression, there has been limited research to explore insomnia-related cognitive and physiological factors specifically in youths with eveningness, especially in the context of depression.

Materials and methods: A total of 112 youths with eveningness (mean age = 18.3 ± 1.7 ; 69.6% female), as defined by a Morningness-Eveningness Questionnaire (MEQ) score of ≤ 41 , were recruited. Participants were classified into depressed (DA group: $n = 59$, mean age = 18.2 ± 1.8 , 76.3% female) and non-depressed groups (Control group: $n = 53$, mean age = 18.5 ± 1.7 , 62.3% female), based on the presence of depressive disorders by DSM-IV criteria as confirmed by the Mini International Neuropsychiatric Interview for Children and Adolescents (MINI-KID) psychiatric interview. Insomnia

severity (Insomnia Severity Index, ISI), dysfunctional sleep beliefs (Dysfunctional Beliefs and Attitudes about Sleep Scale, DBAS-16), and pre-sleep arousal (Pre-Sleep Arousal Scale, PSAS) were assessed.

Results: Depressed participants, as compared to non-depressed participants reported significantly higher levels of insomnia severity (ISI: DA:15.0 vs. Control:1.76, $t = 22.90$, $p < .001$), more dysfunctional sleep beliefs (DBAS: DA 97.2 vs. Control 71.5, $t = 4.36$, $p < .001$), and heightened pre-sleep arousal (PSAS: DA 40.0 vs. Control 30.2, $t = -4.14$, $p < .001$). Linear regression analysis demonstrated that depression was significantly associated with more severe insomnia (ISI: $\beta = 0.77$, $p < .001$), and elevated pre-sleep arousal (PSAS-C: $\beta = 0.24$, $p = 0.02$), after controlling for education level.

Conclusions: These findings highlight a significant association between depression and insomnia among youths with eveningness. In addition, pre-sleep cognitive arousal was elevated in depressed adolescents with eveningness. The findings underscore the importance in attending to insomnia-related factors in assessing depression in adolescents with eveningness. Interventions that address cognitive hyperarousal, alongside mood symptoms may be needed for this vulnerable group.

Associations of sleep characteristics with all-cause, cardiovascular, and non-cardiovascular mortality among rural Chinese older adults: A cohort study

S. Tang¹, J. Lu¹, Y. Du¹, C. Qiu²

¹Shandong Provincial Hospital affiliated to Shandong First Medical University, Neurology, Jinan, China,

²Karolinska Institutet-Stockholm University, Aging Research Center, Department of Neurobiology, Care Science and Society, Stockholm, Sweden

Introduction: The longitudinal associations of sleep timing and time in bed (TIB) with all-cause, cardiovascular, and non-cardiovascular mortality are unclear in Chinese rural populations.

Materials and methods: This population-based cohort study included 2468 participants who were aged ≥ 60 years and residing in rural communities in western Shandong Province. Sleep timing and TIB were assessed using standard questionnaires at baseline in 2014. Mid-sleep time was defined as the halfway point between the bedtime and wake-up time. Vital status until December 2022 and causes of death for all participants were ascertained via death registry plus interviews with informants. Data were analyzed using restricted cubic splines (RCS) and Cox proportional-hazards models.

Results: During the mean follow-up of 7.36 (SD=2.03) years, 657 participants died. The RCS analysis showed non-linear relationships of sleep duration and mid-sleep time at baseline with all-cause and non-cardiovascular mortality. Specifically, when baseline sleep characteristics were categorized into tertiles, the multivariable-adjusted hazard ratio (HR) for all-cause mortality were higher for long sleep duration (>8 vs. 7-8 hours; HR=1.27; 95% CI=1.06-1.53), long TIB (>9 vs. <8 h hours; 1.63; 1.27-2.08), early bedtime (before 9 p.m. vs. 10 p.m. or later; 1.58; 1.00-2.49), and early mid-sleep time (before 1 a.m. vs. 1 a.m.-1.5 a.m.; 1.45; 1.20-1.76). Long TIB was associated with multivariable-adjusted HR of 1.61 (1.15-2.27) for cardiovascular mortality and 1.64 (1.09-2.47) for non-cardiovascular mortality.

Conclusions: Long sleep duration and early sleep timing may be associated with increased risk of all-cause and cardiovascular mortality in rural Chinese older adults. In addition, long TIB was also linked to increased risk of all-cause, cardiovascular, and non-cardiovascular mortality.

Balancing sleep, work, and care: A comparative study of factors associated with wellbeing of caregivers in Japan and New Zealand

R. Gibson¹, S. Koreshi¹, M. Furutani²

¹Massey University, School of Psychology, Palmerston North, New Zealand, ²Kobe University, Graduate School of Human Development and Environment, Kobe, Japan

Introduction: Caregivers provide support to people (often family members) with a variety of health needs. Sleep problems can be common due to awakenings of the care recipient, providing 'around the clock' care, and mood disturbances. Circumstances highlighted as particularly challenging include those when the care recipient has complex needs as well as situations when the caregiver is under-supported

or over-committed, such as reconciling work with care responsibilities. However, factors related to sleep as well as work and caregiving also vary cross-culturally. This research aims to better understand and represent such variations between New Zealand (NZ) and Japanese (JPN) contexts.

Materials and methods: Self-reported sleep duration (per 24-hours) and satisfaction (on a 5-point Likert scale) as well as self-reported fatigue or exhaustion and symptoms of depression (CES-D10) were explored amongst older (≥ 50 years) caregivers who were also working in NZ and JPN. Data included a stratified sample from the NZ Health Work and Retirement (HWR) cohort and a Japanese online survey (including relevant matched and translated items from the HWR study). Binary logistic regression analyses were used to explore the relationship between sleep (amongst demographic, caregiving, and health factors) with likelihood of depression and fatigue/ exhaustion between cultures.

Results: The NZ sample (N=517, 68% female) reported spending a median 38 hours per week working and 8 hours caregiving. They had a median sleep duration of 7 hours and 32% reported being dissatisfied or very dissatisfied with their sleep. The JPN sample (N=590, 51% female) reported spending a median 35 hours per week working and 10 hours caregiving. They had a median sleep duration 6 hours and 60% reported being dissatisfied or very dissatisfied with their sleep. Scores on the CES-D10 revealed that 25% of the NZ sample and 62% of the JPN sample were within range for high depressive symptoms. Furthermore, 25% of the NZ sample and 74% of the JPN sample reported experiencing severe fatigue or exhaustion. Sleep dissatisfaction was independently related to depression for both the NZ (OR 0.51, 95%CI 0.41-0.64) and JPN samples (OR 0.54, 95%CI 0.44-0.66) alongside increased job stress (NZ) and negative carer affect (JPN) as well as lower exercise (both). Sleep dissatisfaction was independently related to severe fatigue/exhaustion for both the NZ (OR 0.63, 95%CI 0.51-0.78) and JPN samples (OR 0.56, 95%CI 0.45-0.69) alongside increased negative carer affect (JPN) as well as younger age, lower income, and lower exercise (both).

Conclusions: These analyses illustrate the differing contexts and wellbeing of older working carers in NZ and JPN. Sleep dissatisfaction was a key independent predictor of depression and fatigue or exhaustion across both contexts. With stress related to work and caregiving also being significant for NZ and JPN samples respectively. Together, this demonstrates the cross-cultural needs of older adults' balancing paid employment and family care. Strategies to support sleep and wellbeing require unique context-dependent considerations.

Acknowledgments: We would like to acknowledge the Health and Ageing Research Team for sharing their guidance. Also - Professor Narihiko Kondo and the International Collaborative Researcher Training Program of Kobe University for supporting this collaboration.

Barriers to Sleep Apnea Diagnosis and Treatment in Shelter Settings: A Qualitative Study of Experiences and Compassionate Care Pathways

P. McLaurin¹, M. Campos-Navarrete¹, A. Yadollahi¹, V. Rac², R. Adams³, O. Sparks³

¹University Health Network, KITE, Toronto, Canada, ²University of Toronto, Toronto, Canada,

³University Health Network, Toronto, Canada

Introduction: Sleep apnea is a prevalent but underdiagnosed condition among individuals experiencing homelessness (IEH), significantly impacting their physical and mental health. In Ontario, Canada, access to diagnosis and treatment for obstructive sleep apnea (OSA) is hindered by rigid healthcare policies and systemic barriers, particularly affecting shelter residents. Despite assumptions of disinterest or non-adherence, prior pilot data suggested strong engagement with OSA care when services are contextually adapted. This study explores individual and systemic barriers to sleep apnea diagnosis and treatment in shelters, identifying critical themes for more equitable and compassionate care.

Materials and methods: A grounded theory methodology guided this qualitative study, integrating trauma-informed and equity-oriented frameworks. Semi-structured interviews were conducted with 20 shelter residents and 5 shelter staff across three Toronto shelter sites between January 2024 and February 2025. Participants were recruited through onsite information sessions and interviewed in private or semi-private settings. Interviews explored barriers to OSA engagement, diagnosis, and treatment, as well as experiences with compassionate care. Transcripts were coded iteratively using Excel-based thematic analysis and constant comparison. Themes were organized across three analytical levels (Engagement, Diagnosis, and Treatment) reflecting the continuum of care and systemic influence.

Results: Across all stages, participants identified profound material, psychological, and institutional barriers. At the Engagement level, barriers included lack of awareness of OSA, mistrust in health

systems, and diminished motivation due to trauma and survival priorities. At the Diagnosis level, logistical obstacles (e.g., lack of transportation, absence of primary care), fear of institutional settings, and cultural and communication mismatches obstructed access. At the Treatment level, standard therapies such as CPAP and oral appliances were often impractical due to shelter conditions, lack of infrastructure, and unmet dental or mental health needs. The misalignment between clinical expectations and shelter realities consistently limited adherence. Across all levels, compassionate care, defined as dignity-based, empathetic, and context-responsive support, emerged as a foundational condition for participation. Residents emphasized that being treated without judgment, with trust and flexibility, was essential to engage with and sustain care.

Conclusions: This study demonstrates that individuals experiencing homelessness are not inherently disinterested in managing sleep apnea but face complex, intersecting barriers at each stage of care. Compassionate care, operationalized through trauma-informed communication, flexible delivery models, and cultural safety, is essential for building trust and fostering health equity. Current diagnostic and treatment pathways are largely misaligned with shelter environments and must be reimaged to account for instability, stigma, and survival pressures. The findings call for co-designed, low-barrier, and system-integrated interventions that prioritize relational engagement and contextual fit. To reduce sleep health disparities in shelter populations, structural reforms in policy, infrastructure, and service design are urgently needed. This research offers actionable insights to inform policy, clinical practice, and future community-based sleep health interventions.

Bedtime at Midnight: Actigraphy-Measured Sleep Dimensions and Socioeconomic Predictors among Toddlers in Dhaka, Bangladesh

A. Sania¹, S. Ameen², T.K. Ayrin², R. Tanzin², L. Chen¹, C. Malette³, S.P. Sarker², R.M. Akhter², N. Pini¹, S. Lee¹, F. Tofail², W.P. Fifer¹, S.E. Arifeen²

¹Columbia University Irving Medical Center, Psychiatry, New York, United States, ²icddr,b (International Centre for Diarrhoeal Disease Research, Bangladesh), Dhaka, Bangladesh, ³New York State Psychiatric Institute, New York, United States

Introduction: Healthy sleep in early childhood supports healthy neurodevelopment and growth, and protects against obesity. Data on children's sleep health and the guidelines that flow from it originate in high-income countries, which may not be relevant to conditions in low- and middle-income settings. Recently, the WHO released 24-hour movement guidelines (sleep, physical activity, and screen time) for children under five, but objective sleep data from LMICs remain sparse. To fill this gap, we measured sleep health dimensions and their predictors among toddlers in Dhaka, Bangladesh, a rapidly urbanizing lower-middle-income context now facing persistent stunting and emerging childhood obesity.

Materials and methods: Data for the present analysis came from 140 healthy toddlers (21 ± 3.65 months) recruited in a prospective cohort study from diverse neighborhoods of Dhaka city. We measured objective sleep using wrist actigraphy. Children wore a Philips Actiwatch 2 for a median of 6 days (interquartile range 5-7). Parent-reported sleep was collected using the Brief Infant Sleep Questionnaire–Short Form (BISQ-SF). Data on socioeconomic predictors, maternal depression, and parenting stress were collected using a study-specific questionnaire, the Edinburgh Postnatal Depression Scale, and the Parenting Stress Index-SF, respectively. Actigraphy data were processed in Philips Actiware and manually rescored to derive sleep dimensions. We used multiple linear regression models to examine socioeconomic and psychosocial predictors of sleep, adjusting for toddler age and sex.

Results: Mean bedtime was 11:50 pm (Standard Deviation, SD 1.2 hours). Nighttime sleep averaged 9.5 hours (SD 1.2), daytime sleep 2.0 hours (SD 0.54), yielding 24-h total sleep of 11.6 hours (SD 0.9). 21.4% of toddlers slept less than 11 hours, below WHO guidelines (11-14 hours) for this age group. Night-to-night variability was high, with an SD of bedtime of 0.8 hours and an SD of night sleep duration of 1.1 hours. Toddler bedtime shifted later with rising household income (p-trend < 0.05). Compared to a household income of 40000 taka/ month, children in 100000-taka and 200000-taka households went to bed 77 (95 % Confidence Interval, CI: 7.5, 126) and 123 (CI: 8.8, 238) minutes later, respectively. Compared to children of fathers with less than 10th grade education, children with fathers with higher-secondary (HSC) and professional (MD/engineer) education were associated with 90 (CI: 24,155) and 77 (CI: 11, 144) minutes longer nighttime sleep. Toddlers of fathers with flexible

work schedules went to bed an hour earlier ($p=0.03$) than those of fathers with fixed schedules. Toddlers in nuclear families slept 38 minutes ($p=0.04$) longer at night and napped 20 minutes ($p=0.08$) less than toddlers in joint families. Maternal education and maternal depression were not significantly associated with toddler sleep dimensions.

Conclusions: Toddlers in Dhaka go to bed late, display considerable night-to-night variability, and nearly one-fifth fail to meet WHO sleep recommendations. Later bedtimes and shorter nighttime sleep were linked with higher household income, joint living arrangements, lower paternal education, patterns that differ from high-income countries, and highlight context-specific predictors. Qualitative studies are needed to understand cultural practices (e.g., late meals, co-sleeping) mediating these associations to inform sleep-promotion strategies suitable for a densely populated South-Asian context.

Bedtime Stories: Sleep Health Education for Pediatric Providers in Community-Based Healthcare Centers

J. Page¹, G. Wang¹, P. Snider Ziporyn², I. Isong¹, M. Ordway³, R. Robbins⁴, J. Owens¹

¹Boston Children's Hospital, Boston, United States, ²University of Vermont, Burlington, United States, ³Yale University, New Haven, United States, ⁴Brigham and Women's Hospital, Boston, United States

Introduction: Pediatric providers are often the first line of defense in promoting healthy sleep practices. However, many receive limited training on implementing foundational sleep health practices. Moreover, anticipatory guidance on sleep for school-aged children remains sparse, potentially contributing to sleep health inequities in communities disproportionately affected by poor sleep. This study aimed to develop and evaluate a sleep health education course for pediatric providers by examining changes in their knowledge and clinical practices.

Materials and methods: Pediatric providers, residents, and nurse practitioners were recruited from two hospital-affiliated centers in Boston. Participants received a personalized link to enroll in the self-paced online course which included six required modules (Basics of Sleep, Sleep and Development, Sleep Health, Consequences of Insufficient Sleep, Sleep Health Disparities, Screening and Referral) and one optional module (Melatonin). All participants completed a course evaluation, a retrospective pretest-posttest survey examining knowledge and intent to change practice by indicating their level of agreement with each statement before and after the course using a five-point Likert scale (1-strongly disagree; 5-strongly agree). Participants received continuing medical education credit and a gift card.

Results: Data collected (December 2024 to May 2025) include 34 consented participants, of which: 11 are in-progress, 1 has not started, and 22 have completed the course. Course completers (18 MDs, 4 nurse practitioners) were on average 35.9 years of age (range= 26-34 years), primarily female (90.9%), majority white (79%) non-Hispanic (90%) with an average of 8.6 years (range= 0.5 – 30 years) of experience. An overwhelming majority (14, 88%) said this course changed their practice. Topics providers rated most highly were basics of sleep and sleep and development. Aspects of the program that learners rated most helpful were text, clinical pearls, and videos. The majority (81.3%) either agreed or strongly agreed that the program was relevant to their practice and found the program interesting and easy to complete. The retrospective pre-test indicators revealed that participants experienced a positive change in knowledge with the overall mean for the six knowledge areas increased from 2.8 (before) to 4.1 (after) ($p<0.001$). The Kruskal-Wallis test results indicate no statistically significant differences between groups based on healthcare profession (all p -values > 0.05).

Conclusions: The results suggest that knowledge among pediatric professionals could be improved through a short educational course. This improvement not only highlights the course's effectiveness but also suggests that similar educational interventions could play a crucial role in enhancing pediatric sleep practices on a wider scale. Through pilot data from this study, we will use the feedback we collect to improve the program. We also hope to assess the efficacy of the program in a large, multiple arm trial with other pediatric professionals.

Acknowledgments: Allan and Gill Gray Foundation

Bedtime Stress and Prefrontal Cortex Hemodynamics During Sleep: A Pilot Study Using Wearable fNIRS and Salivary Biomarkers

Z. Liang^{1,2}

¹Kyoto University of Advanced Science (KUAS), Faculty of Engineering, Kyoto, Japan, ²The University of Tokyo, Institute of Industrial Science (IIS), Tokyo, Japan

Introduction: Psychological stress is a well-known disruptor of sleep quality, yet little is known about how stress modulates brain activity during sleep. While neuroimaging studies have advanced our understanding of stress responses during wakefulness, technical and methodological barriers have hindered investigation of stress-related neural dynamics during sleep. This pilot study aimed to explore whether bedtime stress is reflected in cortical hemodynamics during the first sleep cycle. We further examined which signal features and prefrontal subregions are most sensitive to stress indicators.

Materials and methods: A longitudinal N-of-1 design was conducted with a healthy adult male over 15 consecutive nights. Stress was assessed using three complementary indicators: salivary cortisol (mean = 3.4 nmol/L), secretory immunoglobulin A (sIgA; mean = 295.3 µg/mL), and subjective perceived stress scores (range 2–8; mean = 4). Sleep-related hemodynamics were recorded using a wireless, wearable 27-channel functional near-infrared spectroscopy (fNIRS) system (Brite 24) targeting the prefrontal cortex. Supplementary physiological data (heart rate, respiratory rate, and sleep timing) were collected using Fitbit Sense. fNIRS signals were preprocessed to remove physiological artifacts, and time-, frequency-, and nonlinear-domain features were extracted from both oxyhemoglobin (ΔO_2Hb) and deoxyhemoglobin (ΔHHb) signals. An ensemble feature-ranking algorithm, integrating six machine learning and statistical methods, was used to identify stress-related signal features and channels.

Results: Cortisol was most strongly associated with time-domain features—particularly signal mean at channel 16 (left rostral lateral prefrontal cortex, RLPFC)—with correlation coefficients reaching $|r| = 0.74$. Sample entropy of ΔHHb at channel 26 also showed strong negative associations ($r = -0.70$). sIgA was moderately associated with Hurst exponent and Poincaré plot asymmetry at channels 21 and 26 ($r = 0.53$ – 0.61). Perceived stress showed robust correlations with nonlinear features such as crest factor (ΔHHb , channel 16; $r = 0.68$) and skewness (ΔO_2Hb , channel 16; $r = -0.65$). While each indicator related to distinct feature sets, channel 16 emerged as a common site associated with all three stress measures. Additional associations were observed in the mid- and caudal dorsolateral prefrontal cortex (channels 3 and 20). The ventrolateral PFC showed no significant relationships with any stress markers.

Conclusions: This study introduces a novel, ecologically valid framework for assessing how stress manifests in the sleeping brain. Our findings highlight the relevance of the RLPFC and DLPFC in processing stress during early sleep, extending known wake-state functions of these regions into the nocturnal domain. The integration of wearable fNIRS, real-world biomarker tracking, and personalized analysis (via an N-of-1 design) provides a powerful methodology for sleep neuroscience. These results lay the groundwork for future multi-night, multi-participant studies and demonstrate the potential for next-generation stress monitoring and personalized sleep medicine. As stress increasingly contributes to sleep disorders, tools that noninvasively reveal how the brain processes stress during sleep could support earlier interventions, self-tracking, and more precise behavioral and clinical guidance.

Beyond Manual Scoring: What an EEG-based Sleep Staging Model Learns Compared to AASM Guidelines

P. Gräve¹, P. Zschke¹, T.F. Steinbrinker¹, F. Ehrlich², P. Hempel¹, N. Spicher³, D. Krefting¹

¹University Medical Center Göttingen, Department of Medical Informatics, Göttingen, Germany,

²University Hospital Carl Gustav Carus, Technical University of Dresden, Department of Medical Informatics, Dresden, Germany, ³Technical University of Denmark, Department of Health Technology, Kongens Lyngby, Denmark

Introduction: Deep neural networks (DNNs) have demonstrated high accuracy in automatic sleep staging. However, their decision processes—particularly regarding spectral information—remain poorly understood, which represents a barrier to clinical application. Post hoc explainable AI (XAI) methods can help address this gap by providing insights into the “importance” of specific input segments for a DNN’s decision. However, for time series data, most of these methods operate in the time domain and do not provide information regarding the frequency domain. To overcome this limitation, we extended the established XAI method Integrated Gradients (IG) to enable attribution scoring in the frequency

domain. This allows for the direct identification of spectral EEG features relevant to a DNN's prediction.

Materials and methods: An adapted dense recurrent convolutional neural network (DRCNN) was trained to predict all five AASM sleep stages (Wake, N1, N2, N3, R) from single-channel EEG. The architecture combines dense convolutional feature extraction and a bidirectional LSTM, followed by a softmax output layer. For model development, 4055 randomly selected C3/A2 and C4/A1 EEG recordings from the Sleep Heart Health Study (SHHS) were assigned to the training set, with 20% of these used for validation. An additional 1738 recordings were reserved for testing. All EEG signals were preprocessed by resampling to 100 Hz, amplitude and root mean square normalization, and moving average filtering. The trained model was then used for XAI analysis. We implemented a dedicated frequency processing layer consisting of a Real Fast Fourier Transform (RFFT) on the 30-second EEG segment, followed by an inverse RFFT prepended to the trained DNN. IG was applied to compute frequency-domain attribution scores for 339 EEG recordings, restricted to correctly classified (true positive) samples for all AASM-defined sleep stages. Attribution scores were then averaged across all recordings, yielding stage-wise frequency-domain attribution profiles.

Results: In N3 sleep, a pronounced attribution score peak of 0.0019 at 2 Hz was observed, vastly exceeding all other peaks across sleep stages (all others ≤ 0.0005). N2 was mainly characterized by a negative attribution peak of 0.0005 at 2 Hz. In N1, positive and negative attribution peaks with absolute values ≤ 0.0003 were found between 1.5 and 8 Hz. Across all stages, delta and theta bands (0.5 – 8 Hz) consistently exhibited greater relevance than higher frequency ranges. Additionally, small attribution peaks (≤ 0.0002) were detected around 38 Hz in N1 and wake stages.

Conclusions: Averaged results demonstrate that the frequency-domain XAI method reliably identified established sleep EEG markers, such as low delta activity in N3 and theta band relevance in N1, supporting the physiological validity of the decisions of this particular DNN. The observed peak around 38 Hz in wake and N1 may indicate either noise artifacts or previously unrecognized features. This novel XAI approach enhances the interpretability of DNN-based sleep staging models and may facilitate their integration into clinical workflows.

Acknowledgments: This work was supported by the German Federal Ministry for Research, Technology and Space (BMFTR; 01ZZ2324A, Somnolink). We thank the SHHS for providing access to the EEG datasets.

Bi-directional associations between physical activity and sleep in school-age children: differences across times of day

J.X.T. Seah¹, J.C.-Y. Lo¹

¹National University of Singapore / Yong Loo Lin School of Medicine, Centre for Sleep and Cognition & Human Potential Translational Research Programme, Singapore, Singapore

Introduction: Adequate sleep and physical activity, essential to children's development, have a bidirectional relationship. However, most prior research only considered total daily activity and overlooked the potential contribution of the timing and intensity of physical activity to sleep and the impact of sleep on physical activity at different times of day. In adults, exercise timing has shown mixed effects on sleep, and similar investigations in children are limited. Also, structured school schedules may shape weekday-weekend differences in sleep-activity patterns in children. This study examined (1) weekday-weekend differences in sleep and physical activity, and (2) the bidirectional associations between sleep and physical activity at different times of day, stratified by intensity, in school-age children.

Materials and methods: Wrist-worn accelerometers and sleep diaries measured sleep and physical activity in 129 school-age children (mean age $\pm$ SD = 9.65 $\pm$ 1.37 years; 64 boys) over at least 7 days during the school term. Sleep metrics—time in bed (TIB), total sleep time (TST), sleep onset latency (SOL), wake after sleep onset (WASO), and sleep efficiency—were derived alongside physical activity duration (sedentary behaviour [SED], light physical activity [LPA], and moderate-to-vigorous physical activity [MVPA]). Activity was quantified for early morning (wake–08:59), late morning (09:00–11:59), early afternoon (12:00–14:59), late afternoon (15:00–17:59), early evening (18:00–20:59) and evening (21:00–sleep onset). Paired-samples t tests were used to examine weekday-weekend differences.

Generalised linear mixed models were used to investigate the bidirectional associations between physical activity and sleep, adjusting for age and sex.

Results: Compared to weekdays, children had longer TIB (mean $\pm$ SD: 36.45 $\pm$ 2.00 min) and TST (34.19 $\pm$ 15.00 min, p <0.01) on weekends. Since children woke up later on weekends (mean $\pm$ SD: 36.45 $\pm$ 2.00 min), weekend early mornings showed significantly lower activity levels across all intensities (MVPA: -4.27 $\pm$ 1.82 min; LPA: -24.28 $\pm$ 2.25; SED: -42.46 $\pm$ 25.48, p <0.01). In contrast, late afternoon activity levels were higher on weekends: MVPA increased by 2.69 $\pm$ 3.53 min and LPA by 7.26 $\pm$ 6.74 min, while SED decreased by 6.63 $\pm$ 6.26 min (p <0.02). The bidirectional associations between physical activity and sleep differed across times of day. Early morning activity, regardless of intensity, was associated with greater sleep efficiency that night (p <0.01), while higher sleep efficiency predicted increased SED (p =0.01) and reduced LPA and MVPA (p < 0.01) the next late morning. Early afternoon MVPA was linked to reduced WASO that night (p =0.01), whereas higher WASO predicted increased afternoon MVPA the following day (p =0.03). Late evening activity, regardless of intensity, was consistently associated with shorter TIB, TST, and SOL (p <0.01). In contrast, both TIB and TST were positively associated with MVPA (p <0.04) during the early evening of the following day.

Conclusions: In school-age children, weekday-weekend differences in sleep and physical activity are prominent, and the bidirectional relationships between them are not uniform across times of day. Our findings highlight the importance of considering not just the quantity but the timing of physical activity in its relationship with sleep.

Acknowledgments: NUS supported this work through the start-up grant awarded to Dr June Lo [NUHSRO/2019/075/Startup/01].

BP fluctuations during REM sleep as indicator to cardiovascular risk

E. Baron¹

¹Technion, Medical Faculty, Haifa, Israel

Introduction: Beat to beat Blood pressure fluctuations during REM sleep

We developed the "Circul VS" monitoring system, that consists of FDA cleared BP watch and FDA cleared Pulse Oximeter Ring that work in tandem through the night to produce beat-to-beat BP and SpO2 graphs. In the BP graphs we combine static BP measurements every hour with continuous Dynamic BP estimation from the ring. By providing around 30,000 measurements of BP and SpO2 (every second) we discovered high spikes of BP appearing as bursts during REM sleep in some of the patients. As we will explain later, we see these bursts of high spikes (e.g. from 100 mmHg to 160-200 mmHg) as indicator to Endothelial Dysfunction in controlling the BP and need for treating the endothelial function by lifestyle or medication.

Materials and methods: We used our "Circul VS" system that included BP watch with inflatable bladder and multiple wavelength optical sensors that was spring loaded to ensure constant pressure in the skin. The ring also includes AI algorithms for estimation Dynamic BP from PPG.

Results: Young healthy subjects hardly showed significant fluctuations. As age increased, older adults showed higher and higher fluctuations. Higher Fluctuations were demonstrated during Sleep Apnea events, and their size was correlated to the depth of the Oxygen desaturations.

In the end of the night, a report is automatically generated. The report which appears both on the Circul VS display and also sent to the hospital/clinic EHR system, with Dashboard for the sleep report physician.

The report uses Generative AI to generate text that explains to the physician what s/he can see in the graphs, what is the clinical significance of the finding looking at all graphs simultaneously and ever recommendations for next steps.

This report can be edited by the physician and then signed for reimbursement purposes.

Conclusions: Our hypothesis is that size and spectral content of these spikes bursts during REM indicate deterioration of the Endothelial Function and correlates with the CVD risk, even for patients that are normotensive. This open a new paradigm of assessing hypertension and CVD risk

Acknowledgments: The author wish to express his thanks to Prof. (emeritus) Meir Kryger (Yale Medical School) for his contribution and to Prof. Donald Casey, UMN for his helpful remarks. Also to X-Cardio Corp. KK Tokyo and BodiMetric companies that provided the Circul VS systems.

Bridging the Guideline Gap: Clinically Tested Casein Tryptic Hydrolysate (CTH) and the Combination of CTH-Theanine as First-Line Therapy for Mild to Moderate Insomnia

K. Thiagarajah¹, S. Nam Weng¹

¹Universiti Tunku Abdul Rahman, Allied Health Sciences, Kampar, Malaysia

Introduction: Cognitive-behavioural therapy for insomnia (CBT-I) is recommended as the first-line treatment for chronic insomnia in adult patients of all ages, including those with comorbidities. When the CBT-I approach is not effective, pharmacological intervention can be offered as a short-term (≤ 4 weeks) approach, prescribing benzodiazepines, benzodiazepine receptor agonists, daridorexant, and low-dose sedating antidepressants; a longer-term approach (up to 3 months) with orexin receptor antagonists or prolonged-release melatonin, considering their advantages and disadvantages.

Materials and methods: Antihistamines, antipsychotics, fast-release melatonin, ramelteon, and phytotherapeutics are not recommended for insomnia, as indicated by the recent European Insomnia Guideline. This guideline leaves a significant gap in safe, effective, and well-tolerated options. Bridging that gap, casein tryptic hydrolysate (CTH), a milk-derived protein hydrolysate rich in bioactive peptides such as α -caseozepine, has demonstrated promising anxiolytic and sleep-enhancing effects by modulating the GABAergic system, akin to conventional anxiolytics.

Results: In three randomised, placebo-controlled trials involving 144 participants, oral administration of 150–600 mg/day of CTH for 2 to 4 weeks produced statistically significant improvements in overall sleep quality and sleep latency. Additionally, three more trials involving 84 subjects given the combination of CTH (150–600 mg/day) and theanine (an amino acid derived from green tea; 50–204 mg/day) over 4 to 8 weeks demonstrated a significant reduction in sleep latency in common, while two of the trials showed a significant enhancement in total sleep duration, sleep efficiency, and daytime dysfunction—without causing sedation or dependency.

Conclusions: In contrast to many pharmacological options, both CTH and CTH-theanine formulations consistently exhibit favourable safety profiles, positioning them as compelling candidates for first-line therapy when CBT-I is inadequate. Larger, multinational trials are warranted to further validate these findings and support broader clinical adoption.

Can extending the time between last meal of the day and bedtime improve sleep regularity? A pilot study in Australian adults

C. Gupta¹, N. Nordien¹, S. Khalesi¹, G. Vincent¹, A. Coates², M. Shah¹, S. Ferguson¹

¹Central Queensland University, Adelaide, Australia, ²University of South Australia, Adelaide, Australia

Introduction: Sleep regularity is important for health and wellbeing. Food intake close to bedtime negatively impacts sleep regularity by lengthening sleep onset and reducing sleep duration. Extending the time between the last meal of the day and bedtime could improve sleep regularity. This pilot study investigated, for the first time, whether extending the time between last meal and sleep onset through time-restricting eating (TRE) is feasible for Australian adults and if it impacts sleep regularity.

Materials and methods: Adults ($n=6$, 18–38 y, 5 female) completed 2-weeks baseline with usual eating timing followed by 6-weeks of TRE (10-hours between first and last meal, with last meal by 8pm), and a daily sleep diary. The standard deviations of sleep onset and sleep duration were calculated to indicate sleep regularity. Interviews were conducted to understand lived experience of TRE and sleep regularity.

Results: A one-way ANOVA revealed differences in time between last meal of the day ($p=0.04$), with 2.04 hours between last meal and sleep onset during baseline and 4.00 hours during TRE. There were no significant differences in sleep variables between baseline, 3-weeks TRE, and 6-weeks TRE (onset $p=0.54$; duration $p=0.85$). Participants reported positive experiences of TRE on sleep, commenting that TRE is “TRE helps me be consistent...because if I finish eating at a certain time, then I tend to go to bed at a set time.”

Conclusions: A 10hour TRE was feasible for Australian adults. While there were no significant improvements to sleep regularity after TRE, participants found it easier to have a consistent sleep routine when there was a longer time between eating and sleep. The next step is to build on these findings with objective sleep measures

Causal Relationship Between Metabolites and Obstructive Sleep Apnea Hypopnea Syndrome (OSAHS) Based on Two-Sample Mendelian Randomization Analysis

K. Wu¹, Y. Wang¹, D. Lei¹

¹Shandong University Qilu Hospital, Department of Otorhinolaryngology, Qilu Hospital of Shandong University, Jinan, Shandong, China. NHC Key Laboratory of Otorhinolaryngology (Shandong University), Jinan City, China

Introduction:

Obstructive Sleep Apnea Hypopnea Syndrome (OSAHS), a sleep-related breathing disorder, affects nearly one-fifth of adults worldwide. Identifying the pathogenesis associated with OSAHS is crucial. OSAHS patients exhibit metabolic alterations, which reflect the underlying biochemical activities and states of cells and tissues, directly linking to pathophysiology. Fatty acids, carbohydrates, and amino acids are common metabolites involved in cellular physiological processes, maintenance of cell structure, signal transduction, and cellular activity. Changes in these metabolites may serve as novel biomarkers, providing substantial insights into disease development.

Mendelian randomization (MR) analysis, a key epidemiological method, uses genetic variants as instrumental variables (IVs) to infer causal relationships between exposure factors and outcomes. Compared with traditional observational studies and randomized controlled trials, this approach avoids confounding factors and overcomes challenges such as high research costs and lengthy cycles. This study employed bidirectional two-sample MR analysis to further explore the causal relationship between metabolites and OSAHS.

Materials and methods: Metabolic disorder data and OSAHS data were obtained from OpenGWAS (<https://gwas.mrcieu.ac.uk>). MR analysis utilizes single-nucleotide polymorphisms (SNPs) strongly associated with exposure factors as instrumental variables (IVs). MR analyses were conducted in R (version 4.3.3) using the TwoSampleMR package. The inverse variance weighting (IVW) method served as the primary analysis, supplemented by alternative methods: MR-Egger regression, simple mode, weighted mode, and weighted median. Cochran's Q test assessed statistical heterogeneity among SNPs; MR-Egger regression intercepts analyzed horizontal pleiotropy. Sensitivity analysis was performed using leave-one-out methods. Funnel plots were generated to investigate potential influencing factors. A causal association was inferred if the IVW result had $P < 0.05$ and the causal effect directions of multiple methods were consistent with IVW.

Results: A total of 34,843 SNPs highly correlated with metabolism (all $F > 10$) were included from 1,400 metabolites. From the outcome data, 9,752 SNPs highly associated with exposure were extracted as instrumental variables. In IVW analysis, results with $P < 0.05$ were considered statistically significant. After excluding instrumental variables (IVs) with trends inconsistent with the inverse variance weighting (IVW) method across the remaining four MR analysis approaches, removing IVs with pleiotropy, and performing false discovery rate (FDR) correction, 45 metabolism-related SNPs were finally included, representing two metabolites or metabolite ratios: 2-palmitoyl-GPC (16:0) levels ($OR > 1$) and phosphate to threonine ratio ($OR < 1$).

Conclusions: This study used MR to investigate the causal relationships between 1,440 metabolites and OSAHS. As MR relies on the random allocation of genes during meiosis, it effectively avoids confounding factors and reverse causality compared with traditional observational studies. We found a positive association between 2-palmitoyl-GPC (16:0) levels and OSAHS, and a negative association with the phosphate to threonine ratio. Further validation using clinical samples is needed to confirm these intriguing findings.

Cerebral Metabolic Abnormalities and Disrupted Gut Microbiota in Adolescents with Major Depressive Disorder and Comorbid Insomnia Symptoms: A Proton Magnetic Resonance Spectroscopy Study

S. Zhong¹, X. Song¹, Y. Wu¹, R. Zhang¹, Q. Zhong¹, S. Lai¹, Y. Zhang¹, D. Huang¹, Y. Jia¹

¹Department of Psychiatry, First Affiliated Hospital, Jinan University, Guangzhou, China

Introduction: Adolescents are at an elevated risk of developing major depressive disorder (MDD), which is frequently accompanied by insomnia symptoms (IS). This study aims to elucidate the

mechanisms underlying this comorbidity, focusing on the gut-brain axis by evaluating cerebral metabolism and gut microbiota in adolescent patients with MDD and comorbid IS.

Materials and methods: A total of 102 adolescents diagnosed with MDD were recruited for this study, comprising 68 individuals with comorbid with IS (MDD-IS), 36 individuals without insomnia (MDD-nIS), and 35 healthy controls (HCs). Proton magnetic resonance spectroscopy (^1H -MRS) was employed to measure levels of N-acetylaspartate (NAA), choline-containing compounds (Cho), and creatine (Cr) in the prefrontal white matter (PWM), anterior cingulate cortex (ACC), basal ganglia (BG), thalamus, and cerebellum. Additionally, gut microbiota was analyzed using 16S rRNA gene sequencing of fecal samples.

Results: Compared to HCs, the MDD-IS group demonstrated decreased NAA/Cr ratios in the bilateral PWM and left ACC, as well as decreased Cho/Cr ratios in the right cerebellum. The MDD-nIS group showed decreased NAA/Cr ratios in the right PWM and left ACC. In comparison to the two patient groups, the MDD-IS group exhibited increased NAA/Cr ratio in the left ACC relative to the MDD-nIS group. LEfSe analysis at the genus level revealed an enrichment of *Escherichia*, *Shuttleworthia*, *Enterobacter*, and *Klebsiella*, and other genera in the MDD-IS, while *Fusobacterium*, *Desulfovibrio*, *Erysipelothrix*, and additional genera were more abundant in the MDD-nIS group. Differential analysis indicated that both MDD-IS and MDD-nIS groups exhibited a significantly higher abundance of the *Escherichia* genus compared to HCs, whereas the MDD-nIS group showed a lower abundance of the *Shuttleworthia* genus than HCs. Furthermore, the MDD-IS group had a significantly higher abundance of the *Shuttleworthia* genus compared to the MDD-nIS group. Correlation analyses demonstrated a significant positive correlation between the NAA/Cr ratio in the left ACC and the abundance of *Desulfovibrio* in the MDD-nIS group.

Conclusions: These findings suggest that sleep disturbances in adolescents with MDD may be associated with abnormal metabolism in the prefrontal cortex and cerebellum, as well as dysbiosis of the gut microbiota.

Changes in long-term circadian sleep parameters (365 days) after liver transplantation

¹Hospital Clínico Universitario Virgen de la Arrixaca, UDICA, Murcia, Spain, ²Instituto Murciano de Investigación en Biomedicina (IMIB), El Palmar-Murcia, Spain, ³Hospital Clínico Universitario Virgen de la Arrixaca, Intensive Care Unit, Murcia, Spain, ⁴Hospital Clínico Universitario Virgen de la Arrixaca, Surgery Service, Murcia, Spain, ⁵Universidad de Murcia, Departamento de Producción Animal, Murcia, Spain

Introduction: The state of sleep in patients on the waiting list for liver transplantation has been little studied and is not considered a routine intervention necessary for maintaining their health. The aim of the study was to determine whether undergoing liver transplantation, without further intervention on sleep health, leads to an improvement in sleep-related parameters.

Materials and methods: Sleep-related parameters were monitored using a Kronowise K6 wrist device and the data were analysed using Kronowise 100 software (both from Kronohealth, Murcia, Spain). Patients wore the device on their non-dominant wrist for at least 7 days at two points in time: before the transplant (PRE), at the time of recruitment for this study, and one year after receiving the transplant. Up to 27 parameters related to sleep quality were calculated: Lights off and on (hh:mm), sleep onset and end time (hh:mm), sleep latency (min), total sleep time (min), WASO (min), number of awakenings/hour, sleep efficiency (%), actual sleep time (min), nap duration (min) and nap frequency, light received 2 hours before, during sleep and 2 hours after sleep; blue light received 2 hours before, during sleep and 2 hours after sleep, average activity 2 hours before, during and 2 hours after sleep and total time in bed.

Results: The parameters in which differences were found were average activity before sleep (preTX= 6.9 ± 0.7 vs 1Y= 7.4 ± 0.6 $p < 0.001$), average activity 2 hours after sleep (preTX= 11.8 ± 1.1 vs 1Y= 14.1 ± 1.1 ; $p < 0.001$), total light (PreTx= 549.7 ± 302 vs 1Y= 312.6 ± 165.1 $p < 0.001$) and blue light (PreTx= 263.2 ± 170 vs 1Y= 158.2 ± 67.7 ; $p < 0.001$) during the 2 hours after sleep, and nap frequency (PreTx= 1.1 ± 0.1 vs 1Y= 1.2 ± 0.1 ; $p = 0.005$). Trends towards differences were also found for lights off (hh:mm) ($p = 0.09$), total time in bed (min) ($p = 0.068$) and WASO (min) ($p = 0.092$).

Conclusions: Most parameters related to sleep quality do not change after transplantation, although there is a reduction in light received during the first two hours of sleep, an increase in activity during

the two hours before and after sleep, and an increase in the frequency of naps and awakenings. This means that, although overall health improves and chronic liver disease disappears, patients do not change their sleep habits. In this case, the absence of intervention and the lack of differences show the need for professional intervention on the quality of sleep of patients before and after transplantation.

Changes in short-term circadian sleep parameters (30 days) after liver transplantation

L. Martínez Alarcón¹, M. Jover², J. Sáez³, P. Ramírez Romero⁴, G. Ramis Vidal⁵

¹Hospital Clínico Universitario Virgen de la Arrixaca, UDICA, Murcia, Spain, ²Instituto Murciano de Investigación en Biomedicina (IMIB), El Palmar-Murcia, Spain, ³Hospital Clínico Universitario Virgen de la Arrixaca, Intensive Care Unit, Murcia, Spain, ⁴Hospital Clínico Universitario Virgen de la Arrixaca, Surgery Service, Murcia, Spain, ⁵Universidad de Murcia, Departamento de Producción Animal, Murcia, Spain

Introduction: The state of sleep in patients on the waiting list for liver transplantation has been little studied and is not considered a routine intervention necessary for maintaining their health. The objective of this study was to determine whether undergoing liver transplantation, without further intervention on sleep health, leads to an improvement in sleep-related parameters.

Materials and methods: Sleep-related parameters were monitored using a Kronowise K6 wrist device and the data were analysed using Kronowise 100 software (both from Kronohealth, Murcia, Spain). Patients wore the device on their non-dominant wrist for at least 7 days at two points in time: before the transplant (PRE), at the time of recruitment for this study, and one year after receiving the transplant. Up to 27 parameters related to sleep quality were calculated: Lights off and on (hh:mm), sleep onset and end time (hh:mm), sleep latency (min), total sleep time (min), WASO (min), number of awakenings/hour, sleep efficiency (%), actual sleep time (min), nap duration (min) and nap frequency, light received 2 hours before, during sleep and 2 hours after sleep; blue light received 2 hours before, during sleep and 2 hours after sleep, average activity 2 hours before, during and 2 hours after sleep and total time in bed.

Results: Differences were found in: sleep latency (PreTx= 17.7±2.9 vs 1M=10.6±0.9; p=0.027); Average Temperature during sleep (PreTx= 33.8±0.2 vs 1M=33.1±0.2; p=0.001), Light received during sleep in lux (PreTx=606.1±276 vs 1M= 271±145.8; p=0.014) and blue light received during sleep (PreTx=280±151 vs 1M=95.6±49.6; p=0.022). A latency higher than 20 minutes is considered as pathological; in the pre-transplant period, up to 24.5% of patients had a latency of more than 20 minutes, while one month post-transplant only 1.9% of them did (p=0.016).

Conclusions: There are short-term changes in sleep parameters following liver transplantation. Sleep onset improves; the percentage of patients with insomnia decreases significantly and screen use habits improve significantly.

Changes in the expression of clock genes after liver transplantation

G. Ramis¹, M. Jover², J. Sáez³, P. Ramírez Romero⁴, L. Martínez Alarcón⁵

¹Universidad de Murcia, Departamento de Producción Animal, Murcia, Spain, ²Instituto Murciano de Investigación en Biomedicina (IMIB), El Palmar-Murcia, Spain, ³Hospital Clínico Universitario Virgen de la Arrixaca, Intensive Care Unit, Murcia, Spain, ⁴Hospital Clínico Universitario Virgen de la Arrixaca, Surgery Service, Murcia, Spain, ⁵Hospital Clínico Universitario Virgen de la Arrixaca, UDICA, Murcia, Spain

Introduction: Circadian biological rhythms are governed by a central clock and various oscillators in the organs. The maintenance of these rhythms depends on the expression of certain clock genes, which are either inducible, such as CLOCK or ARNTL, or repressive, such as CRY1, CRY2, PER1, PER2 and others such as RORA. Given that chronic liver disease causes certain sleep disturbances, this study sought to determine the gene expression of these genes before and after liver transplantation.

Materials and methods: Fifteen patients on the waiting list for liver transplants were recruited to participate in the CRONORGAN 21 project, which studied sleep disorders in patients with chronic liver disease. This study investigated the gene expression of these genes in blood mononuclear cells in patients at the time of inclusion on the waiting list, after transplantation in the hospital (1, 3 and 7 days

PT) and 30, 90, 180 and 365 days PT. A q-PCR was performed using beta-actin to perform relative quantification using the method of Livack et al (2001).

Results: Patients show a post-transplant increase in the expression of the inducer genes ARNTL and CLOCK and the repressors CRY1, PER1 and PER2. However, the CRY2 and RORA genes do not change their gene expression. When a linear regression was performed between gene expression and the days after transplantation, it was significant for the expression of RORA ($R=0.285$; $p=0.003$), ARNTL ($R=0.264$, $p=0.003$), CLOCK ($R=0.355$, $p<0.001$) and CRY1 ($R=0.254$, $p=0.005$). However, it was not significant for PER1, PER2 and CRY2. After a significant increase in all genes after transplantation, there is a decrease on days 3 and 7, followed by a progressive increase in gene expression in the genes that increase. RORA clearly shows a different dynamics from the other genes; there is less gene expression after transplantation and it returns to pre-transplantation values from day 30 onwards. CRY2 shows a drop on the third day after transplantation, while none of the other expressions differ from those prior to transplantation. The molecular mechanism that regulates the circadian clock is connected to other pathways such as metabolism, cell growth, DNA regulation and repair, angiogenesis, inflammation, and immune response.

Conclusions: An alteration in the expression of clock genes has previously been observed in animal models of liver disease and in cirrhotic patients. In the future, the gene expression of these genes could be used as an additional indicator of disease severity.

Acknowledgments: The authors would like to thank to all the health personnel in the transplantation unit of the Surgery Service at the Hospital Clínico Universitario Virgen de la Arrixaca

Characteristics and influencing factors of sleep quality in newly employed nurses: a latent profile analysis study

L. Shang¹, R. Yin², Y. Liu², Y. Han², X. Shi²

¹First Affiliated Hospital of Soochow University, Department of Oncology, Suzhou City, Jiangsu Province, China, ²First Affiliated Hospital of Soochow University, Department of Nursing, Suzhou City, Jiangsu Province, China

Introduction:

Sleep deprivation is a known risk factor for multiple chronic conditions, including hypertension, cardiovascular disease, and diabetes. Nurses, especially those newly employed, often experience irregular work schedules and rotating shifts, which can disrupt their sleep patterns. These disruptions may negatively impact both physical and mental health, as well as the quality of patient care. Previous studies have shown that poor sleep quality among nurses is associated with reduced attention, increased risk of errors, and occupational burnout. In China, one study reported an average Pittsburgh Sleep Quality Index (PSQI) score of 7.26 ± 3.56 among nurses, with 42.9% experiencing some degree of sleep disturbance. This study aims to investigate the distribution of sleep disorders among newly employed registered nurses, identify the potential profiles of sleep disorders, and explore the associated influencing factors.

Materials and methods: This cross-sectional study was conducted from September to October 2024 at the First Affiliated Hospital of Soochow University. A total of 362 nurses were surveyed using paper-based questionnaires through face-to-face interviews. Research instruments included the general demographic questionnaire, the Pittsburgh Sleep Quality Index (PSQI), the Transition Shock of Newly Graduated Nurses Scale (TSNGS), the Connor-Davidson Resilience Scale (CD-RISC), and the Simplified Coping Style Questionnaire (SCSQ). Latent profile analysis (LPA) was performed using Mplus 8.3, and multiple logistic regression analysis was conducted using SPSS 25.0. This study aims to investigate the distribution of sleep disorders among newly employed registered nurses, identify the potential profiles of sleep disorders, and explore the associated influencing factors.

Results: Four latent profiles of sleep disorders were identified: the 'Good Sleep Quality Group' (63.9%), the 'Poor Sleep Quality–Insomnia Group' (22.0%), the 'Poor Sleep Quality–Medication-Dependent Group' (7.7%), and the 'Moderate Sleep Quality Group' (6.3%). Logistic regression analysis showed that older nurses were more likely to be classified into the Poor Sleep Quality–Insomnia Group ($OR=1.386$, 95% CI : 1.093–1.759). Nurses with higher levels of transition shock were more likely to fall into the Insomnia Group ($OR=1.035$, 95% CI : 1.013–1.058) and the Medication-Dependent Group ($OR=1.034$,

95% CI: 1.001–1.068). Nurses with more than one year of work experience were more likely to be in the Medication-Dependent Group (OR=0.171, 95% CI: 0.049–0.599) and the Moderate Sleep Quality Group (OR=0.236, 95% CI: 0.068–0.814). Nurses with negative coping styles were more likely to be in the Moderate Sleep Quality Group (OR = 0.297, 95% CI: 0.093–0.945).

Conclusions: Newly employed nurses exhibit significant individual differences in their sleep disorder profiles. Older age, longer employment duration, and higher levels of transition shock are associated with more severe sleep disturbances, while positive coping strategies help alleviate these issues. Future efforts should focus on facilitating transition adaptation among new nurses and enhancing their coping skills to improve sleep quality and occupational health.

Acknowledgments: We sincerely thank the newly employed registered nurses for their participation and support. We also appreciate the Department of Nursing at the First Affiliated Hospital of Soochow University, as well as the faculty and staff who assisted with recruitment and data collection.

Chronotype-Specific Associations Between Lifestyle Factors and Daytime Sleepiness in Japanese Elementary School Children: Focus on Japanese-Style Bathing

S. Ujii¹, A. Chiba², S. Takamine¹, R. Yanagisawa², T. Wakamura¹

¹Kyoto University, Graduate School of Medicine, Kyoto, Japan, ²Kao Corporation, Tokyo, Japan

Introduction: Daytime sleepiness in children has been associated with various lifestyle, sleep, and psychological factors. Among these, pre-sleep bathing has been suggested to promote sleep, and Japanese-style bathing (JSB)—a cultural practice involving soaking in a warm-water bathtub almost every evening—is one such example. Chronotype, or individual preference for morningness or eveningness, may also influence these associations. However, few studies have examined whether the factors associated with daytime sleepiness differ by chronotype in school-aged children. This study aimed to identify lifestyle factors, including JSB, associated with daytime sleepiness by chronotype in Japanese elementary school children.

Materials and methods: A web-based survey was conducted in November 2023, targeting 2,400 pairs of Japanese elementary school children and their parents. After excluding participants using sleep medication or providing incomplete responses, 1,042 pairs were included in the final analysis. Children completed the Pediatric Daytime Sleepiness Scale (PDSS), while parents responded to questions on demographic variables, sleep duration, screen time after 5:00 p.m., JSB-related habits (e.g., frequency of soaking in a warm bath), and the Strengths and Difficulties Questionnaire (SDQ). Chronotype was classified into morning-type, intermediate-type, and evening-type based on the Children's Chronotype Questionnaire (CCTQ). Multiple linear regression analyses were conducted separately within each chronotype group to identify factors associated with daytime sleepiness. This study was approved by the ethics committees of the affiliated institutions.

Results: Among the participants, 214 children were classified as morning-type, 666 as intermediate-type, and 162 as evening-type. Chronotype distribution differed significantly by grade, with the proportion of evening-type children increasing in higher grades ($p < .0001$). Mean PDSS scores differed significantly by chronotype, with morning-type scoring 5.7 ± 4.5 , intermediate-type 9.8 ± 4.7 , and evening-type 14.9 ± 4.9 ($p < .0001$, one-way ANOVA), indicating a significant increasing trend in daytime sleepiness from morning to evening types.

In the morning-type group, PDSS scores were significantly associated with SDQ total difficulties score, screen time after 5:00 p.m., sleep duration, and social jetlag (all $p < .05$; adjusted $R^2 = 0.116$). In the intermediate-type group, SDQ scores, screen time after 5:00 p.m., social jetlag, and frequency of bathtub soaking were significantly associated with PDSS ($p < .05$; adjusted $R^2 = 0.115$). In the evening-type group, only the SDQ score was a significant predictor ($p < .05$; adjusted $R^2 = 0.158$).

Conclusions: The results suggest that psychological, social, and behavioral factors associated with daytime sleepiness differ by chronotype in children. Morning- and intermediate-type children showed greater associations with multiple lifestyle and psychological variables, whereas for evening-type children, only psychological difficulties were linked to sleepiness. Tailored interventions that consider chronotype may be effective for improving daytime functioning in school-aged children.

Acknowledgments: This study was conducted as part of a collaborative research project with Kao Corporation.

Clusters of sleep disturbance in people with systemic lupus erythematosus and associated factors

Y. Chen¹, L. Qian², Q. Wu¹, C. Fritsch³, Y. Wang⁴, P. Chen³, B. Zhu¹

¹Shanghai Jiao Tong University, School of Nursing, Shanghai, China, ²Lujiazui Community Health Service Center, Department of Nursing, Shanghai, China, ³University of Illinois Chicago, College of Nursing, Chicago, United States, ⁴The Hong Kong Polytechnic University, School of Nursing, Hong Kong, Hong Kong, SAR of China

Introduction: Systemic lupus erythematosus (SLE) is a debilitating chronic autoimmune disease. Individuals with SLE often suffer from sleep disturbance, affecting quality of life and even disease progression. Sleep disturbance in people with SLE is very complex and exhibits heterogeneity, posing challenges to the development of personalized interventions. The aim of this study was to investigate heterogeneous clusters of sleep disturbance and associated factors in people with SLE.

Materials and methods: A cross-sectional design was used and 434 people with SLE in China were recruited from an online Community for SLE Outpatient Support. Data were collected via electronic questionnaires. Sleep disturbance was evaluated by the Pittsburgh Sleep Quality Index (PSQI). Other information, such as disease activity, pain, fatigue, depression, and anxiety was also collected using validated instruments, including Systemic Lupus Erythematosus Disease Activity Index 2000, Visual Analogue Score of Pain, Fatigue Severity Scale, Patient Health Questionnaire-9, and Generalized Anxiety Disorder-7. Latent profile analysis was performed to reveal the distinct clusters of sleep disturbance. Multiple logistic regression analysis was performed to investigate factors associated with the clusters.

Results: Participant mean age was 32.9 years and 92.6% were females. All had sleep disturbance (PSQI>5) and their mean PSQI was 8.8 (SD=2.9). Three distinct clusters were identified: mild sleep disturbance with poor sleep quality, adequate sleep duration, and good daytime functioning (50.7%), mild sleep disturbance with poor sleep quality, adequate sleep duration, and poor daytime functioning (30.9%), and moderate sleep disturbance with poor sleep quality, inadequate sleep duration, and impaired daytime functioning (18.4%). There are both overlaps and unique aspects in terms of factors associated with each cluster of sleep disturbance, including age, BMI status, cardiovascular system damage, musculoskeletal system damage, depression, and anxiety. Overall, patients who were overweight, having musculoskeletal system damage or anxiety were more likely to have mild sleep disturbance with daytime functioning significantly impaired. Increasing age, depression, and musculoskeletal system damage could predispose patients to moderate sleep disturbance.

Conclusions: Sleep disturbance in patients with SLE showed three distinct clusters. In clinical practice, healthcare professionals (e.g., nurses) are recommended to prioritize assessment and interventions to those at-risk subgroups. They could also use the above information to develop and provide targeted interventions to address the unique needs of each cluster of sleep disturbance.

Acknowledgments: Bingqian Zhu was supported by “Shanghai Jiao Tong University School of Medicine-Nursing Development Program” and “Shanghai Eastern Talent Plan”.

Co-Designing Sleep Education for Primary Schools: Insights from Australian and Canadian Teachers

G. Rigney¹, P. Williams², T. Benveniste¹, A. Ilie², S. Blunden¹, S. Weiss³, P. Corkum²

¹Central Queensland University, Psychology, Adelaide, Australia, ²Dalhousie University, Halifax, Canada, ³The Hospital for Sick Children, Toronto, Canada

Introduction: Sleep problems affect one in five school-aged children, and poor sleep has been linked to academic difficulties, emotional dysregulation, and long-term health risks. While several school-based sleep programs have been developed, the vast majority (~85%) target high school students, leaving a gap in resources tailored for younger children. Embedding sleep education earlier, during the formative years when lifelong habits are shaped, is essential. However, for sleep education to be effective and sustainable in primary schools, it must be aligned with classroom needs, developmentally appropriate, and integrated into existing educational priorities. The aim of the current research was to utilise a qualitative co-design approach with primary school teachers to inform development of a school-based sleep education program for primary school teachers.

Materials and methods: In Australia, twelve primary school teachers (75% female) participated in six online focus groups after reviewing the *Healthy Sleep for Healthy Schools* (HS4HS) high school program.

In Canada, nine primary school teachers (100% female) participated in individual virtual interviews after viewing the *ABCs of SLEEPING* storybook video. Teachers were asked to provide qualitative feedback on the content and presentation of each resource, the types of teaching and parent resources needed, and potential barriers and facilitators to implementing sleep education in the classroom. Reflexive thematic analyses were undertaken.

Results: In the Australian focus groups, teachers suggested that the content on healthy sleep practices be provided upfront, as this was the most practical and useful information for presenting to young children. A microlearning approach was preferred over longer, structured lessons, with participants recommending more visuals and short videos to support engagement. Age-appropriate resources were considered essential, with teachers highlighting the need for different materials for younger and older primary-aged students. Story-based learning emerged as a top recommendation, and participants also expressed the need for accompanying resources for parents. A key barrier identified was the overcrowded curriculum, but participants offered suggestions such as integrating sleep into existing wellbeing programs and aligning content with Australian curriculum requirements.

In the Canadian interviews, all teachers acknowledged the need for sleep education in the classroom and reported a lack of available sleep resources. The *ABCs of SLEEPING* storybook was viewed as a credible and evidence-based resource. Most teachers found the content to be relevant to their students, particularly messages related to electronics use, and appreciated its engaging illustrations and classroom-appropriate layout. The majority recommended involving parents or caregivers in the education process.

Conclusions: Findings from both co-design studies highlight the need for a short, online teacher learning module paired with supplementary age-appropriate classroom materials to support effective sleep education in primary school settings. Teachers consistently emphasised the importance of aligning content with curriculum and involving families to reinforce sleep messages at home. The *ABCs of SLEEPING* storybook was positively received and offers a strong foundation for developing story-based learning resources. These findings will directly inform the development of a primary school version of *HS4HS*, with a usability and pilot study scheduled in Australia and Canada for 2026.

Comparative Efficacy of Transcutaneous Auricular Vagus Nerve Stimulation (taVNS) versus SSRIs for Sleep Improvement in Depression: An 8-Week Randomized Controlled Trial

C. Lu¹, W. Li¹, P. Tan¹, Y. Zhang¹, Z. Li¹

¹National Clinical Research Center for Mental Disorders, and National Center for Mental Disorders, The Second Xiangya Hospital of Central South University, Psychiatry, Changsha, China

Introduction: Depression is typically accompanied by considerable sleep disorders, which often remain even after treatment. Transcutaneous auricular vagus nerve stimulation (taVNS), a non-invasive neuromodulation therapy, has showed potential in treating depressive symptoms. Some research reveals that taVNS may alter sleep regulation via its effects on the autonomic nervous system and sleep-wake cycle modulation. However, its comparative efficacy with first-line selective serotonin reuptake inhibitors (SSRIs) for improving sleep symptoms in depression remains unclear. This study aims to compare the efficacy of 8 weeks of taVNS treatment with SSRI drug treatment in improving sleep disorders in patients with depression.

Materials and methods: This study included 43 adult patients with depression meeting DSM-5 diagnostic criteria. Participants were randomly assigned to the taVNS group (n=21) or the SSRIs group (n=22) and received 8 weeks of treatment. The taVNS group received 30 minutes of standardized parameter stimulation therapy daily, while the SSRIs group received medication treatment according to clinical guidelines. Sleep outcomes were assessed using the Hamilton Depression Rating Scale (HAM-D) sleep subscale at baseline and post-treatment. Baseline characteristics showed no significant differences between groups in HAM-D sleep scores ($F=2.302$, $p=0.494$; taVNS group: $M=3.71\pm0.332$; SSRIs group: $M=3.32\pm0.462$). Statistical analyses included paired t-tests for within-group comparisons and Mann-Whitney U tests for between-group differences, with effect sizes calculated using Cohen's d.

Results: Both treatment modalities demonstrated significant improvements in sleep symptoms after 8 weeks of intervention. In the taVNS group, HAM-D sleep scores decreased from 3.71 ± 1.52 at baseline to 2.33 ± 1.80 post-treatment ($t(20)=3.15$, $p=0.005$, $d=0.69$), representing a medium effect size

improvement. Similarly, the SSRI group showed reduction from 3.32 ± 2.17 to 1.64 ± 1.33 ($t(21)=3.00$, $p=0.007$, $d=0.64$), also demonstrating a medium effect size. Between-group comparisons using Mann-Whitney U tests revealed no statistically significant difference in treatment efficacy ($U=226.5$, $z=-0.112$, $p=0.911$), with comparable mean ranks between groups (taVNS=22.21; SSRIs=21.80). Both treatments were well-tolerated, with no serious adverse events reported in either group.

Conclusions: This study provides evidence that both taVNS and SSRIs are effective in improving sleep disturbances associated with depression, with comparable efficacy after 8 weeks of treatment. These findings position taVNS as a viable non-pharmacological alternative to SSRIs for managing sleep symptoms in depression, particularly for patients who prefer to avoid medication or experience side effects from pharmacotherapy. The comparable efficacy, combined with taVNS's favorable safety profile, supports its consideration in treatment algorithms for depressed patients with prominent sleep disturbances. Future research should investigate longer-term outcomes, optimal treatment parameters for taVNS, and potential differential effects on specific sleep architecture components.

Comparing sleep markers in a comparative micro-cohort study for mothers with depressive symptoms and a community cohort

J. Ooh¹, A. Lim², N.A. Johari¹, C. Chee², D.Y. Goh¹

¹National University Health System, National University Centre for Women's and Children (NUWoC), Singapore, Singapore, ²National University Health System, Psychological Medicine, Singapore, Singapore

Introduction: Infant sleep is crucial for early development, with maternal mental health being linked to the infant's sleep patterns. While maternal depression can negatively affect various aspects of parenting, its direct impact on infant sleep remains underexplored.

This study aims to compare reported sleep markers of both infants and mothers from the Women's Emotional Health Service (WEHS) to those from the Sleep Easy Programme (SleEP). The WEHS supports mothers identified to have pre-and-postnatal depression or other types of emotional distress through the child's first year of life. The SleEP is the first community-based infant sleep screening and early intervention program in Singapore. We report findings from the first nine months of our collaboration (July 2024 to March 2025).

Hypothesis

It is hypothesized that infants of mothers with depressive symptoms will exhibit more frequent night wakings, shorter sleep durations, and disrupted sleep patterns compared to the community group. It is expected that in the former group, there will be a higher referral need to be referred for sleep interventions.

It is also hypothesized that mothers with depressive symptoms will report a shorter sleep duration compared to the community group.

Materials and methods: A 22-item questionnaire adapted from the Brief Infant Sleep Questionnaire, was administered on parents of infants for both groups during the enrollment. For the SleEP cohort, the parents completed the form during the infant's well-baby visits at the primary care.

A total of 30 mother-infant dyad from the WEHS group and a community sample comprising of 2185 mother-infant dyad are included in this study for the measured time range. Descriptive analysis is used to describe the study sample. Categorical data are presented as frequencies and percentage.

Results: The key findings support our hypotheses that (1) the percentage of infants referred for interventions is significantly higher at 70.0% for the WEHS cohort compared to the community SleEP cohort (26.5%). Of these, (2) they have more frequent night waking (3.5 times) than the SleEP cohort (2.3 times). Interestingly, the infants from the WEHS cohort sleep an average of nearly 30% more (12 hours) than their SleEP infants (8.4 hours).

The mothers from the WEHS cohort have reduced sleep quantity (5.4 hours) than the SleEP cohort (6.4 hours). There are double the number of mothers from the WEHS cohort (57.1%) who reported a significant lack of confidence than the SleEP cohort (29.7%). 66.7% of the WEHS mothers whose

infants needed interventions perceived their sleep to be a moderate or serious problem than 49.1% of the mothers from the SleEP cohort.

Conclusions: Potential mediating factors identified during our related to the WEHS cohort's elevated results are: (1) infants from the WEHS cohort sleep on the same bed and room as their parent(s), (2) there is lack of consistency in bedtime routines (42.9% in WEHS cohort versus 61.2% of the SleEP cohort) for the infants needing interventions.

Acknowledgments: Special thanks go to A/Professors Daniel Goh and Cornelia Chee, Alicia and the many case management officers of the WEHS team who had made this possible.

Comprehensive Sleep Phenotyping in the MoTrPAC Pediatric Study: the iSLEEP Health Profile

A.B. Neikrug^{1,2}, S. Radom-Aizik^{3,2}, I.Y. Chen¹, B.A. Mander², D. Cooper^{3,2}, R.M. Benca⁴

¹University of California Irvine, Psychiatry and Human Behavior, Irvine, United States, ²University of California Irvine, Research Center for Exercise Medicine and Sleep/Pediatric Exercise and Genomics Research Center, Irvine, United States, ³University of California Irvine, Pediatrics, Irvine, United States, ⁴Wake Forest University, Psychiatry and Behavioral Medicine, Winston-Salem, United States

Introduction: Integrating comprehensive sleep assessment into large-scale multidisciplinary studies remains a major challenge, particularly when it comes to generating high-quality, multilevel sleep data and communicating it effectively across disciplines. The Interacting Mechanisms of Sleep and Endurance Exercise in Pediatrics (iSLEEP) study, an ancillary project to the NIH-funded Molecular Transducers of Physical Activity Consortium (MoTrPAC), was designed to embed rigorous, multimodal sleep phenotyping into a systems biology framework. The iSLEEP protocol captures neurophysiological sleep architecture, habitual sleep patterns, and subjective sleep characteristics in youth aged 10–17 years who completed the MoTrPAC study. To support data integration, we developed the iSLEEP Health Profile; a standardized summary that visually synthesizes multimodal sleep data. The profile translates complex sleep data into an intuitive summary, supporting individual-level interpretation and fostering collaboration across research domains.

Materials and methods: A total of 158 MoTrPAC participants were consented to iSLEEP. Assessments included: (1) overnight polysomnography (PSG, Natus Systems) with high-density EEG (hdEEG, 128 channels cap by Waveguard), (2) 7–14 days of wrist-worn actigraphy, (3) daily sleep diaries, and (4) validated questionnaires including the School Sleep Habits Survey (SSHS). Sleep data were scored and reviewed by a boarded sleep physician using Natus SleepWorks software. EEG recordings underwent preprocessing, semi-automatic artifact rejection, and segmentation into concatenated NREM epochs. A Fast Fourier Transformation with a multitaper approach (11 tapers) was applied to estimate absolute and relative spectral power for slow-wave activity (SWA; 0.5–4.5Hz). Actigraphy data (Actiwatch) were scored with reference to sleep diaries and analyzed for sleep continuity metrics. Circadian activity rhythms were derived using parametric modeling (cosine and additive functions) and visualized using Shape Language Modeling (SLM) to capture habitual sleep patterns. A composite Ru-SATED score (composite score that includes regularity, satisfaction, alertness, timing, efficiency, and duration) was calculated by integrating subjective and objective measures. Social jet lag, defined as the difference in sleep timing and duration between school and non-school nights, was computed. Results were integrated into the iSLEEP Health Profile.

Results: 126 (50%, n=63 females) participants completed the full iSLEEP protocol with an additional 26 participants who provided partial data (actigraphy with sleep diary and questionnaires). Among those with full data, 54 (42.9%) were aged 10–13, 27 (21.4%) were classified by MoTrPAC as highly active. A standardized iSLEEP Health Profile page was designed to integrate PSG-derived sleep architecture and SWA topography, actigraphy-based sleep continuity and circadian activity rhythm metrics with SLM visualizations, subjective reports, Sleep Health score, and social jet-lag metrics.

Conclusions: The iSLEEP study was able to embed a detailed sleep phenotyping into large-scale pediatric study and can be used as a model for cross-discipline data integration and communication. The iSLEEP Health Profile offers a replicable framework for integrating behavioral and physiological data, advancing sleep phenotyping standards, supporting translational research, and enabling new cross-disciplinary collaborations. iSLEEP data will be made publicly available alongside MoTrPAC datasets to promote collaboration.

Contemporaneous network analysis of mental health symptoms in middle-aged and elderly patients with OSA

H. Huang^{1,2}, L. Qin^{1,3}, Q. Zhong^{1,3,4}, Y. Wen^{5,1,3,4}, W. Wei^{6,1,3,4}, M. Zhao^{1,3,4}

¹The People's Hospital of Guangxi Zhuang Autonomous Region, Guangxi Clinical Research Center for Sleep Medicine, Nanning, China, ²Guilin Medical University, Graduate School, Guilin, China, ³The People's Hospital of Guangxi Zhuang Autonomous Region, Department of Sleep Medicine, Nanning, China, ⁴The People's Hospital of Guangxi Zhuang Autonomous Region, Guangxi Sleep Respiratory Disease Diagnosis and Treatment Center, Nanning, China, ⁵Guangxi Medical University, Graduate School, Nanning, China, ⁶Guangxi University of Chinese Medicine, Graduate School, Nanning, China

Introduction: To analyze the mental health status and severity of middle-aged and elderly patients with obstructive sleep apnea (OSA), and to construct a network of mental health symptoms in middle-aged and elderly patients with OSA through network analysis, and to identify the core symptoms. **Materials and methods:** A total of 741 patients with OSA who were admitted to the Sleep Medicine department of the People's Hospital of Guangxi Zhuang Autonomous Region from February 2022 to November 2023 were enrolled. The symptomcheck lis1-90 (SCI-90) was used to evaluate the psychological situation of the patients. According to whether the score of each factor of SCL-90 ≥ 2 , it was divided into positive symptom group and negative symptom group of each factor. The network analysis method was used to construct the psychological symptom network, and the core symptoms were identified through the central index, the bridge strength was analyzed, and the psychological and polysomnography characteristics of the positive and negative groups of bridge symptoms were compared.

Results: The most common psychological symptoms of middle-aged and elderly patients with OSA were other symptoms (60.46%), obsessive-compulsive compulsion (45.48%) and somatization (38.87%), and the results of centrality index analysis showed depression ($rs=1.433$, $rb=1.950$, $rc=2.024$), anxiety ($rs=1.109$, $rb=0.942$, $rc=0.727$) and interpersonal sensitivity ($rs=1.006$, $rb=1.278$, $rc=0.587$) as the core symptom. Depression is the primary bridging symptom, followed by interpersonal sensitivity and anxiety. Patients were grouped according to the presence of positive symptoms of anxiety or depression. It was found that patients with anxiety or depression symptoms had lower AHI (Apnea-Hypopnea Index) but were more prone to daytime somnolence.

Conclusions: Depression, anxiety and interpersonal sensitivity are the core symptoms of psychological symptoms in middle-aged and elderly patients with OSA, which provides new ideas for the clinical diagnosis of this population, determines the key intervention targets for clinical treatment, and provides a theoretical basis for reducing the symptom management burden of middle-aged and elderly OSA patients.

Cross-sectional and Longitudinal Relationships Between Multi-Dimensional Sleep Phenotypes and Cognition in the Multi-Ethnic Study of Atherosclerosis (MESA)

C. Paquet¹, E. Powell¹, N. Kozhemiako², C. Castro-Diehl¹, J. Chen³, T. Hughes⁴, S. Bertisch¹, W. Post⁵, S. Purcell², S. Redline¹

¹Brigham and Women's Hospital, Harvard School of Medicine, Boston, United States, ²Brigham and Women's Hospital, Psychiatry, Boston, United States, ³Harvard T.H. Chan School of Public Health, Social and Behavioral Sciences, Boston, United States, ⁴Wake Forest University, School of Medicine, Winston-Salem, United States, ⁵John Hopkins University, Public Health, Baltimore, United States

Introduction: Sleep is critical for maintaining overall brain health and may influence the onset and perpetuation of cognitive impairment. Since sleep is a complex and multi-dimensional construct, we hypothesized that methods employing multi-modal sleep measures across multiple domains (including multi-day sleep-wake rhythms, respiratory disturbances and brain activity during sleep) may help to identify phenotypic composites related to cognitive performance.

Materials and methods: Multimodal sleep measures (actigraphy, polysomnography, patient-reported outcomes) were completed at the 5th follow-up exam (2010 – 2013) of the Multi-Ethnic Study of Atherosclerosis (MESA), a large multiethnic community-based cohort in the United States. Cognitive testing was completed around the 5th follow-up exam, as well as at three other later timepoints during and between the 6th and 7th follow-up exams (2016 - 2024). We performed principal components

analysis (PCA) with varimax rotation on 39 sleep variables from multiple domains of sleep health among the 1,588 participants with complete sleep data at the 5th exam. Digit Symbol Coding Test (DSCT) scores from each of the cognitive timepoints were modeled as the primary outcome. In the cross-sectional analysis, DSCT was regressed onto scores derived from the principal components (PCs) while controlling for potential confounders. In the longitudinal analysis, DSCT was the outcome in linear mixed effects models, such that all participants were included who had a follow-up DSCT score.

Results: Thirteen sleep composites were derived from PCA that explained about 71% of the sample's variance. While adjusting for demographic and lifestyle factors, scores from five PCs representing: (1) EEG power spectral density, (2), rest-activity rhythms, (3), slow wave sleep, (4), spindle density, and (5) spindle and slow oscillation coupling were associated with DSCT, cross-sectionally. For the longitudinal analysis, only one PC, representing actigraphy-based sleep continuity, was associated with cognitive decline.

Conclusions: A data reduction approach to deriving sleep composites based on numerous polysomnography and actigraphy metrics yielded coherent and interpretable associations between multi-dimensional sleep and cognitive performance, identifying associations for both EEG-based and sleep-wake patterns. Future studies with comprehensive measurement of sleep may benefit from similar data-reduction methods to incorporate a high-dimensionality conceptualization of sleep.

Daily Associations of Sleep and Rest-activity Patterns with Pain Intensity in Adults with Chronic Pain

P.Y.-L. To¹, M. Elliott², N. Tang¹

¹The University of Warwick, Department of Psychology, Coventry, United Kingdom, ²University of Birmingham, School of Sport, Exercise and Rehabilitation Sciences, Birmingham, United Kingdom

Introduction:

Sleep and pain share a bidirectional relationship, with emerging evidence suggesting that poor self-reported sleep quality more strongly predicts subsequent pain intensity than vice versa, particularly in individuals with chronic pain (CP). However, sleep comprises only one component of the 24-hour rest-activity rhythm (RAR). Few studies have explored how sleep, daytime activity, and RAR patterns jointly influence next-day pain experiences in individuals with CP. Therefore, this study aimed to investigate whether temporal associations exist between self-reported and actigraphy-measured sleep, physical activity (PA), and 24-hour RAR patterns, and how these variables influence next-day pain in people living with CP in the UK.

Materials and methods: A total of 193 participants with CP wore a MotionWatch 8 (MW8) actigraphy device on their non-dominant wrist continuously for seven days in their natural sleep-wake environment. Participants also completed daily sleep diaries to report sleep efficiency (SR-SE; the proportion of time spent asleep in bed) and sleep quality (SR-SQ; subjective perception of sleep), as well as three daily surveys capturing pain intensity as the outcome variable. Objective actigraphic sleep metrics included actigraphy-derived sleep efficiency (A-SE) and fragmentation index (A-FI), while PA variables encompassed total activity counts (TAC) and total sedentary behaviour (TSB). RAR parameters included intradaily variability (IV; rhythm fragmentation) and relative amplitude (RA; rhythm robustness). Multilevel modeling (MLM) was used to examine the prospective associations between sleep, PA, RAR variables, and next-day pain, accounting for demographic covariates.

Results: In the multilevel modeling (MLM) analysis, higher self-reported sleep quality (SR-SQ; $\beta = -0.057$, $p < .001$, 95% CI [-0.085, -0.013]) and self-reported sleep efficiency (SR-SE; $\beta = -0.051$, $p < .01$, 95% CI [-0.089, -0.028]) significantly predicted lower next-day pain intensity. Conversely, actigraphic measures of sleep efficiency (A-SE) and fragmentation index (A-FI) were not significant predictors of next-day pain intensity. Regarding physical activity (PA) patterns, neither total activity counts (TAC) nor total sedentary behavior (TSB) from the previous day were significant predictors of next-day pain intensity. Similarly, rest-activity rhythm (RAR) parameters reflecting rhythm robustness or fragmentation, including intradaily variability (IV) and relative amplitude (RA), did not predict next-day pain intensity. The MLM results further indicated that pain intensity scores did not significantly vary across the daily surveys or days of measurement. Among demographic covariates, older age ($\beta = 0.152$, $p < .01$, 95% CI [0.053, 0.251]) and higher body mass index (BMI; $\beta = 0.110$, $p < .05$, 95% CI [0.019, 0.200]) were associated with greater reported pain intensity.

Conclusions: Self-reported sleep quality and efficiency emerged as robust and consistent predictors of lower next-day pain intensity, independent of objective activity levels or RAR characteristics. These findings underscore the critical role of high-quality sleep in managing daily pain in individuals with CP and suggest that improving sleep may help mitigate pain regardless of activity levels or circadian rhythm stability. Emphasizing subjective sleep quality could therefore serve as a practical target in chronic pain interventions to enhance daily functioning and quality of life.

Acknowledgments: This study is supported by the Medical Research Council (Ref No: 17/ WM0053, p, IRAS project ID: 223190).

Das-Naglieri cognitive assessment system and serum A β levels contribute to the cognitive evaluation of OSAHS children

X. Li¹, Z. Li¹, X. An¹, C. Yu¹, X. Chen¹, X. Cai¹

¹The Second Affiliated Hospital and Yuying Children's Hospital of Wenzhou Medical University, Department of Pediatrics, Wenzhou, China

Introduction: Obstructive sleep apnea hypopnea syndrome (OSAHS), a prevalent pediatric sleep disorder, is marked by recurrent episodes of apnea and hypoventilation throughout sleep. These events result in hypoxemia and disrupted sleep architecture, which are in turn linked to cognitive deficits. Presently, reliable tools for evaluating such cognitive impairment are scarce. This study aims to evaluate cognitive function in children diagnosed with OSAHS and primary snoring (PS) by employing the Das-Naglieri cognitive assessment system (DN: CAS), measure serum Amyloid- β (A β) protein and investigate the potential relationship between cognitive performance and A β levels in the pediatric OSAHS population.

Materials and methods: Based on the results of all-night polysomnographic monitoring, the 118 participants were categorized into OSAHS and PS groups. The cognitive function of all children from these two groups, along with an age-matched control cohort (n=82), was evaluated with the DN:CAS assessment and serum A β levels were quantified via Enzyme-Linked Immunosorbent Assay (ELISA).

Results: Children with PS showed poorer performance in Planning relative to their healthy counterparts. In the OSAHS group, significant reductions were observed in Full Scale, Planning, and Attention scores. These scores were also inversely associated with the lowest blood oxygen saturation (LSaO₂). Furthermore, serum A β levels were elevated in children with OSAHS and demonstrated a negative correlation with Full Scale and Attention scores, but a positive correlation with the obstructive apnea-hypopnea index (OAHl).

Conclusions: The DN:CAS assessment system is instrumental in evaluating cognitive function, and serum A β levels hold promise as a biomarker for the early diagnosis of cognitive impairment in children with OSAHS.

Daytime dysfunction, self-reported health, and hospitalizations predicting 3-year readmission in adults with systemic lupus erythematosus

R. Yin¹, T. Wu¹, X. Shen¹, M. Yu¹, Z. Xu¹, M. Wang¹

¹The First Affiliated Hospital of Soochow University, Suzhou, China

Introduction: Most systemic lupus erythematosus (SLE) patients have the risk of readmission after discharge, which seriously affects the quality of life of patients and increases the medical burden. However, there are few studies about the readmission of SLE patients. Therefore, this prospective cohort study aims to analyze the occurrence and the impact of mental health and sleep quality on rehospitalization within 3 years of discharge among adult SLE patients.

Materials and methods: Adult SLE patients hospitalized between April 2020 to April 2021 were followed for 3 years. Patients' rehospitalizations were collected through the electronic medical record system. Data was analyzed with descriptive statistics. Multivariate Cox regression analysis was applied to explore risk factors for their re-hospitalization during that period.

Results: A total of 135 SLE patients were included, 46 event cases and 89 censored cases were found in this analysis, with 3 years followed-up. Overall, 3.0% of SLE patients were re-hospitalized within 1 month; 7.4% within 3 months; 11.1% within 6 months; 22.2% within 1 year; 31.9% within 2 years; and 34.1% within 3 years. Multivariate Cox regression analysis showed that, among adult SLE patients, daytime dysfunction (HR=1.564, $P=0.016$) and the number of hospitalizations (HR=1.141, $P=0.011$) were the risk factors for 3-year re-hospitalization, while self-reported health being the protective factor (HR=0.812, $P=0.002$). More specifically, serum ferritin (hazard ratio (HR) =1.005, 1.003, respectively; all $P=0.047$) was the risk factor of 1-month re-hospitalization; serum ferritin and self-reported health were the predictors of 3-month re-hospitalization (HR=1.003, 0.670, respectively, all $P<0.05$); serum ferritin, number of hospitalizations, and number of other diagnoses were the risk factors of 6-month re-hospitalization (HR=1.003, 1.351, 2.200, respectively; all $P<0.05$). For 1-year rehospitalization after discharge in SLE patients, current smoking, number of hospitalizations, and daytime dysfunction were the risk factors (HR=3.631, 1.153, 1.528, respectively; all $P<0.05$). Current smoking (HR=4.919, $P=0.010$) and number of hospitalizations (HR=1.138, $P=0.011$) and were the risk factors of 2-year rehospitalization. Self-reported health was the protective factor for 1-year and 2-year re-hospitalization in patients with SLE (HR=0.821, 0.825, respectively; all $P<0.05$).

Conclusions: The 3-year re-hospitalization in SLE patients was 34.1%. Sleep quality, self-reported health, and number of hospitalizations were the main modifiable predictors for SLE patient's readmission within 3 years of discharge. It is recommended that clinical nurses pay attention to adult SLE with more hospitalizations, severe daytime dysfunction, and poor self-reported health to reduce the 3-year readmission rate.

Delaying Sleep Time: A Multidimensional Investigation of Personality Traits and Neural Correlates of Bedtime Procrastination

M. Cordelli¹, A. Bazzani², C. Iacono², G. Turchetti², U. Faraguna^{3,4}

¹University of Pisa, Department of Translational Research on New Technologies in Medicine and Surgery, Pisa, Italy, ²Sant'Anna School of Advanced Studies, Institute of Management, Pisa, Italy,

³University of Pisa, Department of Translational Research and of New Surgical and Medical Technologies, Pisa, Italy, ⁴IRCCS Fondazione StellaMaris, Department of Developmental Neuroscience, Pisa, Italy

Introduction: Bedtime procrastination is particularly prevalent among evening chronotypes and has been linked to lower self-control, present-oriented time perspective, and increased risk-taking behavior.

This study aims to investigate personality antecedents of bedtime procrastination and frontal alpha asymmetry (FAA) as a possible neural correlate of approach-avoidance motivation in the context of sleep-related decision-making. FAA, which reflects relative activation between the left and right frontal cortex, has been associated with motivational tendencies—greater left frontal activation indicating approach motivation, and greater right activation indicating avoidance.

We hypothesize that within-subject fluctuations in FAA, particularly a shift toward greater left frontal activation in the evening, may be more pronounced in evening chronotypes and individuals with higher levels of bedtime procrastination

Materials and methods: The study was conducted in two phases. Phase 1 (Study 1) involved an online assessment in which participants completed a series of standardized questionnaires to evaluate individual differences in traits such as bedtime procrastination, self-regulation, interoceptive awareness (via the MAIA), time orientation, daytime sleepiness, sleep quality, chronotype and handedness for EEG referencing.

The second phase, Study 2, was conducted in-person. An EEG measurement was conducted for each participant during two sessions on the same day: the first between 8–10 a.m., and the second between 6–8 p.m. During each session, participants also completed the Balloon Analogue Risk Task (BART) to evaluate risk-taking behaviour.

Results: Correlation analyses confirmed previous literature findings: greater morningness and higher self-control are linked to lower bedtime procrastination (BTP), while increased daytime sleepiness correlated with higher BTP. A future-oriented time perspective is negatively associated with BTP, whereas a hedonistic present orientation showed a positive correlation.

Notably, interoceptive awareness, particularly in the Self-Regulation and Not-Worrying domains, is negatively correlated with BTP. These two domains, along with Attention Regulation, also showed a significant negative correlation with sleep quality (PSQI).

AS for Study 2, FAA showed moderate intra-subject consistency between morning and evening session ($\rho = 0.700$, $p = 0.188$), suggesting it may reflect a stable trait-like pattern across the day. However, the difference between evening and morning FAA varied meaningfully among participants ($N=15$).

While no statistically significant correlations emerged, a positive trend was observed between FAA and rMEQ score, indicating that morning type individuals exhibited larger FAA fluctuations across the day, in contrast with evening types FAA. This interpretation contrasts with initial hypotheses and highlights the importance of correct trait-time alignment in neurophysiological measures.

FAA was not significantly associated with BPS or BART. A simple logistic model showed promising but not generalizable accuracy (80%), due to the limited sample.

Conclusions: These preliminary findings emphasize the multifaceted nature of bedtime procrastination, involving both psychological traits and neurophysiological patterns. Results offer a preliminary window into chronotype-sensitive FAA modulation and its potential role in behavioral regulation. Moreover, individual differences in chronotype, self-regulation, interoceptive awareness, and potentially chronotype modulated FAA variation may play a significant role in sleep-related decision-making. Future studies with larger samples and higher temporal granularity are needed to validate these exploratory trends.

Acknowledgments: We thank UNIPi, the participants and Scuola Superiore Sant'Anna for their scientific support

Development of a Trust-Building Research Framework to Address Sleep Health Disparities Among People Experiencing Homelessness (PEH)

M. Campos-Navarrete¹, B. TaghiBeyglou^{2,1}, P. McLaurin³, O. Sparks¹, R. Adams¹, M. Mohammad¹, P. Gnanewaran¹, A. Yadollahi^{1,2}

¹University Health Network, KITE Research Institute, Toronto Rehabilitation Institute, Toronto, Canada,

²University of Toronto, Institute of Biomedical Engineering, Toronto, Canada, ³University of Toronto, Dalla Lana School of Public Health, Institute of Health Policy, Management and Evaluation, Toronto, Canada

Introduction: Sleep health disparities disproportionately affect people experiencing homelessness (PEH), a population that faces significant barriers to accessing timely and effective healthcare. Environmental factors, mental health conditions, and systemic distrust further exacerbate sleep-related challenges. In addressing sleep health disparities among PEH, traditional methodologies often proved insufficient to foster trust and meaningfully engage participants as equal partners. Methods such as participatory action research and trauma-informed care provided valuable insights but lacked specific guidance on how to navigate cultural and systemic barriers in healthcare settings effectively. Recognizing these gaps, this study aimed to co-develop and apply a culturally responsive, trauma-informed research framework tailored to the lived realities of PEH.

Materials and methods: This study was conducted across seven shelters in Toronto, Canada, using a trauma-informed, patient-centered participatory action research (PAR) approach. Collaboration with a community advisory group, including individuals with lived experience, Indigenous knowledge holders, and shelter staff, informed the development of the framework. Research assistants were trained in trauma-informed and anti-oppressive care to ensure the prioritization of participants' dignity and autonomy. Quantitative tools (e.g., portable polysomnography, STOP-BANG) and qualitative methods (e.g., interviews, focus groups) were integrated to assess barriers and unmet needs.

Results: A Trust-Building Framework for Sleep Health Disparities was developed to address trust, systemic inequities, and cultural responsiveness in sleep health delivery. The framework was structured into six stages of the research cycle: readiness, engagement, data collection, analysis, implementation, and evaluation. Each stage incorporated strategies to enhance participant involvement. Specific elements include: training on trauma-informed care and cultural competency, identifying systemic

barriers to sleep health, and building trust-based relationships with stakeholders, including individuals with lived experience, shelter staff, and healthcare providers. Collaborative data interpretation informed tailored interventions such as CPAP devices, mental health supports, and culturally adapted educational materials. Outcomes were assessed through participant feedback, knowledge-sharing workshops, and monitoring the sustainable integration of practices within shelters.

Conclusions: The resulting Trust-Building Framework not only addresses the immediate health needs of PEH but also serves as a scalable model for integrating culturally responsive, community-driven solutions into shelter-based healthcare systems. Its foundation in trauma-informed, culturally responsive, and participatory methods ensures that interventions are grounded in the lived realities of participants. By centering participant voices and fostering interdisciplinary collaboration, this initiative lays the groundwork for sustainable change, promoting health equity and improved sleep outcomes for historically underserved populations.

Diagnostic accuracy of the Stopbang questionnaire against polysomnography for the screening of Obstructive Sleep Apnea in a tertiary hospital in Africa

S. Maseno¹, J. Shah², S. Sokwalla³, J. Bwika⁴

¹Aga Khan University Hospital, Internal Medicine, Nairobi, Kenya, ²Aga Khan University Hospital, Medicine, Nairobi, Kenya, ³Aga Khan University Hospital, Endocrinology, Nairobi, Kenya, ⁴Aga Khan University Hospital, Pulmonology, Nairobi, Kenya

Introduction: Obstructive sleep apnea is a syndrome of upper airway and neuromuscular dysfunction that subsequently causes interruption of normal breathing during sleep. Polysomnography is the gold standard for the diagnosis of obstructive sleep apnea. Obstructive sleep apnea can be categorized as mild, moderate or severe based on an apnea-hypopnea index (AHI) on polysomnography. The recommended treatment using Continuous Positive Airway Pressure ventilation lowers morbidity and mortality rates. The STOPBANG questionnaire has been used as a screening tool for obstructive sleep apnea due to its easy and concise approach. However, even with the increasing prevalence of obstructive sleep apnea and its risk factors such as type 2 diabetes mellitus, obesity and hypertension in Africa, there is limited data on the validity and performance of the STOPBANG questionnaire in the clinical setting in the Sub-Saharan African population. The primary objective of the study was to determine the sensitivity, specificity and accuracy of the STOPBANG questionnaire in screening patients with obstructive sleep apnea as compared to polysomnography at our facility. The secondary objective was to determine the clinical characteristics of patients with obstructive sleep apnea.

Materials and methods: This was a retrospective cohort study of all patients who underwent polysomnography at the Aga Khan University Hospital, Nairobi, Kenya from 1st December 2020 to 30th June 2024. Data on variables was obtained from medical records and collected using the REDCap software based on the data abstraction tool. Data was analyzed using SPSS software.

Results: One hundred and twenty-nine patients underwent polysomnography. Out of the 129, 17 were excluded due to missing data and 112 patients were analyzed. The sensitivity of the STOPBANG questionnaire was 93.98% [CI 86.5%- 98.02%] with a specificity of 34.48% [CI 17.94% -54.33%]. The positive likelihood ratio was 1.43 [CI 1.10 -1.88] with a negative likelihood ratio of 0.17 [CI 0.07-0.47]. The positive predictive value was 80.41% [CI 75.82%-84.32%] while the negative predictive value was 66.67% [CI 42.71%-84.29%]. The accuracy of the STOPBANG questionnaire was 78.57% [CI 69.81%-85.76%]. Obstructive sleep apnea was associated with increasing age ($p=0.001$), male gender ($p=0.0272$), larger neck circumference ($p<0.001$), diabetes mellitus ($p=0.0193$), dyslipidemia ($p=0.001$) and hypertension ($p<0.001$). Presence of snoring, nocturnal hypoxemia and apneic episodes were significantly associated with obstructive sleep apnea ($p<0.001$, $p=0.003$, $p<0.001$ respectively). The above characteristics were also significantly associated with increasing severity of obstructive sleep apnea.

Conclusions: The STOPBANG questionnaire can be utilised for screening of obstructive sleep apnea in patients with sleep-disordered breathing in the clinical setting in Sub-Saharan Africa. As per our study, this should be done especially among patients who are 49 years and above, male patients, those who have diabetes mellitus, dyslipidemia, hypertension and those with an increased neck circumference >40 cm, and considered in those who are 47 years and above and a neck circumference of >37cm. Patients who are high risk for obstructive sleep apnea on the STOPBANG questionnaire should be offered polysomnography to diagnose or rule out obstructive sleep apnea.

Acknowledgments: I am grateful to my supervisors and library staff at the Aga Khan University Hospital, Nairobi for their support during my study.

Differences in circadian sleep parameters depending on gender in patients on the waiting list for liver transplantation

L. Martínez Alarcón¹, M. Jover², J. Sáez³, P. Ramírez Romero⁴, G. Ramis Vidal⁵

¹Hospital Clínico Universitario Virgen de la Arrixaca, UDICA, Murcia, Spain, ²Instituto Murciano de Investigación en Biomedicina (IMIB), El Palmar-Murcia, Spain, ³Hospital Clínico Universitario Virgen de la Arrixaca, Intensive Care Unit, Murcia, Spain, ⁴Hospital Clínico Universitario Virgen de la Arrixaca, Surgery Service, Murcia, Spain, ⁵Universidad de Murcia, Departamento de Producción Animal, Murcia, Spain

Introduction: Sleep is one of the fundamental pillars of health. However, it is not usually studied in patients prior to transplantation. The objective of this study was to determine whether circadian indicators of sleep quality differ between men and women on the liver transplant waiting list.

Materials and methods: Thirty men and 20 women on the waiting list at the Virgen de la Arrixaca University Hospital (Murcia) were included. Sleep-related parameters were monitored using a Kronowise K6 wrist device and the data were analysed using Kronowise 100 software (both from Kronohealth, Murcia, Spain). Patients wore the device on their non-dominant wrist for at least 7 days. Forty-two parameters related to sleep quality (Lights off and on (hh:mm), sleep onset and end time (hh:mm), sleep latency (min), total sleep time (min), WASO (min), number of awakenings/hour, sleep efficiency (%), actual sleep time (min), nap duration (min) and nap frequency, light received 2 hours before, during sleep and 2 hours after sleep; blue light received 2 hours before, during sleep and 2 hours after sleep, average activity 2 hours before, during and 2 hours after sleep and total time in bed) or circadian rhythm (distal temperature, movement in time and acceleration, light and sleep: Mean, IS, IV, RA, CFI, AN, SA and CHS; M5, time at M5, L5, time at L5; L10, time at L10, M10, time at M10) were analysed and a comparison was made using Student's t-test.

Results: As regards sleep parameters; differences were found in latency ($p=0.018$), average activity 2 hours before ($p=0.028$) and after sleep ($p=0.006$), total light ($p=0.027$) and blue light ($p=0.034$) received during sleep. Trends towards differences were also found for nap frequency ($H=1.11$ vs $M=0.78$; $p=0.073$). There were also differences in intradaily variability ($p=0.001$), the M5 value for movement time ($p=0.039$), the L10 value for total light received ($p=0.045$) and trends towards differences in the mean value for temperature ($p=0.054$) and the mean value for light received ($p=0.056$).

Conclusions: Although women sleep less in real terms, they enjoy better quality sleep. This could be related to lower exposure to blue light in the two hours prior to sleep, given that men receive up to 2.5 times more light than women, which could be related to the use of electronic devices or televisions before bedtime. Women have a sleep onset latency that is up to half an hour longer than men. of falling asleep than men. Sleep interventions should focus more on men, as they appear to have worse sleep habits than women.

Differential effects of sleep quality and sleep duration on stress reactivity: implications for mental health and wellbeing of young adults

S. Gadam^{1,2}, K.R. Rossa^{2,3}, C.L. Pattinson^{2,3,4}, S. Shekari Soleimanloo^{1,2}, D. Mann², K.A. Sullivan⁵, P. Salmon⁶, S.S. Smith^{2,3,4}

¹Institute for Social Science Research, The University of Queensland, Brisbane, Australia, ²The Australian Research Council Centre of Excellence for Children and Families over the Life Course (the Life Course Centre), Brisbane, Australia, ³Child Health Research Centre, The University of Queensland, Brisbane, Australia, ⁴The Australian Research Council Centre of Excellence for the Digital Child, The University of Queensland, Brisbane, Australia, ⁵School of Psychology and Counselling, Queensland University of Technology, Brisbane, Australia, ⁶Centre for Human Factors and Sociotechnical Systems, University of the Sunshine Coast, Sunshine Coast, Australia

Introduction: Young adults frequently experience poor and insufficient sleep. Short sleep duration and poor-quality sleep are associated with dysregulation of the autonomic stress response and increased

risk of mental health problems. The mechanisms of this relationship are unclear. Heart rate variability (HRV) provides an indicator of autonomic stress response activity, with higher HRV reactivity often linked to better stress resiliency. We investigated the impact of objective sleep duration and subjective sleep quality on perceived stress and HRV reactivity to cognitive stress.

Materials and methods: 89 participants (mean age = 20.63 years, SD = 1.91 years, female = 63) participated in two laboratory sessions and two 2-week periods of naturalistic actigraphy monitoring to assess variability in habitual sleep duration. Heart rate variability (HRV), specifically root mean square of successive differences (RMSSD), was measured during rest and during the completion of computerised cognitive stress tasks. HRV (RMSSD) reactivity was calculated as the difference between RMSSD during stress and rest at each of two sessions (5 weeks apart), and the change in reactivity over time was assessed. The tasks included the *Flanker Task*, requiring participants to identify the direction of a central arrow while ignoring distracting surrounding arrows, and the *Dimensional Change Card Sort Test*, requiring participants to sort cards based on changing rules (e.g., colour, then shape). Participants also reported their subjective sleep quality and perceived stress levels using the PROMIS Sleep Disturbance and NIH Stress questionnaire.

Results: One-way ANOVAs revealed that improved subjective sleep quality was associated with reduced perceived stress and increased RMSSD reactivity to cognitive stress. This significant association between improved subjective sleep quality and RMSSD reactivity was evident only for a reduction in PROMIS Sleep Disturbances T-score of 6 points or more. Changes in objective habitual sleep duration were not significantly associated with either perceived stress levels or RMSSD reactivity to cognitive stress.

Conclusions: Our findings reinforce the association between sleep and stress, highlighting the role of subjective sleep quality in autonomic responses to stress. These findings identify specific consequences of poor sleep quality on stress physiology. Further research examining other dimensions of sleep (e.g. regularity, timing) and their role in autonomic functioning is needed. Exploration on how sleep duration may influence other important outcomes in young adulthood is also needed. Prioritising sleep as a preventive strategy remains important in both interventions and therapeutic treatments for mental health and wellbeing.

Digital cognitive-behavioral therapy-based treatment for insomnia, nightmares and post-traumatic stress disorder symptoms in wildfire survivors: A randomized feasibility pilot trial

F. Isaac¹, B. Klein², H. Nguyen³, S. Watson⁴, G. Kennedy⁵

¹Federation University, Institute of Health and Wellbeing, Federation University, Ballarat, Australia, ²Federation University, Health Innovation and Transformation Centre, Ballarat, Australia, ³Federation University, Department of Population and Quantitative Health Sciences, UMass Chan Medical School, Worcester, Ballarat, Australia, ⁴Federation University, Ballarat, Australia, ⁵RMIT University, School of Health and Biomedical Sciences, Bundoora, Australia

Introduction: Background: Symptoms of insomnia, nightmares and trauma are highly prevalent in wildfire survivors. However, there are significant barriers to accessing evidence-based treatments for these conditions, leading to poor mental health outcomes for many wildfire survivors.

Objective: This pilot trial evaluated the feasibility of a four-week, digital, self-paced intervention combining cognitive behavioral therapy for insomnia (CBTi), and exposure, relaxation, and rescripting therapy for nightmares (ERRT) in wildfire survivors from Australia, Canada, and the United States of America.

Materials and methods: Methods: Study participants were recruited between May and December 2023 through social media platforms, workshops, conferences, and radio interviews. To be eligible, participants had to meet at least one of the following criteria: a score of ≥ 8 on the Insomnia Severity Index (ISI), and/or a score of ≥ 3 on the Nightmare Disorder Index (NDI), and/or a score of ≥ 31 on the PTSD Checklist – Civilian Version (PCL-5). Thirty wildfire survivors were allocated to either the treatment group (n=16) or the waitlist control group (n=14) in a sequential manner. Participants' ages ranged from 18 to 79 years, with a mean age of 52.50 years (SD = 16.26). The cohort consisted of 19 females (63.3%) and 11 males (36.7%). Participants also completed self-report secondary outcome measures, including the Generalized Anxiety Disorder Questionnaire (GAD-7), the Patient Health Questionnaire (PHQ-9), and the Pittsburgh Sleep Quality Index (PSQI), via the HealthZone digital platform. Participants were informed about the purpose, allocation, and the structure of the study. Assessments were conducted at baseline, post-treatment, and 3-months follow-up, with the waitlist group providing an additional assessment at pre-treatment, after 4 weeks of waiting, and prior to crossing over to treatment. The study employed two analyses including Intention-To-Treat analysis (ITT) as a principal analysis, and Per Protocol (PP) analysis as a secondary analysis.

Results: Results: Mixed-effects linear regression models and difference-in-difference analyses were utilized to assess the intervention's effects. The ITT revealed significant improvements over time (main effect of time) with a 1.64 point reduction ($P=.001$) on the NDI and 10.64 points reduction ($P=.009$) on the PCL-5 at post-intervention. No significant changes were observed in insomnia symptoms. On the secondary measures, there was an interaction effect of condition x time with a 2.22 point reduction ($P<.001$) on the PSQI and a main effect of time with a 6.48 point reduction ($P<.001$) on the PHQ-9. No significant changes were detected on the GAD-7. The PP analysis yielded comparable results for both the primary and the secondary measures.

Conclusions: Conclusion: The findings of this pilot trial demonstrated a reduction in nightmares and trauma symptoms. Future research studies should aim at evaluating the intervention in a more definitive trial with a larger sample size.

Discrepancies Between Self-Set Sleep Plans and Sleep Regularity: Insights from Large-Scale Consumer Wearable Data

Y. Lee¹, S. Shin¹, E. Joo^{2,3}, E.S. Zhou⁴, S. Lee⁵, H. Choi⁶, H. Lee⁶, S. Suh¹

¹Sungshin University, Department of Psychology, Seoul, Korea, Republic of, ²Samsung Medical Center, Department of Neurology, Neuroscience Center, Seoul, Korea, Republic of, ³Sungkyunkwan University, Medicine, Seoul, Korea, Republic of, ⁴Harvard Medical School, Division of Sleep Medicine, Boston, United States, ⁵Ajou University School of Medicine, Department of Psychiatry, Suwon, Korea, Republic of, ⁶Samsung Electronics, Suwon, Korea, Republic of

Introduction: Consistent sleep-wake times are important components of good sleep health. This circadian stability impacts cardiovascular health and daytime cognition. While recent studies suggest that adhering to a sleep plan may support greater sleep regularity, empirical evidence regarding its role in promoting stable sleep-wake patterns remains limited. This study aimed to examine whether sleep/wake times differed based on the presence/absence of a sleep plan across age groups.

Materials and methods: Sleep data were collected from 770,835 Korean users who owned a Samsung Galaxy Watch and were using the Clock app (2,587,530 total records) between 2020 and 2023. The age distribution of the analytic sample included those in their 20s (27.6%), 30s (28.5%), 40s (25.6%), 50s (13.5%), and 60s (4.8%). The Clock app enabled users to set a target time for their bedtime and wake time. Users whose initial sleep plans matched the default system settings were excluded, which accounted for 19% of the sample. Sleep regularity was defined as the average standard deviation of bedtime and wake times. For related analyses, we examined two groups: (1) 595,954 users who had set sleep plans and logged actual sleep records, and (2) 308,437 users without sleep plans (not part of the full sample) who had ≥ 50 valid records during the same period.

Results: No significant difference in sleep regularity was observed between those with and without a sleep plan. Among users who had set sleep plans, those with low (≤ 5 th percentile) and high (≥ 95 th

percentile) sleep variability showed an average deviation of 43 and 182 minutes, respectively. In contrast, users without a sleep plan demonstrated deviations of 48 minutes for low variability and 139 minutes for high variability. Planned sleep schedules showed an age-related advance, with average bedtime of 00:00 (20s), 23:00 (30s–50s), and 22:00 (60s), and corresponding wake times of 07:00 (20s–30s) and 06:00 (40s–60s). The average sleep duration was 6.62 hours (20s), 6.45 hours (30s), 6.53 hours (40s), 6.39 hours (50s), and 6.39 hours (60s). Among participants with a sleep plan, we further examined the association between sleep regularity and discrepancies between planned and actual sleep and wake times. Those with high sleep regularity (≥ 90 th percentile) demonstrated mean discrepancies of 59 minutes for bedtime and 47 minutes for wake time. In contrast, those with low sleep regularity (≤ 10 th percentile) showed substantially larger discrepancies of 190 and 191 minutes, respectively.

Conclusions: In this large-scale study, sleep regularity did not differ by plan setting, suggesting that planning may not ensure more stable sleep–wake patterns. Notably, wake-time delays were also observed among participants with highly regular sleep patterns. These delays may be downstream consequences of late bedtimes or may reflect distinct processes such as sleep inertia, motivational avoidance of daytime activity, or impaired self-regulation upon waking. Future research is needed to clarify these possibilities and to further elucidate the nature of plan–behavior mismatches across sleep–wake patterns.

DistillSleep: Real-Time, On-Device, Interpretable Sleep Staging from Single-Channel EEG

K. Park¹, J. Hong¹, W. Lee¹, H.-W. Shin², H.-S. Kim¹

¹Seoul National University, Graduate School of Data Science, Seoul, Korea, Republic of, ²Seoul National University, Obstructive Upper Airway Research (OUaR) Laboratory, Department of Pharmacology, College of Medicine, Seoul, Korea, Republic of

Introduction: Sleep staging is a fundamental component of clinical decision-making in sleep medicine. Polysomnography (PSG), the current gold standard for sleep staging, requires controlled lab settings and manual scoring, making it inconvenient, time-consuming, and prone to inter-rater variability. These limitations restrict the widespread adoption of sleep medicine.

Although deep learning models have improved automatic sleep staging performance, existing methods depend on large-scale architectures with substantial computational demands, hindering their portability and real-time usability.

In this study, we present DistillSleep, a deep learning framework for on-device, real-time, interpretable sleep staging using single-channel electroencephalogram (EEG).

Materials and methods: DistillSleep consists of (1) a high-capacity teacher model and (2) a 109 k-parameter student model designed for edge-device deployment. Both incorporate a Multi-Wavelength Pyramid module and Transformer-based architecture to capture intra- and inter-epoch features. Feature- and prediction-level knowledge distillation transfers the teacher's expertise to the student, helping the student to not only improve its predictive performance, but also its interpretability. Training and evaluation used >10,000 overnight recordings from six cohorts (SHHS1, PhysioNet 2018, DCSM, KISS, Sleep-EDF, ISRUC), following AASM guidelines. Performance was assessed with Macro-F1. Our tailored architecture enables the clinicians to review intra- and inter-epoch mechanisms internally processed by the model, making DistillSleep interpretable to mitigate 'black-box' concerns.

Results: The teacher achieved state-of-the-art Macro-F1 scores (SHHS1 81.1%, PhysioNet 78.9%, DCSM 81.2%, KISS 80.0%) and provided frequency-resolved saliency maps, inter-epoch context and well-calibrated confidence (ECE 0.07). The student maintained competitive accuracy (up to 79.7% Macro-F1 on four large datasets and two external datasets) while executing <10 ms per 30-second epoch on three embedded platforms (Raspberry Pi 4, Jetson orin nano, Coral dev board), reducing computational load 115-fold versus the best prior method (SleepPyCo). Interpretability was transferred intact to the student, offering clinicians frequency-band importance and inter-epoch context visualizations, and model calibration was further improved by 2.7x.

Conclusions: DistillSleep combines expert-level accuracy, millisecond-scale latency, and transparent decision logic in a single-channel EEG form factor. Our extensive experiments prove its practicality and deployability in real world applications. These capabilities pave the way for point-of-care diagnostics, same-night therapy titration, and large-scale home monitoring, expanding the reach of sleep medicine while retaining clinical trust.

Does gaming disorder symptom status predict poorer sleep quality?

N.J. Lia¹, L. Hale², J. Thomas^{3,4}, D. Christakis⁵, M. Rashid³

¹University of Dhaka, Department of Software Engineering, Dhaka, Bangladesh, ²Stony Brook University, Department of Family, Population, and Preventive Medicine, Renaissance School of Medicine, Stony Brook, United States, ³ITHRA, King Abdulaziz Center for World Culture, Dammam, Saudi Arabia, ⁴University of Liverpool, Department of Public Mental Health and Primary Care, Liverpool, United Kingdom, ⁵Seattle Children's Research Institute, Seattle Children's Hospital, Seattle, United States

Introduction: This study investigates the association between Internet Gaming Disorder (IGD) symptoms and self-reported sleep quality in a large international survey. We assessed whether IGD symptom status (five or more) is associated with poorer sleep outcomes.

Materials and methods: We analysed 2023 survey data from 35 countries (n ≈ 35,000; ~1000 participants per country) to examine how Internet Gaming Disorder (IGD) status relates to self-reported sleep quality across countries (see <https://sync.ithra.com/research>). The survey utilises the Internet Gaming Disorder Scale–Short Form (IGDS9-SF), which is a widely used instrument for assessing Internet Gaming Disorder (IGD) based on the nine Diagnostic and Statistical Manual of Mental Disorders (DSM-5) criteria. IGD status was derived from a gaming disorder symptom score based on DSM-5 proposed criteria: participants scoring 5 or more were categorized as “Screening positive for IGD,” all others were classified as “Not Screening positive for IGD”. Sleep quality was assessed using a scale from 0 (Terrible) to 10 (Excellent). Multivariable linear regression analyses were estimated with sleep quality as the outcome and IGD status as the primary predictor variable with additional adjustment for sociodemographic variables (country, age, sex, highest level of education and employment status).

Results:

In the survey, 11.0% met the criteria of screening positive for IGD.

Unadjusted analyses revealed that average sleep quality scores varied across IGD groups. Participants not screening positive for IGD reported the higher mean sleep score (M = 6.38, S = 2.23), while those screening positive for IGD had lower sleep quality (M = 6.19, S = 2.41).

At the country level, the prevalence of IGD ranged from as low as 2.5% in Germany and 2.6% in the UK, to as high as 24.6% in India, 22.1% in Egypt, and 21.3% in Kuwait. In several countries, the gap in sleep scores between IGD positive and not IGD positive groups exceeded one full point, for example, Chile (5.19 vs. 6.49), Brazil (5.59 vs. 6.67) and Italy (4.79 vs. 5.84).

Regression analysis further confirmed these trends. Compared to participants who are not IGD positive, those with IGD reported significantly lower sleep scores ($\beta = -0.418$, $p < .001$), even after adjusting for country, gender, age, education, and employment status.

Conclusions: These global findings indicate that individuals screening positive for Internet Gaming Disorder (IGD), report consistently lower sleep quality compared to those without IGD. Although IGD prevalence and associated sleep outcomes vary significantly across countries, the overall pattern suggests a negative relationship between problematic gaming behaviors and sleep health. The magnitude of these differences, along with substantial country-level variation, highlights the potential influence of sociocultural, behavioral, or structural factors in shaping how IGD affects sleep.

Does the Child-Pugh classification influence circadian sleep parameters?

L. Martínez Alarcón¹, M. Jover², J. Sáez³, P. Ramírez Romero⁴, G. Ramis Vidal⁵

¹Hospital Clínico Universitario Virgen de la Arrixaca, UDICA, Murcia, Spain, ²Instituto Murciano de Investigación en Biomedicina (IMIB), El Palmar-Murcia, Spain, ³Hospital Clínico Universitario Virgen de la Arrixaca, Intensive Care Unit, Murcia, Spain, ⁴Hospital Clínico Universitario Virgen de la Arrixaca, Surgery Service, Murcia, Spain, ⁵Universidad de Murcia, Departamento de Producción Animal, Murcia, Spain

Introduction: The approach to patients on transplant waiting lists should be holistic, including nutrition, physical exercise and sleep quality, beyond the care of the pathology that afflicts them. However, sleep is not usually evaluated in these patients. In this study, we aimed to evaluate the parameters related to sleep quality and circadian rhythm in patients on the waiting list for liver transplantation depending on the severity classification of the disease using the Child-Pugh scale.

Materials and methods: Fifty patients on the waiting list for liver transplantation at the Virgen de la Arrixaca University Hospital were included. Sleep-related parameters were monitored using a Kronowise K6 wrist device and the data were analysed using Kronowise 100 software (both from Kronohealth, Murcia, Spain). Patients wore the device on their non-dominant wrist for at least 7 days prior to transplantation. At the time of recruitment, they were classified using the Child-Pugh scale, with 13 patients classified as A, 25 as B and 12 as C.

Results: Of all the sleep parameters analysed, differences were found when comparing Child-Pugh B patients with those classified as C in Total Time in Bed (min) (B=509,7±26,1 vs C=573,3±22,4 p=0.048), WASO (min) (B= 50,8±8,1 vs C=92,9±20,1; p=0.04), Number of Awakenings/Hour (B= 2,5±0,5 vs C= 5,1±0,4; p=0.017). Trends towards differences were also found for Lights On (hh:mm) (p=0.077), Total Movement Time (min) (p=0.065) when comparing B and C, in the number of naps per day (p=0.059) comparing A and B, and in WASO (p=0.089), number of awakenings/hour (p=0.089) and average activity 2 hours before bedtime (s) (p=0.085) comparing Child A patients with Child B patients.

Conclusions: A worsening of parameters is observed when comparing patients classified as B versus C, although there are no such differences between A and B. There appears to be a threshold for sleep parameter disturbance, which is more pronounced among patients with intermediate and severe severity. In general, as severity increases, patients spend more time in bed, wake up more times per night, and these awakenings last longer. They also experience more restless sleep with more time spent awake during sleep and less activity in the two hours before going to bed. This sets the guidelines for a possible sleep intervention depending on the severity of the liver disease.

Do perceived sleep sufficiency and measured duration relate to health and well-being in the same way?

H. Ahrensberg¹, A.I. Christensen¹, S. Andersen¹, C.B. Petersen^{2,1}

¹National Institute of Public Health, University of Southern Denmark, Copenhagen, Denmark, ²Center for Clinical Research and Prevention Copenhagen University Hospital - Bispebjerg and Frederiksberg, Copenhagen, Denmark

Introduction: Sleep is crucial for health and well-being, but different dimensions of sleep may affect health differently. This cross-sectional study explores the associations of sleep sufficiency and sleep duration with mental health, physical health, and life satisfaction.

Materials and methods: Data from 1,022 individuals (age ≥16 years) from the Danish Health and Morbidity Survey 2023 were used. Sleep sufficiency was self-reported, while sleep duration was measured by accelerometer. Mental and physical health were assessed using the SF-12 questionnaire, and life satisfaction with the Cantril Ladder scale. Multiple adjusted linear regression models were used to examine associations separately and in four combined categories: (1) low sufficiency, <7/>9 hours (n=106), (2) low sufficiency, 7-9 hours (n=89), (3) high sufficiency, <7/>9 hours (n=271), and (4) high sufficiency, 7-9 hours (n=556).

Results: Low sleep sufficiency was strongly associated with poorer mental health and lower life satisfaction. Specifically, individuals sleeping <7/>9 hours and reporting low sleep sufficiency had

mental health scores 8.6 points (95% CI: -10.8; -6.25) lower than those sleeping 7-9 hours and reporting high sleep sufficiency. In addition, deviations from recommended sleep duration combined with low sleep sufficiency was associated with poorer physical health.

Conclusions: Sleep sufficiency showed a more strongly associated with mental health and life satisfaction than sleep duration alone, indicating that these dimensions are not interchangeable. This highlights the need to consider both aspects in population-based sleep monitoring and public health initiatives.

Dreaming of death: an exploration of the relationship between death anxiety and nightmare severity

I. Dunican¹, M. Turner², H. Meaklim³, D. Cunnington⁴, M. Burge⁵, R. Menzies⁶

¹University of Western Australia, Perth, Australia, ²Edith Cowan University, Perth, Australia, ³University of Melbourne, John Trinder Sleep Laboratory, Melbourne School of Psychological Sciences, Melbourne, Australia, ⁴Sunshine Coast Respiratory & Sleep, Birtinya, Australia, ⁵Monash University, School of Psychological Sciences, Melbourne, Australia, ⁶The University of Sydney, School of Psychology, Sydney, Australia

Introduction: Throughout history and across cultures, humans have been interested in the relationship between dreams, nightmares and death. There is a scarcity of research examining this relationship, and findings have been mixed. This study aimed to (i) quantify the potential prevalence of nightmare severity and death anxiety, explore associations and differences between sexes and age groups, and (ii) examine typical dreams and their relationship to death-related themes.

Materials and methods: A total of n=432 participants (n=128 males and n=304 females) completed a cross-sectional study using the Death Anxiety Beliefs and Behaviour Scale (DABBS), Disturbing Dream and Nightmare Severity (DDNSI) and the Typical Dreams Questionnaire (TDQ).

Results: This study found that 10% had a self-reported sleep disorder, and 47% reported a mental health diagnosis. We found that 15% had clinical scores for DABBS, which was significantly higher in females, and in those with a mental health diagnosis ($p < 0.001$ for all), DDNSI was at 26% for the group. Linear regression identified a significant relationship between DDNSI and DABBS score. Greater levels of death anxiety were significantly associated with ($p = .003$) increased DDNSI scores ($\beta = 0.08$, Adj. $R^2 = 0.019$). When analysing the TDQ, those who had death-related dreams had significantly higher death anxiety and disturbing dreams and nightmares.

Conclusions: This study shows the need for more clinical attention and research on sleep health and its impact on health and well-being.

Effectiveness Of Sleep Intervention on Self-Reported Sleep Indices in Elite Male Cricketers: A Pilot Study from India

M. Sharma¹

¹Sleep Moksha, Panchkula, India

Introduction: While sleep is increasingly recognized as a critical component in aiding the recovery process and enhancing performance in elite athletes, however, research in this area remains quite limited in the Indian context. This study aimed to evaluate the impact of a 4-week sleep intervention on sleep quality, duration, daytime sleepiness, sleep behaviours, issues, and disruptions in elite athletes.

Materials and methods: 20 elite male cricketers (mean age=23.5) underwent 2 weeks of baseline sleep monitoring and assessments (PRE), followed by a 4-week sleep intervention, and a further 2 weeks of monitoring and assessments (POST). Standard questionnaires (PSQI, ESS, ISI, ASSQ, ASBQ) were used to evaluate key sleep indices along with daily self-monitoring with a sleep diary. The sleep intervention focused on sleep education, improving sleep hygiene, enhancing total sleep time, and providing strategies for better recovery. Paired-sample t-tests were used to assess pre- and post-intervention differences.

Results: At baseline, the mean scores on all standardised measures indicated suboptimal sleep patterns among the participants. However, from baseline to post-intervention, analysis showed significant reductions (at $p < 0.05$) in ESS, ASBQ, and (at $p < 0.01$) in ISI, PSQI. Additionally, total sleep time

increased from 7.82 hours at baseline to 8.16 hours post-intervention ($p=0.001$), suggesting positive intervention effects.

Conclusions: Results provide evidence of the effectiveness of sleep intervention in elite male cricketers.

The study highlights a critical concern regarding the prevalence of significant sleep disturbances and daytime dysfunction among the participants. It indicates that there is ample room for sleep improvement. It is strongly recommended that structured sleep interventions (including education on the importance of sleep, optimizing sleep hygiene, and specifically targeting maladaptive sleep behaviours) be integrated into the training programs of elite athletes to enhance both recovery and performance. This may facilitate the sleep upgrading process for recovery and performance by effectively improving sleep indices in elite athletes.

keywords: Sleep quality; Sleep hygiene; elite athlete; sleep behaviour; cricket, recovery.

Acknowledgments: I would like to extend my heartfelt gratitude to all the athletes who took part in this study.

Effect of a Combined Lifestyle-Based Intervention on Sleep among Postgraduate Nursing Students: A Pilot Study of the SEED Program

Y. Dong¹, J.E.G. Embang², C. Goh¹, S. Pang¹, Y. Guo³

¹National University of Singapore, Alice Lee Centre of Nursing Studies, Singapore, Singapore, ²National University Hospital, Singapore, Singapore, ³University of California, Irvine, United States

Introduction: Sleep plays a crucial role in the well-being and functional performance of healthcare professionals. Postgraduate nursing students are particularly vulnerable to poor sleep due to the competing demands of their curricula and shift-based clinical rotations. Moreover, sleep disturbances in this population can significantly impair both learning and clinical performance. While lifestyle factors have been linked to improve sleep outcomes, limited studies have explored the combined synergistic effects of these factors. This pilot study evaluated the impact of the SEED programme—consisting of Sun exposure, Exercise, Education on sleep hygiene, and Diet —on sleep hygiene behaviours and subjective sleep quality among postgraduate nursing students.

Materials and methods: A six-week quasi-experimental study was conducted among 28 postgraduate nursing students, who were non-randomly assigned to intervention ($n = 17$) or control ($n = 11$) groups. Sleep hygiene was assessed using the Sleep Hygiene Index(SHI), and subjective sleep quality was measured using the Pittsburgh Sleep Quality Index(PSQI) at baseline and post-intervention. Due to the small sample size and group baseline differences, non-parametric tests were utilised for PSQI analyses, and ANCOVA was performed to SHI outcomes to adjust for baseline SHI scores.

Results: The intervention group exhibited a modest improvement in mean sleep hygiene scores (Mean $\pm$ SD) (-0.47 ± 3.69), while the control group showed a deterioration in these scores ($+ 2.73 \pm 4.13$). The Mann-Whitney U Test suggests a potential protective effect of the SEED programme on sleep hygiene ($p = 0.055$). However, the group assignment was not a statistically significant predictor of post-intervention SHI scores($p = 0.118$). Notably, baseline SHI emerged as a significant covariate($p=0.011$), indicating that participants with poorer sleep hygiene at baseline were more likely to demonstrate improvement following the intervention. PSQI analyses showed that the intervention group's median PSQI scores decreased from 6.0 to 4.0, while the control group's scores increased from 5.0 to 6.0. Wilcoxon signed-rank test was also done to evaluate within-group changes, revealing that none reached statistical significance for the intervention group ($Z = -1.34, p = 0.179$) nor the control group ($Z = -1.60, p = 0.109$).

Conclusions: The SEED intervention was feasible to implement and demonstrated promising trends towards improving sleep hygiene and maintaining subjective sleep quality among postgraduate nursing students. While statistical significance was not achieved, descriptive trends suggested a protective effect of the SEED programme against worsening sleep among this population. These findings suggest that targeted, multi-component lifestyle interventions may be beneficial in supporting the sleep health of this population. Future studies with larger sample sizes and longer duration are needed to validate such preliminary findings. Incorporating subjective and objective sleep measures may also capture meaningful changes in sleep quality and consolidate behaviour change.

Effect of differences in human ipRGCs stimulation under lighting during sleep

S. Takamine¹, S. Uiji¹, S. Ishiguro¹, Y. Yunoki¹, A. Shimba¹, T. Morita¹, H. Kiriara², T. Nakamura¹, Y. Fukuda³, M. Takao⁴, T. Wakamura¹

¹Kyoto University, Graduate School of Medicine, Kyoto, Japan, ²ELM Inc., 1st Development Dept., Minamisatsuma, Japan, ³The University of Kitakyushu, Department of Architecture, Kitakyushu, Japan, ⁴Tokai University, School of Information Science and Technology, Hiratsuka, Japan

Introduction: In hospital intensive care units (ICUs), nurses want to keep patient rooms as bright as possible at night to facilitate observation. However, the bright lighting conditions at night are not necessarily healthy for the quality of patients' sleep. The intrinsically photosensitive retinal ganglion cells (ipRGCs) are the cells in the retina, which contribute to photic entrainment of human circadian rhythm. Recently, it has become possible to change the ipRGCs stimulus level while maintaining the same light intensity and color rendering using LED light sources. This light source may provide a light environment that ensures clear visibility for nurses without disturbing patients' sleep. In fact, there is no clear evidence as to how differences in ipRGCs stimulation levels at night affect sleep quality. The purpose of this study is to clarify whether the differences of ipRGCs stimulus dose affect human sleep efficiency under lighting during sleep.

Materials and methods: Twenty-two healthy adult males (mean $\pm$ SD: 21.4 $\pm$ 1.9 yr. old) participated in this laboratory experiment. All participants had normal color vision variation (Ishihara test), had no sleep disorder (the score of Pittsburgh Sleep Quality Index), had no medication, and were not smokers. None of the participants were extreme morning or evening types (Morningness-Eveningness Questionnaire) and were shift workers. Experiments were conducted between January and May 2025. For three days prior to experiment onset, participants were asked to maintain a regular sleep-wake schedule (sleep onset at 0000 and waking at 0730). The participants arrived at the experimental chamber at 1300 and stayed for five days. The light condition was kept in 500 lx and 5000 K using special LED light source (ELM Inc. Japan). The participants retired to bed at 0000 and awakened at 0730. The participants slept under dark (0lx, baseline) on the first and the third night, and under lighting (500 lx, 5000 K) on the second and fourth night. Sleep parameters were compared under two lighting conditions: standard LED lighting typically used in hospitals (Control, Melanopic Efficacy of Luminous Radiation, ELR: 1.14 mW/lm), and special lighting to reduce ipRGCs stimulation (Intervention, Melanopic ELR: 0.96 mW/lm) at night. The difference caused by these lighting conditions were not distinguished to the participants. The order of these light conditions was counterbalanced among the participants. Wrist activity was continuously measured with the actigraph (Motion Watch 8, CamNtech Ltd) throughout the experiment. The sleep parameters were used to analyze. This study was approved by the Kyoto University Graduate School and Faculty of Medicine, Ethics Committee. Informed consent was obtained from the participants after an explanation of the purpose of the study.

Results: The sleep efficiency was compared between Control and Intervention at night using a one-way ANOVA. There was no significant difference between Control (84.5 $\pm$ 4.7%) and Intervention (84.7 $\pm$ 5.5%).

Conclusions: The differences in ipRGCs stimulus dose did not affect young healthy people's sleep efficiency under lighting during sleep. Other parameters including rectal temperature and saliva melatonin are ready to be analyzed.

Acknowledgments: This work was supported by JSPS KAKENHI Grant Number 23K18373.

Effect of elinzanetant on wakefulness after sleep onset across subjective and objective measures: post hoc analysis of the NIRVANA phase 2 pilot study in postmenopausal women with sleep disturbances

R.E. Nappi¹, C.N. Soares², G. Zammit^{3,4}, F.C. Baker⁵, H. Joffe⁶, P.M. Maki⁷, C. Caetano⁸, H.-S. Radcliffe⁹, U. Krahn¹⁰, H. Shalhoub¹⁰, F. Kramer⁹, C. Seitz^{10,11}

¹University of Pavia, San Matteo Hospital, Pavia, Italy, ²Queen's University, Kingston, Canada, ³Clinilabs Drug Development Corporation, Eatontown, United States, ⁴Icahn School of Medicine at Mount Sinai, New York, United States, ⁵SRI International, Menlo Park, United States, ⁶Brigham and Women's Hospital, Harvard Medical School, Boston, United States, ⁷University of Illinois Chicago, Chicago, United States, ⁸BAYER Consumer Care AG, Basel, Switzerland, ⁹BAYER AG, Wuppertal, Germany,

¹⁰BAYER AG, Berlin, Germany, ¹¹Institute of Clinical Pharmacology and Toxicology, Charité Universitätsmedizin, Berlin, Germany

Introduction: Nighttime wakefulness is a common and disruptive symptom in postmenopausal women with vasomotor symptoms (VMS). Elinzanetant, a dual neurokinin (NK)-targeted therapy (NK-1 and NK-3 receptor antagonist), has previously shown improvements in patient-reported sleep outcomes. The Phase II NIRVANA pilot trial was the first to evaluate the elinzanetant effect on wakefulness after sleep onset (WASO) using both objective (polysomnography [PSG], Sleepiz One+) and subjective measures (Sleep Diary) in postmenopausal women with moderate-to-severe VMS. This abstract reports the findings from a post hoc analysis to determine whether changes in WASO with elinzanetant were observed across all three modalities.

Materials and methods: In this randomized, double-blind trial, 110 postmenopausal women (mean [standard deviation; SD] age: 54.8 [4.6] years) with PSG-confirmed sleep disturbances (WASO ≥ 30 minutes) and ≥ 20 moderate-to-severe VMS per week were randomized to elinzanetant 120 mg (n=55) or placebo (n=55) once daily for 12 weeks. Sleep disturbances were assessed using in-lab PSG and a patient-reported Sleep Diary for all participants, and with the Sleepiz One+ (Sleepiz AG, Zurich, Switzerland) contactless home-monitoring device in a sub-sample (n=66; elinzanetant: n=33, placebo: n=33). PSG was conducted at baseline, week 4, and week 12 (two consecutive nights per time point). Sleepiz One+ and Sleep Diary data were collected nightly throughout the 12-week treatment period. Data were analyzed on the original scale to provide consistency in data presentation across measures. A post hoc random coefficient model estimated the treatment effects on WASO over the 12-week treatment period across all available nights for each method.

Results: Elinzanetant demonstrated numerical reductions in WASO relative to placebo across all assessment modalities.

PSG: Mean (SD) WASO at baseline was 74.7 (34.8) minutes in the elinzanetant group and 82.8 (34.4) minutes in the placebo group. Random coefficient modeling suggested an overall treatment effect over the 12-week treatment period favoring elinzanetant over placebo (least squares [LS] mean difference: -10.1 minutes; unadjusted 95% confidence interval [CI]: -18.5, -1.6).

Sleepiz One+: Mean (SD) WASO at baseline was 77.7 (52.6) minutes in the elinzanetant group and 61.7 (27.6) minutes in the placebo group. Random coefficient modeling indicated a treatment effect over the 12-week time period favoring elinzanetant over placebo (LS mean difference: -17.7 minutes; unadjusted 95% CI: -27.1, -8.2).

Sleep Diary: Mean (SD) WASO at baseline was 42.4 (25.7) minutes in the elinzanetant group and 45.5 (25.6) minutes in the placebo group. Random coefficient modeling indicated a treatment effect over the 12-week time period favoring elinzanetant over placebo (LS mean difference: -8.1 minutes; unadjusted 95% CI: -14.2, -1.9).

Conclusions: NIRVANA is the first study to integrate gold-standard PSG, continuous home sleep monitoring, and patient-reported outcomes to assess treatment effects on WASO in postmenopausal women with VMS and sleep disturbances. In this post hoc analysis, greater numerical reductions in WASO were seen in the elinzanetant arm compared with placebo across all measurements. These results align with improvements in sleep disturbances observed in previous OASIS trials using patient-reported outcomes, though the exploratory nature and sample size of this analysis highlight the need for larger confirmatory studies.

Acknowledgments: This study was sponsored by Bayer.

Effect of Sleep Quality on Heart Rate Variability in Medical Students: A Cross-sectional Study

P. Dower¹, K.K. Alam¹, G. Kumar¹, M. Gupta¹

¹University College of Medical Sciences, Department of Physiology, New Delhi, India

Introduction: In addition to being a biological necessity, sleep is a key regulator of cardiovascular health, emotional stability, and cognitive functioning. Medical students have particularly poor sleep quality due to their busy schedules, lifestyles choices, and high levels of academic stress. This vulnerable group frequently exhibits early symptoms of autonomic imbalance, a marker of long-term health risks. Heart rate variability (HRV) is a sensitive biomarker of autonomic nervous system (ANS) activity that offers non-invasive window to this physiological interaction. Studies demonstrating the connection between autonomic dysregulation and insufficient sleep continue to underrepresent

medical students. This study aimed to examine the connection between HRV and sleep quality in order to offer a distinct physiological understanding of how sleep disruptions may subtly harm cardiovascular health.

Materials and methods: After receiving the Institutional Review Board Ethical approval, 84 MBBS students, aged 18 to 25, with normal BMIs (18.5-24.9 kg/m²), participated in a descriptive, cross-sectional correlational study. The validated Pittsburgh Sleep Quality Index (PSQI), which measures subjective sleep quality over the previous month, was filled out by the participants. With an ECG recorded in lead II configuration, HRV recordings were made using the Power Lab AD instruments (Australia) under controlled conditions. To determine HRV parameters, a stable 5-minute ECG segment was examined offline using Lab Chart Pro 8. Frequency-domain measurements (Low Frequency [LF], High Frequency [HF], LF/HF) and time-domain indices (SDNN, RMSSD, pRR50) were calculated. Pearson or Spearman tests with a significance threshold of $p < 0.05$ were used to analyze statistical correlations between PSQI components and HRV indices using SPSS v26.0.

Results: Around 71% of students slept fewer than the recommended 7 hours, and a startling 76.2% of students had poor sleep quality (PSQI ≥ 5). 6.44 ± 2.62 was the average global PSQI score. Parasympathetic HRV indices, including HF ($r = -0.358$, $p < 0.01$), pRR50 ($r = -0.288$, $p < 0.01$), and RMSSD ($r = -0.227$, $p < 0.05$), were strongly inversely correlated with poor sleep quality. On the other hand, positive correlations with LF ($r = 0.375$, $p < 0.01$) and LF/HF ratio ($r = 0.390$, $p < 0.01$) indicated sympathetic dominance. Autonomic imbalance was substantially associated with subjective sleep quality, sleep efficiency, and dysfunction during the day.

Conclusions: The study provides a compelling physiological narrative: autonomic dysregulation, which is characterized by decreased parasympathetic and increased sympathetic activity, is significantly linked to poor sleep quality in the medical students. These changes could predict cardiovascular risks in the future. In order to protect the health of tomorrow's healers, there is an increasing need for focused interventions that give sleep hygiene top priority in medical curricula.

Acknowledgments: We express our sincere gratitude to the Indian Council of Medical Research (ICMR) for providing funding for this Short-Term Studentship project (Ref ID: 2023- 05950). Sincere gratitude for the enthusiastic participation and cooperation of the participating students, the Department of Physiology, and the Institutional Ethics Committee.

Effects of a 12-Week Machine-assisted Strengthening Program on sleep health in Frail Older Adults

H.-Y. Chiu¹, W.-S. Lin², K.-T. Chou³

¹Taipei Veterans General Hospital, Hsinchu branch, Zhudong, Taiwan, ²Taipei Veterans General Hospital, Yuanshan branch, Yilan, Taiwan, ³Taipei Veterans General Hospital, Taipei, Taiwan

Introduction: Insomnia is a common sleep-related complaint in the elderly. Rehabilitation has been shown to have multiple benefits for the elderly, and a new trend of machine-assisted strengthening programs has been developed. Therefore, we compared the effects of a 3-month machine-assisted strengthening program to traditional physical therapy according to composite insomnia symptoms related to falling and the SATED questionnaire among community-dwelling frail older adults.

Materials and methods: A randomized controlled trial included 59 frail older adults (mean age: 78.0 ± 8.2 years) in north-eastern Taiwan. The intervention group (N=31) underwent a 12-week machine-assisted strengthening program using SMARC system, performing twice-weekly sessions that targeting 8 muscle groups, while the control group (N=28) received traditional physical therapy. We reviewed the sleep health of the participants with a self-reporting questionnaire, including composite insomnia symptoms related to falling and the SATED scale.

Results: The control group showed no statistical significant change in SATED questionnaire and composite insomnia symptoms related to falling before and after traditional rehabilitation. The intervention group showed improvement in composite insomnia symptoms related to falling (-0.65 ± 0.91 , $p < 0.01$). When focusing on individual insomnia symptoms, the intervention group showed statistical improvement on 'trouble falling asleep' (-0.13 ± 0.34 , $p = 0.04$), 'trouble with waking up during the night' (-0.29 ± 0.46 , $p < 0.01$), and 'trouble with waking up too early and not being able to fall asleep again' (0.20 ± 0.40 , $p = 0.01$).

Conclusions: Machine-assisted strengthening can improve the participants' composite insomnia symptoms related to falling and individual aspects of insomnia. Larger-scale research is still needed for further understanding.

Effects of a behavioral sleep extension intervention on actigraphically measured sleep and patient reported outcomes

K. Baron¹, J. Duffecy², A. Bress¹, M. Conroy¹, S. Simonsen¹, C. Allen², T. Greene¹

¹University of Utah, Salt Lake City, United States, ²University of Illinois at Chicago, Chicago, United States

Introduction: Up to 1/3 of adults in the world sleep less than the recommended 7 hours, which increases risk for chronic disease, depression and poorer quality of life. The goal of this study was to test the effects of an 8 week behavioral sleep extension intervention among adults with elevated blood pressure and objective sleep duration < 7 hours per night.

Materials and methods: Adults ages 18 and above with self-reported sleep duration <7 hours were screened in person for blood pressure criteria and then underwent 7 nights of at home actigraphy, 24 hours of ambulatory blood pressure recording and one night of home sleep apnea screening. Inclusion criteria were sleep duration <7 hours and time in bed <7 hours, insomnia severity index <15 and apnea hypopnea index ≤15 events/hour and resting office blood pressure >120 systolic blood pressure and/or 80 diastolic blood pressure. Eligible participants were randomized to an 8 week intervention that consisted of brief telephone coaching, a fitbit and weekly educational content versus health education and a brief phone call. Participants received monthly follow-ups from 8 weeks to 6 months and no intervention from 6-12 months. Data were analyzed using longitudinal models.

Results: The study screened 360 participants for objective study criteria and 120 participants were eligible and randomized into the study, N=60 were assigned to the sleep extension intervention (age m=42.2, sd=11.3, n=25 females) and N=60 were assigned to the health education control group (age m=41.0, sd=10.2, n=23 females). Retention was high in both groups (intervention =97% at 8 wks and 96% at 12 mos, control 98% at 8 wks and 97% at 12 mos). Most participants (79%) were working full time. Adherence to the intervention and control sessions was 100% because any missed sessions could be completed the following week. The intervention group demonstrated a greater change in sleep duration (m= +25.0 sd=4.8 min compared to the control group (m=+10.8 sd=4.8 min, p=.032) at the primary endpoint of 8 weeks. We detected no significance differences between the groups in sleep duration changes from baseline at 6 or 12 months or in other actigraphy measures including sleep efficiency, wake after sleep onset or sleep midpoint at any of the timepoints. The intervention group demonstrated greater improvement in depression scores (intervention m=-1.8 sd=.33 versus control m=-0.1, sd= 0.33, p<.001) but there were not other significant changes in self-reported sleep quality, sleep related impairment or perceived stress.

Conclusions: Results demonstrate a behavioral sleep extension led to increased sleep duration and improved mood with short term coaching but effects were not maintained following the intervention. Future research is needed to understand variability in sleep outcomes and techniques to maintain sleep changes over time.

Effects of B vitamin intake on sleep duration and pulse wave velocity: a cross-sectional study based on NHANES

Y. Chu¹, H. Xu¹, S. Yin¹

¹Shanghai Sixth's People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China

Introduction: Sleep duration exhibits a U-shaped relationship with cardiovascular disease (CVD) risk and arterial stiffness, where both short (<7 h) and long (>9 h) sleep are independent risk factors. Although B vitamins, particularly riboflavin (B2), improve vascular endothelial function, their association with sleep duration remains mechanistically unclear. Our prior genetic study identified a missense variant in the riboflavin transporter *SLC52A3* (OR=0.83; 95%CI: 0.79-0.88; P<0.01) associated with obstructive sleep apnea severity, suggesting a nutrient-sleep-vascular link. Leveraging NHANES 2021-

2023 data, this cross-sectional study aimed to examine associations between dietary B vitamin intake and sleep duration categories and to assess their joint effects on arterial stiffness.

Materials and methods: We analyzed adults from NHANES 2021-2023 with complete data on dietary B vitamins (B1/B2/B3/B6/B9/B12, choline), sleep duration, and pulse wave velocity. Sleep duration was categorized as short (<7 h), optimal (7-9 h), or long (>9 h) according to National Sleep Foundation guidelines. Total vitamin B intake was calculated from both dietary sources and supplements. ePWV was calculated using a validated equation from the Reference Values for Arterial Stiffness Collaboration. Survey-weighted multinomial logistic regression assessed associations between B vitamin intake and sleep duration categories, with restricted cubic splines (RCS) used to model non-linear relationships. Models were adjusted for age, sex, BMI, race and blood pressure as key covariates. **Results:** Among 4,599 adults (median age 46.8 years; 48.5% male), participants meeting recommended B vitamin intake had higher odds of optimal sleep (OR=1.62, 95%CI: 1.38-1.91). This association followed U-shaped curves, strongest for vitamin B2. ePWV was higher in short sleepers (843 cm/s) than in optimal sleepers (827 cm/s; $P<0.001$). Moreover, vitamin B intake significantly modified the sleep-ePWV association: among short sleepers, each 1-SD increase in B2 intake reduced ePWV by 3.36 cm/s (95%CI: 2.36-4.36; $P<0.05$). Significant interactions were also observed for vitamins B1, B3, B6, and choline ($P<0.05$).

Conclusions: Adequate B vitamin intake, especially riboflavin, is associated with optimal sleep duration and reduced arterial stiffness in short sleepers. While the cross-sectional design limits causal inference, nutritional interventions targeting B vitamins may nonetheless benefit cardiovascular health in individuals with sleep disturbances.

Effects of Physical Activity on Sleep and Cardiovascular Health Across the Adult Lifespan in Singapore

T. Martin¹, J.L. Ong¹, S. Qin¹, C.S. Soon¹, X.Y. Chua¹, L.H. Ling², W.P. Koh³, M.W. Chee¹

¹National University of Singapore, Centre for Sleep and Cognition, Singapore, Singapore, ²National University of Singapore, Department of Cardiology, National University Heart Centre, National University Health System, Singapore, Singapore, ³National University of Singapore, Healthy Longevity Translational Research Programme, Singapore, Singapore

Introduction: Regular physical activity is widely recognised to improve sleep and is associated with reduced cardiovascular disease risk and mortality. However, prior literature has typically focused on a single age group, often relying on subjective measures of physical activity. The present study examined the relationship between objectively measured daily physical activity (PA; defined as the combined duration of light and moderate-to-vigorous physical activity) and both sleep and cardiovascular health across three cohorts spanning the adult lifespan in Singapore.

Materials and methods: A four-week subset of activity and sleep data, collected using the Oura Ring, was drawn from three cohorts: university students ($n = 500$, mean age = 19.9 ± 1.34), working adults ($n = 329$, mean age = 41.4 ± 10.2), and older adults ($n = 1,030$, mean age = 74.0 ± 2.63). Cardiovascular risk factors – body mass index (BMI) and pulse wave velocity (PWV) – were collected and analysed only for the working and older adult cohorts, given the lower expected risk among student age range. Sleep outcomes (duration, timing, efficiency) were analysed across all cohorts. Multilevel models were conducted on 38,586 nights of data to uncover the within-subject impact of PA duration on sleep outcomes.

Results: Descriptive analyses showed that older adults engaged in the longest PA durations ($M = 416.91$ min, $SE = 2.9$), predominantly in the morning. In contrast, working adults ($M = 345.23$ min, $SE = 3.7$) and university students ($M = 313.83$ min, $SE = 3.05$) had shorter PA durations, predominantly occurring in the evenings. Among working adults, PA was clustered around commute and meal times, while university students' PA typically flanked their academic lessons. After adjusting for age and gender, PA duration was negatively correlated with BMI ($r = -0.12$, $p < .001$) and PWV ($r = -0.10$, $p < .001$). A linear mixed-effects model, controlling for age, gender, weekdays and PA timing preferences, across all subjects revealed that longer PA duration predicted shorter total sleep time ($p < .001$), later bedtimes ($p < .001$), and earlier wake times ($p < .001$) within subjects. However, longer PA duration was also associated with higher sleep efficiency ($p < .001$) and shorter wake-after-sleep-onset (WASO; $p < .001$).

Conclusions: These results highlight increasing objectively measured PA duration with increasing age, which differs from subjective findings in other cohorts. However, the association between greater PA

duration and reduced cardiovascular risk align with existing literature, as indicated by lower BMI and PWV. Moreover, despite longer PA duration predicting shorter sleep duration, its associations with higher sleep efficiency and lower WASO suggest that it does not negatively impact sleep.

Effects of thermal and olfactory control of bedroom air on sleep restfulness during summer: A randomized crossover trial

C. Yasumoto¹, S. Hanaoka¹, O. Nishigami¹, S. Hashimoto¹, Y. Sakata¹, K. Kuriyama², T. Yoshiike²

¹Daikin Industries, Ltd, Technology and Innovation Center, Settsu, Japan, ²National Center of Neurology and Psychiatry, Department of Sleep-Wake Disorders, National Institute of Mental Health, Kodaira, Japan

Introduction: An optimized and relaxing bedroom environment is essential for maintaining sleep health. Experimental evidence suggests that dynamically controlling the ambient temperature during the night promotes homeostatic and circadian regulation of sleep more effectively than static control. Olfactory stimulation with fragrances (e.g., lavender oil) has been reported to affect sleep through parasympathetic modulation. Sleep restfulness, the feeling of being rested after sleep, is considered a marker of sleep health because it is related to health outcomes, including mortality. However, it is unclear whether the dynamic thermal and olfactory control of bedroom air alters sleep restfulness.

Materials and methods: In this randomized crossover trial, 23 healthy adults were recruited and instructed to sleep at home under 3 different thermal and olfactory conditions using an air conditioner and a diffuser for 3 consecutive weeks during the summer months. The conditions were Constant Temperature (CT), in which the bedroom temperature was maintained at 26°C; Dynamic Temperature (DT), in which the bedroom temperature was gradually increased from 26°C to 28°C; and DT with Olfactory Stimulation (DT/OS), in which DT was combined with olfactory stimulation using lavender oil during the sleep onset period. Each condition consisted of three consecutive nights and was separated by a four-day washout period. Sleep restfulness, a subjective measure of sleep quality, was assessed using a visual analog scale and compared across conditions. Participants' night sleep was quantified using in-home sleep electroencephalography. Linear mixed models were used to determine whether thermal and olfactory interventions in bedroom air promoted sleep restfulness.

Results: Seven participants were omitted, primarily due to technical issues, resulting in a final sample of 16 participants (14 male/2 female; mean $\pm$ SD age: 53.8 $\pm$ 7.2 years). Participants reported feeling more rested after sleep in the DT/OS condition (mean $\pm$ SD: 67.1 $\pm$ 21.3) than in the CT (59.7 $\pm$ 19.1, P = .010) and DT (59.3 $\pm$ 23.3, P = .007) conditions. Sleep duration, sleep continuity, and sleep structure did not differ across conditions.

Conclusions: The data suggest that olfactory stimulation during sleep onset promotes restorative sleep. The development of novel dynamic thermal control of bedroom air warrants further investigation. Optimizing bedroom air may be important for promoting sleep health.

Acknowledgments: We thank Nishino N, Emoto S, Okumoto M, and Goto Y for their assistance with the methodology and data collection.

Emotional labor moderating the impact of work rumination on sleep quality among newly graduated nurses in China

R. Yin¹, X. Shi¹, Y. Han¹, L. Mao¹, L. Chen¹

¹The First Affiliated Hospital of Soochow University, Suzhou, China

Introduction: The year 2024 marks the first year that Jiangsu Province deeply implemented the national policy of two-year standardized training for newly graduated nurses. The work intensity and learning content faced by newly graduated nurses in 2024 have increased significantly. Under such heavy pressure, coupled with the pressure of role transformation, their psychological state trend requires the urgent attention of nursing managers. For this group, maintaining a healthy mindset, getting sufficient sleep, working when it's time to work and resting when it's time to rest are the keys for them to smoothly get through this period. However, the sleep and working conditions of newly graduated nurses in the first year of policy implementation remain unclear at present. Therefore, this study aims to explore the sleep and working status of this group, investigate the moderating role of

emotional labor on the associations of rumination with sleep quality, so as to identify a reference for the subsequent arrangement of standardized training work.

Materials and methods: In the descriptive, cross-sectional study, one hundred and ninety-three newly graduated nurses (nurses with <1 year of work experience) were included in the study. Data were collected using the Chinese version of the Pittsburgh Sleep Quality Index (PSQI), Work-Related Rumination Questionnaire (WRRQ), Emotional Labor Scale (ELS) to measure sleep quality, rumination, and emotional labor, respectively. SPSS and Mplus were applied to perform descriptive and moderated mediation analysis, respectively.

Results: In the first year of work, the prevalence of poor sleep quality among newly graduated nurses was as high as 72.2%, and 62.2% of them slept for less than 7 hours per day. The total score of newly recruited nurses' surface acting strategy was 25.83 ± 4.35 , 14.58 ± 2.51 for deep acting strategy, and 10.50 ± 1.87 for expression of genuine emotion. Newly recruited nurses-emotional labor strategies were used from highest to lowest frequency as the expression of surface acting, deep acting, and genuine emotion, with the mean entry score of 3.69, 3.62, and 3.50, respectively. The mean values of affective rumination and problem-solving pondering were 15.23 ± 0.36 and 15.32 ± 0.26 respectively, indicating the medium level of work rumination. Work rumination and emotional labor strategies were associated with sleep quality (Standardized $\beta = 0.676$, $P < 0.001$; $\beta = -0.191$, $P = 0.043$, respectively). In addition, work rumination had an indirect impact on sleep quality by influencing emotional labor strategies (Standardized $\beta = 0.318$, $P = 0.001$). Thus, a moderated model involving emotional labor for explaining the impact of work rumination on poor sleep quality was supported among newly graduated nurses within <1 year of work experience.

Conclusions: In the first year of the two-year standardized training, the sleep quality of newly graduated nurses during the standardized training period is very poor, and the sleep duration was seriously insufficient. Emotional labor strategies moderated the relationship between work rumination and sleep quality. Nursing managers need to pay attention to the sleep of nurses during this period, adjust the training content in a timely manner to relieve their stress, help regulate their psychological state, distinguish work from life, and ultimately improve their sleep quality.

Enhancing Pediatric Sleep Health: Development of an Interdisciplinary Educational Course for Primary Care and Sleep Medicine Providers

A. Wani¹, A. Shakkotai², B. Kancherla³, D. Ingram⁴, R. Bhattacharjee⁵, R. Llyod⁶, C. Canapari⁷, L. Petito³, E. Eccleston^{8,8}, F. Stocker⁸

¹UT Southwestern Medical Center, Pediatrics and Family and Community medicine, Plano, United States, ²UT Southwestern Medical Center, Pediatrics, Plano, United States, ³Texas Childrens, Baylor College of Medicine, Pediatric Pulmonology/ Sleep, Houston, United States, ⁴University of Missouri-Kansas City School of Medicine, Pediatrics, Kansas City, United States, ⁵Rady Childrens Hospital San Diego, Pediatrics, San Diego, United States, ⁶Mayo Clinic, Pediatrics, Rochester, United States, ⁷Yale University, Pediatrics, New Haven, United States, ⁸American Association of Sleep Medicine, Instructional Design, Darien, United States

Introduction: Pediatric sleep disorders are common, underrecognized contributors to behavioral, cognitive, and physical health problems in children. While pediatric sleep medicine is a growing field, most primary care and general sleep medicine providers receive minimal training in pediatric-specific sleep assessment and management. To address these gaps, the American Academy of Sleep Medicine (AASM), in collaboration with eight pediatric sleep medicine experts and AASM education staff, developed a targeted educational course to build knowledge and clinical confidence in this area. The course was designed using evidence-based instructional practices grounded in adult learning theory, which emphasizes learner self-direction, practical application, and integration with prior experience (Knowles, 1980; Merriam & Bierema, 2014). Development followed best practices in curriculum design, including needs assessment, goal alignment, and iterative content review (Harden, 2000). AASM staff with formal training in instructional design and adult education played an integral role in shaping the structure, delivery, and accessibility of the course.

Materials and methods: Eight pediatric sleep practitioners from diverse clinical and academic settings collaborated with AASM instructional design staff to plan and create the course. A comprehensive needs assessment was conducted using member surveys, literature review, and feedback from AASM-accredited centers. The course was designed to be asynchronous, modular, and adaptable to various

practice environments. It features didactic content, case-based learning, clinical algorithms, and downloadable decision-support tools. Key topics include behavioral insomnia, circadian rhythm disorders, sleep-disordered breathing, parasomnias, and appropriate referral strategies.

Results: The final course includes eight modules totaling approximately six hours of CME-accredited content. Each module is designed for flexible, self-paced engagement and includes evidence-based materials, real-world case vignettes, and practical tools for clinical use. Content is tiered to accommodate varying levels of experience among learners and emphasizes actionable strategies for screening, diagnosis, management, and interdisciplinary collaboration.

Conclusions: This collaborative initiative highlights the effectiveness of combining clinical expertise with professional instructional design to create relevant, high-impact education for healthcare providers. By addressing critical knowledge gaps in pediatric sleep medicine, the course serves as a scalable model for cross-disciplinary learning. Future efforts will focus on evaluating learner outcomes, updating content based on emerging evidence, and expanding access to a broader provider audience. This effort supports the AASM's mission to promote high-quality sleep care and improve outcomes for children and families

Introduction: Sleep is a vital physiological process essential for physical recovery, cognitive function, and emotional balance. Its quality is influenced not only by individual and behavioral factors but also by environmental conditions in the sleep setting. Among these, thermal comfort and indoor air quality, particularly ambient temperature and carbon dioxide (CO₂) concentration, are increasingly recognized as important modulators of sleep architecture and continuity. Suboptimal thermal conditions and elevated CO₂ levels may impair sleep efficiency, reduce total sleep time, and increase the frequency of nocturnal awakenings. This study presents preliminary data from the HypnosAir Project (www.hypnosair.com), which investigates the impact of indoor environmental conditions on sleep quality.

Materials and methods: Participants were recruited through convenience sampling and met strict inclusion criteria: age between 25 and 45 years, healthy, non-smokers, and free of diagnosed sleep, cardiovascular, respiratory, neurological, or psychiatric disorders. Female participants were included only if they were not pregnant, breastfeeding, menstruating, or in peri- or post-menopausal stages. Each participant underwent continuous monitoring over seven consecutive days and nights between February and April 2025. Sleep was assessed using actigraphy, while environmental conditions—temperature, relative humidity, and CO₂ concentration, were measured continuously in the bedroom environment. A total of 295 nights were analyzed. Sleep parameters included total sleep time (TST), sleep onset latency (SO), wake after sleep onset (WASO), number of awakenings, and sleep efficiency (SE). Data analysis was performed using SPSS, applying descriptive statistics and multiple linear regression, with confirmation of Gauss-Markov assumptions.

Results: The average values observed were as follows: TST 447.85 ± 83.19 minutes, SO 41.84 ± 31.16 minutes, WASO 10.67 ± 14.81 minutes, number of awakenings 16.46 ± 9.90, and SE 89.39 ± 5.74%. Environmental measurements showed an average temperature of 19.72 ± 1.92 °C, relative humidity of 77.34 ± 7.00%, and CO₂ concentration of 1684.32 ± 925.61 ppm. Regression results indicated that a

1 °C increase in ambient temperature was associated with a 5.8-minute reduction in TST and 1.1 fewer awakenings per night. No statistically significant associations were observed between temperature and SO, WASO, or SE. Likewise, CO₂ concentration was not significantly associated with any sleep parameter in this preliminary analysis

Conclusions: These initial results suggest that thermal comfort, especially ambient temperature, has a measurable impact on sleep, particularly in reducing total sleep time and the number of awakenings. Although no significant effects of CO₂ were identified at this stage, ongoing data collection and analysis are expected to elucidate further the interplay between indoor environmental conditions and sleep physiology. These findings highlight the importance of considering environmental optimization as a component of sleep health promotion strategies.

Acknowledgments: This study is funded by the Fundação para a Ciência e a Tecnologia (PTDC/CTAAMB/3263/2021).

ESTeeM: Burden of Menopause-Related Sleep Disturbances, Quality of Life, and Work Productivity in a Real-World Setting

P.M Maki¹, C.N Soares², F.C Baker³, L. Larkin⁴, R.D Holzmann⁵, J. Dorey⁶, I. Gkioni⁷, C. Dinkel-Keuthage⁵, N. Schoof⁵, M. Graziano Custodio⁸, H. Shalhoub⁵, E. Kapoor⁹

¹University of Illinois Chicago, Chicago, United States, ²Queen's University, Kingston, Canada, ³SRI International, Menlo Park, United States, ⁴Ms Medicine, Mariemont, United States, ⁵BAYER AG, Berlin, Germany, ⁶Bayer Healthcare SAS, La Garenne-Colombes, France, ⁷Syneos Health LLC (providing service to Bayer), Morrisville, United States, ⁸BAYER Consumer Care AG, Basel, Switzerland, ⁹Mayo Clinic Center for Womens Health, Mayo Clinic, Minnesota, United States

Introduction: Sleep disturbances affect up to two-thirds of menopausal women, elevating the risk of cardiometabolic, cognitive, and mental health issues and affecting quality of life (QoL). Menopausal hormone therapies, antidepressants, and hypnotics only provide transient or incomplete relief and/or can raise safety/tolerability concerns. The Evaluation of Sleep disturbances in Menopause (ESTeeM) is an observational cohort study quantifying the burden, unmet need, and treatment patterns of women with menopause-related sleep disturbances.

Materials and methods: ESTeeM is recruiting up to 1,000 U.S. women aged 40–65 years in natural or surgical menopause who self-report sleep disturbances. For 28 days, women complete a Daily Morning Diary (DMD; sleep- and vasomotor symptoms [VMS]-related questions). At baseline (study entry), Day 14, and Day 28, women complete surveys including the Insomnia Severity Index (ISI), the Menopause-specific Quality Of Life (MENQOL) questionnaire, and the menopause-specific Work Productivity and Activity Impairment (mWPAI) questionnaire. Here, we conducted an interim analysis to characterize sleep disturbances assessed with the DMD across the first week, along with MENQOL and mWPAI at baseline. Unless otherwise stated, results are reported as mean (standard deviation).

Results: This analysis included 404 women (age: 55.0 [5.3] years; age at menopause: 48.2 [7.3] years); 88.1% had natural menopause and 11.9% surgical. Overall, 71.8% were white, 13.4% Black/African American, 10.6% Asian, 3.2% other races, and 1.0% multiracial. Over half (61.4%) of the sample did not use any intervention (pharmacological or non-pharmacological) for sleep, while 34.4% used supplements (e.g., melatonin [45.3%], *Valeriana officinalis* [1.4%]), 5.9% menopausal hormonal therapies, 3.2% sedating antidepressants or other psychiatric agents, 2.7% Z-drugs, and 2.0% benzodiazepines (data points not mutually exclusive).

Week 1 DMD VMS data (n=348) revealed that 76.7% reported nocturnal VMS on an average of 4.0 (2.1) nights/week with 3.9 (13.4) episodes/night; 63.8% reported daytime VMS on an average of 3.8 (2.2) days/week with 4.3 (13.9) episodes/day.

Week 1 DMD sleep data (n=347) revealed that 85.9% of women reported ≥1 sleep disturbance(s), with an average of 2.3 (1.2) awakenings per night. Sleep onset latency was 51.0 (44.2) minutes, wakefulness after sleep onset was 41.7 (30.9) minutes, total sleep time was 6.3 (1.4) hours across 8.4 (1.3) hours in bed, and sleep efficiency was 75% (14%).

Of 313 women who completed the ISI, 44.4% reported sub-threshold insomnia, 39.3% had clinical insomnia (33.2 % moderate, 6.1 % severe), and 16.3 % had no clinically significant insomnia. MENQOL total score (n=319) was 3.7 (1.43). Among women completing the mWPAI questionnaire (n=313), general activity impairment was 30.8% (25.2%). Of the 73.2% who reported current employment,

absenteeism was low (2.9% [9.1%]), but productivity losses were evident with work impairment at 28.7% (25.7%) and presenteeism at 27.3% (24.3%).

Conclusions: In a cohort of menopausal women with sleep disturbances, nighttime awakenings were common; sleep efficiency was low, and ~40% had clinical insomnia. Menopause symptoms moderately impacted health-related QoL, and impaired activity and work productivity. Further analyses will investigate smartwatch-derived sleep metrics, treatment patterns (e.g., usage, adherence, and satisfaction), and subgroup comparisons by VMS status and medication use.

Estimating Apnea-Hypopnea Index from Short-Duration Electrocardiograms

S. Shubhangi¹, N. Makaram¹, S. Kalyanaraman², K. Renganathan³, R. Swaminathan¹

¹Indian Institute of Technology Madras, Department of Applied Mechanics and Biomedical Engineering, Chennai, India, ²Medway Institute of Pulmonology, Pulmonology, Chennai, India, ³Medway Institute of Pulmonology, Respiratory Medicine, Chennai, India

Introduction: Sleep apnea, a disorder characterized by recurrent upper airway collapse during sleep. This leads to intermittent hypoxia, sleep fragmentation, and notable cardiovascular issues. The Apnea-Hypopnea Index (AHI), typically assessed via overnight polysomnography, is crucial for diagnosis. This study explores the feasibility of estimating AHI using just one hour of single-channel electrocardiogram (ECG) data.

Materials and methods: The Physionet SA-ECG database was utilized for this study. This open-access dataset comprises 70 ECG recordings, typically 8 hours long, with expert-labeled apnea annotations based on simultaneously recorded respiration signals. These recordings are categorized into groups reflecting varying apnea severity (Class A: AHI ≥ 10 and at least 100 minutes of apnea; Class B: AHI ≥ 5 and 5-99 minutes of apnea; Class C: AHI < 5 and less than 5 minutes of apnea). The ECG signals in the database are sampled at 100 Hz. For this study, a one-hour segment from these overnight recordings was used to demonstrate the efficacy of short-duration analysis.

Our methodology involves extracting heart rate variability (HRV) from short-duration ECG recordings and utilized Heart Rate Fragmentation (HRF), a novel measure of signal nonlinearity, alongside conventional frequency-domain features to characterize apnea. An XGBoost classifier was then trained on these features to estimate AHI. We employed a leave-one-out cross-validation approach to evaluate performance. Additionally, a correlation analysis was conducted to assess the relationship between our short-duration HRV features and the overnight clinical apnea scores.

Results: The results indicate that HRV dynamics effectively characterizes apnea severity even with limited signal duration ($p < 0.05$). Both short-duration HRF ($p > 0.4$) and frequency-domain features ($p < 0.6$) showed significant correlation with long-term AHI scores ($p < 0.05$). In the classification task, these features, combined with the XGBoost classifier, resulted in a F1-score of 93.55%.

Conclusions: In conclusion, we demonstrate that HRV analysis with HRF metrics, provides a reliable and efficient method for early detection and severity assessment of sleep apnea. This proposed framework, leveraging short-duration ECG data and machine learning, has strong potential for scalable and accessible sleep apnea screening in both clinical and home-based settings.

Evaluating Obstructive Sleep Apnea as a Predictor of Postoperative Bleeding in Chronic Rhinitis Surgery

C.Y. Huang^{1,2}, Y.-L. Hwang³, J.-Y. Liao¹, H.-L. Teng¹, T.-Y. Shih¹, J.-W. Hsieh²

¹Ditmanson Medical Foundation Chia-Yi Christian Hospital, Otolaryngology, Chiayi City, Taiwan,

²National Yang-Ming Chiao Tung University, College of Artificial Intelligence, Tainan city, Taiwan,

³Chia-Yi Chang Gung Memorial Hospital, Department of Oral and Maxillofacial Surgery, Chiayi, Taiwan

Introduction: According to published literature, patients diagnosed with obstructive sleep apnea (OSA) are at a higher risk of postoperative complications, such as adverse cardiac events, respiratory complications, reduced oxygen saturation, and an increased likelihood of admission to the intensive care unit (ICU). Additionally, patients with sleep-disordered breathing often experience nasal obstruction and seek surgical solutions. However, the relationship between obstructive sleep apnea and the risk of complications following nasal obstruction surgery has not been previously explored.

Materials and methods: From March 2023 to July 2024, records were reviewed for patients diagnosed with chronic rhinitis lasting over six months who underwent nasal obstruction surgery after showing poor response to one month of treatment with corticosteroid nasal sprays or oral medications. These patients experienced significant impacts on their quality of life or sleep quality. The study evaluated the treatment outcomes, complications, and risk factors one month after undergoing surgery for chronic rhinitis. The surgical procedure primarily involved inferior turbinate radiofrequency surgery. Variables analyzed included age, sex, body mass index (BMI), allergic rhinitis scores (24-hour reflective total nasal symptom score, rTNSS), nasal obstruction scores (nasal obstruction symptom evaluation scores, NOSE), hypertension, OSA, medication-induced rhinitis, history of nasal surgery, and concurrent procedures such as septoplasty, posterior nasal nerve ablation, adenoidectomy, tonsillectomy, and soft palate surgery.

Results: A total of 325 patients undergoing nasal surgery for CR were included, with 48 patients (14.8%) classified as having OSA and 277 patients (85.2%) as non-OSA. The mean age was similar between groups (41.1 ± 7.7 vs. 38.9 ± 10.0 years, $p = 0.147$). Males constituted a significantly higher proportion in the OSA group compared to the non-OSA group (91.7% vs. 62.5%, $p < 0.001$). BMI was also higher in the OSA group (28.9 ± 4.9 vs. 25.1 ± 4.3 kg/m², $p < 0.001$). Preoperative rTNSS scores averaged 6.3 ± 2.8 , improving to 2.5 ± 2.0 postoperatively (60.3%, $p < 0.001$). NOSE scores improved from 11.5 ± 4.1 to 2.7 ± 3.7 (76.5%, $p < 0.001$), with nasal obstruction-related sleep disturbance scores improving by 79.43% ($p < 0.001$). Diagnosed as OSA (OR, 5.105; 95% CI, 1.222–21.328; $p = 0.025$) and hypertension (OR, 5.809, 95% CI, 1.134–29.744; $p = 0.035$) were identified as independent risk factors for major epistaxis-related complications in our study cohort. OSA patients also exhibited significantly higher overall complication rates (22.9% vs. 4.3%, $p = 0.005$), epistaxis events (18.8% vs. 3.6%, $p = 0.012$), and major epistaxis (14.6% vs. 1.8%, $p < 0.018$). Both OSA and non-OSA groups showed significant postoperative symptom improvement in rTNSS and NOSE scores ($p < 0.001$).

Conclusions: Obstructive sleep apnea and hypertension were identified as significant risk factors for postoperative complications and bleeding following chronic rhinitis surgery, with no significant association observed between these factors and the preoperative severity of rhinitis or the inclusion of additional surgical procedures during the operation. Chronic rhinitis surgery effectively improves poor nighttime sleep quality in patients with nasal obstruction, with significant differences observed as early as one month postoperatively.

Evaluating the Effectiveness of Awareness of Environmental Stressors on Improving Sleep Quality in a Hot Climate Region: A Longitudinal Randomised Controlled Trial

R. Al Sayed¹, R. Christoforou¹, L.N. Wiedermann¹, M. Schweiker^{1,2}, J.-F. Harmsen^{1,2,3}

¹Healthy Living Spaces lab, Institute for Occupational, Social and Environmental Medicine, Medical Faculty, RWTH Aachen University, Aachen, Germany, ²Chair of Healthy Living Spaces, Faculty of Architecture, RWTH Aachen University, Aachen, Germany, ³Department of Nutrition and Movement Sciences, NUTRIM School for Nutrition and Translational Research in Metabolism, Maastricht University Medical Center, Maastricht, Netherlands

Introduction: Environmental stressors, such as temperature and light, can negatively affect occupants' health and wellbeing. Likewise, sleep can be affected by various environmental stressors; particularly hot temperatures often disturb sleep. However, evidence-based interventions on behavioural and psychological adaptation (BPA) in the context of sleep and the built-environment remain scarce.

Therefore, this study aimed to test the effectiveness of an educational intervention that increases awareness of managing environmental stressors at bedtime to improve sleep quality through BPA.

Materials and methods: A randomised-controlled field study including a BPA intervention took place from August to November 2024 in Cyprus, where daily maxima were predicted to exceed 35°C (World Meteorological Organization). The intervention comprised a 3-hour awareness session, aimed at educating participants about the significance of sleep and strategies for improving sleep quality in the presence of environmental challenges. Key topics included the impact of elevated temperatures, indoor and outdoor noise, the role of the circadian rhythm in regulating sleep, and the effects of indoor air quality.

The intervention group (IG) received the awareness session before data collection and monitoring of their sleep environment, while the control group (CG) received the session after data collection. Both groups received wearable sensors (ActiGraph wGT3X-BT® for sleep quality and iButton® for

peripheral skin temperature) and stationary sensors (MSR145® and VOLTcraft DL-161S for environmental conditions) to wear/install in their bedrooms, for five consecutive days. The primary outcomes were objective sleep quality measures: sleep onset latency, sleep efficiency, total sleep time, wake after sleep onset, and the sleep fragmentation index. Concurrently, as secondary subjective measures around sleep and awakening time, participants completed behavioural and psychological questionnaires (such as restoration, alertness, bedtime activities and routine), as well as perception and comfort questionnaires for each environmental aspect (thermal, visual, acoustic, and olfactory).

Results: Thirty-two adults (14 females, 2 non-binary) were randomly assigned to the CG (n=16; mean±SD; age: 32.3±9.7 years, body mass index [BMI]: 26.1±4.9 kg/m², Chronotype: 04:20±78.2) or the IG (n=16; age: 36.3±13.2 years, BMI: 23.9±3.9, Chronotype: 03:48±102.5). At baseline, sleep quality was measured employing the Pittsburgh Sleep Quality Index (CG: 7±3, IG: 5.6±2, p=0.152) and Snyder et al.'s (2018) single-item subjective sleep quality questionnaire (CG: 5.8±2, IG: 7.1±1.7, p=0.026). The highest recorded outdoor temperature over the study period was 35.6°C (23.2±4.3) on 14. and 28.09.2024 at 13:20 and 12:30, respectively. While the lowest recorded temperature was 12.9°C on 06.11.2024 at 02:15. Relative humidity ranged from 19% to 97% (59±18).

During the congress, we will present our findings on the objective sleep data, the behavioural and psychological variables, and the differences between the two groups, alongside a QR code for accessing the awareness material.

Conclusions: By evaluating the effectiveness of raising awareness about the link between environmental stressors and sleep quality in hot climates, the present study could guide practical strategies for addressing sleep disturbances in hot climates.

Evaluating the Sleep Cancer Rest (SleepCaRe) Trial for Improving Health-Related Quality of Life (HRQoL) in Women Undergoing Chemotherapy for Breast Cancer - A Randomised Controlled Trial

R. Wallace¹, M. Alexander, M. Alexander^{2,3}, D. Day^{4,5}, J. Diggins⁶, M. Ftanou⁶, V. Aedo-Lopez⁷, B. Bei⁸, R. Blum⁹, F. Boyle¹⁰, T.T. Do⁸, P. Francis^{6,11}, S. Garland¹², D. Mortimer⁸, S. Sharma¹³, L. Stafford^{14,15}, M. White⁷, J. Wiley⁸

¹Monash University, School of Psychological Sciences, Notting Hill, Australia, ²Peter MacCallum Cancer Centre, Pharmacy Department, Melbourne, Australia, ³The University of Melbourne, Sir Peter MacCallum Department of Oncology, Melbourne, Australia, ⁴Monash Health, Department of Oncology, Melbourne, Australia, ⁵Monash University, Melbourne, Australia, ⁶Peter MacCallum Cancer Centre, Melbourne, Australia, ⁷Monash Health, Melbourne, Australia, ⁸Monash University, Melbourne, Australia, ⁹Bendigo Cancer Centre, Bendigo, Australia, ¹⁰Patricia Ritchie Centre for Cancer Care and Research Mater Hospital North Sydney, Sydney, Australia, ¹¹The University of Melbourne, Melbourne, Australia, ¹²Memorial University, Newfoundland, Australia, ¹³Ballarat Regional Integrated Cancer Centre, Ballarat, Australia, ¹⁴University of Melbourne, Melbourne, Australia, ¹⁵The Royal Melbourne Hospital, Melbourne, Australia

Introduction: Sleep disturbances are prevalent among women undergoing chemotherapy for breast cancer and impact health-related quality of life (HRQoL). Few trials have evaluated sleep-targeted interventions in this population using preference-based HRQoL outcomes. We present a pre-registered, secondary outcome of HRQoL for sleep intervention trial among women with early or advanced breast cancer receiving chemotherapy.

Materials and methods: This six-week, remotely delivered, randomised controlled trial compared Cognitive Behavioural Therapy for Insomnia (CBT-I), Bright Light Therapy (BLT), their combination (CBT-I+BLT), and an active control (Sleep Hygiene Education, SHE) on self-reported HRQoL as measured by the PROMIS Preference (PROPr) score (-0.022 "All Worst", 1.0 "Full health"). All interventions involved emails, a therapist-assisted consultation, and midpoint check-in tailored to cancer patients, providing varying therapeutic and psychoeducational content (e.g., CBT-I's behavioural/cognitive strategies, BLT's structured morning light exposure). Assessments occurred at baseline, midpoint (3-weeks), post-intervention (6-weeks), and follow-ups (3-months; 6-months).

Results: 219 women receiving chemotherapy (Mean 50.7y) were recruited. At baseline, average HRQoL was low (PROPr score = 0.27). Main effect analyses showed that CBT-I led to a significant improvement from baseline to post-intervention (0.06 point-change, p = .012; SMD = 0.34), though

these gains were not sustained at six-months follow-up ($p = .096$). BLT showed no significant effects at either timepoint ($p \geq .519$), and no CBT-I*BLT interaction was observed (all $p \geq .759$). From baseline to post-intervention, within-group analyses showed the largest HRQoL improvements in the CBT-I (0.14 point-change, $p < .001$; SMD = 0.83) and CBT-I+BLT groups (0.14 point-change, $p < .001$; SMD = 0.79), while smaller gains were seen in SHE (0.09 point-change, $p = .003$; SMD = 0.53) and BLT groups (0.07 point-change, $p = .024$; SMD = 0.42).

Exploratory analyses suggested treatment effects may differ by cancer stage and insomnia severity. In metastatic cancer patients, neither CBT-I nor BLT showed significant main effects (all $p \geq .210$), though both yielded small-to-moderate effect sizes with BLT yielding a slightly larger improvement in HRQoL than CBT-I at both timepoints. Significant within-group improvements were observed across all groups at post-intervention only (all $p \leq .013$). In individuals with clinically significant insomnia (ISI ≥ 15), CBT-I significantly improved HRQoL at post-intervention ($p = .014$, SMD = 0.51), and BLT had no meaningful change (SMD = 0.01). Significant within-group improvements were observed across CBT-I and CBT-I+BLT groups at post-intervention only (both $p \leq .034$). In individuals with subthreshold insomnia (ISI ≤ 14) showed no significant main effects (all $p \geq .212$), though significant within-group improvements were observed across all groups at post-intervention (all $p \leq .038$).

Conclusions: CBT-I improves HRQoL in women undergoing chemotherapy for breast cancer, with effects strongest post-treatment. These findings highlight the importance of addressing sleep disturbances in cancer care. Benefits were particularly notable in patients with clinically significant insomnia symptoms, suggesting CBT-I may be especially effective for this subgroup. These findings point to the value of brief, targeted interventions during active treatment. Future research should explore strategies for specific groups, including patients with metastatic disease or varying insomnia severity.

Exacerbated sleep disorders, delayed sleep pattern, and effectiveness of online interventions during COVID-19 pandemic

M. He¹, S. Wang¹, C. Zang¹, J. Liu¹, M. Yi², Y. Zhang¹, X. Su¹

¹Central South University, Department of Respiratory & Sleep Medicine, Xiangya Hospital, Changsha, China, ²Central South University, School of Life Sciences, Changsha, China

Introduction: COVID-19 pandemic and its following social response have been posing extra stress on sleep health and new challenges to sleep health management. This study aims to evaluate the direct and indirect association between COVID-19 and sleep health, including obstructive sleep apnea (OSA), insomnia, and sleep patterns.

Materials and methods: First, standard procedures for meta-analysis were performed. Weighted Mean Difference (WMD) and Odds Ratio (OR) were respectively applied to assess the severity and risk differences of sleep disturbances between the compared groups. OR was also applied to assess COVID prognosis risk differences between those with sleep disturbances and controls. p value of <0.05 is defined as significant. Then, questionnaires were collected from mainland China about COVID-19 infection and sleep quality from January 2023 to March 2023. Also, impairment and related factors for sleep quality before, during, and after COVID-19 infection were identified.

Results: COVID-19 infection is associated with a higher risk for OSA (OR=1.22, $p=0.0002$) and insomnia (OR=1.82, $p=0.01$). Among COVID-19 patients, those comorbid with OSA were at higher risk for worse clinical outcomes (OR=2.18, $p<0.00001$). Additionally, , COVID-19 lockdown is associated with delayed sleep pattern, exacerbated insomnia (Insomnia Severity Index (ISI), WMD=1.44, $p<0.0001$). Despite the pandemic, online Cognitive Behavioral Therapy for Insomnia (CBTI) improves overall insomnia severity by ISI (WMD=-4.34, $p <0.00001$), insomnia symptoms, and psychiatric health. COVID-19 infection significantly reduced sleep quality ($p<0.001$), and it did not recover to pre-infectious level even after recovery from COVID-19 infection ($p<0.001$). Among the participants, risk factors for decreased sleep quality included age, gender (female), poor lifestyle habits such as smoking and drinking, risk associated with comorbid severe COVID-19.

Conclusions: There is a bidirectional association between the COVID-19 pandemic and sleep disturbances. Online CBTI is effective in improving insomnia during the pandemic.

Examining the Associations of Sleep Duration and Disturbances With Hypertension in Metropolitan Cities in India

M. Biswas¹

¹National Institute of TB and Respiratory Diseases, Department of Pediatrics, New Delhi, India

Introduction: In South Asia, rapid and unplanned urbanization coupled with globalization has led to lifestyle changes characterized by high intake of calorie-rich foods, reduced physical activity, and elevated psychological stress, thereby increasing the risk of overweight, hypertension, diabetes, and cardiovascular diseases. Sleep duration and disturbances are potential risk factors for hypertension. Although hypertension is highly prevalent in South Asia, there is limited knowledge about how these sleep-related factors are associated with it in this region.

Materials and methods: This study utilized cross-sectional data from the baseline survey of the Centre for Cardiometabolic Risk Reduction in South Asia (CARRS), which recruited representative samples of adults aged over 20 years from Delhi and Chennai (India) between 2018 and 2021. Hypertension was identified based on either self-reported treatment or measured blood pressure (BP) readings of $\geq 140/90$ mm Hg. Information on usual sleep duration, insomnia, and snoring was gathered through the 'Sleep Habits Questionnaire,' while excessive daytime sleepiness (EDS) was assessed using the Epworth Sleepiness Score. Logistic regression and linear regression analyses were conducted with hypertension and BP as the outcome variables, respectively. Covariates included age, gender, education level, wealth index, family history of hypertension, and body mass index (BMI). Multiple imputation methods were employed to address missing data.

Results: The prevalence of hypertension in the study population was 34.7%, with an average sleep duration of 8.2 hours. Insomnia, snoring, and excessive daytime sleepiness (EDS) were reported by 13.6%, 28.7%, and 4.6% of participants, respectively. After adjusting for covariates, both moderate and habitual snoring were found to be significantly associated with higher odds of hypertension (odds ratios [OR] of 1.18 and 1.47, respectively). Additionally, rare, occasional, and frequent insomnia were linked to elevated odds of hypertension (ORs of 1.41, 1.39, and 1.34, respectively). No significant associations were observed between sleep duration or EDS and hypertension.

Conclusions: Moderate and habitual snoring were highly prevalent and showed a positive association with hypertension, particularly among young adults and women living in metropolitan areas of South Asia. Insomnia at any severity level was also linked to increased odds of hypertension. Further research, particularly robust longitudinal studies, is needed to better understand the relationship between sleep-related factors and hypertension in this population.

Experts' Perceptions of the Potential of Exergames to Improve Sleep Quality: An Exploratory Analysis

J.P.P. Rosa^{1,2}, A.G. Oliveira¹, J.C.R. Neto³, R.V.T. Dos Santos⁴, B.R. Gobato^{1,2}, F.d.N. Oliveira^{1,2}, L.J. Lima^{1,2}, R.A.D. Silva⁵, F.S. Lira⁶

Introduction: Promoting regular physical activity is recognized as an effective approach to improving sleep health and overall well-being. Exergames, which combine physical activity with digital interactivity, have been proposed as an innovative strategy to encourage consistent exercise engagement. While these technologies are gaining traction as tools to support both physical and mental health, their effectiveness in enhancing sleep quality, particularly in comparison to traditional exercise modalities, remains insufficiently explored. This study aimed to investigate expert perceptions of the potential of exergames to improve sleep quality, with particular attention to differences across professional backgrounds and years of experience in the field.

Materials and methods: A cross-sectional exploratory study was conducted using an online questionnaire (Google Forms®) administered to experts identified through a bibliometric analysis of

databases (PubMed, Scopus, and Web of Science) focused on the intersection of physical activity and sleep research. Quantitative data were analyzed using descriptive statistics, chi-square tests, the Mann-Whitney U and Kruskal-Wallis tests, along with effect size estimates (Cohen's d). For qualitative data, thematic clustering of open-ended responses was performed to identify recurring physiological mechanisms attributed to exergames with the potential to enhance sleep health. The study was approved by the Research Ethics Committee of São Paulo State University (UNESP) under protocol number CAAE: 87225025.8.0000.5465.

Results:

A total of 15 experts from diverse fields—primarily Exercise Science (40%), Sleep Medicine (33%), and Neuroscience (27%)—participated in the study. Most held a PhD (73.3%) and had over 10 years of experience (73.3%) in the sleep-exercise interface. The majority had published on the topic (86.7%), were familiar with exergame literature (66.7%), and 46.7% had practical or academic experience with exergames. Overall, 76.9% considered exergames potentially effective for improving sleep. Experts with >10 years of experience were significantly more likely to endorse efficacy ($p = .032$, $d = 0.59$). Frequently cited mechanisms included reduced arousal, shorter sleep onset latency, stress modulation, and mood improvement. Thematic clustering of open responses identified three profiles: (0) psychobiological modulation, (1) neuroendocrine/circadian regulation, and (2) general physical benefits. A heatmap showed Exercise Science experts aligned with clusters 0 and 1, while Sleep Medicine experts were more associated with cluster 2, suggesting disciplinary differences in perceived mechanisms.

Conclusions: Most experts perceive exergames as a potentially effective tool to improve sleep quality, especially through mechanisms related to arousal reduction, mood, and circadian modulation. These perceptions vary by academic background and years of experience. Findings support further investigation into exergames as a non-pharmacological intervention for sleep, and highlight the need to tailor approaches based on user profiles and professional guidance in shaping evidence-based strategies for integrating exergames into sleep health promotion.

Acknowledgments: This research was conducted with the support of the São Paulo State University (UNESP) - Pró Reitoria de Pesquisa (PROPe) 14/2024 – Support for Research in Assistive Technologies Developed by Interinstitutional Groups in the State of São Paulo.

Exploring Barriers to Sleep Hygiene Among Chronic Short Sleepers Using Reflexive Thematic Analysis: A Pilot Study

H.Y.D. Ma^{1,2}, E.Y.Y. Lau^{1,2,3}, W. Wang^{1,2}

¹The Education University of Hong Kong, Department of Psychology, New Territories, Hong Kong, SAR of China, ²The Education University of Hong Kong, Analytics\Assessment Research Centre, New Territories, Hong Kong, SAR of China, ³The Education University of Hong Kong, Centre for Psychosocial Health, New Territories, Hong Kong, SAR of China

Introduction: Sleep hygiene (SH), a set of behavioural and environmental practices conducive to good sleep is essential for achieving sufficient and restorative sleep (Irish et al., 2015). For individuals experiencing chronic short sleep, maintaining good SH is particularly important because limited sleep duration already hinders restorative processes. Drawing on the Health Belief Model (HBM; Becker et al., 1974) and Social Cognitive Theory (SCT; Bandura, 1977), various barriers may hamper the implementation and execution of SH practices effectively. Therefore, the current pilot study aimed to uncover a) the most common barriers to SH in chronic sleepers, and b) whether some barriers are more easily addressed than others.

Materials and methods: 11 chronically short sleepers ($M_{age} = 25$, $SD = 1.5$) completed sleep hygiene (SH) and extension (SE) interventions carried out in two sessions conducted by one of two trained researchers in motivational interviewing. In the first (T1) session, a) the SH intervention aimed to identify and address any potential barriers (e.g., late-night media use) to good sleep and to provide SH psychoeducation. Conducted four (± 1) days after the SH intervention (T2), b) the sleep extension (SE) intervention aimed to review the contents and goals of the SH intervention, to provide further guidance on SH issues, and to set a 90-minute sleep extension schedule for the following week. To evaluate the most common barriers, SH goals, and whether one is able to address poor SH, we adopted

the six-phase qualitative reflexive thematic analysis (Braun & Clarke, 2020) due to the narrative nature (i.e., notes made by experimenters) of the interview data with our small sample size. The intervention notes were first translated into English and formatted. The cleaned data was then assigned labels based on the identified theme of the content, with this step repeated two more times to reduce redundancies (i.e., conceptual overlap) by combination or removal of theme categories.

Results: The most commonly reported barrier to SH and sufficient sleep was media use (i.e., late-night use; in-bed use right before sleep). While most behavioural barriers were addressed at T2 (e.g., caffeine intake; late-night media use), factors associated with one's sleep setting (e.g., noisy surroundings; small and messy bedroom; late-night interaction with roommates) appear more persistent and difficult to modify (see [Table 1](#)).

Conclusions: Using thematic analysis, we identified late-night media use as the most common and modifiable barrier, while environmental factors related to sleep setting might be more resistant to change. Our findings, aligned with the HBM and SCT models, underscore the importance of setting personalised and specific goals to effectively address barriers, as evidenced by the reported reduction or elimination of behavioral barriers following the SH intervention. These results highlight the need for future SH interventions to personalize goal-setting strategies and to target key barriers to action.

Acknowledgments: This work is supported by the General Research Fund of the Research Grants Council, HKSAR, China (EdUHK#18609423).

Exploring Social Determinants and Gender Variations in Sleep Health Disparities: Initial Findings from a Descriptive Study in Hong Kong 2024

V. Lok¹, M. Liu¹, R.Y. Chung¹, J.H. Kim¹

¹The Chinese University of Hong Kong, JC School of Public Health and Primary Care, Faculty of Medicine, New Territories, Hong Kong, SAR of China

Introduction: Sleep health is influenced by social and structural factors such as income, housing, commuting, and noise. This study examines sleep duration, sleep latency, and sleep adequacy and associated factors in Hong Kong, the city with high income inequality and the lowest per capita living space in the world.

Materials and methods: An anonymous, cross-sectional telephone survey was conducted on adults in Hong Kong, 2024 (n=500). Descriptive statistics (mean, standard deviation, and frequencies) summarized sleep data: (1) sleep duration, (2) time to fall asleep (sleep latency), and (3) sleep adequacy. Associated sociodemographic (e.g. sex, income), behavioural (e.g. exercise habits, commuting time) and environmental factors (e.g. housing type, ambient noise, residential area) were also examined to identify patterns in sleep disparities using multivariable regression analyses.

Results: Preliminary findings show that sociodemographic factors are significantly associated with sleep. In particular, females and people with lower income reported shorter sleep duration (mean < 6.1 hrs), longer time to fall asleep (mean > 36 minutes), and lower sleep adequacy (mean < 7.6 hrs) than higher income groups and males (p<0.05). Noise disturbances were more also common in lower-income groups, worsening sleep outcomes. Behavioural and environmental factors also contribute significantly to poor sleep quality (p<0.05).

Conclusions: Targeted interventions are required to address sleep inequalities in those sociodemographic groups with poor sleep such as women and lower income individuals. Since personal and environmental factors contribute to sleep health disparities in Hong Kong, there is a need for sleep interventions that go beyond the personal level. As sleep is a vital component of good health, sleep health should be included in public policy discussions in high population density, urban environments.

Exploring the Bidirectional Causal Associations between Sleep Traits and Metabolomic Profile in Humans

J. Wei¹, H. Wu¹, X. Tan^{1,2}

¹Zhejiang University School of Public Health, Big Data in Health Science, Hangzhou, China, ²Karolinska Institutet, Clinical Neuroscience, Stockholm, Sweden

Introduction: Unhealthy sleep patterns are common phenomena which may lead to a spectrum of adverse cardiometabolic outcomes. Metabolites play pivotal roles in the relevant underlying mechanisms, yet the causal associations between sleep and metabolome in humans remain unclear.

Materials and methods: This study applied one-sample Mendelian randomization (MR) to explore the relationship between sleep traits (sleep duration per day, short sleep duration (≤ 6 h), long sleep duration (≥ 9 h), and insomnia) and 249 metabolites among 166,436 participants from UK Biobank. Initially, the two-stage least squares approach was performed to explore causality. Subsequently, inverse-variance weighted and complemented methods were used as sensitivity analysis to further test the robustness of the results. Reverse MRs from each metabolites to sleep variables were also conducted.

Results: Genetically predicted insomnia was causally associated with level of most lipids and led to increased levels of acetoacetate, glycoprotein acetyls, and decreased levels of citrate. Genetically predicted sleep duration was causally associated with increased average diameter for low density lipoprotein particles. Short sleep duration caused an increased the level of triglycerides in very low density lipoprotein subclass, apolipoprotein B to apolipoprotein A1 ratio and a decreased level of high density lipoprotein. We found no causal evidence for the effects of metabolites on any sleep variable.

Conclusions: Our study found that insomnia may lead to a wide range of metabolic disturbances, particularly in lipid metabolism, with short sleep similarly impacting lipid metabolic processes. This suggests that sleep traits may cause adverse outcomes through certain metabolic pathways.

Exploring the Impact of Sleep Hygiene Knowledge and Practices on Sleep Health: A Cross-Sectional Survey of Hong Kong Adults, 2024

V. Lok¹, M. Liu¹, R.Y. Chung¹, J.H. Kim¹

¹The Chinese University of Hong Kong, JC School of Public Health and Primary Care, Faculty of Medicine, New Territories, Hong Kong, SAR of China

Introduction: Sleep health, a critical component of overall well-being, has previously been closely linked to sleep hygiene (SH). The study aims to investigate how SH knowledge and actual SH behaviors, along with self-reported health status, influence sleep quality outcomes across different age groups and demographics among Chinese adults residing in a high living density region.

Materials and methods: An anonymous, cross-sectional, telephone survey was conducted on adults from Hong Kong (n=500) in 2024. The study obtained information about the participant's sociodemographic information, living situation, self-rated health, SH knowledge, SH behaviors (using Sleep Hygiene Index instrument). Multiple linear regression analysis, controlling for sociodemographic factors, was used to explore how these factors predicted self-reported sleep quality, as assessed with the Pittsburgh Sleep Quality Index.

Results: Over the past month, the mean overall sleep quality score (scored 0 to 3, 3 indicating poor sleep quality) was 1.2 with a standard deviation (SD) of 0.77. Their average sleep duration was 6.36 hours (SD = 1.28). The mean SH knowledge score was 11.1 out of maximum 14 points (SD = 1.74), and the mean SH behaviors score was 9.98 points out of 26 (SD = 5.13). Multivariable analysis showed that individuals with higher SH knowledge scores reported better sleep quality, while those with poorer SH behaviors scores had worse sleep outcomes. Self-rated mental health, including stress, anxiety, and depression, significantly predicted sleep quality, with poorer mental health linked to worse sleep outcomes ($p < 0.05$). Additionally, older age, female gender, and diagnosed sleep apnea were significantly associated with worse sleep health ($p < 0.05$). Furthermore, the SH knowledge score ($B = 0.65$, $p < 0.05$) was a significant predictor of SH behaviors score, indicating that higher SH knowledge scores were associated with better SH behaviors scores.

Conclusions: Both personal factors, such as SH knowledge, and health factors, contribute to sleep health disparities. As SH knowledge predicts actual SH behaviors scores, enhancing this knowledge should be a priority in health promotion. Future interventions should aim to improve sleep hygiene through education while also addressing broader issues like mental health and sleep disorders.

Acknowledgments: Health and Medical Research Fund (HMRF) of Hong Kong, China-ORKTS Project ID 21220771

Exploring the Influence of Emotion Regulation on Emotional Naps: A Preliminary Study

F.-C. Hsiao¹, S.-F. Chen¹

¹Ming Chuan University, Department of Counseling, Clinical and Industrial/Organizational Psychology, TaoYuan, Taiwan

Introduction:

Previous studies identified five types of naps: dysregulative, replacement, emotional, appetitive, and mindful naps. Among these, emotional naps are taken explicitly to enhance mood, alleviate stress, or avoid particular behaviors. While the mutual relationship between sleep and emotions is well-established, existing research predominantly emphasizes naps' capacity to enhance mood rather than explicitly examining their emotion-regulation properties. Addressing this gap, the current research aimed to investigate the phenomenon and emotional regulatory effects of emotional naps within a Taiwanese context.

Materials and methods:

Participants were initially recruited through an online survey. This initial screening phase collected comprehensive data including demographic information, sleep and nap habits, napping motivations, chronotype, depression (CES-D), perceived stress (PSS), coping strategies (Brief COPE), and emotional states (assessed via the Self-Assessment Manikin, SAM scale). From this initial pool, 22 individuals were selected to participate in a subsequent, more intensive one-week experimental phase designed to examine the direct effects of emotional regulation. Inclusion criteria for this experimental phase were stringent, ensuring a focused and relevant sample. Participants were required to: (1) self-report taking emotional naps, (2) be non-shift workers who did not nap after dinner, (3) have no history of major physiological diseases or significant surgical history, (4) be free from severe psychiatric conditions (e.g., schizophrenia, bipolar disorder) or psychotic symptoms (e.g., hallucinations, delusions), (5) report no sleep disorders, and (6) not be continuously using illicit substances or non-prescription medication. During the one-week experimental period, participants maintained daily sleep diaries and wore actigraphy devices continuously. Emotional states were recorded twice daily using the SAM scale at 1 PM and 5 PM, with participants additionally noting any occurrences of emotional naps. SAM scale indicators included pleasure, arousal, dominance, stress, and fatigue, each ranging from 1 to 5.

Results:

Nonparametric analyses (Wilcoxon signed-rank test) indicated that emotional naps significantly reduced fatigue ($Z = -2.174$, $p = .03$; pre-nap: $M = 3.14$, $SD = 0.52$; post-nap: $M = 2.70$, $SD = 0.57$), but showed no significant differences in pleasure, arousal, dominance, or stress. In contrast, in non-emotional nap conditions, a significant increase in dominance was observed post-nap ($Z = -2.04$, $p = .04$; pre-nap: $M = 2.48$, $SD = 1.02$; post-nap: $M = 2.93$, $SD = 0.86$), while no significant changes were found in pleasure (pre: $M = 2.29$, $SD = 0.64$; post: $M = 2.43$, $SD = 0.77$), arousal (pre: $M = 3.19$, $SD = 0.87$; post: $M = 2.92$, $SD = 1.16$), stress (pre: $M = 2.04$, $SD = 0.82$; post: $M = 2.28$, $SD = 0.76$), or fatigue (pre: $M = 2.49$, $SD = 0.71$; post: $M = 2.32$, $SD = 0.45$).

Conclusions: Emotional naps effectively alleviated fatigue but did not significantly influence emotional or stress regulation. Due to the reliance on self-reported home-based experiments in this study, confounding factors cannot be entirely excluded. Future research is encouraged to further elucidate the nuanced impacts and underlying mechanisms of emotional naps.

Exploring the Sleep of Young Children in Aotearoa New Zealand: Associations with Ethnicity and Maternal Depression in and Beyond the Perinatal Period

M.L. Carter¹, S.-J. Paine², B.M. Sweeney¹, J.E. Taylor³, T.L. Signal¹

¹Massey University, Sleep Wake Research Centre, Wellington, New Zealand, ²University of Auckland, Te Kupenga Hauora Maori, Auckland, New Zealand, ³Massey University, School of Psychology, Palmerston North, New Zealand

Introduction: Sleep plays a vital role in children's health. Sleep development is influenced by a complex interplay of biopsychosocial factors. There is emerging evidence to suggest perinatal depression (PND) is one such factor, but further investigation is needed. In Aotearoa/New Zealand, ethnic inequities in the social determinants of health produce sleep health disparities that are evident from preschool age through adulthood; it is currently unclear whether they exist in infants. To address these research gaps, secondary data from the *Moe Kura: Mother and Child, Sleep and Wellbeing in Aotearoa/New Zealand* study (Moe Kura) were analysed in two studies. Kaupapa Māori research principles informed the study designs.

Materials and methods: First, sleep health equity, socio-ecological factors associated with infant sleep, and the characteristics of mother-perceived infant sleep problems were investigated using data from 383 Māori and 702 non-Māori mother-infant dyads at 12 weeks postpartum. Next, longitudinal relationships between maternal depression and infant and pre-schooler sleep health in 262 Māori and 594 non-Māori dyads were examined using data collected during pregnancy, 12 weeks postpartum, and 3 years post-birth. Multivariable and ordinal logistic models assessed the impact of different socio-ecological factors on infant sleep. Binary logistic models examined longitudinal associations between PND and infant and preschooler sleep, adjusting for key socio-demographic variables.

Results: Key developmental markers of infant sleep did not differ by maternal ethnicity. There were some ethnicity-based differences in sleep location. Bed-sharing and several socio-demographic factors were related to different dimensions of infant sleep and mother-perceived sleep problems. Bivariate associations were found between prior and concurrent depressive symptomology and many of the infant and pre-schooler sleep outcomes. Prenatal depressive symptoms remained independently associated with shorter-than-recommended sleep durations in preschoolers after controlling for key covariates.

Conclusions: Results show sleep at 12 weeks is highly variable and is associated with numerous socio-ecological factors. Sleep appears to be one pathway by which PND confers risk for poor child health outcomes. Findings support the need for more and better perinatal psychological services.

Acknowledgments: We gratefully acknowledge the contribution of the participating women and children. We also thank individuals and organizations who assisted in promoting the study during participant recruitment, the research assistants who helped with data entry, and the study advisory group for their guidance and support. This study was conducted with funding from the Health Research Council of New Zealand (HRC 08/547 and 09/255) and Massey University. M. L. Carter was supported during this project by a Vice Chancellor's Doctoral Scholarship from Massey University.

Eyes Wide Open: Understanding the Barriers, Facilitators, and Motivators to Adolescent Sleep through Photovoice

C. Ewart¹, J. Inchley¹, A. Martin¹, S. Simpson¹

¹University of Glasgow, CSO/MRC Social and Public Health Sciences Unit, Glasgow, United Kingdom

Introduction: Poor sleep among adolescents is a growing public health concern. At present, efforts to improve adolescent sleep have largely focused on individual-level behaviour change, with limited population level impact. Public health efforts to improve sleep, such as school-based sleep education, have demonstrated mixed-effectiveness and implementation challenges in real-world settings. Existing interventions have also failed to engage stakeholders in their development, potentially limiting their effectiveness and acceptability. The aim of this study was to engage adolescents, parents, and teachers through Photovoice, to understand the barriers and facilitators to adolescent sleep, as well as motivating factors to promote healthy sleep among adolescents. Photovoice is Community-Based Participatory Research method that gives voice to and empowers participants, providing unique insights into health issues, and promotes critical dialogue for change.

Materials and methods: This study was conducted in three schools across Scotland between January – December 2024. Forty-two adolescents aged 11 – 15 years (M = 13.1, 56% female) were conveniently sampled to participate in a photography exercise, participatory analysis workshop, photo-elicitation interview (n = 36) and share their photos at a school exhibition. Focus groups were also conducted with teaching staff (n = 14) and parents (n = 10). Thematic analysis of interview/focus group data was conducted, guided by themes from the participatory analysis, along with narrative analysis of texts, workshop discussions and exhibition feedback. Themes were inductively analyzed across the

socioecological model to identify leverage points and potential intervention targets to improve adolescent sleep.

Results: Factors influencing sleep identified among adolescents, parents, and teachers included societal factors (social norms, curriculum, school start times, and public health policy), physical and social environmental factors (school, home, digital, physical and social spaces), and individual factors (lifestyle choices and behaviours, mental wellbeing). Factors motivating young people included knowledge and beliefs about sleep, perceived and experienced benefits of good sleep, and social support.

Conclusions: Using Photovoice gave voice to young people and facilitated engagement and discussion with stakeholders. Potential areas identified for development include earlier school intervention, sleep education, parental support, peer influence, public health messaging, gamification, online spaces, and whole-school approaches to sleep health. Findings highlight the complexity of individual, environmental and societal factors influencing sleep, which will inform the development of a multi-level intervention to promote healthy adolescent sleep.

Factors and associations related to sleep quality in patients with tinnitus

P. Manajit¹, N. Kittinawawit¹, P. Nitivanichsakul², P. Numthavaj³, W. Wongpipathpong²

¹Mahidol university, Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand, ²Mahidol University, Chakri Naruebodindra Medical Institute, Faculty of Medicine Ramathibodi Hospital, Samut Prakan, Thailand, ³Mahidol University, Department of Clinical Epidemiology and Biostatistics, Faculty of Medicine, Ramathibodi Hospital, Bangkok, Thailand

Introduction: Tinnitus is a phantom symptom of hearing sounds with an unexplained source. The sound could become more perturbing when sleeping in quiet surroundings at night. Many people with tinnitus suffer from sleep difficulties, and some have psychological distress, such as depression and anxiety. Here, we aim to explore the relationship among the severity of tinnitus, sleep quality, and anxiety/depression.

Materials and methods: This prospective cross-sectional study was conducted at Chakri Naruebodindra Medical Institute (CNMI), a medical school hospital, from May 2023 to March 2025. Patients diagnosed with tinnitus aged over 18 years and lasting more than 3 months were enrolled. Data were collected using three standardized questionnaires: Tinnitus Handicap Inventory (THI) for tinnitus severity, Pittsburgh Sleep Quality Index (PSQI) for sleep quality, and Hospital Anxiety and Depression Scale (HADS) for symptoms of anxiety and depression. PSQI is divided further into 3 subscores of sleep efficiency, perceived sleep quality, and daily disturbance. Pure tone audiometry was also administered to objectively evaluate hearing in participants. Correlation analyses among the three questionnaire scores were performed by IBM SPSS statistical software.

Results: A total of 115 participants met the inclusion criteria after careful evaluation and completed the questionnaires. Sixty-one (61) of 115 participants were female (53%) with an average age of 59.44 ± 12.60 years. The tinnitus severity across all participants was predominantly classified as mild handicap severity (18-36 points), with a mean total THI score 31.51 ± 21.64 points. The sleep quality assessment using the PSQI in tinnitus patients shows a mean total PSQI score of 7.84 ± 3.77 , indicating poor sleepers. Additionally, total THI scores showed a positive correlation with the total score of PSQI ($r = 0.19$ p value 0.042). The daily disturbance subscale of PSQI exhibited a strong correlation with total THI scores, with correlation coefficients of $r = 0.280$ (p value 0.002).

In the corner of psychological distress, assessment using the HADS revealed that most participants were within the normal range (76.5% for the anxiety subscale and 82.6% for the depression subscale). However, both the anxiety and depression subscales of HADS showed a positive correlation with tinnitus severity ($r = 0.284$, p value 0.002).

Conclusions: Patients with tinnitus may have an associated impact on sleep quality. This might lead to daily disturbance, which may worsen tinnitus perception and contribute to emotional distress.

Acknowledgments: We would like to thank the patients for their participation in this study. We also extend our gratitude to Miss Oranitcha Chanthawon and Miss Boontharik Boonrod for their dedicated efforts in coordinating the project management.

Factors influencing sleep quality among persons with systemic lupus erythematosus through the lens of Spielman's three-factor insomnia model

R. Yin¹, J. Chaiard², P. Thungjaroenkul², J. Deeluea²

¹PhD Candidate at the Faculty of Nursing, Chiang Mai University, Chiang Mai, Thailand, ²Faculty of Nursing, Chiang Mai University, Chiang Mai, Thailand

Introduction: Individuals with systemic lupus erythematosus (SLE) have reported poor sleep quality both globally and in China. Previous studies have identified several factors associated with sleep quality in this population. However, the influencing factors remain unclear and inconsistent. According to Spielman's Model (3P Model), existing evidence has primarily focused on predisposing and precipitating factors, while perpetuating factors have been under-explored. Therefore, this study aimed to investigate the predisposing (age, BMI, disease activity), precipitating (fatigue, pain, depression, anxiety), and perpetuating (sleep hygiene practices) factors associated with sleep quality among Chinese individuals with SLE.

Materials and methods: This cross-sectional study was conducted among individuals with SLE recruited from a tertiary hospital in China between December 2024 and April 2025. Data were collected online using a demographic questionnaire, the Chinese version of the Pittsburgh Sleep Quality Index (PSQI), the Fatigue Severity Scale (FSS), the Hospital Anxiety and Depression Scale (HADS), the Sleep Hygiene Practices Scale (SHPS), the Pain Visual Analogue Scale (VAS), and the Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K). Descriptive statistics and regression analysis were used to analyze the data.

Results: A total of 329 individuals with SLE were included in the analysis. The mean age was 37.15 ± 11.51 . Females accounted for 93.0%. Of these, 210 (63.8%) reported poor sleep quality. Regression analysis revealed that age ($\beta=0.197, p < 0.001$), disease activity ($\beta=0.100, p = 0.022$), fatigue ($\beta=0.113, p = 0.021$), pain ($\beta=0.190, p < 0.001$), anxiety ($\beta=0.221, p < 0.001$), and sleep hygiene practices ($\beta=0.298, p < 0.001$) were significant predictors of sleep quality, explaining 43.2% of the variance in PSQI scores ($F(6, 322) = 40.742, p < 0.001$). Among these, sleep hygiene practices, which are a perpetuating factor, were the most influential predictor, followed by anxiety, age, pain, fatigue, and disease activity.

Conclusions: In line with the 3P Model, this study identified predisposing, precipitating, and perpetuating factors that influence sleep quality among Chinese individuals with SLE. These findings provide valuable insight for designing targeted and effective interventions aimed at improving sleep quality and overall well-being in this population.

Factors influencing the implementation of a general practice nurse-delivered model of care for the assessment and management of chronic insomnia and obstructive sleep apnea: a qualitative study of patient and practice staff perspectives

N. Grivell^{1,2,3,4}, E. Hoon^{2,5}, J. Fuller⁶, C.L. Chai-Coetzer^{1,2,7}, R. McEvoy^{1,2}

¹Flinders University, FHMRI Sleep Health/Adelaide Institute for Sleep Health, Flinders Health and Medical Research Institute, College of Medicine and Public Health, Adelaide, Australia, ²Flinders University, National Centre for Sleep Health Services Research, College of Medicine and Public Health, Adelaide, Australia, ³University of Melbourne, Department of Physiotherapy, Faculty of Medicine, Dentistry and Health Sciences, Melbourne, Australia, ⁴Austin Health, Institute for Breathing and Sleep, Melbourne, Australia, ⁵University of Adelaide, Discipline of General Practice and School of Public Health, Faculty of Health Sciences, Adelaide, Australia, ⁶Flinders University, College of Nursing and Health Sciences, Adelaide, Australia, ⁷SA Health, Department of Respiratory, Sleep Medicine and Ventilation, Southern Adelaide Local Health Network, Adelaide, Australia

Introduction: Long wait times for obstructive sleep apnea (OSA) and limited access to cognitive behavioural therapy for insomnia (CBTi) have led to a re-evaluation of traditional approaches to assessment and management. General practice nurse-delivered models of care have been explored to improve access to best practice care. Randomised controlled trials have demonstrated efficacy of models of care within the context of a controlled setting however they are not yet integrated into routine care. Understanding factors that influence implementation will inform translation into clinical practice. This study explored the barriers and facilitators to the implementation of a nurse-delivered model of care for the assessment and management of chronic insomnia and OSA in an Australian general practice from the perspective of clinicians and patients.

Materials and methods: A qualitative study informed by implementation science theory and phenomenology. Semi-structured interviews were conducted with patients after they were offered or received the model of care and with clinicians as they implemented the model of care. Patients with chronic insomnia were offered nurse-delivered CBTi or digital CBTi. Patients at high risk of OSA were offered a limited channel sleep study for assessment of OSA, followed by APAP titration and CPAP setup if needed. Interviews were audio recorded and transcribed verbatim. Patient data were analysed using a deductive Framework Analysis followed by an inductive thematic analysis to ascertain the barriers and facilitators to implementation from the perspective of patients. Clinician data were analysed using Interpretive Phenomenological Analysis to explore the perspective of clinicians throughout the implementation process and the factors influencing implementation of the model of care.

Results: Interviews were conducted with 31 patients, 13 with a diagnosis of chronic insomnia and 18 at high risk of OSA, and five general practitioners, two practice managers, and one general practice nurse. General practice nurse-delivered models of care for non-complex chronic insomnia and OSA were acceptable to patients and clinicians on the proviso that there is adequate funding for staff to deliver the interventions and that models of care are within the financial reach of patients. General practice staff were motivated to deliver the model of care by improved access to sleep health care and expected benefits for patients. Patient motivation to engage with the model of care was influenced by their perceived severity of their condition and by their trust in the staff delivering the intervention. Fear of the negative implications of not treating OSA motivated patients who were diagnosed with OSA to engage with treatment. A lack of access to government-subsidised CPAP machines in general practice was identified by clinicians as a significant barrier to future translation of the OSA pathway.

Conclusions: This study demonstrates that patients and clinicians are supportive of general practice nurse-delivered models of care and highlights the importance of co-design with patients and clinicians when designing models of care for chronic sleep disorders. Exploring the perspectives of patients and clinicians has identified factors that should be considered in future implementation trials of general practice nurse-delivered models of care for chronic sleep disorders.

Fewer pre-night shift awakenings is associated with positive mood during the night shift among female rotating shift nurses

C. Imes¹, C. Kline², E. Chasens¹, S. Sereika¹, L. Burke²

¹University of Pittsburgh, School of Nursing, Pittsburgh, United States, ²University of Pittsburgh, School of Education, Health and Human Development, Pittsburgh, United States

Introduction: Sleep plays a vital role in emotional regulation. The circadian misalignment that occurs with night shift work can negatively impact mood and well-being. Nursing can be highly emotionally and demanding work. Failure to control or manage one's mood can affect patient outcomes and the long-term mental health of the nurse. The purpose of this secondary analysis was to explore associations between pre-shift sleep measures and mood reported during the night shift among female rotating shift nurses.

Materials and methods: This study used data from a pilot/feasibility ecological momentary assessment (EMA) study that collected, in real-time, objective sleep and mood from rotating shift nurses for up to 24 days. Objective sleep data, including total sleep time (TST), sleep onset latency (SOL), sleep efficiency (SE), wake after sleep onset (WASO), and number of awakenings, were collected using a Spectrum Plus actigraph worn on the non-dominant wrist. EMA monitoring included up to three random prompts during waking hours that assessed location and mood. Mood responses were classified as positive (e.g., happy, energetic) or negative (e.g., tense, annoyed, frustrated). The associations between pre-night shift sleep measures and the presence of positive (no/yes) and negative mood (no/yes) during the night shift were explored using logistic mixed-effects modeling. Only EMA data collected while participants worked the night shift were used in the analysis.

Results: The female participants who completed the random EMA prompts when working night shift (N = 18) had a mean ($\pm$ SD) age of 27.7 ± 5.0 years and a mean 4.6 ± 4.5 years of night shift experience. Participants completed the random prompts on a mean of 3.7 ± 2.0 night shifts. Mean pre-night shift sleep measures were TST of 434.3 ± 142.5 minutes, SOL of 15.0 ± 19.3 minutes, SE of $83.8 \pm 7.9\%$, WASO of 42.0 ± 31.5 minutes, and 35.1 ± 13.6 awakenings. Negative and positive mood were reported on 50.0% and 23.5% of shifts, respectively. Pre-shift sleep measures were not associated with

reports of negative mood during the subsequent night shift. However, fewer pre-night shift awakenings ($\text{Exp}(B) = -0.841$, 95% CI = $-0.707, -0.961$; $p = 0.009$) were associated with higher odds of reporting a positive mood during the following night shift.

Conclusions: While negative mood was highly prevalent on night shift in this sample, pre-shift sleep measures were not associated with reports of negative mood. This suggests that other, unmeasured, factors such as patient acuity, staffing ratios, or personal issues may be contributing to the presence of negative mood. Reports of positive mood during the night shift were less common but associated with fewer pre-shift awakenings. Healthier sleep may allow night shift nurses to better manage the challenges and issues faced during the night shift, resulting in a more positive mood. Additional studies are needed to further examine the factors contributing to the mood of nurses working the night shift and its impact on patient and nurse outcomes.

Acknowledgments: This work was supported by the University of Pittsburgh's Healthy Lifestyle Institute.

Floor routine to sleep routine: A qualitative inquiry into the retirement of female ex-gymnasts

A. Montero^{1,2}, M. Drummond², J. Baranoff³, R. Adams¹

¹Flinders University, FHMRI Sleep Health, Bedford Park, Australia, ²Flinders University, SHAPE Research, Bedford Park, Australia, ³The University of Adelaide, School of Psychology, Adelaide, Australia

Introduction: Currently, little is known about how retirement from youth sport affects wellbeing. Gymnastics is a unique sport, requiring intense devotion from a young age and often results in early retirement, presenting equally unique challenges during the transition out of sport. Previous research has explored female gymnasts' athletic identity, body image, and eating behaviours following retirement, but aspects such as sleep, education, and support post-retirement have been overlooked. This study aimed to identify former elite female gymnasts' challenges regarding sleep post-retirement and how they can be better supported during this transition.

Materials and methods: Critical realism and the biopsychosocial model underpinned this research. Thirteen female ex-gymnasts (mean age = 21.1 ± 3.1 years) from New Zealand participated in one-on-one semi-structured interviews to better understand the challenges they face in relation to their sleep and mental health. Interviews were conducted online via Microsoft Teams or Zoom, with an average duration of 31.5 ± 8.1 minutes. Transcribed interviews were analysed using reflexive thematic analysis techniques.

Results: Four key themes were identified: (i) abuse of the coach-athlete relationship (coach-originated pressures culminate into poor wellbeing); (ii) drastic lifestyle and social change (transition out of sport impacting identity, sleep, and mental health); (iii) inadequate education and support (insufficient resources and support, and misinformation/lack of education surrounding mental health and sleep); and (iv) potential for change (improvement is viable with indication of imminent change).

Conclusions: Findings indicate why mental health and sleep issues occur for gymnasts during and after their sporting careers and highlight why they remain untreated. This research informs how gymnasts can be better supported while competing and transitioning out of the sport. Findings provide preliminary insight into how sleep and mental health are influenced by youth gymnastics participation and potentially other high-performance sports that may result in retirement at an early age.

Acknowledgments: The authors would like to thank the participants who shared their vulnerable stories to improve knowledge and attitudes towards sleep in sport.

Global Sleep Patterns: A Large-Scale Multivariate Analysis of Sleep Determinants and Health Interactions

S. Ooi¹

¹Princeton University, Princeton, United States

Introduction: Sleep is a fundamental biological process essential for cognitive function, emotional regulation, and overall physiological well-being. Despite its importance, modern lifestyles have significantly altered sleep behaviors, leading to widespread concerns about sleep deprivation and

quality deterioration. The proliferation of digital technology, increasing work-related stress, and environmental disruptions have emerged as key contributors to sleep disturbances. While numerous studies have examined sleep patterns, most research has been limited in scope, focusing on specific populations, geographic regions, or singular determinants. A large-scale, comprehensive investigation that incorporates multiple interrelated factors affecting sleep across diverse global populations remains a crucial gap in sleep science. Addressing this gap is imperative for developing targeted interventions aimed at improving sleep health worldwide.

Materials and methods: This study aims to provide an extensive, data-driven examination of global sleep patterns by analyzing 722,538 individual responses. Through a multivariate analytical approach, we seek to elucidate the intricate interactions between demographic, technological, psychological, and environmental determinants influencing sleep architecture. By leveraging advanced statistical methodologies and machine learning techniques, this study presents a novel perspective on sleep epidemiology, highlighting key predictive factors that contribute to sleep quality and duration.

A cross-sectional, observational study was conducted utilizing a validated 30-item sleep assessment instrument distributed across diverse global populations. A combination of hierarchical regression, structural equation modeling, and machine learning algorithms was applied to analyze sleep determinants. The study examined variables including sleep duration, bedtime routines, technology usage, psychological stress, environmental factors, and demographic influences. Data-driven insights were extracted to model the multifaceted nature of sleep interactions.

Results: Our findings reveal key determinants of sleep patterns across a large, diverse sample:

- **Sleep Duration:** The mean sleep duration was 6.4 ± 1.2 hours, with 52% of individuals experiencing chronic sleep insufficiency (<7 hours/night). Significant age-related variations in sleep duration were observed ($F = 42.3$, $p < 0.0001$).
- **Technological Influence:** 67% of participants engaged in pre-sleep electronic device use, which correlated with increased sleep latency ($r = 0.476$, $p < 0.0001$) and an average sleep onset delay of 38.2 ± 12.5 minutes.
- **Psychological Stress:** Work-related stress was the leading self-reported sleep disruptor (62%), with high-stress individuals exhibiting a 3.7-fold increased risk of insomnia (OR 3.7, 95% CI: 3.2-4.3). Anxiety was identified as a barrier to sleep in 55% of respondents.

Our findings challenge traditional, unidimensional sleep models by unveiling a dynamically interconnected sleep experience shaped by modern societal influences. The research underscores the necessity of holistic, personalized sleep interventions that address digital exposure, stress management, and environmental modifications. These insights provide an empirical foundation for public health initiatives aimed at mitigating sleep-related disorders and enhancing overall well-being.

Conclusions: This large-scale analysis illustrates the profound complexity of contemporary sleep experiences, emphasizing the need for integrative strategies that account for technological, psychological, and environmental interactions. By leveraging data-driven methodologies, our study contributes to a deeper understanding of sleep health, paving the way for more effective, personalized interventions.

Green space exposure and sleep among pregnant women in the GEMS study

D. Grigsby-Toussaint¹, A. Rodriguez Acevedo¹, J. Yang¹, U. Nwanaji-Enwerem¹, Y. Romero-Ramos¹, N. Zeltzer¹, H. Tran¹, B. Daniel¹, K. Holder², J. McGeary³, K. Mwenda⁴

¹Brown University, School of Public Health, Providence, United States, ²Brown University, Warren Alpert Medical School, Providence, United States, ³Brown University, Psychiatry and Human Behavior, Warren Alpert Medical School, Providence, United States, ⁴Brown University, Population Studies Training Center, Providence, United States

Introduction: Greenspace has been linked to numerous health benefits among pregnant women, such as improving birth outcomes, reducing the risk of developing obesity, and decreasing symptoms associated with adverse mental and physical health outcomes. Consequently, the UN has adopted universal access to greenspace among women and

children as a Sustainable

Development Goal to reach by 2030. Although exposure to greenspace has been shown to have numerous health benefits in relation to pregnancy, few prospective studies using non-static measures of green space with low-income pregnant women currently exist in the United States. This pilot study sought to address these gaps by following pregnant women through their pregnancy (beginning in the first 24 weeks), using objective measures of greenspace exposure and sleep (e.g., GPS- and accelerometer- derived).

Materials and methods: Low-income pregnant women (n=32) in the ongoing Project GEMS study in Rhode Island were recruited to concurrently wear a GPS and an actigraph for seven days at a minimum of two time points during pregnancy. Specific inclusion criteria include a) aged 18 years of age or older, b) within the first 24 weeks of pregnancy, c) expecting a singleton birth. The actigraph was used to derive Total Sleep Time (TST, hours), Sleep Efficiency (SEF), and Wake After Sleep Onset (WASO, minutes). The GPS was used to identify stay points (defined as spending five minutes or more in one particular place) and trajectory paths across the day. Measures of green space exposure included the Normalized Difference Vegetation Index (NDVI) values which were extracted and averaged and tree canopy coverage within 100m, 200m, and 500m circular buffers surrounding each participant's stay points and trajectory paths. T-test results compared sleep measures between high and low greenspace exposure groups, based on a median green-space cut-off among pregnant women.

Results: Seventy-five percent of the women in our project identified as Hispanic or Latino, 37% had a yearly income of less than \$5000, and a mean age of 30.5 ($\pm$ 4.3) years during the first 24 weeks of pregnancy. On average, TST was 6.83 hours, SEF 78%, and WASO 52 minutes. Women residing in areas with higher levels of green space exposure based on NDVI values had higher TST (7.9hrs vs. 6.9hrs, $p=0.02$) at the 500m circular buffer. Moreover, women living in areas with higher percentages of tree canopy had higher TST (7.98hrs vs. 7.0hrs, $p=0.04$) at the 200m and 500m circular buffers, and lower WASO (58minutes vs. 45 minutes, $p=0.05$) at the 100m circular buffer. There were no statistically significant differences observed for SEF between the groups for any green space measures.

Conclusions: Green space exposure is positively associated with total sleep time and WASO among this sample of low-income pregnant women. A larger sample size of women, including measures over the course of the entire pregnancy, and the exploration of additional socio-environmental factors are needed to confirm the robustness of the findings.

Acknowledgments: We thank the women for their participation in this study. Funding is provided by the Division of Research and the Population Studies and Training Center at Brown, and NIHMD R01MD016241

Head Rocking Enhances Deep Sleep During Daytime Naps: Evidence from a Motorized Pillow Study

K. Yamamoto¹, K. Oyama¹, Y. Kawamura², K. Kishimoto¹, N. Shiozawa¹, S. Okada¹

¹Ritsumeikan University, Shiga, Japan, ²AxRobotix Corporation, Tokyo, Japan

Introduction: Recent attention to sleep quality has highlighted its impact on physical and mental health. Short naps, in particular, have been shown to improve attention and memory (Dutheil et al., 2021). As interest in daytime productivity and health maintenance grows, so does the demand for better nap quality. Vestibular stimulation has been reported to enhance sleep, with whole-body rocking shown to promote sleep onset and increase NREM sleep (Perrault et al., 2019). However, most studies focus on whole-body movement, and the effects of head-only rocking remain unclear. This study investigates how head rocking during napping, using a specially designed motion pillow, affects sleep architecture as measured by polysomnography (PSG).

Materials and methods: The pillow used in this study was designed with a structure that allows control of its height using a stepping motor and a ball screw mechanism. By utilizing this mechanism, the pillow can periodically change its vertical position, providing sinusoidal rocking stimulation to the head at a frequency of 0.125 Hz (one cycle every 8 seconds). Eleven participants completed two nap sessions on separate days: one with head rocking, the other without. Polysomnography (PSG) was used to record electroencephalography (EEG), electrooculography (EOG), and electromyography (EMG). Sleep stages were scored, and the time course of the proportion of delta waves in the EEG was analyzed.

Results: After excluding two participants due to incomplete recording data, the analysis was conducted on the remaining nine participants. In the rocking condition (S), the number of wake epochs was higher, and the number of N2 stage epochs was lower compared to the no-rocking condition (NS). Additionally,

the number of N3 stage epochs was higher in the S condition. Furthermore, the proportion of delta waves during non-wake EEG periods was significantly higher in the S condition. A Mann-Whitney U test revealed a statistically significant difference ($p < 0.05$).

Conclusions: In this study, we investigated the effects of head-only rocking during napping using a motorized pillow on sleep architecture. The observed increase in N3 sleep and the elevated proportion of delta waves suggest that head-only rocking can induce effects similar to those reported with whole-body rocking. This may be attributed to the activation of the vestibular system in the head, which is thought to mediate these effects (K. Kompotis et al., 2019). The increase in wake epochs can be explained by the inclusion of two participants who were unable to fall asleep under the rocking condition, likely due to a mismatch between the stimulation frequency and their physiological preferences. It is assumed that the 0.125 Hz stimulation may have overly activated their vestibular system, causing symptoms akin to motion sickness (O'Hanlon & McCauley, 1974). Future studies should focus on designing individually optimized stimulation parameters to prevent such adverse responses.

Head-to-head comparison of a contactless home sleep monitor with polysomnography in women with sleep disturbances associated with menopause

F. Kramer¹, A. Trigg², H.-S. Radcliffe², U. Krahn¹, C. Seitz^{3,4}, M. Rullan⁵, H.U. Babu⁵, J. Krauss⁶

¹BAYER AG, Wuppertal, Germany, ²BAYER PLC, Reading, United Kingdom, ³BAYER AG, Berlin, Germany, ⁴Institute of Clinical Pharmacology and Toxicology, Charité Universitätsmedizin, Berlin, Germany, ⁵Sleepiz AG, Zurich, Switzerland, ⁶Sleepiz AG, Zurich, United Kingdom

Introduction: Sleep disturbances are common in menopausal women, yet repeated in-lab polysomnography (PSG) assessments are often limited by cost and inconvenience. Sleep monitoring in a natural environment may provide valuable insights in clinical trials. This study evaluated the agreement and accuracy between the reference standard PSG and the Sleepiz One+, a contactless home sleep monitor using radar technology to measure vital parameters and bodily movements during sleep, in assessing sleep/wake status in this population.

Materials and methods: In the NIRVANA study, menopausal women with sleep disturbances underwent simultaneous Sleepiz One+ and PSG recordings for six nights, across three assessments (two consecutive nights each at baseline, week 4, and week 12). PSG was conducted in qualified sleep laboratories by trained staff and scored manually by two independent scorers blinded to treatment, following American Academy of Sleep Medicine (AASM) guidelines. Sleepiz data were analyzed automatically using proprietary algorithms. Time synchronization between modalities was achieved using PSG's "lights-off"/"lights-on" markers and respiratory signal alignment. Only high-quality, synchronized datasets were included, resulting in 237,258 epochs (standard 30-second intervals used in sleep scoring) from 66 subjects for analyses, which were compared one by one to assess sleep/wake classification. Agreement between modalities was assessed using sensitivity, specificity, overall accuracy, and prevalence-adjusted bias-adjusted kappa (PABAK), presented as the mean across subjects with 95% confidence intervals (CIs). Parameter-level comparisons (e.g., wakefulness after sleep onset [WASO], total sleep time, sleep efficiency) are ongoing. Data from both methods contribute to the assessment of fitness-for-purpose of the home sleep monitor to assess sleep-related endpoints in the study population in future clinical studies.

Results: Epoch-level comparison showed that Sleepiz achieved a mean sensitivity of 0.91 (95% CI: 0.89, 0.94) for detecting sleep, a specificity of 0.64 (95% CI: 0.60, 0.68) for detecting wake, and had an overall accuracy of 0.86 (95% CI: 0.84, 0.88) compared with PSG. PABAK was 0.72 (95% CI: 0.68–0.76), indicating substantial agreement. Analysis at the parameter-level is ongoing; however, preliminary parameter-level comparisons showed that Sleepiz underestimated WASO by 4.8 minutes, latency to persistent sleep by 9.6 minutes, total sleep time by 7.1 minutes, number of awakenings by 0.4, and duration of awakenings by 1.0 minutes. Sleep efficiency was overestimated by 2.1%.

Conclusions: Epoch-level comparison and preliminary parameter-level results show good agreement between Sleepiz and PSG in menopausal women with sleep disturbances. These results support the use of Sleepiz as a contactless tool for sleep assessment at home in clinical trials. Without the burden of traditional PSG, the Sleepiz device enables continuous home recordings over longer periods and broader data collection in a natural setting. This study extends previous validations of Sleepiz in healthy

and sleep-disordered populations, confirming the device's fitness for purpose in menopause-related sleep research. Ongoing analyses will further validate the technology for clinical applications.

Healthcare measures adopted by medical students to mitigate brain function impairment caused by sleep deprivation: a qualitative interview study using health belief model

X. Wu¹, Q. Su¹, X. Ni¹

¹Guangdong Provincial Hospital of Chinese Medicine, Guangdong Provincial Academy of Chinese Medical Sciences, The Second Clinical School of Guangzhou University of Chinese Medicine, Guangzhou, China

Introduction: Research indicates that sleep deprivation impairs brain function in healthy adults. As future healthcare providers, medical students' strategies to address these effects may offer insights into managing sleep-related health issues. This study explored sleep-deprived medical students' willingness to adopt compensatory measures and decision-making processes when experiencing symptoms of impaired brain function.

Materials and methods: Approved by the Ethics Committee of Guangdong Provincial Hospital of Chinese Medicine (No. YE2022-266), semi-structured qualitative interviews were conducted with participants who reported notable symptoms of brain function impairment following sleep deprivation, focusing specifically on whether they had adopted any measures to alleviate symptoms, the reasons for their choice, and their subjective evaluations of these measures. The participants were all full-time Chinese medicine students interning in Guangzhou, reporting an average sleep duration <7 hours in the past week. Thematic analysis and the health belief model (HBM), including perceived susceptibility (PSU), perceived seriousness (PSE), perceived benefits (PBE), perceived barriers (PBA), self-efficacy (SE), and cues to action (CA), guided data analysis. Each participant signed a written informed consent form before enrolment.

Results: Informed by HBM, qualitative data shows that all respondents reported using one or more measures to mitigate symptoms of sleep-deprivation-related brain impairment, demonstrating high PSU. These strategies were categorized as: lifestyle adjustments (sleep extension, dietary modifications including caffeine and sugar intake, and physical exercise) which were most preferred for accessibility and minimal side effects, indicating high PBE, and medical treatments including Chinese herbal medicine (CHM) like proprietary Chinese medicines and CHM decoctions, external traditional Chinese medicine (TCM) therapies including acupuncture, tuina massage, and foot bathing, and over-the-counter (OTC) non-TCM supplements such as melatonin. CHM and external TCM therapies were preferred over non-TCM supplements because of fewer side effects. PBA included significant side effects, high cost, and poor accessibility. Participants with higher PSE chose more strategies, while those with lower PSE believed adjusting lifestyle habits was sufficient to alleviate their current symptoms, without considering medical treatments. These choices are mainly driven by life experience, medical knowledge reserves, and independent research (SE). In addition, peer recommendations (CA) also influenced choices. Notably, the academic background did not uniformly predict preferences as some participants avoided or even resisted medical treatments, even the TCM treatments they were familiar with.

Conclusions: HBM analysis reveals that medical students' compensatory measure selection is primarily driven by subjective factors (high PSU/PSE/PBE/SE promoting engagement) and hindered by objective barriers (PBA). Interventions for sleep deprivation-related impairment should employ dual strategies: cognitive restructuring to enhance risk awareness and improved resource allocation to increase accessibility. The personalised preferences of different participants highlight the necessity of customised health promotion methods. However, these findings should be interpreted with caution. All participants received TCM training as part of their education, and the city of Guangzhou, where they lived and studied, has a well-established TCM culture.

Acknowledgments: This study was funded by Guangzhou University of Chinese Medicine, China (No. GZY2025GB0111), NATCM's Project of High-level Construction of Key TCM Disciplines (No. ZYYZDXK-2023154) and College Students' Innovative/Entrepreneurial Training Plan Program (No.X202110572294).

Healthcare-seeking and paediatric sleep disordered breathing in substandard housing: preliminary findings from an urban cohort

C.Y. Chan¹, K.C.C. Chan¹, E.Y. Chen¹, F.C Lam¹, A.K Wu¹, J.H Chan¹, L.L Wong¹, H.H Sin¹, E.S Chung¹, H.W Yu¹, D.Y Lai¹, E.L. Wong¹

¹The Chinese University of Hong Kong, Hong Kong, Hong Kong, SAR of China

Introduction: Physical housing environment has a crucial role in sleep health in early life and childhood. However, little is known about the prevalence of parent-reported sleep disordered breathing and its socioeconomic determinants in housing vulnerable populations.

Materials and methods: A territory-wide survey was conducted from April to June 2025 with a convenient sample of Chinese subdivided unit residents and their children aged 2 – 17 years. Household socioeconomic information (income, education, social status), years of residence in substandard houses, children's sex, age and body mass index (BMI) z-score, healthcare utilisation, and Paediatric Sleep Questionnaire (PSQ)-measured sleep-related breathing disorder (SRBD) symptoms were collected. Logistic regressions were used to examine associations between positive PSQ scores (defined as ≥ 0.33) and household socioeconomic information, after adjusted for the child's BMI.

Results: Among 164 dyads interviewed (mean age of child [SD]= 8.46 [3.43] years; 57.1% male), 17.1% (n=28) had PSQ score ≥ 0.33 , indicating a high risk for SRBD, but only 2 dyads (3.57%) have sought medical attentions. A positive PSQ score (≥ 0.33) had a marginally significant association with female children (adjusted odds ratio (aORs) [95% confidence intervals (CIs)] = 2.87 [0.99 - 10.22], $p=0.078$). Household income, parental education, self-perceived social status and years of residence had no significant associations with positive PSQ scores after adjusting for children's BMI z-score.

Conclusions: SRBD symptoms are common among children in subdivided housing, but few seek medical care. Socioeconomic factors showed no significant association with the presence of significant SRBD symptoms, though a marginal gender difference warrants further study.

Healthy shiftwork: Co-designed, clickable, credible

G. Vincent¹, A. Shriane¹, G. Rigney¹, T. Kolbe-Alexander², M. Sprajcer¹, C. Hilditch³, R. Stanton¹, M. Thomas¹, J. Paterson⁴, S. Ferguson¹

¹Central Queensland University, Adelaide, Australia, ²University of Southern Queensland, Brisbane, Australia, ³San Jose State University, San Jose, United States, ⁴Flinders University, Adelaide, Australia

Introduction: Young adults (18–25 years) working shifts face increased risks of sleep and circadian disruption, contributing to long-term health consequences. Despite this, age-appropriate and accessible sleep health resources are lacking. This project aimed to develop and translate tailored, evidence-based content into engaging formats for young shiftworkers.

Materials and methods: A participatory co-design approach was used, involving 48 co-designers including young, current, and former shiftworkers, workplace health and safety professionals, science communicators, and academic researchers. Co-designers participated in online workshops to identify relevant content areas and shape the tone and delivery of the resources. Reflexive thematic analysis of workshop transcripts identified core themes, which were aligned with scientific evidence to guide resource development.

Results: Five key themes were identified: (1) sleep science, (2) impacts of poor sleep, (3) habits influencing sleep, (4) strategies to improve sleep, and (5) workplace recommendations. These themes were translated into three primary delivery modes:

a) An interactive website featuring in-depth, accessible content; b) A pictorial infographic summarising key takeaways; c) an animated video for digital and social media use.

A consistent visual identity and tone were applied to ensure appeal and usability for young audiences.

Conclusions: This project demonstrates how participatory methods can inform not only what content is developed, but how it is delivered. Translating sleep health science into youth-friendly formats may enhance engagement and impact. Evaluation of reach, usability, and behaviour change outcomes is now warranted.

High Resolution Measurement of Sleep Position During Pregnancy and the Impact on Infant Birthweight

D. Wilson^{1,2,3}, D. Mann¹, I. Szollosi², L. Callaway^{4,5}, A. Kothari^{5,6}, P. Terrill¹

¹The University of Queensland, School of Electrical Engineering and Computer Science, Brisbane, Australia, ²The Prince Charles Hospital, Sleep Disorders Centre, Brisbane, Australia, ³Institute for Breathing and Sleep, Melbourne, Australia, ⁴Royal Brisbane and Women's Hospital, Women's and Newborn Services, Brisbane, Australia, ⁵The University of Queensland, Faculty of Medicine, Brisbane, Australia, ⁶Redcliffe Hospital, Department of Obstetrics and Gynaecology, Redcliffe, Australia

Introduction: Pregnant women are advised to sleep laterally from 28 weeks of gestation, due to increased risk of stillbirth in those who report “going-to-sleep” in the supine position. Whilst sleep onset position is modifiable, body position throughout the night occurs in a state of altered consciousness and may be challenging to control, and to self-report accurately. Objective measurement is needed to confirm sleep position as a risk factor for stillbirth. Sleep position in polysomnography is traditionally classified as supine or lateral, but during pregnancy this dichotomy fails to consider important subtleties regarding the haemodynamic mechanisms of tilted sleeping positions and fetal wellbeing. Firstly, this study aimed to characterise sleep position during pregnancy with precise measurement techniques and assess the impact of discretisation of supine sleep on infant birthweight. Secondly, this study aimed to evaluate the accuracy of self-reported sleep position during pregnancy.

Materials and methods: A tri-axial accelerometer was worn around the abdomen for 7 nights, between 32-36 weeks of pregnancy. Body position was measured continuously in degrees of roll. Supine was defined crudely as 0°= fully supine to 45° left or right tilt versus more precisely as 0-15°, 15-30° and 30-45°. Participants completed a sleep diary each morning reporting if they slept on their back the previous night (“no”, “yes - <1hr”, “yes - >1hr”). Infant birthweights were converted into customised centiles based on gestation at delivery, gender, parity and maternal height and weight.

Results: A total of 565 nights were recorded across 85 women. The median (IQR) proportion of supine positioning (0-45°) across the week was 13.1% (5.0, 25.0) equivalent to 65.9 (25.4, 124.6) minutes per night, however this was reduced to 2.1% (0.1, 4.7) or 9.6 (0.8, 24.3) minutes when considering only strict supine positioning (0-15°). Of time spent supine, 45.4% was within 30-45°, compared to 26.1% and 28.5% in less tilted positions of 15-30° and 0-15° respectively. Birthweight centile was not related to overall time spent supine (0-45°) overnight ($r_s = -.07$, $p = .54$) or when constrained to 0-30° supine ($r_s = .03$, $p = .78$) or 0-15° supine ($r_s = .06$, $p = .59$). Women reported “no” back sleeping on 57% of nights, however only 38% of these nights were considered accurate (<10 minutes objectively recorded). Conversely, the 14% of nights reported as >1 hr back sleeping were accurate 97% of the time. Overall, self-reported time-on-back category was accurate only 43% of nights (Kappa = 0.21 (0.16, 0.25), $p < .001$ indicating poor agreement).

Conclusions: Over half of the pregnant women studied spent at least an hour in the supine position overnight, although a favoured 30-45° lateral tilt meant that little time was spent sleeping flat on the back. Supine sleep was not associated with birthweight, suggesting that, at the measured supine exposures, the fetus was minimally impacted from aortocaval compression potentially impacting uteroplacental supply. The inaccuracies surrounding self-reported sleep position highlights the need for objective evaluation of educational campaigns around sleep position during pregnancy.

Home-Based Oropharyngeal Myofunctional Therapy for Habitual Snoring: A Randomized Controlled Trial of Snoring Severity and Sleep Quality

R. Patel¹, A. Kaur²

¹MVPS College of Physiotherapy affiliated by Maharashtra University of Health Sciences, Community Physiotherapy, Nashik, India, ²MVPS College of Physiotherapy affiliated by Maharashtra University of Health sciences, Community Physiotherapy, Nashik, India

Introduction: Habitual snoring affects up to 45 % of adults, leading to sleep fragmentation, daytime fatigue, and partner disturbance. Upper-airway collapse during sleep often stems from weakened oropharyngeal muscles. Myofunctional exercises targeting the tongue, soft palate, and related structures have shown promise in small case series, but most studies focus solely on acoustic snore metrics, overlooking overall sleep quality. We therefore designed a randomized, assessor-blinded trial

to determine whether a 6-week home-based oropharyngeal exercise program could concurrently reduce snoring severity—measured by our novel Snoring Severity Scale (SSS; frequency, loudness, duration, partner disturbance, daytime symptoms; range 0–20 and improve subjective sleep quality (PSQI; range 0–21)

Materials and methods: In this Parallel-group RCT forty adults aged between 18–60 with habitual snoring (≥ 3 nights/wk; SSS ≥ 8 ; PSQI > 5) were randomized (1:1) to Exercise (daily 20 min oropharyngeal routine 6 days/week for 6 weeks, $n=20$) or Control (single sleep-hygiene session, $n=20$) for 6 weeks, with a 2-week follow-up. Co-primary outcomes were Snoring Severity Scale (SSS) and Pittsburgh Sleep Quality Index (PSQI) at Week 6; secondary outcome was daytime sleepiness (Epworth Sleepiness Scale, ESS; 0–24). Outcome assessors and analysts were blinded. Data was analyzed by ANCOVA for SSS and PSQI and ESS and maintenance tested via paired t-test

Results: Thirty-eight participants completed Week 6 (Exercise $n=19$; Control $n=19$). Adherence in Exercise arm was 92% (SD 5%); no serious adverse events. At Week 6, the Exercise group showed a mean SSS reduction of 5.6 ± 1.8 points versus 0.7 ± 1.0 in Control (between-group Change -4.7 ; 95% CI -5.8 to -3.6 ; $p < 0.001$; $d=2.2$). PSQI improved by 4.3 ± 1.2 points in Exercise versus 1.1 ± 1.0 in Control (Change -3.0 ; 95% CI -3.8 to -2.2 ; $p < 0.001$; $d=2.5$). ESS decreased by 3.2 ± 1.0 versus 1.0 ± 0.9 (Change -2.1 ; 95% CI -3.1 to -1.1 ; $p = 0.002$; $d=1.7$). Gains persisted at Week 8.

Conclusions: A structured, home-based oropharyngeal myofunctional therapy program significantly reduces snoring severity and improves sleep quality with sustained effects. The Snoring Severity Scale proves a responsive, practical tool for clinical and research monitoring. This low-cost, scalable intervention merits broader implementation and further investigation in diverse populations

Acknowledgments: Dr. Vasantrao Pawar Medical College and Research Center and MVPS College of Physiotherapy for the support, the statistician for expert guidance, and the patients for their valuable participation in making this study possible.

How the Visual Urban Landscape Influences Sleep Health via Subjective Neighborhood Evaluation

X. Wang¹, J. Yuan¹, D. Matsushita¹

¹Osaka Metropolitan University, Graduate School of Human Life and Ecology, Osaka City, Japan

Introduction: Sleep is closely linked to neighborhood qualities, and since vision plays a central role in how we experience urban environments, exploring the influence of landscape features offers promising insights into sleep research. Environmental effects on sleep partly operate through psychological mechanisms. However, most previous urban sleep studies have focused either on objective landscape characteristics or individuals' subjective evaluations of their neighborhoods, rarely both in conjunction. Additionally, few studies have considered how landscapes influence sleep through environmental evaluations. For measuring landscapes, previous studies used street audits, which are inefficient and limited in capturing quantitative features such as sky and greenery. Subjective evaluations have often been assessed through questionnaire surveys. Although effective in capturing neighborhood evaluations, this method is subject to individual bias and limited in reproducibility.

This study aims to address the above research gaps by examining the complex relationship between objective visual landscapes, subjective neighborhood evaluations, and sleep health outcomes.

Materials and methods: Sleep health data were collected from 1,089 adults. Insomnia and sleepiness were assessed using the Athens Insomnia Scale and the Epworth Sleepiness Scale, where higher scores indicate poorer sleep health.

Using Computer Vision techniques, pixel-level landscape elements (e.g., greenery, sky) were identified in neighborhood street view images (SVIs), localized to participants' postal codes. Based on existing theories, we derived objective measures of visual landscape quality, as reflected in greenness, walkability, enclosure, and complexity.

We fine-tuned models linking landscapes to subjective evaluations using the Place Pulse 2.0 dataset, which provides global imagery and crowdsourced evaluations reflecting collective judgment. Using those models, we batch-generated model-predicted subjective evaluations of the neighborhood SVIs: safety, non-boredom, non-depressiveness, wealth, liveliness, and beauty.

Structural equation modeling was used to evaluate indirect pathways from objective landscape quality to sleep outcomes via subjective evaluations, while controlling demographic factors.

Results: Regarding insomnia, positive significant indirect effects were observed from visual greenness via non-depressiveness ($\beta = -0.030$, $p = 0.05$); walkability via non-boredom (-0.009 , 0.05); complexity

via both non-depressiveness ($-0.018, < 0.001$) and non-boredom ($0.014, 0.025$).

Regarding sleepiness, greenness showed positive marginally significant indirect effects via safety ($-0.017, 0.056$), non-depressiveness ($-0.034, 0.037$), and wealth ($-0.018, 0.050$). Walkability had a significant indirect effect via non-boredom ($-0.012, 0.019$). Complexity showed marginally significant indirect effects via non-depressiveness ($-0.018, 0.077$), and negative significant indirect effects via non-boredom ($0.015, 0.020$) and liveliness ($0.014, 0.020$).

Conclusions: This study suggested the mediating role of subjective evaluations in linking visual landscape to sleep outcomes. Greenness was associated with lower levels of insomnia and sleepiness, primarily via reduced depression, enhanced safety and perceived wealth. Walkability also contributed to reduced sleep problems through decreased boredom. Complexity had mixed effects, reducing sleep problems via non-depressiveness but increasing them via liveliness, suggesting visually stimulating environments may raise arousal.

One limitation is the lack of analysis on which specific visual elements in street qualities were most influential. Future studies should isolate these components to better guide urban design for sleep health.

Acknowledgments: This study was supported by JSPS KAKENHI [Grant Number 24K01053], and JST SPRING [Grant Number JPMJSP2139].

Hyperbaric Oxygen Therapy And Its Physiological Mechanisms Affecting Sleep Disturbances: A Narrative Review

S. Duong-Quy^{1,2,3}, T.V. Hoc^{4,5,3}

¹Lam Dong Medical College, Sleep Center, Da Lat, Vietnam, ²Penn State University, Penn State College of Medicine, Hershey, United States, ³Vietnam Society of Sleep Medicine, Da Lat, Vietnam, ⁴Taipei Medical University, International Master/Ph.D. Program in Medicine, Taipei, Taiwan, ⁵Thai Nguyen University of Medicine and Pharmacy, Department of Internal Medicine, Thai Nguyen, Vietnam

Introduction: Hyperbaric oxygen therapy (HBOT), traditionally utilized to improve oxygen for conditions such as decompression sickness and non-healing wounds, has recently garnered attention for its potential therapeutic effects on various sleep disturbances. Sleep is a complex physiological process that is sensitive to oxygen homeostasis, and disruptions in oxygenation can significantly alter sleep architecture and sleep efficiency.

Materials and methods: This narrative review explores the evolving evidence on HBOT's role in modulating sleep physiology and alleviating common sleep disorders, including obstructive sleep apnea (OSA), central sleep apnea (CSA), insomnia, and altitude-related sleep disturbances.

Results: We figure out the basic principles of HBOT, including pressure settings, treatment therapy, and the physiological responses associated with hyperoxia. The effects of HBOT on sleep disturbances through multiple physiological mechanisms, including the reduction of inflammation and oxidative stress, reversal of tissue hypoxia, modulation of cytokines and immune response, improvement in sleep architecture, reduction of sleep-related pain and fatigue, effects on brain regions involved in sleep regulation, improvement in pulmonary function and oxygenation, reduction of arousal threshold and loop gain, and effects on psychological symptoms, all of which are critical in the pathophysiology of sleep disorders.

For OSA, HBOT has shown promise in modulating upper airway muscle tone and reducing intermittent hypoxia-induced oxidative damage, potentially improving apnea-hypopnea index (AHI) and oxygen saturation in select patient populations. In the context of CSA, especially in patients with heart failure or opioid-induced apnea, HBOT may influence central respiratory drive through effects on brainstem chemoreceptor sensitivity and autonomic balance. However, clinical data remain limited, and the risk of suppressing hypoxic ventilatory drive must be considered.

Insomnia, particularly in cases associated with neuroinflammation or traumatic brain injury, may respond to HBOT through its neurorestorative and anti-inflammatory effects. Preliminary clinical studies suggest improvements in sleep efficiency, latency, and subjective sleep quality following multiple sessions of HBOT, though standardized protocols and randomized trials are lacking.

At high altitudes, hypobaric hypoxia commonly induces periodic breathing and sleep fragmentation. HBOT has been investigated as a countermeasure to altitude-induced sleep disruption, with studies indicating improved nocturnal oxygenation, reduced arousals, and stabilization of breathing patterns in both acclimatized and unacclimatized individuals. Overall, the current literature provides compelling

physiological rationale and preliminary clinical evidence supporting the application of HBOT in select sleep disorders. However, significant gaps remain, including heterogeneity in treatment protocols, small sample sizes, and limited long-term follow-up. Further studies are needed to elucidate optimal patient selection, treatment duration, and safety considerations, especially in vulnerable populations.

Conclusions: This review highlights the potential of HBOT as an adjunctive or alternative approach in sleep medicine and encourages future interdisciplinary research to validate its efficacy and safety. Understanding the mechanistic links between hyperoxia, neurophysiology, and sleep regulation may open new therapeutic pathways for refractory or comorbid sleep disturbances.

Identifying and managing sleep disorders in patients with fibromyalgia

N. Lovato¹, A. Reynolds¹, S. Whittle^{2,3}, C. Ruediger², K. Dyer², N. Watson², T. Gill^{3,4}, R. Adams¹, C. Hill^{2,3}
¹Flinders University, Adelaide, Australia, ²Rheumatology Unit, The Queen Elizabeth Hospital, Adelaide, Australia, ³Adelaide Medical School, University of Adelaide, Adelaide, Australia, ⁴Freemasons Centre for Men's Health and Wellbeing, University of Adelaide, Adelaide, Australia

Introduction: Fibromyalgia is a chronic condition marked by widespread pain, fatigue, and sleep problems. However, little is known about the presentation and management of sleep problems in these patients. This study aimed to 1) characterise sleep/wake patterns and sleep disorder presentations in participants with fibromyalgia, and 2) assess changes in sleep and fibromyalgia symptoms with individualised sleep disorder treatment.

Materials and methods: Women with fibromyalgia were recruited from the Rheumatology Unit at The Queen Elizabeth Hospital, South Australia. Participant sleep and activity for two-weeks was established using an under-mattress sleep sensor (Withings Sleep Analyser, WSA), sleep diaries and a wrist accelerometer (GENEActiv). Screening questionnaires included Berlin Sleep Questionnaire (OSA), Epworth Sleepiness Scale (ESS), Flinders Fatigue Scale (FFS), the Sleep Condition Indicator (SCI), and Fibromyalgia Impact Questionnaire Revised (FIQ-R). Self-reported anxiety, depression, other co-morbidities, as well as medication use, were collected. Results were reviewed by sleep psychologists and a sleep physician. Those determined to be at risk for a sleep disorder were offered individualised sleep disorder treatment, which involved cognitive behaviour therapy for insomnia (CBTi) and personalised chronotherapeutic approaches (bright light therapy, melatonin) delivered by sleep psychologists, and/or continuous positive airway pressure (CPAP) therapy with or without positional (POS) therapy, as appropriate and prescribed by the sleep physician.

Results: Data from 23 women (aged 50.5±15.6years, BMI 32.8±9.3kg/m²) with pain duration ranging from 18 months to over 40 years were investigated. Sixteen women completed a sleep diary, indicating low sleep efficiency (73%±11.5). All were assessed as 'high-risk' for a sleep disorder, with eight at 'high-risk' for two or more sleep disorders (7 obstructive sleep apnoea; OSA), 12 insomnia, 6 circadian rhythm sleep wake disorders; CRSWD). Five women had delayed, and one had advanced, circadian rhythms. Fatigue scores exceeded those commonly observed for participants living with medical conditions more broadly in the community (21.7±5.8 vs. 20.4±6.2). Co-morbid anxiety and depression were reported by 65% and 35% of the women, respectively. Thirty-nine percent of participants reported being woken by pain nightly, and 43.5% reported their pain prevented sleep on 1-3 nights per week. Over half of the participants (56.5%) reported taking medication at night for pain. Ten women were referred for individualised sleep disorders treatment. Seven provided responses to post-treatment questionnaires and reported clinically meaningful improvements in their fatigue (mean change=6.7; Minimal Clinically Important Difference [MCID]=3.4), and FIQ score (mean change=10.6; MCID=8.1).

Conclusions: Fibromyalgia is associated with complex and co-morbid sleep disorders. Screening, identifying and managing sleep disorders using personalised treatment approaches may be an important therapeutic target for patients with fibromyalgia to improve sleep quality, daytime functioning, and fibromyalgia symptoms.

Identifying and Predicting Emotionally Relevant Sleep Disturbance Patterns in Dementia Family Caregivers: A Machine Learning Approach to Objective-Subjective Discrepancy

T. Wakui^{1,2}, Y. Otake³, S. Obuchi¹

¹Tokyo Metropolitan Institute for Geriatrics and Gerontology, Tokyo, Japan, ²Research & Development Center for Health Services of University of Tsukuba, Ibaraki, Japan, ³Nara Institute of Science and Technology, Nara, Japan

Introduction: One of the major challenges in home-based care for older adults with dementia is sleep disruption experienced by family caregivers, often caused by dementia-related symptoms such as day–night reversal and nighttime urinary frequency. These disruptions significantly impact caregiver burden and mental health; however, the actual conditions and patterns of such disturbances remain poorly understood. In particular, repeated awakenings after bedtime are difficult to detect through self-reported sleep measures alone. This study aimed to comprehensively assess caregiver sleep disturbances by combining objectively measured sleep data (via accelerometer-based activity trackers), subjectively reported sleep disruption, and daily self-reported psychological health indicators. These integrated data were used to classify patterns of sleep disruption and to evaluate the predictive accuracy of next-day psychological outcomes—such as emotional exhaustion—as well as depressive symptoms assessed after 60 days, using machine learning techniques.

Materials and methods: Family caregivers who provided care at least once a week to community-dwelling older adults aged 65 and over—certified as requiring long-term care in Japan—were recruited nationwide through an online survey company. Participants were instructed to wear an activity tracker to monitor sleep and to record daily caregiving status along with self-reported emotional indicators over a 60-day period. A baseline questionnaire was administered to collect demographic and caregiving-related information. Sleep and wake data were recorded at 2-minute intervals (yielding 720 data points per day), and were combined with both subjective reports of sleep disturbances and daily emotional indicator data. Non-wear periods during nighttime were excluded from analysis. For classification of sleep disturbance patterns, dimensionality reduction was performed using t-SNE, followed by k-means clustering. To predict multiple psychological health indicators, including emotional exhaustion, deep learning was applied using a neural network model with 5-fold cross-validation. The study was approved by the Ethics Committee of the Tokyo Metropolitan Institute for Geriatrics and Gerontology.

Results: A total of 199 participants (57.3% male; mean age 55.5 years) completed the activity tracker measurements and recordings, excluding 9 who withdrew before the study and 2 who dropped out due to the death of the care recipient or the caregiver's health issues. A total of 11,815 sleep disturbance datasets (excluding non-wear nights) were analyzed. Clustering via t-SNE revealed five distinct groups of caregiver sleep/wake patterns. This classification enabled the prediction of subjective emotional exhaustion with 73.1% accuracy, exceeding the accuracy of random prediction.

Conclusions: These findings suggest that machine learning can be used to quantify and predict emotional burden using only objectively measured data from activity trackers. This indicates that such objective data contain embedded information related to caregivers' emotional exhaustion. The predictive model demonstrates the potential for integrating technology into caregiver support systems.

Identifying sleep associations in women across five countries: a global smartwatch-based study

C.N. Soares¹, F.C. Baker², P.M. Maki³, J. Lee⁴, M. Kim⁴, D. Lee⁴, R. Choi⁵, J. Choi⁴, H. Pak⁴, N. Schoof⁶, J. Dorey⁷, E.I. Eroglu⁶, E. Bolinger⁶, C. Caetano⁸, C. Moeller⁶, C. Dinkel-Keuthage⁶

¹Queen's University, Kingston, Canada, ²SRI International, Menlo Park, United States, ³University of Illinois at Chicago, Chicago, United States, ⁴Samsung Electronics, Suwon, Korea, Republic of, ⁵Samsung Electronics America, California, United States, ⁶BAYER AG, Berlin, Germany, ⁷Bayer Healthcare SAS, La Garenne-Colombes, France, ⁸BAYER Consumer Care, Basel, Switzerland

Introduction: Sleep disturbances—including difficulties falling asleep, staying asleep, or waking early—are common among midlife women and may be influenced by age, physical activity, weekend/weekday patterns, and cultural context. However, large-scale, cross-cultural comparisons using objective sleep measures remain limited. Wearable devices offer a novel, scalable approach to study sleep health globally. Using Samsung Galaxy Watch data, this study examined associations of age, BMI, physical activity, and country with sleep parameters in a large, international cohort of women.

Materials and methods: We analyzed sleep data from 192,500 women aged 20–65 years, each with ≥7 nights of sleep recordings, from the US, South Korea, Germany, France, and the UK (n=38,500 per

country). Sleep parameters included total sleep period duration (TSPD; time from sleep onset to final awakening), total sleep time (TST; time asleep within TSPD), and wake after sleep onset (WASO; log-transformed). Linear mixed models assessed associations with age (5-year intervals), weekday/weekend patterns, physical activity (step counts and active time tertiles), and country (US as reference). An exploratory model included age-by-country interactions.

Results: Overall, across the whole data set, mean (SD) values were: TSPD 439.4 (92.0) minutes, TST 391.2 (81.9) minutes, and WASO 48.3 (33.5) minutes. Age distributions were comparable across countries, with approximately 1/3 of women aged ≥ 50 years.

TSPD: Weekend nights were associated with ~24 minutes longer TSPD (+5.4%). Age and physical activity effects were small (± 5 minutes). Women in South Korea had the shortest TSPD, averaging 27 minutes less (-6.2%) than US women.

TST: TST declined with age, with women aged 60–65 sleeping 17 minutes less (-4.4%) than those aged 20–24. Women in age groups ≥ 50 had 13–17 minutes less TST (-3.3 to -4.4%) than those aged 20–24. Weekend nights were associated with ~21 minutes longer TST (+5.3%) compared to weeknights, while activity-related differences in TST were small (< 3 minutes; $< 1\%$). Similar to TSPD, women in South Korea showed, on average, a 25-minute shorter TST (-6.3%) vs. US women.

WASO: WASO increased with age; women in age groups ≥ 50 had 5–11 minutes more wakefulness (+15–32%) than those aged 20–24. A small weekend effect was observed (+2 minutes; +5.4%). Activity effects were minimal (< 1 minutes; -1.1% to -2.5%). Country differences were small: UK (+1.5 minutes) and South Korea (-1 minute) vs. US.

Interaction Effects: Age-related WASO increases were consistent across countries, except in South Korea, where effects were more pronounced. Other significant interactions are thought to be due to the large sample size and have limited clinical relevance.

Conclusions: In this large, international cohort of women, who provided multiple nights of wearable data, country-specific differences in TST and TSPD were evident, particularly in South Korea. The effects of age on TST and WASO were generally similar across countries, except for South Korea, where age effects on WASO were more pronounced. These findings underscore the potential of smartwatch data for large-scale sleep research.

Individual Variations in Stress-Related Sleep Patterns

E. Ngan¹, L. Balter¹, G. Kecklund¹, T. Sundelin¹

¹Stockholm University, Stockholm, Sweden

Introduction: Stress is a pervasive factor that can disrupt sleep, which plays a crucial role in recovery and overall health. While the harmful effects of stress on sleep are widely recognized, the degree of this impact may vary across individuals. This study aims to investigate the relationship between daily stress and subsequent sleep duration in order to identify distinct patterns of stress-related sleep behavior.

Materials and methods: Self-reported daily stress and sleep duration from 800 participants across three weeks ($M = 15.5$ days, $SD = 4.36$ days), were analyzed to explore the relationship between daytime stress and sleep duration the following night. A linear mixed model was used to assess within-person associations between stress and subsequent sleep duration, including random intercepts and slopes. To further examine heterogeneity in stress-sleep dynamics, k-means clustering analysis was conducted based on the individual slopes derived from the mixed model.

Results: Higher daily stress was significantly associated with shorter sleep duration the following night, with a decrease of approximately 7.5 minutes per unit increase in stress ($b = -7.47$, $SE = 0.67$, $p < .001$). The model also indicated substantial variability in both baseline sleep duration and individual stress-sleep slopes, and a likelihood ratio test confirmed significant individual variability in the stress-sleep association ($\chi^2(2) = 41.59$, $p < .001$), justifying the inclusion of random slopes.

To explore this variability, the clustering analysis revealed three distinct groups, each with unique stress-sleep dynamics. One group ($n = 417$) exhibited a moderate negative relationship between stress and sleep, with an average slope of $b = -7.40$. As stress increased, sleep duration decreased moderately. Another ($n = 196$) showed a steeper decline in sleep duration with a slope of $b = -13.07$, indicating a higher sensitivity to stress, where even moderate increases in stress predicted a significant reduction in sleep. The third group ($n = 187$) displayed a minimal negative relationship between stress and sleep, with a slope of $b = -1.77$, suggesting that stress had little predictive effect on sleep duration for these individuals.

Conclusions: While the group-level trend suggests that daily stress generally predicts shorter sleep, large individual differences exist. For some sleep may function as a deliberate recovery response protecting from the negative impact of stress, while for others, stress may moderately or heavily impair sleep. These findings underscore the heterogeneity in the stress-sleep relationship, reinforcing the importance of tailoring interventions to individual stress-sleep profiles, as uniform strategies may overlook key subgroups.

Influence of Climate Changes on Sleep. Systematic Review

A. Büttner-Teleaga¹

¹Institute of Cognitive Science, Woosuk University, Wanju-gun, Korea, Republic of

Introduction: Climate changes could lead in changes of sleep and sleep pattern as well as in sleep disorders and chronobiological changes, beginning with a poor quality of sleep, reinforced by a shift of the sleep-wake rhythm and lead in severe sleep disorders. Their prevalence and incidence are unknown until now. Both sleep disorders and chronobiological changes have a wide variety of causes and usually appear as a comorbid disorder in various somatic and psychiatric diagnoses, mental disorders and treatments. There can be many different predictors of sleep disorders and chronobiological changes, such as predisposition or pre-existing diseases, caused and / or reinforced by climate changes.

Materials and methods: A systematic literature review related to Climate changes and Sleep was carried out and 1,649 studies were evaluated. The articles were identified through PubMed, PsycInfo, and Web of Knowledge; a total of 30 publications were included in the analysis.

Results: A total number of ninety-five studies of the topic climate changes and sleep were identified; thirty of them were analysed, based on different criteria (climatic and civilization-related changes, natural disasters and special weather phenomena).

Conclusions: The review found that changes of sleep, of sleep pattern and of sleep quality as well as different sleep disorders (such as insomnias, hypersomnias, parasomnias) and chronobiological changes can be predicted for very different reasons. Personalized treatment of climatic-related changes would be needed to improve the mental and / or physical condition of these patients.

Influence of Sociodemographic, Personal and Lifestyle Factors on Sleep Quality and Stress-Coping Strategies Among Trainees in a Tertiary Hospital

R. Aliñab¹, P. Diamante²

¹The Medical City-Ortigas, Neurology, Pasig, Philippines, ²The Medical City, NEUROLOGY, Pasig, Philippines

Introduction: Healthcare workers, especially physician trainees, are often required to work demanding shifts exceeding 24 hours, which expose them to various stressors and impact sleep quality and patterns.

Materials and methods: This study investigated the impact of sociodemographic, personal, and lifestyle factors on sleep quality among hospital trainees in a tertiary hospital in the Philippines and explored their coping mechanisms for managing stress. This analytic, cross-sectional study was conducted among hospital trainees (fellows, non-surgical, and surgical residents) in a tertiary hospital. Data were gathered through an online survey using three validated questionnaires: the Pittsburgh Sleep Quality Index, Brief COPE, and FANTASTIC Lifestyle Questionnaire.

Results: Out of 107 respondents, 92 were included in the study, with the majority of respondents single, female, and working shifts over 24 hours. The study revealed an 85% prevalence of poor sleep

quality, with an average sleep duration of 5.7 hours. Sleep duration was significantly associated with working hours and marital status in the non-surgical resident group. Poor sleep quality in general negatively impacted lifestyle factors, especially in surgical residents. Problem-focused coping was the most commonly used strategy, especially among fellows, while surgical residents scored lower in emotion-focused strategies like humor and religion. Avoidant coping, though generally low, was more evident through self-distraction.

Conclusions: This study highlights a high prevalence of sleep deprivation among physician trainees, linked to poor sleep quality and influenced by lifestyle factors. It recommends implementing consistent work shifts, reducing long consecutive hours, and introducing educational programs on sleep hygiene and institutional support to improve trainees' well-being and coping strategies.

Acknowledgments: I sincerely acknowledge my co-author, Dr. Pearl Diamante, for her invaluable contributions, and the residents and fellows of The Medical City Ortigas for their participation in the survey, which was instrumental to this work.

Integrative analysis of association and causal inference identify interactions between asthma and multiple sleep traits

W. Zhao¹, Y. Zhang², Z. Chen³, H. Ouyang³, M. He², S. Wang², B. Tang⁴, X. Su², M. Yi³

¹Central South University, Xiangya School of Medicine, Changsha, China, ²Central South University, Department of Respiratory & Sleep Medicine, Xiangya Hospital, Changsha, China, ³Central South University, School of Life Sciences, Changsha, China, ⁴Central South University, Department of Neurology, Xiangya Hospital, Changsha, China

Introduction: The overlap of asthma and sleep traits is common, and possibly vary depending on patient age. This study aimed to estimate the associations and causal links of asthma with sleep traits including obstructive sleep apnea (OSA), insomnia, excessive daytime sleepiness (EDS) and sleep duration in adults and non-adults.

Materials and methods: Quantitative analysis was performed to find impaired sleep domains in asthma and assess their risk associations by odds ratio (OR). Then, a two-sample Mendelian randomization (MR) was conducted to evaluate their causality by using published Genome-wide association study summary statistics. The primary method was inverse-variance weighting, and several complementary methods were applied as sensitivity analyses.

Results: A total of 90 studies with 2556734 participants were included in quantitative analysis. Our results showed that parameters representing the severity of OSA, sleep quality and sleepiness were higher in asthma than non-asthma controls. Besides, asthma was related to high risk of these sleep traits (ORs of 1.44~2.08). Conversely, these sleep traits were associated with increased asthma risk with ORs ranging from 1.24 to 1.82. However, these findings were not consistent in some subgroup analyses. In MR analysis, primary results demonstrated that genetically predicted asthma was associated with a higher risk of OSA (OR[95% CI]=1.075[1.032,1.121]), which was consistent in three sensitivity analyses with ORs ranged from 1.075 to 1.089.

Conclusions: There are mutually reinforcing risk associations between asthma and four sleep traits. Further, asthma has robust causal effect on increasing OSA risk. These findings may provide direction and evidence for studying related mechanisms and intervention strategies.

Intervening in sleep early to support maternal mental health: short sleep and symptoms of sleep disordered breathing prior to pregnancy are associated with depressive symptoms in late pregnancy

TL. Signal¹, D. Muller¹, B. Sweeney¹, S.-J. Paine²

¹Massey University, Sleep/Wake Research Centre, School of Health Sciences, College of Health, Wellington, New Zealand, ²University of Auckland, Growing Up in New Zealand, Faculty of Medical and Health Sciences, Auckland, New Zealand

Introduction: The identification and treatment of sleep problems in pregnancy has shown promise for supporting maternal mental health. The current study aimed to add to our understanding of when to intervene and what aspects of sleep to intervene in, by investigating a range of sleep metrics prior to

and in late pregnancy and their association with depressive symptoms in late pregnancy for Indigenous and non-Indigenous women.

Materials and methods: Data were drawn from the first data collection wave (late pregnancy) of a prospective longitudinal study of perinatal sleep health in Indigenous and non-Indigenous women. Clinically significant symptoms of depression, measured with the Edinburgh Postnatal Depression Scale (<13 vs. ≥13), was the outcome variable in logistic regression models. Predictors in a pre-pregnancy model were usual sleep duration in 24 hours (≤6 hrs, >6hrs - ≤9hrs, >9 hrs); frequency of a good night's sleep (<3 days/week vs. ≥3 days/week); and presence of loud snoring, long pauses between breaths while asleep, and legs twitching or jerking while asleep (all present/absent). Ethnicity (Māori/non-Māori), socio-economic deprivation (NZ Deprivation Index quintiles), parity (nulliparous/multiparous), history of diagnosed depression (yes/no), relationship status (happy/unhappy and not applicable), life stress (<2 vs. ≥2 stressful events) and BMI (obese/not obese) were covariates. The late pregnancy model included the above with the addition of daytime sleepiness (Epworth Sleepiness Scale, <10 vs. ≥10), presence of restless legs (yes/no), and poor sleep quality and symptoms of insomnia (General Sleep Disturbance sub-scales, <3 nights/week vs. ≥3 nights/week).

Results: Data were provided by 406 Māori and 738 non-Māori women between 35-37 weeks gestation. Twenty-two percent of Māori women and 15% of non-Māori women had clinically significant depressive symptoms. In pre-pregnancy models, after adjusting for all covariates and sleep variables simultaneously, short sleep (≤6 hours) and reports of any loud snoring prior to pregnancy independently increased the odds of depressive symptoms in late pregnancy 2.7 and 1.5 times respectively. In late pregnancy models, short sleep and any loud snoring increased the odds of depressive symptoms 1.6 and 2.0 fold. Difficulty falling asleep and excessive daytime sleepiness were also significant in this adjusted model, with an increase in the odds of depressive symptoms by 1.8 and 1.6 times.

Conclusions: The finding that sleep pre-pregnancy was associated with depressive symptoms in late pregnancy points to an opportunity to identify and intervene in sleep issues very early in pregnancy as one possible way of supporting perinatal mental health. Any interventions must be designed to meet the needs of Indigenous women who are at greatest risk of experiencing poor mental health in the perinatal period.

Acknowledgments: We gratefully acknowledge the contribution of the participating women. Thank you to those who assisted with recruitment and data entry, and the study advisory group for their guidance and support. This study was conducted with funding from the Health Research Council of New Zealand (HRC 08/547 and 09/255) and Massey University.

Interwoven threads: hormonal regulation, stress and the sleep-pain dyad in women

S. Gupta¹

¹Rak Dental Care & Implant Centre, Orofacial Pain & Dental Sleep Medicine, Ras Al Khaimah, United Arab Emirates

Introduction: Sleep and pain, chronic pain in particular, share a deeply intertwined and bidirectional relationship. However, emerging evidence highlights a significant sex-based disparity in this dynamic relationship, with women disproportionately affected by chronic pain and sleep disturbances. This presentation explores the unique neurobiological, hormonal, and psychosocial mechanisms that underpin this phenomenon in females.

Materials and methods: To elucidate the multifactorial interactions between sleep disruption, pain perception, and the female sex, with a focus on hormonal fluctuations, stress reactivity, and their collective impact on pain modulation. Drawing from current interdisciplinary research, this presentation synthesizes findings from sleep medicine, pain neuroscience, endocrinology, and psychoneuroimmunology. Special attention is given to the role of the menstrual cycle, perimenopause, and stress-induced hormonal changes (e.g., cortisol and estrogen) in modulating pain sensitivity and sleep architecture.

Results: Women are more likely than men to experience sleep disorders such as insomnia and to report heightened pain sensitivity. Hormonal fluctuations across the menstrual cycle and life stages significantly influence both sleep quality and pain thresholds. Chronic stress further exacerbates this relationship through dysregulation of the hypothalamic-pituitary-adrenal (HPA) axis, amplifying both

sleep disruption and central sensitization of pain pathways. These factors often coexist with mood disorders, creating a feedback loop that sustains poor sleep and persistent pain.

Conclusions: Understanding the sex-specific interactions among sleep, pain, and hormonal regulation is critical for the development of targeted, gender-sensitive interventions. This presentation calls for an integrative approach that addresses both biological and psychosocial contributors to improve sleep and pain outcomes in women.

Acknowledgments: NONE

Investigating differential rhythmicity in circadian biomarkers using skin perspiration wearables

A. Ramasubramanya¹, P. Singh¹, K.-C. Lin¹, S. Prasad^{1,2}, S. Muthukumar²

¹University of Texas at Dallas, Texas, United States, ²EnLiSense LLC, Allen, United States

Introduction: With advancements in wearable technologies like smartwatches, there has been growing interest in developing noninvasive sensors that can integrate with wearables for real-time health monitoring. The focus of this research is the detection of melatonin through perspiration, which contains similar biomarkers found in blood at measurable concentrations and develop a sensor algorithm for real-time melatonin monitoring in perspiration. The research aims to analyze circadian patterns in melatonin and cortisol and understand how light exposure impacts melatonin levels and explore whether perspiration can serve as a reliable surrogate for saliva in tracking melatonin.

Materials and methods: Features were extracted from the raw sensor data collected using a continuous, non-invasive wearable biosensor designed to measure circadian biomarkers. The primary objective was to model circadian patterns in circadian biomarkers, melatonin and cortisol. The raw sensor data was pre-processed to remove noise. To train and validate the model, interpolated melatonin levels derived from discrete saliva samples were used as the output variable. A total of 23 participants were included in the study, and strict protocols were implemented to control external variables that could influence cortisol and melatonin secretion. Participants refrained from caffeine, stimulants, and alcohol consumption after 6 p.m. to prevent disruption of the natural circadian cycle. To minimize light exposure, they remained in dim lighting conditions (less than 5 lux) from 10 p.m. to 4 a.m., which was verified using wrist-worn light exposure monitors. Physical activity levels were also monitored using wearable devices to account for potential activity-related effects on melatonin secretion. This controlled environment ensured the collection of consistent, high-quality data for the training and validation of machine learning models.

Results: Perspiration concentrations strongly correlated with salivary levels, with Pearson's coefficients of 0.89 for cortisol and 0.78 for melatonin. Bland-Altman analysis confirmed agreement, with narrow limits for cortisol (-4.68 to 6.13 ng/mL) and moderate variability for melatonin (-11.76 to 18.16 pg/mL). Circadian rhythmicity assessed via CircaCompare and Hedges' g revealed significant trends, with cortisol peaking in the morning ($g = 1.0831$) and melatonin highest at night ($g = 0.7575$). ANOVA showed significant temporal and age-related variations ($p < 0.0001$), with younger individuals exhibiting stronger rhythms. Correlation heatmaps indicated robust intra-age group relationships for melatonin and an age-related decline in light sensitivity in older adults. Machine learning models achieved high predictive accuracy, with R^2 values of 0.95 for cortisol and 0.96 for melatonin and RMSEs of 1.29 ng/mL and 3.12 pg/mL, respectively.

Conclusions: Perspiration-based wearable sensors integrated with machine learning offer a promising solution for real-time, non-invasive monitoring of cortisol and melatonin. This technology lays the foundation for advancing personalized tools for stress and sleep management. The research demonstrates the efficacy of a non-invasive sensor to monitor cortisol and melatonin in perspiration continuously. Utilizing statistical tools and assessing circadian rhythm, significant patterns were identified that aligned with established circadian rhythms and showed how melatonin is affected by environmental factors like light. The rhythmicity data from Circacompare validates that the sensor algorithm effectively captures cortisol's and melatonin's natural cycles.

Investigating the Effects of Pre-Sleep Virtual Reality Relaxation Experiences on Subjective and Objective Sleep Outcomes (Pilot RCT)

Y. Yap¹, M. Takac¹, V. Nguyen¹, S. Syed¹, M. Dragh¹, C. Kuong¹, O. Troynikov², G. Vesty³, O. Hamilton⁴, F. Zambetta⁵, B. de Courten¹, R. Conduit¹

¹RMIT University, School of Health & Biomedical Sciences, Melbourne, Australia, ²RMIT University, School of Engineering, Melbourne, Australia, ³RMIT University, School of Accounting, Information Systems and Supply Chain, Melbourne, Australia, ⁴RMIT University, School of Architecture & Urban Design, Melbourne, Australia, ⁵RMIT University, School of Computing Technologies, Melbourne, Australia

Introduction: Currently, the use of electronic devices before sleep is not advised by health experts due to findings regarding the effects of blue light on the circadian clock and cognitive arousal such devices can produce before sleep. This broad assumption has recently been challenged by recent evidence that the use of electronic devices, in the context of producing relaxation and reducing cognitive arousal, can provide improved sleep outcomes.

Virtual reality (VR) technologies have shown therapeutic benefits for several conditions, including phobias, depression, post-traumatic stress disorder, social anxiety and pain. In many of these studies, improvements in sleep quality are reported as a secondary outcome. The aim of this study was to assess the effects of a purpose-built VR Pre-sleep experience over a traditional pre-sleep relaxation activity (reading) on sleep quality across a week in the home of young adults.

Materials and methods: Thirty-five young adults (9 M, 26 F, mean age 22.6 yrs, SD = 3.6), participated in a randomised crossover study across two weeks. After an initial orientation session, participants engaged in a VR Relaxation Experience (Liminal VR Pty Ltd) or Relaxation Control (reading a self-chosen book) for 10 mins before sleep each night for one week for each condition in a randomised order. For the duration of the experiment, participants wore a wrist actigraphy unit (wGT3X-BT, Actigraph LLC) to record their sleep/wake profiles at home while also using a sleep diary. On the last two nights of each week, participants sleep was recorded using portable polysomnography (PSG; Z-Machine Insight+, General Sleep Corporation).

Results: Statistical analyses of the first 35 participants indicated that on average:

- The VR condition had 3% better PSG recorded sleep efficiency compared to the reading control (82.1% vs 85.1%, $t(34) = 2.49$, $p = .02$).
- The VR condition showed 3.5 minutes shorter PSG recorded sleep onset latency compared to the reading control condition (5.3 mins vs 8.8 mins), trending towards statistical significance, $t(34) = 1.89$, $p = .07$ (NS).
- None of the mean actigraphy measures between conditions were statistically significant.
- Further subgroup analysis of 21 participants with poor initial sleep at baseline (PSQI > 5) showed no difference in results.

Conclusions: Findings from 35 participants indicated initial evidence that VR showed some significant improvements in PSG recorded sleep efficiency but no other sleep measures. VR could be a potential sleep aid. However, further research and refinement of the study design are needed.

Acknowledgments: We would like to thank Liminal VR Pty Ltd for providing VR headsets and software.

Large-Scale Investigation into Sleep Health: Patterns and Challenges in Chinese Population

X. Fu^{1,2}, W. Zhang^{1,2}, X. Liu³, X. Gao^{1,2,4}, Z. Huang^{4,5}

¹Peking University School and Hospital of Stomatology, Department of Orthodontics, Beijing, China,

⁵School of Basic Medical Sciences; State Key Laboratory of Medical Neurobiology and MOE Frontiers Centre for Brain Science, Institutes of Brain Science, Joint International Research Laboratory of Sleep, Shanghai Medical College, Fudan University, Shanghai, China

Introduction: Sleep is essential for our physical health, memory, and overall well-being. Understanding how people sleep is essential for public health. Traditional sleep studies often rely on subjective reports or are limited in scale. This study aimed to investigate the basic sleep patterns and common sleep issues in a large sample of the Chinese population.

Materials and methods: Data were collected from 93,640 participants. Objective sleep data—specifically, sleep duration, sleep onset time, and awake time—were collected using commercial wearable devices up to 300 days. Subsamples of participants who completed validated questionnaires, including the Pittsburgh Sleep Quality Index (PSQI) to assess subjective sleep quality, the Athens Insomnia Scale (AIS) to evaluate insomnia symptoms, and the Stop-Bang questionnaire to screen for high risk of obstructive sleep apnea (OSA) were selected for further analyses. Statistical analyses involved descriptive statistics and subgroup analyses. Ethical approval for the study was granted by the Institutional Review Board of Shanghai Medical College, Fudan University.

Results: The survey revealed an average sleep duration of 6.75 ± 1.60 hours. A substantial proportion (36.16%) of participants slept less than 6 hours per night, while 48.56% slept 6-8 hours, and 15.28% slept more than 8 hours. Sleep duration showed slight seasonal variations, being longer in spring (6.78 h) and winter (6.77 h), and shorter in summer (6.67 h) and autumn (6.68 h). The mean sleep onset time was 00:01, and the mean waking-up time was 06:43. Notably, 47.57% of individuals initiated sleep after midnight, and 13.69% after 02:00. Sleep onset time varied across generations, with those born before 1970 averaging at 23:02, compared to 00:33 for those born after 2000. Widespread sleep disturbances were reported, with an average of 1.4 nightly awakenings and common issues including difficulty falling asleep, frequent awakenings/early waking, and nighttime urination, affecting the vast majority and varying with age. PSQI assessments indicated that only 26.99% of participants experienced good sleep quality (PSQI score ≤ 5). Conversely, $52.95\% \pm 5.55\%$ reported mild sleep problems (PSQI score 6-10), $18.17\% \pm 4.29\%$ had moderate problems (PSQI score 11-15), and $1.89\% \pm 1.51\%$ faced severe problems (PSQI score 16-21). The prevalence of insomnia symptoms, as measured by the AIS, was notably high, affecting 73.39% of the surveyed subsample. Furthermore, the Stop-Bang questionnaire identified 17.49% of respondents as being at high risk for OSA.

Conclusions: This survey indicates that a significant portion of the Chinese population experiences insufficient sleep duration, poor sleep quality, and a high prevalence of insomnia symptoms, alongside a considerable risk for OSA. These findings highlight a substantial public health concern and underscore the need for increased awareness and strategies to improve sleep health across the population.

Latent physical activity profiles of people with chronic pain: Associations with pain severity, sleep and accelerometer-measured rest-activity rhythm

P. To¹, M.T. Elliott², N.K.Y. Tang¹

¹University of Warwick, Department of Psychology, Coventry, United Kingdom, ²University of Birmingham, School of Sport, Exercise and Rehabilitation Sciences, Birmingham, United Kingdom

Introduction: Approximately one-third of the global population experiences chronic pain (CP), significantly impacting daily activities and altering patients' engagement patterns. Recent research highlights that individuals with CP exhibit diverse pain-related activity patterns, underscoring the need for profiling-based approaches. Although previous studies have explored differences among activity profiles in terms of pain experiences and physical activity, limited attention has been given to differences in sleep and 24-hour rest-activity rhythms (RAR). This study aimed to apply latent profile analysis (LPA) to categorize individuals with CP by self-reported activity patterns, and subsequently examine differences across these profiles regarding pain experiences, sleep quality, and accelerometer-derived RAR.

Materials and methods: 195 participants with chronic non-cancer pain (CNCP), aged 18–65, were recruited in the UK. Eligibility required experiencing CNCP for ≥ 3 months. Participants completed baseline questionnaires assessing pain-related activity patterns (Patterns of Activity Measure–Pain, POAM-P: subscales of avoidance, overdoing, pacing), insomnia severity (Insomnia Severity Index, ISI), and pain severity and interference (Brief Pain Inventory–Short Form, BPI-SF). Actigraphic sleep quality (Actigraphic Total Sleep Time, A-TST; Sleep Efficiency, A-SE) and 24-hour RAR (MESOR – overall physical activity level; Amplitude – robustness of RAR; Intradaily Variability, IV – fragmentation of RAR) were objectively measured using wrist-worn accelerometers (MotionWatch 8) over a 7-day ecological momentary assessment (EMA). LPA identified distinct subgroups based on the three POAM-P subscales. Between-profile differences in pain, sleep, and RAR were analysed using Analyses of Covariance (ANCOVAs), adjusting for demographic covariates (age, gender, BMI).

Results: LPA identified four distinct profiles based on the three POAM-P subscales: “assorted activity regulation – moderate use” ($n = 101$, 51.8%), characterized by moderate use of all three strategies;

“overdoing” (n = 39, 20%), defined by high overdoing but low avoidance and pacing; “avoidant pacing” (n = 39, 20%), marked by high avoidance and pacing but low overdoing; and “assorted activity regulation – minimal use” (n = 16, 8.2%), showing minimal use of all strategies. ANCOVAs revealed significant differences in pain outcomes: the “assorted activity regulation – minimal use” profile reported the lowest pain severity and interference, while the “avoidant pacing” profile reported the highest. No significant differences emerged in sleep quality (ISI, A-TST, A-SE). However, RAR variables differed significantly: the “avoidant pacing” group showed the lowest MESOR and amplitude but the highest IV, reflecting lower activity and more disrupted rhythms. In contrast, the “assorted activity regulation – minimal use” group exhibited the highest MESOR and amplitude and the lowest IV, indicating more robust, stable daily activity rhythms.

Conclusions: This study highlights that distinct POAM-P profiles are associated with differing pain experiences and 24-hour activity rhythms. Understanding these profiles may enable clinicians to tailor more individualized interventions. Notably, minimal use of activity regulation strategies was linked to better outcomes, suggesting that a less pain-reactive, “non-action” approach may benefit CP management, challenging the contemporary assumption that activity pacing is the core intervention among CP patients.

Acknowledgments: This study is part of the Warwick Study of Mental Defeat in Chronic Pain (WITHIN) and is supported by the Medical Research Council (Ref No: 17/WM0053, IRAS project ID: 223190).

Linkages between sleep quality, sleep duration, and physical frailty among Older Adults in India

M. Biswas¹

¹National Institute of TB and Respiratory Diseases, Department of Pediatrics, New Delhi, India

Introduction:

The global population is experiencing a significant shift towards aging due to increased longevity and decreased fertility rates. Low- and middle-income countries, like India, are experiencing a rate of ageing three times faster than their wealthier counterparts. Given the rapid increase in India's aging population, it is crucial to identify factors linked to frailty among older Indians. The present study aimed to investigate the relationships between sleep quality, sleep duration, and physical frailty in older adults in India. In addition, it explored whether these associations differed by gender.

Materials and methods: This secondary analysis utilized data from the 2015 Wave 2 of the Study on Global Ageing and Adult Health (WHO-SAGE) in India, including a sample of 6,512 adults aged 49 years and above. Pre-frailty and frailty were measured using a modified version of the frailty phenotype developed by Fried and colleagues. Sleep quality and duration were assessed through self-reports. Multinomial and multivariable logistic regression models were employed to investigate the associations between sleep quality, sleep duration, and physical frailty (as well as its individual components), and to examine whether gender moderated these associations.

Results: About 66.8% were classified as pre-frail and 25.2% as frail. Compared to individuals with good sleep quality, those reporting poor sleep quality had significantly higher odds of frailty (Adjusted Odds Ratio [AOR]: 2.79; 95% Confidence Interval [CI]: 1.37–5.66). Comparing older adults obtaining the recommended 7–8 hours of sleep, those sleeping 9 hours or more exhibited a lower likelihood of both pre-frailty (AOR: 0.73; CI: 0.57–0.93) and frailty (AOR: 0.68; CI: 0.51–0.91). When examining specific frailty components, individuals with longer sleep duration had reduced odds of experiencing exhaustion (AOR: 0.86; CI: 0.73–1.00) relative to those with age-appropriate sleep duration. Additionally, frailty was more evident among older men with poor sleep quality and short sleep duration (<7 hours per night) than women with similar sleep patterns. While inadequate sleep quality was not associated with any frailty components in older women, in older men, it was significantly linked to higher odds of exhaustion (AOR: 4.28; CI: 2.28–8.06), weak grip strength (AOR: 2.31; CI: 1.46–3.67), and low physical activity (AOR: 2.81; CI: 1.10–7.21).

Conclusions: The findings of this study suggested notable associations between sleep quality, sleep duration, and physical frailty among older adults in India. Poor sleep quality was linked to an increased likelihood of frailty, while longer sleep duration was associated with a reduced prevalence of frailty, independent of sleep quality. Furthermore, the impact of poor sleep quality and shorter sleep duration on frailty was more pronounced among older men than women, highlighting the importance of developing targeted interventions to address sleep-related issues within this population.

Liproxstatin-1 Attenuates Chronic Intermittent Hypoxia-Induced Aorta Injury via Metabolic Reprogramming of the Pentose Phosphate Pathway

W. Chen¹, J. Chen¹, H. Xie¹, F. Wei¹, S. Huang¹, Y. Liu¹, N. Lian¹

¹The First Affiliated Hospital of Fujian Medical University, Department of Respiratory and Critical Care Medicine, Fuzhou, China

Introduction: (1)Obstructive sleep apnea (OSA), a common sleep disorder, is pathophysiologically characterized by chronic intermittent hypoxia (CIH) resulting from recurrent upper airway collapse. (2)OSA-induced endothelial dysfunction serves as the pivotal mechanistic link bridging hypoxia and cardiovascular pathology.

Ferroptosis pathway is particularly relevant to vascular pathophysiology, as evidenced by recent investigations into endothelial dysfunction mechanisms.

(3)Liproxstatin-1 (Lip-1) is a potent ferroptosis inhibitor.

(4)The purpose of this study is to elucidate whether Lip-1 exerts its protective effects against CIH-induced vascular injury through metabolic reprogramming.

Materials and methods: Twenty-four male Sprague-Dawley rats (7-8 weeks old) and rat aortic endothelial cells (RAOECs) were stratified into four experimental cohorts: 1) Normoxic control, 2) CIH exposure (8 hour/day, 6%–21% O₂ cycling, 12 weeks), 3) CIH+vehicle, and 4) CIH+Lip-1. Western blotting quantified protein expression of key ferroptosis regulators—glutathione peroxidase 4 (GPX4), cystine/glutamate antiporter solute carrier family 7 member 11 (SLC7A11), and acyl-CoA synthetase long-chain family member 4 (ACSL4)—using β -actin for normalization. Cellular viability was assessed via CCK-8 assay after 24h hypoxia exposure. Flow cytometry with specific fluorescent probes (DCFH-DA for ROS, FerroOrange for Fe²⁺, C11-BODIPY for lipid ROS) quantified oxidative stress parameters. Commercial ELISA kits measured malondialdehyde (MDA), reduced glutathione (GSH), and NADPH/NADP⁺ ratios following manufacturer protocols. Mitochondrial ultrastructure was evaluated through transmission electron microscopy (TEM). Targeted metabolomic profiling (LC-MS/MS) mapped central carbon metabolism alterations, focusing on PPP intermediates.

Results: Oil Red O staining revealed that CIH treatment dysregulated lipid metabolism in aortic tissues. Western blotting analysis demonstrated that the protein abundance of GPX4 and SLC7A11 were significantly reduced in aortic tissues of CIH-induced rats and RAOECs ($p < 0.05$), whereas ACSL4 expression was markedly upregulated ($p < 0.05$). Consistently, in CIH-exposed RAOECs, cell viability was notably decreased, accompanied by elevated levels of ROS, Fe²⁺, lipid ROS, and MDA ($p < 0.05$). Conversely, GSH content and the NADPH/NADP⁺ ratio was significantly diminished ($p < 0.05$). Notably, transmission electron microscopy (TEM) revealed mitochondrial damage in the CIH group, characterized by ruptured mitochondrial membranes and disorganized matrix components. Furthermore, hierarchical clustering analysis profiling indicated that CIH disrupted metabolites of the pentose phosphate pathway (PPP). Strikingly, co-treatment with Lip-1 reversed the aforementioned pathological alterations.

Conclusions: CIH induces ferroptosis-driven arterial endothelial injury through a PPP-dependent mechanism, characterized by NADPH depletion, redox imbalance, and impaired GPX4-mediated antioxidant defense. The PPP remodeling—manifested as suppressed glucose-6-phosphate dehydrogenase activity and diminished NADPH synthesis—creates a permissive environment for iron-catalyzed lipid peroxidation. Lip-1 exerts multi-modal protection by 1) restoring SLC7A11-mediated cystine uptake, 2) enhancing GPX4 activity to neutralize lipid hydroperoxides, and 3) preserving PPP flux to maintain NADPH pools for glutathione regeneration. These findings position Lip-1 as a promising therapeutic candidate for OSA-related vascular complications and highlight metabolic reprogramming of the PPP as a novel target for endothelial protection in hypoxic conditions. Further clinical translation requires investigation of optimal dosing regimens and long-term safety profiles in OSA models.

Acknowledgments: This work was supported by the Graduate Academic Exchange Fund of Fujian Medical University.

Mapping the Evidence: A Scoping Review of Sleep Health in Community-Dwelling Older Adults

S. Öberg¹, C. Sandlund², B. Westerlind^{3,4,5}, D. Finkel³, L. Johansson³

¹Jönköping University, School of Health and Welfare, Department of Nursing Science, Jönköping, Sweden, ²Karolinska institutet, Department of Neurobiology, Care Sciences and Society, Stockholm, Sweden, ³Jönköping University, School of Health and Welfare, Institute of Gerontology, Jönköping, Sweden, ⁴Linköping University, Department of Health, Medicine and Caring Sciences, Linköping, Sweden, ⁵County Hospital of Ryhov, Department of Geriatrics, Jönköping, Sweden

Introduction: Sleep health is a multifaceted concept including sleep duration, sleep continuity/efficiency, timing, alertness during waking hours, and perceived sleep quality. Among older adults, sleep disturbances are common and linked to adverse health outcomes such as frailty, physical and mental health issues, increased healthcare utilization, and mortality. Despite the high prevalence of poor sleep health among older people, the broader concept of sleep health in community-dwelling older populations has not been comprehensively reviewed. The aim of the study was to synthesize existing knowledge on sleep health among community-dwelling older adults (aged 65 and over), covering all five core dimensions of sleep health. The review also sought to identify key knowledge gaps and future research priorities.

Materials and methods: The review followed a systematic scoping methodology. Literature searches were conducted in Medline, CINAHL, and PsycINFO to identify peer-reviewed studies published in English or Swedish that included participants aged ≥65 years living in community settings. Only studies addressing all five sleep health dimensions were included. Data results on sample size, sleep variables, and health outcomes were extracted and synthesized.

Results: Eight studies met the inclusion criteria, where seven studies originated from USA and one study from Taiwan. Seven studies were based on data from a male and female osteoporosis registry. The studies had sample sizes ranging from 1,413 to 6,485 with a mean age between 76 – 83.6. The findings suggest that multidimensional sleep health is an important indicator of well-being in older adults. Poor sleep health, especially when two or more dimensions are impaired, was associated with higher risks of depression, higher healthcare cost, and mortality. Sex-based differences were notable: women reported poorer sleep and more frequent daytime napping, which itself was linked to higher mortality. In contrast, individuals reporting better sleep health had lower odds of frailty. Very few studies included adults aged 80 and above, limiting generalizability to the oldest-old population.

Conclusions: The scoping review highlights a clear need for more nuanced and inclusive research on sleep health in community-dwelling older populations. Future studies should include diverse samples, particularly the oldest age groups, and account for contextual factors such as care settings and sleep medication use. A more comprehensive understanding of sleep health is essential for developing effective interventions to support successful healthy aging.

Menopausal Hormone Therapy and Cardiovascular Outcomes in Menopausal Women with Obstructive Sleep Apnea

Y. Lin^{1,2}

¹Taoyuan Chang Gung Memorial Hospital, cardiology, Taoyuan, Taiwan, ²Taoyuan Chang Gung Memorial Hospital, health care center, Taoyuan, Taiwan

Introduction: Menopause exacerbate the risk of cardiovascular events in women with obstructive sleep apnea (OSA). The efficacy and safety of menopausal hormone therapy (MHT) in cardiovascular outcomes in this population remain unclear.

Materials and methods: We conducted a propensity score-weighted cohort study using data from 363 menopausal women with OSA from a tertiary medical hospital. Patients were stratified based on MHT use (59 treated vs. 304 untreated). Baseline demographics, comorbidities, and apnea-hypopnea index (AHI) were balanced via overlap weighting. Outcomes included heart failure (HF) and major adverse cardiovascular events (MACE), analyzed using Cox regression with follow-up periods of 3 and 10 years.

Results: After weighting, baseline characteristics including age, AHI, and comorbidities showed no significant differences between groups. At 3 years, MHT was not significantly associated with reduced risk for HF (HR: 0.800, 95% CI: 0.167-3.837, p=0.781) or MACE (HR: 0.815, 95% CI: 0.226-2.932, p=0.754). Similarly, at 10 years, no significant reductions were observed in HF (HR: 0.836, 95% CI: 0.277-2.521, p=0.751) or MACE (HR: 0.902, 95% CI: 0.359-2.265, p=0.826).

Conclusions: Menopausal hormone therapy in menopausal women with OSA did not significantly impact the incidence of heart failure or major cardiovascular events over both short and long-term follow-up periods. Further studies with larger cohorts are warranted to confirm these findings.

Meta-analysis of the studies about smartphone usage time relation to sleep quality among medical students

T. Desudchit¹, Y. Chatmeeboon¹, K. Arunjaroensuk¹, K. Muntaga¹, S. Phromjiam¹

¹Srinakharinwirot University, Medicine, Nakhon Nayok, Thailand

Introduction: Smartphone usage has become a part of daily life among medical students, often leading to concerns about its impact on sleep quality. Given the demanding nature of medical education, adequate sleep is crucial for cognitive function, academic performance, and overall well-being. This meta-analysis aims to systematically evaluate the relationship between smartphone usage time and sleep quality among medical students.

Materials and methods: A comprehensive search of electronic databases (PubMed, Google scholar, Science direct, Cochrane review and Clinical trial.gov) was conducted to identify studies published between June 2014 and June 2024. Inclusion criteria were studies that assessed smartphone usage time and its correlation with sleep quality using validated measurement tools among medical students. Data extraction and quality assessment were performed independently by two reviewers. Statistical analyses were conducted to determine pooled effect sizes and heterogeneity among the studies.

Results: A total of 20 studies involving 2,823 medical students were included. The meta-analysis revealed a significant negative correlation between smartphone usage time and sleep quality, overall odds ratio of smartphone addiction to non-addiction for poor sleepers is 3.33 (95%CI = 1.45-7.61), with the high heterogeneity at 91%. The P-value for heterogeneity is below 0.00001, the p-value for overall effect = 0.004.

This indicates that increased smartphone use is associated with poorer sleep quality. Subgroup analyses showed that the relationship was stronger in studies using objective measures of sleep quality compared to self-reported measures. Additionally we analyzed poor sleep quality between genders. The overall odds ratio of poor sleep quality between male to female is 1.87 (95% CI = 1.16-3.01), with the low heterogeneity of 0% , p-value for heterogeneity = 0.90, overall effect p-value = 0.010.

Conclusions: The findings of this meta-analysis suggest that excessive smartphone usage is significantly associated with poor sleep quality among medical students. Future research should focus on differences between pre-clinical student, clinical student and postgraduate students sleep quality

Metabolic characterization of sleep phenotypes from a multidimensional metabolomics perspective and sleep-metabolic networks

Z. Chen¹, R. Lin², S. Jian¹, H. Ouyang¹, B. Tang³, X. Su⁴, M. Yi¹, Y. Zhang⁴

¹Central South University, School of Life Sciences, Changsha, China, ²Central South University, Department of Psychiatry, The Second Xiangya Hospital of Central South University, Changsha, China, ³Central South University, Department of Neurology, Xiangya Hospital, Changsha, China, ⁴Central South University, Department of Respiratory & Sleep Medicine, Xiangya Hospital, Changsha, China

Introduction: Sleep traits interact extensively with metabolism; different sleep traits can correlate with each other through homologous metabolites, forming a complex sleep-metabolism network. This study will assess the bidirectional relationships between 1091 plasma metabolites and 10 sleep traits, focusing on specific metabolic pathways and shared gene loci, and evaluate the metabolic association between sleep traits.

Materials and methods: We first assessed the causal relationships between plasma metabolites and sleep traits using bi-directional Mendelian randomization analysis. Bayesian network modeling was used to clarify the metabolic associations among sleep traits. We then identified two important

metabolic pathways through enrichment analysis and pathway analysis. Co-localization analysis further elucidated the genetic associations between sleep traits and plasma metabolites.

Results: A total of 145 metabolites significantly influenced sleep traits. The metabolite category most influencing sleep trait is lipids, and the sleep trait most influenced by plasma metabolites is sleep duration. Metabolites affecting both napping and sleep duration are enriched in "Biosynthesis of unsaturated fatty acids" pathway, whereas chronotype-associated metabolites enriched "Caffeine metabolism" pathway. Network analysis positioned napping as the central node connecting 7 other phenotypes. Co-localization analyses finally reveal 7 genetic variants shared across 26 sleep-metabolite pairs, with a shared genetic variant between daytime sleepiness and napping.

Conclusions: This study highlights the plasma metabolites that causally/genetically associate with sleep traits and two important enriched metabolic pathways, as well as metabolic associations between different sleep traits. We hope that will provide valid evidence for unraveling the metabolic mechanisms of sleep health and the metabolic associations between sleep traits.

Modeling Sleep Health Trends among U.S. College Students, 2019–2024: Descriptive Secondary Analysis of ACHA-NCHA III/IIIb

F.L. Capistrano^{1,2}

¹Health Culture Foundation, Arlington, United States, ²University of Essex, Public Health, Colchester, United Kingdom

Introduction: Sleep is foundational to student health and performance, yet multi-semester national trends are rarely synthesized. We summarized publicly available ACHA-NCHA III/IIIb estimates (2019–2024) to describe patterns in five sleep indicators: weeknight duration, weekend duration, sleep onset latency (SOL), daytime tiredness, and days felt well-rested.

Materials and methods: We compiled semester-level percentages and calculated means across 11 terms. Primary analyses were descriptive because observations are repeated cross-sectional aggregates rather than the same individuals over time. As an exploratory step, we conducted repeated-measures ANOVA with Bonferroni-adjusted pairwise comparisons across mutually exclusive response categories (e.g., <7 h, 7–9 h, ≥10 h). Where strata were available, we summarized undergraduate (UG) vs postgraduate (PG) patterns for key categories (e.g., <7 h weeknights; ≥31-min SOL).

Results: On weeknights, the mean proportion reporting 7–9 hours was 49.5%, versus 40.2% for <7 hours and 1.2% for ≥10 hours. On weekends, 63.6% reported 7–9 hours, 19.3% <7 hours, and 8.1% ≥10 hours. Daytime tiredness was frequent: 38.3% reported 3–5 days/week and 29.0% reported 6–7 days; only 3.9% reported 0 days. Feeling well-rested was uncommon most days: 34.7% reported 1–2 days/week, 30.1% 3–5 days, 17.3% 0 days, and 8.8% 6–7 days. SOL means were 34.1% for <15 minutes, 26.1% for 16–30 minutes, and 28.4% for ≥31 minutes. Exploratory pairwise comparisons indicated statistically significant separations among categories for weeknights, weekends, SOL, tiredness, and well-rested days (all $p < .05$), consistent with large descriptive gaps. UG-PG summaries were directionally similar to overall estimates.

Conclusions: College students continue to experience disrupted sleep patterns and widespread fatigue, with parallel trends in stress and psychological distress. These persistent issues suggest systemic misalignments between student wellness needs and academic and institutional demands. Colleges and universities should adopt holistic wellness strategies that target both sleep and mental health such as integrated sleep education, access to mental health resources, brief cognitive-behavioral therapy for insomnia (CBT-I), and the reform of academic structures to support recovery and rest.

Acknowledgments:

We thank the American College Health Association for making semester-level data from the ACHA-NCHA III/IIIb publicly available for research purposes.

Multidimensional sleep health associates with depression symptoms in university students

Y. Zhu¹, Y. Jin², J. Ma¹, V. Kok¹, J. Gooley¹

¹Duke-NUS Medical School, Singapore, Singapore, ²National University of Singapore, Singapore, Singapore

Introduction: Healthy sleep is important for mental wellbeing. Sleep problems frequently emerge in young adulthood and often precede the onset of depression. It is therefore important to identify sleep health metrics that can be used to predict mental health problems. The goal of our study was to determine dimensions of sleep health that are most closely associated with depression symptoms in university students using the Ru-SATED sleep health framework. We hypothesized that multidimensional sleep health scores would be negatively associated with depression scores. Based on prior work, we predicted that sleep satisfaction and alertness would be the sleep health dimensions most closely associated with depression symptoms.

Materials and methods: Sleep behavior was measured over 2 weeks in 547 university students (21.32 y $\pm$ 1.78 y; 63.2% female) using wrist actigraphy devices and daily diaries. Sleep data were analyzed using the Ru-SATED sleep health framework. Actigraphy data were used to determine the number of days that students met daily criteria for healthy sleep duration, timing, regularity, and efficiency. Diaries were used to assess self-rated sleep satisfaction and alertness. Students received a score of 0 to 4 for each sleep dimension based on the number of days they met criteria for healthy sleep. These scores were summed to derive a composite sleep health score (range=0-24). The Center for Epidemiologic Studies Depression Scale-Revised (CESD-R) was used to measure depression symptoms (range=0-80). Linear regression was used to test whether sleep health composite scores predicted depression scores. Multiple linear regression was used to test associations of the 6 sleep health dimensions with depression scores when entered into the model as individual predictors.

Results: Results for simple linear regression showed that higher composite sleep health scores predicted lower depression and explained 15.0% of variance in CESD-R scores ($R^2=0.15$, $P<0.001$). The multiple regression model, which allowed the predictive weights of individual sleep health dimensions to vary, explained 31.4% of variance in CESD-R scores ($R^2=0.31$, $P<0.001$). "Satisfaction" and "Alertness" were the only sleep health dimensions with statistically significant associations with CESD-R score. The CESD-R score decreased by 2.37 points for each additional day of the week that students reported being satisfied with their sleep, and by 3.03 points for each additional day per week that students reported feeling alert.

Conclusions: University students with better multidimensional sleep health had fewer depression symptoms. However, individual sleep health dimensions in the RuSATED framework differed in the strength of their association with depression scores. Sleep health metrics that give more weight to self-rated sleep satisfaction and alertness may perform better at predicting depression symptoms in young adults. Future studies should compare the performance of unweighted and weighted sleep health scores at predicting mental health outcomes.

Acknowledgments: The work was funded by the Ministry of Education, Singapore (MOE2019-T2-2-074) and the National Research Foundation, Singapore (NRF2016-SOL002-001).

My Sleep Recipe: A Bedtime Book to Support Sleep Health in School-Age Children

J. Page¹, G. Wang¹, R. Robbins², J. Roth¹, J. Owens¹

¹Boston Children's Hospital, Boston, United States, ²Brigham and Women's Hospital, Boston, United States

Introduction: Reading at bedtime has numerous benefits for child sleep and development, including fostering positive sleep associations, reduced sleep onset latency, and longer sleep duration. Additionally, bedtime reading promotes cognitive development, emotional regulation, and helps to align child and parent expectations around sleep, all of which contribute to better overall sleep quality. Despite these clear benefits, many children's books on sleep are developed for very young children, very rarely portray children from diverse backgrounds, or fail to depict the realities of obtaining healthy sleep while offering clear suggestions to mitigate poor sleep. In this study, we aimed to develop a bedtime book for school-aged children and assess the utility of the book on parent's perceptions of their child's bedtime routines.

Materials and methods: In collaboration with three community centers, we utilized the Reach Out and Read model to distribute the bedtime story book during the well child visit to school-aged children (4-8 years old) comfortable communicating in English and/or Spanish. The bedtime book, "My Sleep Recipe",

was crafted and developed over multiple iterations, with feedback from our advisory board, caregivers, and sensitivity readers to insure content validity for the target population. The book utilizes the "RESTED" framework (Routine and Regularity; Environment; Screens; Timing; Expectations; Duration) to convey basic principles of healthy sleep. Inside of the book, families received study information by scanning a QR code to consent and complete a one-time survey. The survey asked about general demographic questions, perceptions of the book and their child's sleep, and took approximately 5 minutes to complete.

Results: Data collected from October 2024 to May 2025 includes 17 participants (9 Hispanic/Latino), were mostly female (14, 82.3%), with an average age of 35.5 years (range=26-46 years), and the majority (15, 88.2%) received government health insurance. All families reported reading to their child at least twice per week, with a quarter reading daily. Participants reported an average of five bedtime activities per night. The most frequently rated bedtime activities included brushing teeth, reading, and putting on pajamas. Since receiving the book, all participants indicated that they looked at the book with their child at least twice, with 58.8% spending more time reading at bedtime and going to bed earlier or at the same time. The most frequent change in bedtime routine was a reported decrease in electronic use before bedtime (6, 35.3%) and followed a more consistent bedtime, (5, 29.4%).

Conclusions: Incorporating a bedtime book into a sleep routine can be an essential tool for fostering healthy sleep. Given the potential of bedtime books to positively influence sleep and development, further research should incorporate developmentally and culturally appropriate material and examine the use of various bedtime books and other story formats that older children may prefer, and how these tools can be adapted and maximized to help bedtime for school-aged children.

Acknowledgments: This project was funded by the American Academy of Medicine Sleep Foundation Grant 295-CS-23. We would like to thank the author Nancy Rothstein and illustrator Garcia Thomas for making this work possible.

Neurobehavioral effects of one night of partial sleep deprivation in school-age children and adolescents: a meta-analysis

A.K. Yee¹, A. Dorgham¹, J.C. Lo¹

¹National University of Singapore, Centre for Sleep and Cognition, Yong Loo Lin School of Medicine, Singapore, Singapore

Introduction: In adults, one night of restricted sleep may impair alertness and sustained attention. For children and adolescents, some have argued that because of brain immaturity, the effects of sleep deprivation on these neurobehavioral functions may not be as prominent, and they may have a higher ability to compensate for acute sleep loss. This meta-analysis aimed to synthesize findings from experimental studies that investigated the effects of one night of partial sleep deprivation on alertness and cognitive functions in school-age children and adolescents.

Materials and methods: Ninety-one articles were retrieved from databases such as PubMed and PsycINFO, and 11 articles which met the inclusion criteria were included in this meta-analysis. All the analyses were conducted using R, and a random effects model were used to pool the effect sizes from the studies. The neurobehavioral functions investigated include objective and subjective alertness, executive function, complex attention, sustained attention, declarative memory, and processing speed. An intra-study meta-analysis was carried out for those studies that investigated more than one cognitive domain to obtain an overall effect size to be included in the meta-analysis. Effect sizes were coded such that a negative effect size reflects neurobehavioral impairments following partial sleep deprivation.

Results: The mean age of the participants (N = 350) was 13.97 (SD = 0.97) years. The average total sleep time (TST) of the partially sleep deprived group was 4.28 (SD = 1.79) hours, while the control group had an average TST of 8.68 (SD = 4.01) hours. One night of partial sleep deprivation decreased objective alertness ($g = -1.69$, $p < 0.01$), and its impairing effect on subjective alertness was numerically smaller and marginally non-significant ($g = -1.49$, $p = 0.07$). One night of partial sleep deprivation did not have any significant impact on overall cognition ($g = 0.12$, $p = 0.44$) or individual cognitive domains ($|g| = 0.04$ to 0.30 , $p > 0.15$).

Conclusions: Objective alertness is prominently impaired after one night of partial sleep deprivation in school-age children and adolescents; however, they might not perceive such deficit, since a corresponding decrease in subjective alertness was not detected in this meta-analysis. We did not find

any significant impairment in the cognitive functions investigated after a single night of partial sleep deprivation. This finding should not be interpreted as a reason for children and adolescents to curtail their sleep, as cognitive deficits might accumulate over more nights of partial sleep deprivation in these age groups. Lastly, the differences in findings from this age group and adults may be explained by differences in brain development.

Acknowledgments: This study was supported by a grant from the National University of Singapore awarded to Dr June Lo (NUHSRO/2021/078/NUSMed/05).

Nocebo Effects on the Duration of First-Night Effect in Insomnia Patients: A Polysomnographic Study

L. Wang¹, S. Hu¹, H. Sun¹

¹Peking University Sixth Hospital, Peking University Institute of Mental Health, NHC Key Laboratory of Mental Health (Peking University), National Clinical Research Center for Mental Disorders (Peking University Sixth Hospital), Beijing, China

Introduction: The first night effect (FNE) is a phenomenon where individuals experience sleep disturbances during the first night in unfamiliar environment. This phenomenon may compromise the first night's polysomnography (PSG) results and impede daytime function. Previous studies have demonstrated that placebo administration can mitigate the FNE in healthy individuals but exacerbate sleep in insomnia patients. However, duration of FNE under continuous placebo intervention in insomniacs remains undetermined. This study aims to investigate the variation of the FNE in insomnia patients with continuous placebo administration.

Materials and methods: This study enrolled 68 patients with insomnia disorder (DSM-5 criteria). Participants underwent four consecutive nights of PSG in a sleep laboratory following a 4-day placebo intervention. PSG data were analyzed using the Friedman test for differences across nights, with post hoc comparisons conducted via the Nemenyi method and Bonferroni correction.

Results: Following placebo intervention, significant differences were observed across key sleep parameters between the first and second nights : wake after sleep onset (WASO) decreased from (114.81 ± 78.10) minutes to (81.80 ± 54.34) minutes ($p = 0.001$), sleep efficiency (SE) improved from (69.84 ± 17.95)% to (76.02 ± 15.24)% ($p = 0.005$), N3 sleep duration increased from (42.95 ± 34.13) minutes to (53.63 ± 32.56) minutes ($p < 0.001$), REM sleep duration rose from (64.91 ± 54.79) minutes to (75.43 ± 48.35) minutes ($p = 0.002$), and REM sleep percentage increased from (17.71 ± 13.57)% vs (19.39 ± 11.75)% ($p = 0.018$). Following post-hoc comparison analysis, these parameters stabilized without further significant changes from the second night onward ($p > 0.05$).

Conclusions: The study indicates that placebo intervention may elicit the FNE in insomnia patients but may not impact its duration. Sleep parameters demonstrate stabilization starting from the second night. Future research should examine individual response differences.

Non-Rapid Eye Movement Parasomnias & their Impact on the Academic Performance in Medical University Students: A Cross Sectional Study

F. Iftikhar¹, S. Mushtaq², K. Amir¹, A.A. Khan³

¹Foundation University Medical College, MBBS, Islamabad, Pakistan, ²Foundation University Medical College, Islamabad, Pakistan, ³Foundation University Islamabad, Internal Medicine, Islamabad, Pakistan

Introduction: Parasomnias are disruptive motor episodes during sleep transitions, classified into rapid eye movement (REM) and non-rapid eye movement (NREM) types. NREM parasomnias (arousal disorders) include confusional arousals, sleepwalking, and sleep terrors. Despite knowing that parasomnias can negatively impact mental health, there is a noticeable dearth of studies on parasomnias among university students. This study aims to ascertain the prevalence of arousal disorders, their association with sleep quality, and their impact on the academic performance of university students.

Materials and methods: A quantitative cross-sectional study was carried out with validated questionnaires to collect online data using stratified random sampling after obtaining ethical approval from the ethical review board of Foundation Medical College. Rao soft was used to determine sample size with a 95% confidence interval and a 5% margin of error. The study included both male and female

MBBS students at Foundation University School of Health Sciences. All descriptive and inferential statistical tests including Pearson chi-square test, t-test, and ANOVA test were applied using SPSS 26, and a p-value of < 0.05 was considered statistically significant.

Results: The sample consisted of $n=175$ participants of ages ranging from 18-25 years [19.82 ± 3.99]. There were $n = 96$ (54.9%) female participants and $n = 79$ (45.1%) male participants in terms of gender distribution. The PSQI (Pittsburgh Sleep Quality Index) score of participants ranged from 0-15 with a mean PSQI score of 6.74 ± 3.15 (PSQI score of ≥ 5 is indicative of poor sleep quality). On assessing the prevalence of NREM parasomnias a total of $n=84$ (48%) had confusional arousals, $n=29$ (16.6%) had sleepwalking, and $n=74$ (42.3%) had sleep terror. The results of the ANOVA test indicate no significant association ($p=0.387$) between academic performance (last exam score) and sleep quality (PSQI score). The t-test suggests a significant association between sleep quality (PSQI score) and the occurrence of confusional arousals ($p=0.006$), sleepwalking ($p=0.03$), and sleep terror ($p=0.04$). The Pearson chi-square test yields a significant association between academic performance (last exam score), and sleepwalking ($p=0.037$).

Conclusions: The study reveals a notable prevalence of NREM parasomnias among medical students. The study concludes that individuals with poor sleep quality (high PSQI scores) are more likely to experience NREM parasomnias. However, the results of the study are not generalizable, and this warrants the need for further large-scale multicenter study, and future work could be done on evaluating awareness, knowledge, and various perceptions related to it.

Objective Analysis of Sleep Quality and Academic Performance Trends in Medical Students Using Wearable Technology

M. Gogichadze¹, I.S. Joao¹, S.A.M. Bonjar², N.E. Mgbedo², N. Landia³, D.I. Odzelashvili⁴

¹The University Of Georgia, Medical Department, Tbilisi, Georgia, ²The University Of Georgia, Medical, Tbilisi, Georgia, ³The University Of Georgia, Head of Medical Department, Tbilisi, Georgia, ⁴The University Of Georgia, Assistant of School of Health Sciences, Tbilisi, Georgia

Introduction: Optimal sleep is crucial for cognitive function, mental health, and academic success. Medical students, due to rigorous schedules, often experience disrupted sleep, impacting scholastic success. This study analyses sleep quantity and quality among international medical students at the University of Georgia using wearable technology, examining correlations between sleep metrics and academic performance, moving beyond subjective self-reports for precise data.

Materials and methods: An experimental study was conducted on 50 medical students (26 females, 24 males) who self-reported sleep deprivation. Sleep data was collected over seven consecutive days using the Huawei Band 3 Pro, which tracks deep sleep, light sleep, REM sleep, sleep continuity, breathing quality, and night-time awakenings. Data was extracted from the Huawei Health app on the eighth day, stored in an Excel sheet, and analyzed using SPSS (Version 26). Pearson correlations were used to assess relationships between sleep variables and academic performance, while t-tests examined gender differences. Ethical approval was obtained, and strict confidentiality was maintained.

Results: Participants had a mean Night Sleep Points score of 78.35, indicating generally good sleep quality. The average deep sleep continuity score was 89.74, suggesting minimal disturbances during deep sleep, which is crucial for memory consolidation. Breathing quality was high, with an average score of 95.24, reflecting stable and efficient respiratory patterns during sleep. A significant positive correlation was observed between Breathing Quality and Deep Sleep Continuity ($r = 0.42$, $p < 0.05$), highlighting the role of proper respiratory function in uninterrupted deep sleep. Additionally, Night Sleep Points correlated moderately with Breathing Quality ($r = 0.34$), reinforcing the link between overall sleep quality and respiratory health.

Regarding academic performance, while the correlation with sleep metrics was weak, a positive trend was observed between deep sleep percentage and perceived academic performance ($r = 0.252$, $p = 0.078$). This suggests a potential relationship that may become clearer with a larger sample size.

A gender-based analysis of breathing quality revealed noticeable differences. Males demonstrated generally higher breathing quality scores, with their median and interquartile range sitting higher on the scale compared to females. This suggests that a larger proportion of males experience better

respiratory efficiency during sleep. Although some overlap was observed, the overall trend indicates superior breathing quality among male participants.

Conclusions: This study highlights the potential role of wearable sleep technology in objectively assessing sleep patterns among medical students. Findings suggest that medical students generally maintain good sleep quality, with high deep sleep continuity and excellent breathing scores. While no strong correlation was found between sleep quality and academic performance, results emphasize the importance of deep sleep and respiratory efficiency for overall well-being. The study also revealed gender differences in breathing quality, suggesting potential physiological or lifestyle influences. Future research should include larger sample sizes, control additional variables, and explore potential gender-based differences further. Universities should consider integrating sleep education and wellness programs to support student mental health and cognitive performance.

Objectively-defined sleep regularity is associated with macrovascular and microvascular complications among individuals with type 2 diabetes – a cohort study

Y. Zheng¹, X. Tan^{1,2}

¹Zhejiang University School of Public Health, Department of Big Data in Health Science, Hangzhou, China, ²Karolinska Institutet, Department of Clinical Neuroscience, Stockholm, Sweden

Introduction: To assess the association of accelerometer-measured sleep regularity with macrovascular and microvascular complications among individuals with type 2 diabetes (T2D).

Materials and methods: A total of 3,862 participants with type 2 diabetes at baseline from UK Biobank (UKB) were included. The sleep regularity metrics measured by wrist-worn accelerometers include sleep regularity index (SRI) and sleep duration SD. Macrovascular complications included coronary heart disease (CHD) and stroke. Microvascular complications included diabetic neuropathy, diabetic kidney disease, and diabetic retinopathy. Cox proportional hazard models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for macrovascular and microvascular complications.

Results: During a median follow-up of 8.0 years, 410 composite macrovascular and 615 composite microvascular events occurred. Compared to participants in the highest tertile of SRI (regular sleepers), those in the lowest tertile were at higher risk of composite macrovascular complications (HR 1.29, 95% CI: 1.01-1.66) and stroke (1.97, 1.08-3.58). Compared to participants in the lowest tertile of sleep duration SD (regular sleepers), those in the highest tertile were at higher risk of composite macrovascular complications (1.44, 1.12-1.84), CHD (1.40, 1.07-1.82), and stroke (2.07, 1.13-3.81). For microvascular complications, no significant association of sleep regularity metrics was found (all $P > 0.05$). However, the dose-response analysis suggested a potential nonlinear association between SRI and diabetic neuropathy, with lower SRI consistently associated with higher risk of diabetic neuropathy compared with the median of SRI (HR 1.92, 95%CI: 1.28-2.88, 5th percentile vs. 50th percentile).

Conclusions: An irregular sleep pattern across days is clinically relevant for increasing the risk of macrovascular complications and diabetic neuropathy among individuals with type 2 diabetes.

Acknowledgments: We are grateful to all the participants of UK Biobank and all the people involved in building the UK Biobank study.

Obstructive sleep apnea physiological burdens and cognitive performance in older community dwelling American adults

P. Pahari¹, J.L. Gills¹, E. Valkanova², A. Dharmapuri¹, A. Sogade¹, J. Dominguez¹, A. Parekh^{3,4}, D.M. Rapoport³, K. Korey³, A.E. Mullins³, I. Ayappa³, A.W. Varga³, R.S. Osorio¹, O.M. Bubu¹

¹New York Grossman School of Medicine, Department of Psychiatry, New York, United States,

²University of South Florida, Department of Epidemiology, Tampa, United States, ³Ichan School of Medicine, Mount Sinai, Division of Pulmonary, Critical Care and Sleep Medicine, New York, United States, ⁴Icahn School of Medicine, Department of AI and Human Health, New York, United States

Introduction: Obstructive sleep apnea (OSA) is characterized by frequent intermittent hypoxemia, a highly prevalent nocturnal breathing disorder, and a universal public health problem. OSA severity, as defined by apnea-hypopnea index (AHI), is associated with cognitive impairment and a higher risk of Alzheimer's disease. However, oxygen saturation (SpO₂) based metrics such as hypoxic load and

ventilatory burden showed better adverse outcome predictive power than AHI. Thus, this study investigated whether these OSA-related physiological burdens, i.e., hypoxic load and ventilatory burden, are associated with cognitive performance in community-dwelling older adults.

Materials and methods: The study is part of a longitudinal study that included 135 clinically cognitively normal (i.e., clinical dementia rating scale, CDR=0) white non-Hispanic (37.8%) and black African American (56.3%) community-dwelling older adults (median age, 65.9 yr.) who participated in the sleep, aging, and brain health study at NYU. Cognitive performance was assessed using the unified dataset (UDS 3), an extensive neuropsychological battery test assessing various cognitive domains, including global cognition (MoCA), verbal memory, visuospatial, attention, language category fluency, processing speed, and executive function. Total sleep time (TST), ventilatory burden (VB) defined as proportion of abnormal breaths (<50% normalized amplitude), and hypoxic burden (HB) defined as the summation of desaturation areas (>3%) calculated from SpO₂ signal, were computed from an overnight polysomnography (PSG) conducted at Mount Sinai Integrated Sleep Centre. Linear mixed regression models were used to investigate the association between ventilatory and hypoxic burden and cognitive performance. Models were adjusted for age, race, sex, BMI, TST, and slow wave activity.

Results: The average TST for participants was 5.31 (Q1: 4.5 - Q3: 6.8) hr. BMI was 29.4 (Q1: 24.6 - Q3: 32.6), and AHI was 9.6 (Q1: 5.3 - Q3: 11.13). For each unit increase in hypoxic and ventilatory burden, the cognitive performance decreased on the MoCA (HB: β -0.179, VB: -0.0289, $p < 0.001$) and attention (HB: β -0.102 and VB: β -0.761, $p < 0.001$) tasks. Similarly, the elevated hypoxic and ventilatory burden was associated with increased time taken to complete executive function tasks (HB: 0.295 and VB: β 0.834, $p < 0.001$). In contrast, the language fluency test (HB: β 0.163 and VB: β 0.569, $p < 0.001$) and verbal memory test (HB: β 0.128 and VB: β 0.345, $p < 0.001$) scores were higher, indicating a better performance with elevated hypoxic and ventilatory burden. However, AHI had no significant association with decreased cognitive performance. In addition, there was no statistically significant association between the visuospatial and processing speed task-specific performances and hypoxic and ventilatory burden.

Conclusions: In this sample of cognitively normal older community-dwelling adults, OSA-related hypoxic and ventilatory burden were each associated with decreased cognitive performance in global cognition, with domains subserving attention, processing speed, and executive function driving these findings. The relatively better performance noted in language fluency and verbal memory domains in this population may reflect various underlying compensatory mechanisms associated with higher education.

Obstructive sleep apnea syndrome and prothrombotic markers (alpha 2 antiplasmin a2AP and tissular plasminogen inhibitor 1 PAI-1)

A.D. Maieran¹, C.-V. Magda², D.A. Todea¹

¹"Iuliu Hatieganu" University of Medicine and Pharmacy, Pulmonology, Cluj-Napoca, Romania,

²Pneumology Hospital "Leon Daniello", Pulmonology, Cluj-Napoca, Romania

Introduction: Obstructive sleep apnea (OSA) is a chronic and prevalent condition that is associated with endothelial dysfunction, atherosclerosis and predisposes to a global cardiovascular risk and significant general morbidity and mortality. Despite its high prevalence and the susceptibility of patients with cardiovascular disease to stressors, OSA is still underrecognized and untreated in daily clinical practice. Inflammation is a major factor in the development and progression of cardiovascular disease, and OSA is associated with the excessive release of pro-inflammatory and pro-thrombotic mediators that contribute to the development of atherosclerosis and cardiovascular complications in these patients.

Materials and methods: A prospective observational study was conducted that included 56 patients diagnosed with moderate/severe OSA and 32 healthy patients. The collected data included personal information (sex, age), anthropometric measures (weight, height, BMI), associated diseases (cardiovascular, pulmonary and metabolic), parameters recorded by cardiorespiratory polygraphy (AHI, ODI, number of apneas, number of hypopneas, snoring index, average O₂ saturation, minimum O₂

saturation, T90, maximum pulse, minimum pulse, predominant sleep position), evaluation of the Epworth sleepiness scale at diagnosis. In the morning following the nocturnal cardiorespiratory polygraphy, biological samples were collected for a complete blood count to determine neutrophil to lymphocyte ratio (NLR) and ELISA testing of PAI-1 and a-2-AP.

Results: The present study aimed to investigate the proinflammatory status of patients with OSA quantified by NLR, and they had a higher NLR value compared to the control group, so that, independently of the BMI value, the obesity disposition, the associated comorbidities, they present a low-grade systemic inflammation. The majority of patients had obesity (84%) and severe OSA (93%) with a mean AHI of 66.3 events/hour of sleep and a mean oxygen saturation 88%. The predisposition to the development of cardio- and cerebrovascular diseases is clear, especially since the NLR value was higher in patients with arterial, mixed dyslipidemia, strongly influencing atherogenesis and the evolution of cardiac pathology.

Regarding antifibrinolytic markers, both PAI-1 and a-2-AP had statistically significantly higher values in the group of patients with OSA compared to the control (0.15177 ng/ml vs 0.12926 ng/ml, $p < 0.05$; 0.48325 pg/ml vs 0.34757 pg/ml, $p < 0.05$). In fact, patients with OSA develop a chronic prothrombotic status that may underlie major cardiovascular events.

Conclusions: The present study showed that the NLR value was higher in patients with severe OSA which associated arterial hypertension, mixed dyslipidemia, strongly influencing atherogenesis and the evolution of cardiac pathology. Regarding antifibrinolytic status, OSA patients had statistically significantly higher values of the studied biomarkers compared to the control group. Thus, patients with OSA develop a chronic prothrombotic status, reason why they need to be multidisciplinary evaluated at the time of the diagnosis. This study aimed to find new markers in the evaluation of OSA patients since there are important comorbidities associated with OSA.

Obstructive Sleep Apnea Syndrome, Excessive Daytime Sleepiness and Essential Hypertension – Clinical-Pathogenetic correlations

C. Magda¹, A. Maieran², D. Todea²

¹Clinical Hospital of Pneumophthisiology “Leon Daniello”, Cluj Napoca, Cluj-Napoca, Romania,

²University of Medicine and Pharmacy Iuliu Hatieganu, Cluj-Napoca, Romania

Introduction: Obstructive sleep apnea syndrome (OSA) is a chronic respiratory disease characterized by partial (hypopnea) or total (apnea) cessation of breathing associated with a drop in oxygen saturation. The resumption of the physiological respiratory cycle is associated with increased sympathetic activity leading to intermittent hypoxemia $\pm$ hypercapnia, changes in blood pressure and pulse values. The relationship between OSA and arterial hypertension (HTN) is incompletely elucidated, with multiple mechanisms involved, such as alterations in the autonomic nervous system, hormonal and inflammatory changes, changes in intrathoracic pressure, with hemodynamic consequences and alterations in the physiological structure of sleep. In addition to chronic inflammation and intermittent nocturnal hypoxemia, the triggering of mechanical, autonomic, chemical and inflammatory mechanisms, OSA has become an independent risk factor of cardiovascular pathologies.

Materials and methods: We conducted a prospective study which included 126 adult patients diagnosed with moderate or severe sleep apnea and arterial hypertension. They had previously confirmed OSA diagnosis and HTN established following a specialized cardiological evaluation. The data studied included personal information, anthropometric indices, the presence of comorbidities, nocturnal cardiorespiratory polygraphy parameters and Epworth sleepiness scale assessment (at diagnosis and at 6 months). In the evaluation of hypertensive cardiovascular pathology, the duration in months since the diagnosis of HTN was assessed, compliance with the hyposodium diet, the presence of antihypertensive treatment and the mean and maximum value of systolic and diastolic blood pressure (BP) quantified by Holter BP at diagnosis, 3 months and 6 months were monitored. Also, these data were dynamically correlated with the Calgary Quality of Life Index (SAQLI).

Results: The present study demonstrated a positive proportional correlation between the degree of excessive daytime sleepiness and daytime and nocturnal BP values. Excessive daytime sleepiness becomes a predictor for severe OSA, and the increase in BP values at the time of OSA diagnosis is influenced by both OSA severity and obesity.

Patients with indication for home airway positive pressure therapy (CPAP) show a significant reduction in daytime and nocturnal systolic and diastolic BP values at 6 months, under conditions of good

compliance.

We used the Calgary Questionary to assessed the quality of life (QoL) in included patients and we concluded that those with daytime sleepiness had a decreased QoL. However, by implementing positive airway pressure therapy, a significant improvement is achieved, 6 months after initiation.

Conclusions: The present research brings additional information to a major global health problem. Patient associating OSA, HTN and excessive daytime sleepiness had higher BP values and decreased QoL at the moment of the diagnosis with significant improvement 6 months after CPAP initiation. Therefore, sleep apnea syndrome has become a pathology that requires a multidisciplinary, individualized approach, depending on the comorbidities it associates with and the patient's symptoms.

Occupational Exposure to Physical and Chemical Hazards and Sleep disturbance: The Mediating Role of Pre-Sleep Arousal

S.-S. Cho¹, M.-Y. Kang²

¹Dong-A university college of medicine, Departement of occupational and Environmetal Medicine, Busan, Korea, Republic of, ²Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, b Department of Occupational and Environmental Medicine, Seoul, Korea, Republic of

Introduction: Occupational exposure to physical and chemical hazards could adversely affect sleep health. However, few studies investigate the role of pre-sleep arousal (PSA) in occupational sleep health. This study investigates the relationship between occupational exposure to physical and chemical hazards and sleep disturbances, focusing on the mediating role of PSA.

Materials and methods: This cross-sectional study used baseline data from the Korean Work, Sleep, and Health Study (KWSHS), including 4,430 wage workers aged 20–65. Occupational exposure (e.g., to noise, vibration, heat, cold, dust, vapors, and environmental tobacco smoke) was measured through structured questionnaires. Sleep disturbances were assessed using the Insomnia Severity Index and the Pittsburgh Sleep Quality Index–Korean version. PSA was evaluated using the Pre-Sleep Arousal Scale, including cognitive and somatic subscales. Logistic regression and causal mediation analyses were performed, adjusting for demographic, occupational, behavioral, and health-related covariates.

Results: Exposure to occupational hazards, including noise, vibration, high temperatures, and environmental tobacco smoke, was significantly associated with increased insomnia symptoms and reduced sleep quality. PSA, particularly somatic arousal, mediated the relationship between these exposures and sleep disturbances, indicating that higher PSA levels partially explain the adverse impact of occupational hazards on sleep.

Conclusions: The findings suggest that occupational exposure to physical and chemical hazards contributes to sleep disturbances among workers, with PSA serving as a significant mediator. Interventions aimed at reducing workplace hazard exposure and managing PSA may be effective strategies for improving sleep health in occupational settings.

Acknowledgments: This research is supported by the National Research Foundation of Korea (NRF-2021R1C1C1007796).

OSA Screening Questionnaires – What's New? Introducing the “GPSS” – General Practice Sleep Scale

T. Howarth¹, Y. Fatima², H. Garg³, S. Heraganahally⁴

¹Charles Darwin University, Faculty of Health, Darwin, Australia, ²University of the Sunshine Coast, Thompson Institute, Queensland, Australia, ³Darwin Private Hospital, Darwin Respiratory and Sleep Health, Darwin, Australia, ⁴Royal Darwin Hospital, Respiratory and Sleep Medicine, Darwin, Australia

Introduction: Obstructive sleep apnoea (OSA) is a prevalent global health issue, affecting nearly one billion individuals worldwide. Over the past decades, various OSA screening questionnaires have been developed to identify individuals at risk. This study aimed to review the available OSA screening tools and discuss the features of more recent tools, with a focus on the General Practice Sleep Scale (GPSS), which is designed specifically for screening OSA in general practice settings.

Materials and methods: A comprehensive literature search was conducted using PubMed with keywords such as “OSA screening,” “Sleep apnea screening,” and “Sleep apnea questionnaire.”

Additional tools were identified by reviewing the reference lists of retrieved articles. Screening tools were analyzed based on their design features and country of origin.

Results: A total of 22 OSA screening tools were identified, including the Epworth Sleepiness Scale (ESS, 1991) and the Top End Sleepiness Scale (TESS, 2021). Of the remaining 20 tools, three were published in the 1990s, five between 2000–2010, ten between 2011–2020, and two between 2021–2025, with the GPSS being the most recent (2025). The majority originated from the USA (n=6), followed by Brazil (n=4), Canada (n=3), Australia (n=2), and one each from Germany, Belgium, Switzerland, Poland, and Japan. Most tools incorporated variables such as body mass index (BMI), neck circumference, age, sex, and snoring history. Recent tools, particularly the GPSS, were more likely to incorporate comorbidity information and use multiple risk thresholds rather than binary criteria.

Conclusions: The evolving understanding of sex-based differences and metabolic impacts of OSA has informed the design of newer screening tools such as the GPSS. The GPSS represents a promising advancement and warrants further evaluation and adaptation across diverse populations.

Oscillatory population-level activity of dorsal raphe serotonergic neurons in sleep-wake disorders

X. Li¹, Y. Si¹, T. Lu¹, J. Shi^{1,2}

¹Peking University, National Institute on Drug Dependence, Beijing, China, ²Peking University, Beijing Key Laboratory of Drug Dependence, Beijing, China

Introduction: The incidence of sleep-wake disorders is increasing, with the core pathological process involving abnormal changes in brain electrical activity related to the regulation of sleep-wake cycles. Studies have shown that 5-hydroxytryptamine (5-HT) neurons in the dorsal raphe nucleus (DRN) play a crucial role in regulating sleep-wake processes by releasing 5-HT to the prefrontal cortex (PFC), a downstream brain region, thereby altering sleep-wake states. However, the role of the DRN 5-HT neuronal pathway to the PFC in sleep-wake disorders and its underlying mechanisms remain unclear.

Materials and methods: Firstly, we performed synchronized electroencephalogram (EEG) recordings with fiber photometry to monitor the activity dynamics of 5-HT neurons in DRN across different sleep-wake phases. Secondly, sleep-wake disorder animal models were established using acute restraint stress (ARS) and chronic restraint stress (CRS). We assessed the effects of restraint stress on total sleep duration and sleep architecture in mice, while simultaneously examining whether the activity of DRN 5-HT neurons was altered during these processes. Next, miniscope was employed to record the activity of DRN 5-HT neurons during restraint stress and to evaluate their reactivation patterns during subsequent sleep periods. Subsequently, fiber photometry was utilized to monitor fluctuations in 5-HT neurotransmitter levels within PFC during sleep in animals exposed to ARS or CRS. Finally, patch-clamp electrophysiology was conducted to investigate the electrophysiological properties of DRN 5-HT neurons and PFC neurons in animals subjected to ARS or CRS.

Results: The population oscillatory activity of DRN 5-HT neurons projecting to PFC exhibited tight coupling with distinct sleep-wake phases. Specifically, DRN 5-HT neurons displayed heightened activity during wakefulness, reduced activity during non-rapid eye movement (NREM) sleep, and nearly ceased firing during rapid eye movement (REM) sleep. Mice subjected to CRS developed significant sleep-wake disturbances, characterized by shortened REM sleep latency, prolonged REM sleep duration, and an increased probability of transitions from NREM to REM sleep compared to controls. Furthermore, CRS mice exhibited distinct activity patterns of DRN 5-HT neurons across sleep-wake phases relative to unstressed controls. Notably, during NREM sleep, the magnitude of DRN 5-HT neuronal activity in CRS mice was significantly greater than that in controls. Importantly, DRN 5-HT neurons activated during restraint stress showed reactivation during subsequent sleep periods, as captured by miniature fluorescent microscopy. This reactivation phenomenon suggests a potential link between stress-induced neuronal activation and sleep dysregulation. Chemogenetic activation of the DRN 5-HT to PFC neuronal circuit mimicked the effects observed in CRS-treated mice. Furthermore, chemogenetic inhibition of the DRN 5-HT to PFC circuit effectively rescued the CRS-induced sleep disturbances. Suppressing the activity of this circuit restored baseline sleep architecture, normalized REM sleep parameters, and reduced aberrant phase transitions.

Conclusions: The DRN-PFC 5-HT pathway critically regulates sleep-wake dynamics and mediates stress-induced sleep disturbances. -CRS disrupts sleep architecture by amplifying DRN 5-HT neuronal activity during NREM sleep, promoting REM sleep abnormalities, and enhancing stress-activated neuron reactivation during sleep. These findings highlight the DRN-PFC 5-HT circuit as a therapeutic target for stress-related sleep disorders.

Parental Sleep Loss: Effects of Parental Bedtime Procrastination on Parental Sleep

M. Kim¹, S. Shin¹, G. Jo¹, B. Bei^{2,3}, L. Astbury², S. Suh¹

¹Sungshin University, Department of Psychology, Seoul, Korea, Republic of, ²Monash University, School of Medicine, Turner Institute for Brain and Mental Health, School of Psychological Sciences, Nursing and Health Sciences, Victoria, Australia, ³Royal Women's Hospital, Centre for Women's Mental Health, Victoria, Australia

Introduction: Bedtime procrastination (BP) is the intentional delay of sleep to reclaim personal time and is associated with sleep-related difficulties. Parents of young children often report irregular sleep patterns, reduced personal leisure time, and heightened parenting stress, which may contribute to the use of BP as a coping strategy to restore a sense of control. Despite its relevance, there is limited research on BP in parents. This study aimed to explore parental BP and to investigate its associations with parental sleep.

Materials and methods: This study utilized data from a randomized controlled trial targeting parental cognitions about their child's sleep. Participants were 94 parent and child (6–24 months) dyads. Parents completed daily sleep diaries for their own sleep and their child throughout a 4-week intervention period, and for one week at each follow-up assessment (4 weeks and 12 weeks post-intervention). The sleep diaries included scheduled bedtime (SBT; the time each day that parents reported intending to go to bed), light-off time (LO; actual time attempting to sleep), wake after sleep onset (WASO), and parental total sleep time (TST). BP was calculated as the difference between SBT and LO. Child sleep indicators included WASO, TST, nap duration, and nighttime parenting involvement (the total time spent attending to the child during the night). Two multiple linear regression models were conducted to examine the effects of child- and parent-related sleep factors on parental TST. Model 1 included children's nap duration and nighttime parenting involvement as predictors. Model 2 added parental BP to assess its incremental contribution.

Results: Mean age of the parents was 33.61 ± 3.37 years (95.7% female), and the mean age of children was 12.62 ± 5.62 months (53.2% girls). A total of 4,374 sleep diaries were collected. The mean duration of parental BP was 44.52 minutes ($SD = 65.01$ minutes). In Model 1, children's nap duration and nighttime parenting involvement were significantly associated with parental TST (adjusted $R^2 = .044$). Increases in children's nap duration were significantly associated with shorter parental TST ($\beta = -0.042$, $p < .001$). Similarly, each additional minute of nighttime parenting involvement was linked to a 0.692-minute reduction in parental TST ($\beta = -0.050$, $p < .001$). In Model 2, all predictors remained statistically significant. Notably, each additional minute of parental BP was associated with a 0.766 minute decrease in parental TST ($\beta = -0.334$, $p < .001$), indicating Model 2 explained more variance in parental sleep duration (adjusted $R^2 = .30$) compared to Model 1 (adjusted $R^2 = .044$).

Conclusions: These findings suggest that parental sleep is influenced not only by external demands such as child sleep patterns but also by modifiable behavioral factors such as bedtime procrastination. This underscores the potential to improve parental sleep by focusing on bedtime behaviors. Results indicate that interventions aimed at improving parental sleep should address both caregiving-related demands and modifiable behavioral patterns such as bedtime procrastination.

Acknowledgments: This work was supported by the Ministry of Education of the Republic of Korea and the National Research Foundation of Korea (NRF-2021S1A5A2A03061721).

Pediatric Sleep Assessment Tools: Classification, Comparison, and Applications of Artificial Intelligence

B. Shen¹, P. Fan², X. Wang², C. Tu², X. Zhang², S. Qin²

¹Shanghai Children's Medical Center, Department of Nursing, Shanghai, China, ²Shanghai Jiao Tong University, School of Nursing, Shanghai, China

Introduction: Sleep quality is vital to children's growth, cognitive development, and overall health. Accurate assessment of pediatric sleep is essential for the early detection and intervention of sleep disorders. This paper reviews commonly used subjective and objective pediatric sleep assessment tools worldwide. These tools are categorized and compared based on different age groups, and their advantages, limitations, and applicability are analyzed.

Materials and methods: Subjective sleep assessment tools are found to be simple, convenient, cost-effective, and easy to implement. However, attention should be paid to the potential impact of recall bias on the results. Commonly used tools include sleep diaries, ISAS, BISQ, BISQ-R, TSAS, TCSQ, BEARS, CSHQ, SDSC, ASHS, and ASWS. These instruments assess various aspects such as sleep duration, sleep-onset difficulties, nighttime awakenings, sleep-disordered breathing, snoring, morning wake-up problems, daytime sleepiness, and co-sleeping. Objective sleep assessment tools, such as polysomnography (PSG) and actigraphy, record physiological signals. These tools are used to evaluate wake-sleep states and sleep stages, and PSG is considered the gold standard for assessing pediatric sleep-disordered breathing. Recent studies have explored innovative applications of artificial intelligence (AI) in sleep assessment. Including automated sleep staging based on PSG data and real-time monitoring using wearable devices combined with machine learning. Furthermore, an intelligent assessment system has also been proposed, which covers the entire process of screening, diagnosis, and intervention.

Results: Therefore, when selecting assessment tools, factors such as age appropriateness, assessment content, accessibility, reliability and validity, and cultural adaptability should be comprehensively considered. This helps achieve a more comprehensive and accurate evaluation of pediatric sleep. In addition, this paper introduces localized Chinese versions of assessment scales for infancy (ISAS, TSAS) and adolescence (ASHS, ASWS). These tools provide evidence-based support for clinical tool selection and intervention optimization.

Conclusions: It is suggested that future efforts focus on multi-source data integration, technological ethics, and model generalizability to support the continued advancement of precision and intelligence in pediatric sleep assessment.

Perceived barriers and facilitators to delayed school start times in Dutch and Flemish secondary schools

A. Vandendriessche¹, D. Heemskerk², B. Deforche¹, M. van Stralen²

¹Ghent University, Gent, Belgium, ²Vrije Universiteit Amsterdam, Amsterdam, Netherlands

Introduction: Sleep is essential for adolescents' mental, cognitive, and physical health. However, many adolescents sleep too little and of poor quality. A key cause is the mismatch between adolescents' delayed biological clock and early school start times, leading to chronic sleep deprivation. Delaying school start times is a potentially effective strategy to improve adolescent sleep. This study aims to explore barriers and facilitators to implementing later school start times in Dutch and Flemish secondary schools as perceived by school leaders.

Materials and methods: Semi-structured interviews (n = 18) were held with key stakeholders (i.e. school leadership or student support staff) from three categories of secondary schools in Flanders and The Netherlands: (1) schools that have implemented later start times, (2) schools that have considered such changes, and (3) schools firmly opposed to it. The interview guide was based on the MIDI (Measurement Instrument for Determinants of Innovation) framework. Interviews were recorded, transcribed, and thematically coded in MaxQDA 24.8.0.

Results: Stakeholders identified both barriers and facilitators across the phases of adoption, preparation, implementation, and continuation of delaying school start times. Adoption was often hindered by logistical concerns, ingrained routines, and perceived scheduling conflicts, though facilitated by awareness of adolescent sleep needs and renewed school vision. Preparation was facilitated by stakeholder communication, participatory planning, and adapting schedules and regulations. Implementation challenges included public transport mismatches and concerns about later end times, but benefits such as calmer school mornings, improved student alertness, and more meaningful interactions were frequently observed. Continuation was facilitated by alignment with broader educational visions, teacher and student satisfaction, and perceived health and performance benefits.

Conclusions: Successfully shifting school start times requires more than overcoming logistical barriers; it depends on strong internal leadership, alignment with pedagogical values, and a culture that allows for experimentation and adaptation. Open communication with staff and families plays a key role in building trust and support. At the same time, system-level actors—such as educational networks or government bodies—have an important role to play.

Perinatal Subjective Sleep Disturbance and Circulating Cytokine Levels: Bidirectional Examinations

M. Okun¹, R. Cox², J. Carroll³, K. Ross⁴, C. Dunkel Schetter⁵, M. Coussons-Read⁶

¹UCCS, Biofrontiers Center, Colorado Springs, United States, ²Washington University in St. Louis, Department of Psychological and Brain Sciences, St. Louis, United States, ³UCLA, Cousins Center for Psychoneuroimmunology, Los Angeles, United States, ⁴Athabasca University, Psychology, Athabasca, Canada, ⁵UCLA, Psychology, Los Angeles, United States, ⁶UCCS, Psychology, Colorado Springs, United States

Introduction: Adaptational changes in cytokines across the gestational are essential to a healthy pregnancy. High levels of proinflammatory cytokines may result in systemic inflammation often linked to less favorable delivery and maternal outcomes. Likewise, systemic inflammation in the postpartum period may confer increased mood disorders. Significant sleep disturbance, such as poor sleep quality or efficiency, is associated with increases in inflammatory cytokines. Hence, sleep disturbances may precipitate chronic inflammatory changes which are considered a risk factor for poor delivery or maternal outcomes, such as preterm birth or mood disorders. On the other hand, inflammation is noted to impart disturbed sleep as well as adverse outcomes. This preliminary evaluation assessed whether sleep disturbances were associated with circulating cytokine markers across the perinatal period.

Materials and methods: These data were collected as part of the Healthy Babies Before Birth (HB3) study. Perinatal women ($N = 169$) who had available inflammation and sleep data from 4-times points: 8-16 weeks, 30-36 weeks, 6 months and 1-year postpartum were included. Sleep data were ascertained from the Pittsburgh Sleep Quality Index (PSQI) and cytokines were assayed using a custom V-PLEX human immunoassay plate. Multi-level models using maximum likelihood estimation examined within-subjects and between-subjects effects considering four sleep variables (PSQI total (overall sleep quality), sleep duration, mid-sleep timing, and sleep efficiency (SE)) and the cytokines (INF- γ , IL-6, -8, 10, and TNF- α) as well as the IL-6/IL-10 ratio across the 4 timepoints. Multi-level models were also used to test reverse relationships, whether inflammation predicted sleep variables.

Results: Participants were $M_{age}=31.3$ (5.6) years of age, with $M_{educ}=16.0$ (3.1) years of education. Over 75% were married and White. Between subjects' analyses indicate that poor sleep quality was significantly associated with the IL-6/IL-10 ratio ($\beta=.16$, $p<.05$). Shorter sleep duration was also significantly associated with higher IL-8 ($\beta=-.11$, $p<.05$), IL-6 ($\beta=-.14$, $p<.05$), and the IL-6/IL-10 ratio ($\beta=-.18$, $p<.01$) between-subjects, as well as higher IL-8 at the subsequent timepoint ($\beta=.09$, $p<.05$). Lastly, mid-sleep timing was significantly associated with a higher IL-6/IL-10 ratio at the next time point ($\beta=.07$, $p<.05$). No associations were noted for SE. For the reverse relationships, only one significant result emerged: later mid-sleep timing predicted lower IL-8 levels at the next timepoint ($\beta=0.07$, $p<.05$).

Conclusions: Corroborating the limited literature, sleep disturbances, including poorer sleep quality, shorter sleep duration, and later mid-sleep timing, are associated with greater circulating levels of pro-inflammatory cytokines and a higher ratio of IL-6/IL-10. Addressing the bidirectional nature of these variables, we also tested whether the sleep variables predicted inflammation. Only a single association emerged. Later mid-sleep timing was associated with higher inflammation. While these data suggest that sleep influences inflammation, more so than the reverse, further exploration of these pathways is needed. The data imply that the behavior of sleep may be an ideal candidate for intervention in order to mitigate adverse pregnancy outcomes.

Persistent Hypoxia in an Apparently Healthy Woman

P. Adimi Naghan¹, F. Mohammadi Aniloo¹, M. Mirza Aghazade¹

¹Shahid Beheshti Medical University, Masih daneshvari Hospital, Sleep Lab, Tehran, Iran, Islamic Republic of

Introduction: Hypoxia, a reduction in blood oxygen levels, can result from various factors. Pulse oximetry is a common tool for measuring hemoglobin oxygen saturation and serves as an alternative to invasive ABG analysis. This case report highlights the diagnostic and therapeutic complexities of a rare case of chronic hypoxia on pulse oximetry in an apparently healthy 40-year-old woman who incidentally discovered the condition.

Materials and methods: A 40-year-old female patient with a history of controlled hypothyroidism and thalassemia minor incidentally noted low SpO₂ (79-83%) on pulse oximetry during the COVID-19 pandemic, despite normal initial pulmonary and cardiac evaluations. One year later, during her pregnancy (achieved via IVF), her nocturnal hypoxia worsened, necessitating oxygen therapy. Post-delivery, PSG revealed moderate obstructive sleep apnea. Despite improvement in respiratory events with CPAP, her SpO₂ did not rise above 90%. Concurrent ABG with pulse oximetry confirmed normal arterial oxygen saturation (SaO₂) versus the low pulse oximetry SpO₂ (82%). Cardiovascular shunt evaluation was negative. Ultimately, methemoglobinemia with a level of 1.8% was diagnosed, explaining the discrepancy between pulse oximetry and ABG.

Results: This case underscores the importance of accurate differential diagnosis in chronic hypoxia, especially when pulse oximetry readings are inconsistent with clinical and other paraclinical findings. Differential diagnoses include pulmonary and cardiac diseases, vascular shunts, and methemoglobinemia. Methemoglobinemia, even at low levels (1.8% in this patient), can lead to spuriously low SpO₂ readings by pulse oximetry. The concomitant diagnosis of obstructive sleep apnea also contributed to transient hypoxic events. The impact of pregnancy on the severity of sleep apnea and nocturnal hypoxia was also a notable point.

Conclusions: In the presence of chronic hypoxia on pulse oximetry that does not correlate with initial clinical and paraclinical findings, rare differential diagnoses, such as methemoglobinemia, should be considered. An arterial blood gas (ABG) is essential to confirm true oxygen saturation. Thorough evaluation for sleep-disordered breathing is also crucial in these patients. Concurrent management of both methemoglobinemia and sleep apnea is vital for improving quality of life and preventing long-term complications.

Acknowledgments: We sincerely thank all the medical staff, nurses, and personnel from various departments who participated in the care and monitoring of this patient. Furthermore, we express our sincere gratitude for their contributions and gratitude to the patient for her cooperation and permission to publish this case report.

Personalized Sleep Extension in a Pilot Study: Effects and Moderators

W. Wang^{1,2}, E.Y.Y. Lau^{1,3,2}, H.Y.D. Ma^{1,2}, C.H. Chan¹

¹The Education University of HongKong, Psychology, HongKong, Hong Kong, SAR of China, ²The Education University of HongKong, Analytics\Assessment Research Centre, HongKong, Hong Kong, SAR of China, ³The Education University of HongKong, Centre for Psychosocial Health, HongKong, Hong Kong, SAR of China

Introduction: Chronic short sleep is associated with adverse health outcomes, yet effective behavioral interventions remain understudied. This pilot study examined the efficacy of a tailored sleep extension (SE) intervention incorporating behavior change techniques and explored the moderators of treatment response.

Materials and methods: Eleven chronically short-sleeping adults (<6.5 hours; 25±1.5 years) completed a 3-day baseline, 4-day sleep hygiene education (SH), and 7-day 90-min SE protocol. Daily sleep was assessed via actigraphy and sleep diary. We first assessed overall intervention effects on seven sleep parameters, then examined phase-specific changes in sleep duration. Given substantial between-participant variability in sleep response (ICC = 28–54%), we further tested whether baseline individual characteristics moderated SE outcomes using simple slope analysis for significant moderators.

Results:

SE significantly improved sleep duration but showed mixed effects on sleep quality and stability. SH increased time in bed ($\beta = 0.72$ h, $p = 0.019$), SE further increased time in bed ($\beta = 1.49$ h, $p < 0.001$),

and tended to increase actual sleep duration ($\beta = 0.55$ h, $p = 0.059$). However, increased sleep duration was accompanied by greater fragmentation ($\beta = 9.435$, $p = 0.015$) and lower sleep efficiency ($\beta = -5.49$, $p = 0.024$), although no change in subjective sleep quality. And, intervention did not change sleep efficiency, latency, and circadian timing. Exploratory analysis showed that emotional stability, baseline sleep duration, and sleep barrier reduction during interviews would moderate the SE effect on actual sleep duration.

Conclusions: This pilot study supports the feasibility and effectiveness of a personalized SE protocol in extending sleep among short-sleeping adults. While SE increased sleep duration, it also led to greater fragmentation, suggesting a trade-off during adaptation. Importantly, individuals with lower emotional stability, longer baseline sleep duration, and more barriers solved benefited the most. These findings highlight the need to tailor behavioral sleep interventions based on individual psychological and sleep-related characteristics.

Acknowledgments:

We would like to thank the students who assisted with the pilot data collection: Ou Yang Yuxuan, Cai Yi Xuan, Akira Basa Okabe, and Tian Yu Wei. We also extend our gratitude to all the study participants.

Physical activity, weekend catch-up sleep, and depressive symptoms: Mediating effects of high-sensitivity C-reactive protein

S.-Y. Kim¹

¹Ewha womans university, college of medicine, Psychiatry, Seoul, Korea, Republic of

Introduction: We aimed to examine the effect of physical activity (PA) and weekend catch-up sleep (WCS) on depressive symptoms by evaluating their effects on high-sensitivity C-reactive protein (hsCRP) levels.

Materials and methods: Data were collected from 10,715 adults aged ≥ 19 years. PA and depressive symptoms were assessed using self-report scales. The WCS was calculated by subtracting self-reported average weekday sleep hours from weekend sleep hours, and serum hsCRP levels were measured using immunoturbidimetric methods. Given that depressive symptoms are characterized by their multifaceted nature, we identified specific symptoms associated with hsCRP levels. Path analysis was used to investigate the association between PA, WCS, hsCRP, and depressive symptoms, and that between PA, WCS, hsCRP, and specific symptoms related to hsCRP.

Results: Higher levels of PA and WCS were associated with a decreased risk of depressive symptoms through lowering hsCRP levels. Among various depressive symptoms, sleep problems and appetite changes were associated with hsCRP. In pathway analyses using them as dependent variables, higher levels of PA and WCS were also associated with a decreased risk of sleep problems and appetite changes through lowering hsCRP levels.

Conclusions: Increased levels of PA and WCS may help alleviate depressive symptoms, particularly sleep problems and appetite changes, by mitigating chronic inflammation. Therefore, ensuring adequate exercise time and compensating for inadequate weekday sleep during weekends are crucial for maintaining mental well-being.

Planned Study Protocol: Sleep Health Among Older Adults – A Register-Based Cross-Sectional Study within NEAR-Aging

S. Öberg¹, C. Sandlund², F. Iredahl³, B. Westerlind^{3,4}, L. Johansson⁴, D. Finkel⁴

¹Jönköping University, School of Health and Welfare, Department of Nursing Science, Jönköping, Sweden, ²Karolinska institutet, Department of Neurobiology, Care Sciences and Society, Stockholm, Sweden, ³Linköpings University, Department of Health, Medicine and Caring Sciences, Linköping, Sweden, ⁴Jönköping University, School of Health and Welfare, Institute of Gerontology, Jönköping, Sweden

Introduction: Sleep disturbances are common among older adults and are often associated with physical and mental health issues, as well as reduced quality of life. However, the relationship between various dimensions of sleep health and factors such as lifestyle, health status, quality of life and demographics remains insufficiently explored. The National E-infrastructure for Aging Research (NEAR) is a Swedish research consortium that gathers extensive registry data from older adults, providing a unique opportunity to investigate these associations. The aim is therefore to explore the associations between sleep health dimensions and lifestyle habits, physical and mental health, quality of life, and demographic factors in individuals aged 65 and older.

Materials and methods: A retrospective cross-sectional design will be used to enable objective conclusions from the collected registry data. The study population consists of individuals aged 65 and older who have responded to questions related to the sleep health dimensions. Data will be extracted from NEAR-aging studies that include variables related to the five sleep health dimensions: sleep duration, sleep continuity/efficiency, sleep timing, daytime sleepiness, and subjective sleep quality. Related variables will include physical activity, somatic and mental health conditions (e.g., depressive and anxiety symptoms), subjective memory function, self-rated health and quality of life, lifestyle habits (alcohol and tobacco use) as well as demographic data (age, sex, marital status, educational level). Statistical analyses will include descriptive statistics, group comparisons, and correlation analyses. The study is approved by the Swedish Ethical Review Authority and financed by the Medical Research Council of Southeast Sweden.

Results: The study is expected to reveal significant associations between different dimensions of sleep health and various factors related to physical and mental health, quality of life, lifestyle, and demographics in older adults in a Swedish context. Individuals with poorer sleep health are likely to report more mental health symptoms, reduced physical and cognitive functioning, lower quality of life, and less healthy lifestyle habits. Also, the results is also expected to reveal beneficial health outcomes associated to individuals reporting good sleep health. Reported poor sleep health or good sleep health dimensions, may also be prevalent in specific demographic groups, such as by age, sex, or educational level. Moreover, each sleep dimension may show distinct patterns of association with health and behavior.

Conclusions: The study conclusion is anticipated to highlight the complex interplay between sleep health and multiple domains of well-being in older adults. The findings may support the importance of holistic health assessments in aging populations and promote the integration of sleep health evaluations into routine geriatric care. Ultimately, this study could contribute to the development of targeted, multidimensional interventions aimed at improving sleep and overall health for older persons.

Polysomnographic comparison of sleep architecture between patients with disorders of consciousness and healthy controls

S. Dai^{1,2}, Y. Xue^{3,4}, C. Yang^{3,5}, F. Wang^{3,5}, L. Ye^{1,2}, J. Huang^{2,6}, S. Laureys^{7,8}, H. Di^{3,4}

¹Hangzhou Normal University, School of Clinical Medicine, Hangzhou, China, ²Hangzhou Normal University, The Affiliated Hospital, Hangzhou, China, ³Hangzhou Normal University, International Vegetative State and Consciousness Science Institute, Hangzhou, China, ⁴Hangzhou Normal University, School of Basic Medicine, Hangzhou, China, ⁵Hangzhou Normal University, School of Nursing, Hangzhou, China, ⁶Dalian Medical University, School of Clinical Medicine, Dalian, China, ⁷University Hospital of Liege, GIGA-Consciousness Coma Science Group, Neurology Department, Liege, Belgium, ⁸Laval University, Joint International Research Unit on Consciousness, CERVO Brain Research Centre, Québec, Canada

Introduction: Disorders of consciousness (DoC) involve prolonged impairments in awareness and wakefulness. Sleep architecture, particularly the presence of deep and REM sleep, has been suggested as a potential indicator of residual brain function and recovery potential. However, systematic comparisons between DoC patients and healthy individuals using polysomnography (PSG) are limited.

Materials and methods: In the current prospective study, patients diagnosed with DoC (more than one month post-injury) and their age- as well as sex-matched healthy controls were recruited. All DoC patients underwent 24-hour PSG monitoring in a hospital setting, while healthy controls underwent 12-hour standardized PSG in our sleep lab. Key parameters included total sleep time (TST), sleep efficiency, proportions of N1, N2, N3, REM sleep, and the presence of sleep-disordered breathing (SDB), evaluated by the apnea-hypopnea index (AHI).

Results: Five DoC patients (mean age 60.6 ± 13.4 years) and three healthy controls (mean age 54.2 ± 11.2 years) were included in this preliminary analysis. Average sleep efficiency in the DoC group was 67.1%, which was comparable to 68.3% in controls. In the patient group, the average proportions of sleep stages were: N1 at 5.9%, N2 at 13.9%, N3 at 69.5%, and REM at 10.7%, with an AHI of 2.9. In the control group, N1 accounted for an average of 7.8%, N2 for 44.7%, N3 for 31.5%, and REM for 16.0%, with an AHI of 0.9. These preliminary results suggest that DoC patients showed significantly reduced N2 and REM sleep, while a markedly increased proportion of N3 sleep, and more frequent SDB compared to healthy individuals.

Conclusions: Sleep architecture differs substantially between DoC patients and healthy individuals. PSG-based assessment may provide objective markers of residual brain function and support the development of sleep-informed approaches for consciousness evaluation and neurorehabilitation.

Acknowledgments: We are deeply thankful to all the patients, their families, and the healthy individuals who participated. This work was funded by the Hangzhou Normal University Seed Fund (no. 8015C52725101091) and the Intergovernmental International Science and Technology Innovation Cooperation & Strategic Science and Technology Innovation Cooperation (no.2022YFE0141300).

Poor sleep behaviour from childhood to adolescence is associated with polycystic ovary syndrome in adolescence: Findings from the Raine Study

N.K. Abdul Jafar¹, J. McVeigh², C.J. Bennett³, P.R. Eastwood⁴, R.J. Hart⁵, D.R. Mansfield⁶, A.E. Joham¹, C.T. Tay¹, L.J. Moran¹

⁴Health Futures Institute, Murdoch University, Perth, Australia, ⁵The University of Western Australia, Division of Obstetrics and Gynaecology, Faculty of Health and Medical Sciences, Perth, Australia,

⁶Monash Lung and Sleep, Monash Health, Clayton, Australia

Introduction: Poor sleep behaviour is highly prevalent in females with polycystic ovary syndrome (PCOS), but its relationship with PCOS during childhood and adolescence is unclear. This study compares the longitudinal sleep behaviour trajectories and specific sleep behaviours from childhood to adolescence in those with and without PCOS.

Materials and methods: Caregivers of index participants (Gen2) of the Raine Study completed the Child Behavior Checklist (CBCL) questionnaire at ages 5-, 8-, 10- and 14-years. The CBCL includes six sleep behaviour items, each rated as '0' (not true), '1' (somewhat/sometimes true) or '2' (very/often true), which were summed to generate a composite score. A higher score indicates poorer sleep behaviour. PCOS status was assessed at 14-year using the 2018 adolescent Rotterdam criteria. Sleep behaviour composite scores were analysed longitudinally using generalized estimating equations at each time point and across time from 5-, 8-, 10- to 14-years. Prevalence of each sleep behaviour item from ages 5- to 14-years were also determined.

Results: N=187 participants with fully completed sleep behaviour and PCOS data were included, consisting of 29 (15.5%) diagnosed with PCOS. After adjusting for age of menarche, body mass index percentiles, family income, and symptoms of anxiety/depression, participants with PCOS exhibited poorer sleep behaviour trajectory compared to participants without PCOS that worsened over time from ages 5- to 14-years (mean difference (MD)=0.65, 95% confidence interval (CI)=0.23 to 1.07, $p=0.003$). Poor sleep behaviour trajectories did not differ significantly between participants with and without PCOS at age 5 (MD=0.09, 95% CI= -0.39 to 0.58, $p=0.71$), but diverged significantly from age 8 (MD= 0.76, 95% CI=0.14 to 1.37, $p=0.016$) until age 14 (MD=1.04, 95% CI=0.36 to 1.72, $p=0.003$). Specifically, compared with participants without PCOS, those with PCOS had a higher prevalence of several poor sleep behaviours during childhood, including trouble sleeping (24.1–69.0% vs. 7.0–43.7% at ages 5, 10, and 14), being overtired without good reason (34.5–79.3% vs. 20.3–53.8% at ages 5, 8,

and 14), and sleeping less than most kids (24.1–48.3% vs. 11.4–31.0% at ages 10 and 14). Other sleep problems such as nightmares, talking or walking in sleep, and sleeping more than most kids showed smaller or inconsistent differences between groups.

Conclusions: Our findings suggest that participants with PCOS diagnosed at adolescence have poorer sleep behaviour patterns during childhood compared to participants without PCOS. In children with diagnosed PCOS at adolescence, poor sleep may worsen hormonal imbalances and metabolic issues, potentially increasing insulin resistance and obesity, and further sleep problems in a vicious cycle. Future research should identify and address childhood sleep problems, leading to better interventions and support.

Poor sleep quality in students with good academic performance in a medical school in Venezuela

O. Medina-Ortiz^{2,1,3,4}, C. Cárdenas⁵, R. Peña³, M. Arenales³, E. Medina³, A. Pérez³, E. Torres-Santos², N. Medina-Sánchez⁶, V. Bermudez¹, D. Rivera², M. Riaño-Garzón³

¹University Simón Bolívar, Cúcuta, Colombia, ²University of Santander, Medicine, Cúcuta, Colombia,

³University of the Andes, San Cristóbal, Venezuela, ⁴Venezuelan Academic of Sleep Medicine, San Cristóbal, Venezuela, ⁵Venezuelan Academic of Sleep Medicine, Caracas, Venezuela, ⁶Metropolitan College, San Cristóbal, Venezuela, ⁷University Simón Bolívar, Barranquilla, Colombia, ⁸De la Costa University, Barranquilla, Colombia

Introduction: The demands of the medical career can affect the quality of sleep of students, which could affect their academic performance, however, those who sleep less dedicating night hours to their studies, could have better grades. The objective of this study was to determine the sleep quality of medical students at a university in Venezuela and its relationship with academic performance.

Materials and methods: Observational, descriptive, cross-sectional study. All first, second, and fourth year medical students at the University of the Andes in San Cristóbal, Venezuela, were invited to participate. After signing the informed consent, the Pittsburgh Sleep Quality Index was applied and was related to their academic performance. Statistical analysis was performed with SPSS 22 and significance was considered less than 0.05. For categorical variables, Chi-square was used and for numerical variables, Pearson's correlation. The study was approved by the Ethics Committee of the Universidad de Los Andes.

Results: A total of 90 students were included. The mean age was 23.70 years (SD: 3.17; min: 20 and max: 35), 57.8% were women. The average grade point average was 15.75 out of 20 (SD: 2.20; min: 10 and max: 20). The average PSQI was 8.46 (SD: 3.47; min: 2 and max: 17), (23.3% good, 56.7% moderate, and 20% poor). Sleep latency was 21.94 minutes (SD: 17.21; min: 1 and max: 90) and mean nighttime sleep was 5.23 (SD: 1.04; min: 2 and max: 8). Students with better academic performance had higher PSQI scores (Pearson 0.027; P=NS). None of the students with excellent academic performance scored for good sleep quality, while 26.7% of them scored for poor sleep quality, compared to students with regular academic performance, of whom 33.3% scored for good sleep quality and 20% for poor sleep quality (P=NS). No significance was found in any of the other study variables.

Conclusions: The sleep quality of medical students at the University of the Andes in Venezuela tends to be poor overall, but those with better academic performance have an even worse sleep quality, probably because they dedicate more hours to their study and responsibilities, at the expense of their sleep hours.

Acknowledgments: Thanks are given to the Simón Bolívar University, Santander University, Los Andes University and the Venezuelan Academy of Sleep Medicine for their collaboration in carrying out this study.

Poor subjective sleep quality independently predicts greater disability and functional decline in older adults at-risk of dementia

A. Suraev¹, L. Mowszowski¹, C. Ireland¹, K. Bassett¹, A. Lam¹, Z.M. Schrire¹, S. Naismith¹

¹University of Sydney, Healthy Brain Ageing Program, Brain and Mind Centre, Sydney, Australia

Introduction: Dementia is characterised by progressive cognitive and functional decline, and sleep disturbance is an early prodromal feature, occurring years before formal dementia diagnoses. It is unclear if the presence of sleep disturbance in older adults with cognitive concerns is also linked to disability and functional decline. This study aims to determine if sleep quality is predictive of these features in a well-characterised cohort of community-dwelling older adults at-risk of dementia.

Materials and methods: Baseline data were drawn from the larger longitudinal Healthy Brain Ageing (HBA) cohort (total N = 1469), comprising community-dwelling older adults aged ≥ 50 years (mean $\pm$ SD age, 67.5 ± 8.9 ; 59.5% female) with new-onset cognitive concerns. Subjective sleep quality was measured with the Pittsburgh Sleep Quality Index (PSQI). Disability and functional decline were assessed using the 36-item WHO Disability Assessment Schedule (WHO-DAS Global Score) and the HBA-Functional Assessment Questionnaire (HBA-FAQ), respectively. Key covariates included age, depression (Geriatric Depression Scale, GDS-15), and comorbidity (Cumulative Illness Rating Scale, CIRS). Two multiple linear regression analyses were conducted to determine the unique variance in WHO-DAS ($n = 507$) and HBA-FAQ ($n = 828$) scores explained by PSQI, after statistically controlling for age, GDS-15, and CIRS.

Results: Two multiple linear regression models examined the independent contribution of subjective sleep quality (PSQI) to disability and functional impairment. In the first model predicting WHO-DAS global disability scores ($N = 507$; Adjusted $R^2 = .455$, $p < .001$), poorer PSQI scores significantly predicted greater disability ($\beta = 0.154$, $sr^2 = 2.0\%$, $p < .001$), even after controlling for age, depressive symptoms (GDS-15), and comorbidity (CIRS). In this model, GDS-15 ($\beta = 0.533$, $sr^2 = 23.6\%$) and CIRS ($\beta = 0.195$, $sr^2 = 3.4\%$) were also significant predictors (both $p < .001$), while age was not. In the second model predicting HBA-FAQ functional impairment scores ($N = 828$; Adjusted $R^2 = .378$, $p < .001$), poorer PSQI scores again significantly predicted greater functional impairment ($\beta = 0.175$, $sr^2 = 2.6\%$, $p < .001$), independent of covariates. GDS-15 ($\beta = 0.551$, $sr^2 = 25.5\%$) and older age ($\beta = 0.097$, $p = .001$) were also significant predictors in this model, while CIRS was not.

Conclusions: Poorer subjective sleep quality consistently and independently predicted both greater overall disability and increased functional impairment in community-dwelling older adults at risk of dementia, even after accounting for depressive symptoms, age, and comorbidity. While depressive symptoms were also strong predictors, the distinct contribution of PSQI across different functional measures underscores its importance. These findings suggest addressing subjective sleep disturbances may be a valuable target for interventions to mitigate functional decline in this vulnerable population.

Acknowledgments: The authors would like to thank all the participants of the Healthy Brain Ageing Clinic for their invaluable contributions to this research.

Postpartum maternal sleep disruption is associated with perception of infant temperament: Findings from a 6-month longitudinal study

M. Okun¹, R. Cox²

¹UCCS, Biofrontiers Center, Colorado Springs, United States, ²Washington University in St. Louis, Department of Psychological and Brain Sciences, St. Louis, United States

Introduction: Accumulating evidence links postpartum sleep disruption to adverse infant outcomes, including deficits in infant-maternal bonding. Infant temperament, or individual differences in infant reactivity and self-regulation, represents a combination of heredity, maturation, and context. For example, mothers with higher postpartum depression and anxiety perceive their infants as having more difficult temperaments. Maternal perception of infant temperament is likely also influenced by maternal sleep. We examined the associations between maternal postpartum sleep and maternal perception of infant temperament and the moderating effect of maternal depression and anxiety over 6 months following delivery.

Materials and methods: Postpartum women with a history of depression ($n=166$) completed self-report measures of their sleep (Pittsburgh Sleep Quality Index, PSQI), depression (Edinburgh Postnatal

Depression Scale), and anxiety (Generalized Anxiety Disorder Scale-7), and a parent-report measure of infant temperament (Infant Behavior Questionnaire, IBQ) once per month for 6 months following delivery. The IBQ includes 3 temperament factors: surgency/extraversion (e.g., smiling, activity level), negative affectivity (e.g., sadness, recovery from distress), and orienting/regulation (e.g., duration of oriented attention, low intensity pleasure). The sleep duration and sleep efficiency components and PSQI total score were examined as predictors. Concurrent associations between maternal sleep and infant temperament and interactions with maternal anxiety and depression were tested via 2-level multilevel models. Predictors were person-mean centered at level 1 (month level) and grand-mean centered at level 2 (person level).

Results: Maternal reports of infant surgency/extraversion, negative affectivity, and orienting/regulation significantly increased over time (p 's < .001), and maternal self-reported sleep duration, efficiency, and quality significantly increased over time (p 's < .001). Months with shorter sleep duration and lower sleep quality were significantly associated with higher maternal-reported infant negative affectivity (p 's < .01), and months with shorter sleep duration, lower sleep quality, and lower sleep efficiency were associated with significantly lower maternal-reported infant orienting/regulation (p 's < .05). Mothers who reported lower sleep efficiency and lower sleep quality on average also reported significantly higher infant negative affectivity (p 's < .05). Depression symptoms moderated the effects of sleep efficiency and quality on maternal-reported infant negative affectivity at the person level, such that lower infant negative affectivity was reported by those with lower depression symptoms and higher sleep efficiency (p = .05) and quality (p < .05). Anxiety symptoms also moderated the effect of sleep efficiency on maternal-reported negative affectivity at the person level, such that higher infant negative affectivity was reported by those with higher anxiety and lower sleep efficiency (p < .05).

Conclusions: Maternal perception of infant negative affectivity and orienting/regulation was associated with postpartum maternal sleep disruption. Maternal perception of infant orienting/regulation may be specifically sensitive to acute disruptions in postpartum sleep, whereas maternal perception of infant negative affectivity is linked to both acute and more trait-like maternal sleep disruption. Lower depression symptoms may buffer trait-like effects of maternal sleep disruption on perception of infant negative affectivity, whereas higher anxiety symptoms may be sensitizing. These findings highlight the importance of maternal sleep health for infant outcomes.

Postpartum Sleep Health as a Network: Mapping Multidimensional and Contextual Dynamics

Z. Gou¹, M. Crowther¹, S. Verma^{1,2}, A. Isvoranu³, B. Bei¹

¹Monash University, School of Psychological Sciences, Faculty of Medicine, Nursing, and Health Sciences, Melbourne, Australia, ²Sleepnatal, Melbourne, Australia, ³National University of Singapore, Department of Psychology, Singapore, Singapore

Introduction: In the postpartum period, women experience significant sleep disruptions, affecting not just sleep quality but also how rested, alert, and satisfied they feel. Sleep health is a multidimensional construct encompassing sleep satisfaction, alertness, sleep timing, efficiency, and duration. Despite its multidimensional nature, prior research has largely focused on individual domains, with little attention to the interactions between domains. Moreover, sleep, particularly during the postpartum period, is embedded within a complex interplay of psychosocial contexts. This study aims to model interrelations among sleep health domains and their maternal, infant, and psychosocial correlates.

Materials and methods: Participants were a community sample of nulliparas 4–12 months postpartum. Sleep health was assessed using five domains: (1) Sleep Satisfaction was assessed using two items from the Insomnia Severity Index: sleep dissatisfaction and distress related to sleep. (2) Alertness was assessed using Fatigue Severity Scale, Epworth Sleepiness Scale, and Karolinska Sleepiness Scale. (3) Sleep Timing was calculated via bedtime deviation and rise deviation, which quantified the misalignment between participants' preferred and actual sleep/wake timing. (4) Sleep Efficiency was assessed using sleep onset latency and wake after sleep onset. (5) Sleep Duration was assessed by total sleep time. Maternal cognitive sleep factors included Glasgow Sleep Effort Scale and Dysfunctional Beliefs and Attitudes about Sleep; Infant sleep factors included infant daytime/nighttime total sleep time, sleep onset latency, and wake after sleep onset; Social-support factors included emotional and instrumental support, and proportion of nighttime support.

Network structures were estimated using Gaussian Graphical Model, where nodes represent variables

and edges represent conditional associations after controlling for all other variables in the network. To identify influential variables, strength centrality, bridge centrality, and expected influence were computed.

Results: The study included 329 participants (Mean_{age} = 31.76, SD_{age} = 4.67), with infants averaging 7.04 months old (SD = 2.60). For the sleep health network, the strongest connection was observed between sleep dissatisfaction and sleep-related distress (Satisfaction domain), followed by the association between distress and fatigue (Satisfaction and Alertness), and sleep onset latency and total sleep time (Efficiency and Duration). Nodes ranked highest in both strength centrality and expected influence were distress, fatigue, and dissatisfaction. For the integrated network with sleep health and contextual factors, maternal cognitive sleep factors showed the most extensive associations, particularly with satisfaction, alertness, and efficiency. Infant-related variables were linked primarily to efficiency and alertness, while social support factors had fewer direct connections. Maternal sleep effort demonstrated the highest bridge strength.

Conclusions: Postpartum sleep health is not only multidimensional, but the domains are interconnected. During the first postpartum year, distress with sleep and fatigue played central roles in overall sleep health. Further, amongst maternal, infant, and psychosocial correlates of sleep health examined, sleep effort emerged as a modifiable factor that exerted a strong influence on maternal sleep health. These findings contribute to a growing shift toward an integrated, multidimensional approach to postpartum sleep health. Distress with sleep, fatigue, and sleep effort may be prioritised in as therapeutic targets in sleep health interventions.

Predicting Insomnia Symptoms in University Students Using Machine Learning: The Roles of Stress, Dietary Intake, and Nature Connectedness

Y.F. Poon^{1,2}, S.S. Lau^{1,2}, W.L. Chui^{1,2}, L.H. Lam³

¹Hong Kong Baptist University, Research Centre for Environment and Human Health, School of Continuing Education, Shek Mun Campus, Hong Kong, SAR of China, ²Hong Kong Baptist University, College of International Education, School of Continuing Education, Shek Mun Campus, Hong Kong, SAR of China, ³The Hong Kong Polytechnic University, University Research Facility in Behavioral and Systems Neuroscience, Hung Hom, Hong Kong, SAR of China

Introduction: University students are particularly vulnerable to stress and sleep disturbances as a result of the psychological and adaptive challenges that come with transition to adulthood. The study aims to advance understanding of sleep problems among young people taking into account key risk factors, including stress, dietary intake and nature connectedness.

Materials and methods: A cross-sectional survey was conducted among 420 university students in Hong Kong. The Insomnia Severity Index (ISI) was used to assess the symptoms of insomnia disorder. The Perceived Stress Scale 4 (PSS-4) was used to measure perceived stress. The Short Food Frequency Questionnaire (FFQ) was used to measure dietary intake. Nature Relatedness Scale (NR-6) was used to assess the level of nature connectedness. Additional data on demographics, chronic conditions, alcohol use, smoking, and screen time were also collected. Participants were categorized into two classes: (i) those with clinical insomnia of moderate severity or above (ISI ≥ 15), and (ii) those without clinical insomnia (ISI < 15). To identify key predictors of clinical insomnia, the Extreme Gradient Boosting (XGBoost) machine learning algorithm was applied using Python. The dataset was split into training and validation sets in a 7:3 ratio with stratification. Given the imbalance class distribution within the dataset, the Synthetic Minority Oversampling Technique (SMOTE) was applied to the training data.

Results: Of the 420 participants, 8.6% (*n* = 36) were identified as having moderate or severe clinical insomnia. The mean age of participants was 20.7 years (standard deviation = 1.93), 28.3% were male, and 22.6% reported having a chronic condition. The XGBoost model achieved a balanced accuracy rates of 82% for predicting moderate severity or above clinical insomnia. The most predictive factors, in order of importance, were perceived stress level, whole milk intake, nature connectedness, fresh fruit consumption, and intake of seafood and shellfish.

Conclusions: These findings offer valuable insights into the complex interplay between insomnia, stress, dietary intake, and nature connectedness. The results also highlight the potential of machine learning models to identify individuals at elevated risk of insomnia based on the factors of stress level, dietary intake, and nature connectedness in the future research.

Acknowledgments: The authors thank all participants who took part in this study. Predictive and prognostic markers in the complex screening and diagnosis of Obstructive Sleep Apnea Syndrome

A. Maierian¹, C. Magda², D. Todea¹

¹University of Medicine and Pharmacy Iuliu Hatieganu, Cluj-Napoca, Romania, ²Clinical Hospital of Pneumophthisiology "Leon Daniello", Cluj Napoca, Cluj-Napoca, Romania

Introduction: Obstructive sleep apnea syndrome (OSA) is a common but often underdiagnosed sleep disorder characterized by repeated interruptions in breathing during sleep, followed by intermittent decreases in oxygen saturation. Consequently, people with OSA experience fragmented sleep, multiple nocturnal and daytime symptoms, with a significant negative impact on their general health and quality of life.

Given the important complications of this pathology and its increased prevalence in the general population, the developed diagnostic methods and the difficult access to them, it is necessary to create preventive models by identifying the predictive factors of this pathology, in order to increase awareness and expand the possibilities of investigation of this pathology.

Materials and methods: The study group included a number of 30 consecutively selected patients, with an increased risk of sleep apnea quantified by the STOP-BANG questionnaire and the Epworth Sleepiness Scale (ESS). The data studied included: anthropometric measurements, the presence of comorbidities, nocturnal cardiorespiratory polygraphy parameters, the level of fractional nitric oxide in exhaled air (FeNO) and the mean and maximum level of End Tidal CO₂ (EtCO₂) assessed by continuous nocturnal capnography.

Results: The majority of patients had at the diagnosis excessive daytime sleepiness (ESS > 10 points). In the analyzed group, the mean age at the time of diagnosis was 55.60±10.55 years, with a predominance of male gender and 63.3% had at least one associated cardiovascular pathology. The mean level of FeNO in the studied group was 26.03±17.387 ppb, without being influenced by the presence of comorbidities, SASO severity or body mass index (BMI). The mean level of EtCO₂ was 44.70 ±3.879 mmHg, 43% of the subjects having values above the physiological limit.

There was a statistically significant correlation between BMI and ESS (p=0.001) and also between apnea-hypopnea index (AHI) (p=0.001) and the presence of cardiovascular comorbidities (p=0.004). In addition, it was observed that patients with severe OSA had higher EtCO₂ levels compared to those with moderate OSA (p=0.001), and there was a statistically significant correlation between Desaturation Index (ODI), Time spent at oxygen saturation ≤90% (T90%) and EtCO₂ level (p=0.001 and p=0.001, respectively). Following the study, statistically significant relationships between anthropometric indices and OSA severity were reported in the group of patients diagnosed with OSA, and as a predictive and severity marker, EtCO₂ plays a central role, having higher levels in patients with severe OSA and important desaturations which associated obesity.

Conclusions: Nocturnal monitoring of CO₂ levels can play a crucial role in the complex evaluation of patients with obstructive sleep apnea syndrome, especially in those with identified risk factors (obesity, associated cardiovascular pathology). The use of this parameter in current clinical practice can facilitate the adjustment of an appropriate, individualized treatment and reduce the risk of associated complications.

Detailed analysis is required, on large groups of patients, in order to study the complex relationships between these identified markers (FeNO, EtCO₂) and the severity of obstructive sleep apnea syndrome, the presence of comorbidities with the aim of developing effective screening and diagnostic models.

Preliminary Efficacy of Transdiagnostic Intervention for Sleep-Circadian dysfunction adapted for common mental disorders: A case series

J.A. Johnson¹, P.M. Sudhir¹, S. Sundar A.¹, R. Yadav¹

¹National Institute of Mental Health and Neurosciences, Department of Clinical Psychology, Bangalore, India

Introduction: Sleep and common mental disorders contribute to global public health challenges. Sleep has been established as a modifiable transdiagnostic contributor in the onset and maintenance of psychopathology. The role of sleep in influencing the illness trajectory, with effects on frequency of relapses, severity, and duration of episodes, calls for interventions targeting sleep across mental health conditions. The Transdiagnostic Intervention for sleep-circadian dysfunction (TranS-C) adopts a sleep health promotion perspective and was adapted in individuals with common mental disorders to reduce the dilemma of sequentially or concurrently targeting sleep. While previous studies have looked at sleep through the lens of Cognitive behavioural therapy for insomnia with individuals with primary insomnia and associated comorbidities, the TranS-C operates from a transdiagnostic preventative lens rather than a medical model. Previous research suggests that apart from behavioural symptoms, maladaptive cognitive processes—such as dysfunctional beliefs about sleep, repetitive negative thinking (RNT), and perfectionistic tendencies—play a key role in the bidirectional relationship between sleep and mood.

Materials and methods: The feasibility and preliminary efficacy of an adapted TranS-C protocol are displayed through a case series of five adults with common mental disorders (CMD), recruited from outpatient services at a tertiary mental health hospital. Individuals with a CMD meeting a cut-off score of > 5 (indicating sleep disturbances) in the Pittsburgh Sleep Quality Index and who had stabilisation of medication for four weeks were recruited. Outcome measures included sleep quality, mood (depression and anxiety symptoms), RNT, dysfunctional beliefs about sleep, and self-efficacy. Participants received 10-12 weekly sessions incorporating cognitive-behavioural strategies and psychoeducation targeting shared sleep and mood mechanisms. The outcomes were measured at pre-, post-, and follow-up of 3 months.

Results: The individuals recruited had primary diagnoses of health anxiety, recurrent depressive disorder, generalised anxiety disorder, PTSD in remission, and chronic insomnia. Negative affect and rigid perfectionism were common personality domains observed in the sample. The findings indicate a significant change in mood and sleep disturbance severity post-intervention. Additionally, there was a reduction of repetitive negative thinking, dysfunctional beliefs and an increase in cognitive flexibility and self-efficacy that was seen post-intervention.

Conclusions: These findings provide preliminary evidence for the utility of the modular, transdiagnostic intervention for individuals with CMDs and comorbid sleep-circadian dysfunction. The promising outcomes underscore the importance of targeting shared cognitive-affective mechanisms and support the need for future controlled trials to establish efficacy and generalizability. Moreover, addressing sleep-circadian dysfunction as a modifiable factor may enhance treatment outcomes and illness trajectories for individuals with comorbid and complex mental health challenges.

Acknowledgments: The first author would like to acknowledge the Institute for fellowship support for her PhD.

Preliminary Findings on Sleep Patterns in Working Women of Menopausal Generation in Japan

M. Arima¹, Y. Edagawa², K. Suzuki³, N. Shirato⁴, C. Kawahara⁵, Y. Miwa⁶

¹Showa Medical University, Department of Medical Education, School of Medicine, Tokyo, Japan,

²Ritsumeikan University, Graduate School of Technology Management, Osaka, Japan, ³Aichi Medical University, Department of Health and Psychosocial Medicine, Aichi, Japan, ⁴Showa Medical University, Department of Obstetrics and Gynecology, Tokyo, Japan, ⁵Teikyo University, Simulation Center, Tokyo, Japan, ⁶Women's Healthcare Awareness & Menopause Network Society, General Affairs Department, Tokyo, Japan

Introduction: Currently, approximately 40% of working women in Japan are in their mid-40s to 50s, which corresponds to the menopausal age group. This demographic also shows a high rate of labor force participation. Therefore, supporting the health and well-being of this population is considered crucial to maintaining overall workforce productivity. However, many women experience difficulties balancing menopausal symptoms with work, and sleep-related issues in particular have been reported to affect job performance. In this study, we present our interim findings from a project funded by the

Japan Agency for Medical Research and Development, which investigates the impact of menopausal symptoms on work productivity. Specifically, we report on the measurement of sleep status among working women in the menopausal age group. The objectives of this investigation are to assess sleep disturbances as menopausal symptoms and to clarify their impact on work productivity.

Materials and methods: The study aims to include 50 working women in their 20s to 30s as a comparison group, and 50 working women in the menopausal age group (40s to 60s) as the primary study population. Participants put on a wearable, simplified electroencephalogram device. The SmartSleep™ device (Philips, Koninklijke Philips N.V., the Netherlands) used in this study was placed on the women's heads during sleep for approximately three weeks, from bedtime to wake-up time. The device is connected to a smartphone, which collects sleep data such as sleep depth and sleep duration. One week after the start of the measurement and again at the end of the two-week measurement period, participants completed web-based questionnaires regarding their subjective sleep quality, sleep duration, and work productivity. The study commenced in December 2024 and is scheduled to be conducted over five terms. To date, two waves have been completed.

Results: A total of 16 participants were included in the first wave and 19 participants in the second wave. In the first wave, 44% were in their 40s and 56% in their 50s. In the second wave, 46% were in their 40s, 34% in their 50s. The self-reported average sleep duration was 359 minutes in the first wave and 383 minutes in the second wave. However, the actual measured sleep duration was 281 minutes in the first wave and 283 minutes in the second wave, indicating a discrepancy between perceived and actual sleep duration. The proportion of deep sleep was 37.5% in the first wave and 31.3% in the second wave. The presenteeism score, assessed using the WHO-HPQ (World Health Organization Health and Work Performance Questionnaire), was 59.4 in the first wave and 61.6 in the second wave.

Conclusions: These results provided an overview of the sleep conditions, including deep sleep, among women in the menopausal age group. We plan to complete the remaining study waves and accumulate further data to compare menopausal and younger women. We also aim to clarify the relationship between menopausal symptoms, sleep conditions, and work productivity.

Acknowledgments: This study was funded by the Japan Agency for Medical Research and Development (AMED). We also thank all the participants for their valuable contributions.

Prenatal Parental and Partner Sleep Predict Coparenting Quality Across the First Year Postpartum

L. Bai¹, B. Crosby², L. Tikotzky³, M. Feinberg², D. Teti²

¹Capital Normal University, Beijing, China, ²The Pennsylvania State University, University Park, United States, ³Ben-Gurion University of the Negev, Beer-Sheva, Israel

Introduction: Linkages between poor sleep and impairment of individuals' daily functioning are well-established. However, research examining the impact of sleep on family functioning is limited. Building upon previous work linking sleep with parenting (Bai et al., 2020, 2025; King et al., 2020), and the ecological model of coparenting (Feinberg, 2003), the current study investigated how prenatal parental and partner sleep predicts coparenting during the first year postpartum, with infant sleep and other relevant variables statistically controlled. Adopting a family systems approach (Cox & Paley, 1997), both parents' and partners' sleep patterns were considered in the examination. By focusing on prenatal sleep, we aim to document prenatal markers that providers can use to identify and support families vulnerable to coparenting challenges before delivery.

Materials and methods: 210 First-time expectant mothers (≥18 years) and their partners participated in an NIH-funded randomized controlled trial evaluating coparenting interventions. Parental prenatal sleep across 7 consecutive days was assessed using AW-64 actiwatches in the 3rd trimester. Because sleep is multi-faceted, several sleep indicators were considered, including *fall asleep time*, *wake minutes after sleep onset* (WASO; total awake minutes from fall asleep time to wake time), *total sleep time* (TST; the elapsed time from fall asleep time to wake time subtracted by WASO) averaging across 7 days, and *variability in sleep duration* (VSD, the standard deviation of TST across 7 days). At 1, 3, 6, and 12 months postpartum, mothers and fathers separately reported their coparenting perceptions via the Coparenting Relationship Scale (Feinberg et al., 2012), with higher scores indicating better perceived overall coparenting.

Results: Longitudinal actor-partner interdependence models within a multilevel modeling framework were conducted to examine the interactive effects of parental and spousal prenatal sleep on postnatal coparenting perceptions. Fathers reported higher coparenting quality than mothers on average ($p <$

.05), and coparenting satisfaction decreased over time in both parents. After controlling for infant TST, prenatal coparenting expectations, prenatal depression, race, family sociodemographic risk, and intervention status (control vs. intervention), parental and partner TST interacted to predict change in coparenting across 1 to 12 months ($p = .01$). Specifically, families where both parents had longer prenatal TST reported higher initial coparenting quality, and this advantage persisted over time. In contrast, families where both parents had shorter prenatal TST reported lower 1-month coparenting that remained consistently lower over time. Notably, families where only one parent had short TST showed significant decreases in coparenting quality over time. Additionally, greater prenatal VSD in parents but not partners was independently predictive of poorer postnatal coparenting experiences, with the effect remaining stable across time. No effect of prenatal WASO, fall asleep time, or any infant sleep variable on coparenting was obtained.

Conclusions: Our findings suggest that parental sleep patterns can be an easily assessed marker for identifying families at risk for coparenting difficulties before delivery. Our results suggest that coparenting transition-to-parenthood interventions can benefit from targeting prenatal sleep health in parents before they transition to first-time parenthood.

Prevalence and Psychological Profiles of Comorbid Obstructive Sleep Apnoea and Post-Traumatic Stress Disorder in a UK General Population Sample

N. Mumenah^{1,2,3}, I. Hartescu¹, D.J. Morris^{4,5}, J.B. Barker¹

¹Loughborough University, School of Sport, Exercise and Health Sciences, Loughborough, United Kingdom, ²Department of Respiratory Therapy, College of Applied Medical Sciences, King Saud bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia, ³King Abdullah International Medical Research Centre, Riyadh, Saudi Arabia, ⁴The Centre for Developmental and Complex Trauma, St. Andrews healthcare, Northampton, United Kingdom, ⁵University of Buckingham, Medicine and Life Sciences, Buckingham, United Kingdom

Introduction: Post-Traumatic Stress Disorder (PTSD) impacts 4% of UK and 5.6% of adults worldwide. PTSD is strongly linked to sleep disorders, including Obstructive Sleep Apnoea (OSA). Emerging evidence suggests a bidirectional relationship between OSA and PTSD, with overlapping hyperarousal mechanisms exacerbating both conditions. Evidence also suggests the risk of OSA in people with PTSD may have a differential profile to developing OSA. This study examines the prevalence and psychological profiles of comorbid OSA and PTSD in a UK general population sample.

Materials and methods: Three-hundred-eighteen adults (75.8% female; 29.9% aged 34-44 years) completed validated online questionnaires, including the STOP-BANG (OSA risk), PCL-17 (DSM-5 PTSD symptoms classification), PSAS (pre-sleep arousal), ESS (daytime sleepiness), HADS (depression and anxiety), B-PSQI (sleep quality), and EQ-5D-5L (quality of life). Participants were grouped into OSA-only risk (low, intermediate, and high) and OSA+PTSD categories. Chi-square tests were used to examine associations between group classifications and key demographic or psychological factors.

Results: Prevalence: 87.7% of participants were PTSD-symptomatic. High OSA risk (STOP-BANG ≥ 5) occurred in 13.3% of PTSD-symptomatic individuals whereas 5.1% non-symptomatic ($\chi^2=7.899$, $P=0.019$).

Demographic profile:

Males predominantly belonged to (OSA+PTSD), particularly in the high-risk OSA and symptomatic PTSD (35.3% of males), ($\chi^2=79.80$, $P < 0.001$, $ES = 0.354$). Additionally, 77.8% of high-risk OSA and symptomatic PTSD participants were <45 years vs. 50% >45 in OSA-only ($\chi^2=79.04$, $P < 0.001$). Median BMI was significantly higher in (OSA+PTSD) (36.41 kg/m^2) vs. OSA-only (25.71 kg/m^2 ; $P < 0.001$).

Psychological characteristics:

Pre-sleep arousal: Somatic arousal affected 98.1% of (OSA+PTSD) in contrast to 73.3% OSA-only ($\chi^2=43.989$, $P < 0.001$).

Daytime sleepiness: Among those with severe excessive daytime sleepiness, 25.0% were classified in the high-risk OSA symptomatic PTSD, while no participants with this level of sleepiness were in the OSA-only group, ($\chi^2(20) = 37.79$, $P = 0.009$, $ES = 0.172$).

Psychological Distress: Individuals with both anxiety and depression were predominantly classified in the (OSA+PTSD) (44.5%), while those with no anxiety or depression were more likely to be in the OSA-only group (30.6%), ($\chi^2(15) = 72.98$, $P < 0.001$, $ES = 0.277$).

Sleep Quality: Poor sleep quality (B-PSQI > 5) was more prevalent in the (OSA+PTSD) group,

particularly in the high-risk OSA symptomatic PTSD subgroup (13.1%) and the intermediate- OSA risk symptomatic PTSD subgroup (29.8%), ($\chi^2(5) = 15.68, P = 0.008, ES = 0.222$).

Quality of Life: “Poor” quality of life was reported exclusively by individuals in the (OSA+PTSD) group (20.0% in both intermediate- and high-risk symptomatic subgroups), while no participants in the OSA-only group reported poor quality of life, ($\chi^2(15) = 43.81, P < 0.001, ES = 0.314$).

Conclusions: Individuals with comorbid OSA and PTSD represent a distinct psychological and health profile, marked by younger age, male predominance, elevated BMI and heightened somatic arousal. They also exhibit greater psychological distress, excessive daytime sleepiness, and significantly poorer quality of life. findings underscore the urgent need for comprehensive screening protocols to go beyond traditional OSA risk factors, particularly in individuals with PTSD. Early identification and integrated treatment approaches targeting both conditions are essential to reduce the cumulative burden of this complex phenotype and improve health outcomes.

Prevalence, profile and perioperative outcomes of patients with Obstructive Sleep Apnea in a Low-resource center

A. Ojo¹, M. Komolafe², T. Ojumu¹

¹Obafemi Awolowo University Teaching Hospitals Complex, Anaesthesia and Intensive care, Ile-Ife, Nigeria, ²Obafemi Awolowo University Teaching Hospitals Complex, Internal Medicine (Neurology), Ile-Ife, Nigeria

Introduction: OSA is a major but under-recognised public health disorder in Africa.^{1,2} Genetic and cultural factors make Blacks to be susceptible. OSA is associated with significant perioperative morbidity.² Useful data from LRCs are scarce, leading to sub-optimal care.

Objectives: To determine the OSA prevalence among surgical patients, associated factors, cultural variables, and perioperative outcomes, in a low-resource center.

Materials and methods: Methods: This mixed-methods study was conducted at a level-3 teaching hospital in Nigeria. Through convenience sampling, we retrieved 264 records of surgical patient. Data were cleaned, sorted, and summarised using the IBM SPSS 25.0. These include demographics, socioeconomic status, BMI, co-morbidities, STOP-BANG questionnaire score, PSG or HSAT OSA diagnosis, access to CPAP device, history of corrective surgery e.g., UPPP, anaesthesia technique, and surgical outcomes e.g., difficult airway, delayed recovery, postoperative hypoxia, and unplanned ICU admission. Quantitative analysis employed descriptive statistics i.e., frequencies, and mean, inferential tests i.e., chi-square test was used for categorical associations, and logistic regression was used for outcome predictors. Qualitative data included cultural beliefs, sleep patterns, duration and other profile, feeding practices, and use of traditional medicine. Thematic analysis involved manual coding. Mixed-methods integration summarised quantitative and qualitative data. The strength of the study is methodological triangulation, while limitations are convenience sampling bias and retrospective design.

Results: This retrospective analysis of 264 surgical cases revealed a 28.8% (n=76) OSA prevalence via STOP-BANG questionnaire screening. No patient had PSG or HSAT sleep study for OSA diagnosis. OSA was statistically associated with obesity (p=0.001, aOR 3.2, 95% CI 2.1-5.0), low socioeconomic status (p=0.001, aOR 2.6, 1.5-4.3), hypertension (p=0.001, aOR 1.9, 1.2-3.1), and sedentary lifestyle (p=0.001, aOR 2.2, 1.3-3.6), while smoking showed no association (p > 0.05, aOR 1.1, 0.8-1.5). Strikingly, 72% of screened patients prefer traditional medicine, resulting in delayed presentation (mean symptom period: 4.2±1.8 years). Surgical management was limited to tonsillectomy in 15.5% (n=41), with no patients receiving UPPP, MMA, or perioperative CPAP use. Among OSA patients (n=76) undergoing non-OSA surgeries, general anaesthesia (35.5%, n=27) showed statistically higher complication rates vs regional anaesthesia (63.2%, n=48): difficult intubation (12.9% vs 0%, p<0.001), postoperative hypoxia (21.2% vs 3.8%, p=0.002), and unplanned ICU admission (9.1% vs 2.3%, p=0.018).

Conclusions: This study highlights critical gaps in OSA care Nigeria. Lack of access to sleep studies suggest system failure. STOP-BANG is used for OSA screening and diagnosis. Strong association with obesity, and hypertension underscores need for integrative screening programs. Increased community education, access to sleep studies, and CPAP device will transform surgical outcomes in resource-limited settings.

CPAP: continuous positive airway pressure

Prevalence, Risk Factors, Harm Perception, Attitude and Effect on Sleep Quality Towards Sugar Consumption Among University Students in Lebanon: A Cross-Sectional Study

A. Nassar¹, W. Trad¹, B. Naseri¹, T. Sawan¹, L. Francis¹, C. Tauk¹, M. Abou Chedid¹, C. Salameh¹, S. Assaad¹

¹Holy Spirit University of Kaslik (USEK), School of Medicine and Medical Sciences, Jounieh, Lebanon

Introduction: Sleep has been a major concern among university students and may be influenced by dietary factors. With increased ready-made foods and sugar dense meal consumption, students are more frequently exposed to high levels of added sugars which has been linked to poor sleep outcomes and health. This study aims to assess the prevalence, risk factors, harm perception, and attitude of sugar consumption and its correlation with sleep quality among Lebanese university students.

Materials and methods: In a cross-sectional study of 404 Lebanese university students age range from 18 to 34, sleep quality was measured using Pittsburgh sleep quality index (PSQI), a 16-item questionnaire (score range 16–65, where higher scores indicated better sleep). Food Frequency Questionnaire (FFQ) and Beverage Questionnaire (BEVQ-15) were used to assess dietary sugar intake via a composite score derived from cereals, sweets, snacks, and sweet beverages (score range 24–195, where higher scores indicated greater sugar intake).

Results: Data normality was confirmed with skewness and kurtosis assessments, and Pearson correlation analysis revealed a significant inverse relationship between sugar consumption and sleep quality ($r = -0.256$, $p < 0.001$). Moreover, simple linear regression analysis indicated that each one-unit increase in the sugar consumption score corresponded to a 0.09 point decrease in sleep quality, with the model accounting for approximately 7% of the variance.

Conclusions: These findings suggest that higher intake of added sugars is independently associated with poorer sleep quality among Lebanese university students, identifying dietary sugar as a modifiable risk factor for sleep disturbances and supporting the need for targeted nutritional interventions and further longitudinal research using objective sleep measures.

Process evaluation of the implementation of a participatory developed school-based healthy sleep intervention in adolescents

A. Vandendriessche¹, K. Leta¹, M. Verloigne¹, B. Deforche¹

¹Ghent University, Gent, Belgium

Introduction: Insufficient sleep among adolescents negatively impacts their mental and physical health. This study evaluates the process (delivery, participation, experience, context, maintenance and perceived impact) of a participatory developed healthy sleep intervention to provide insight into the underlying mechanisms of intervention effects and to formulate recommendations for future healthy sleep interventions in adolescents.

Materials and methods: After implementation in three secondary schools, questionnaires were administered in students ($n = 1075$), teachers ($n = 13$) and parents ($n = 55$). In addition, 14 focus group interviews with students ($n = 92$) and three individual interviews with school management were conducted. SPSS and NVivo were used for descriptive and thematic content analyses.

Results: Participants were generally satisfied with the intervention. Intervention components that were visible within the school context (i.e. kick-off event, posters, gadgets, class competition with Fitbits) were considered most successful since they sparked conversations about sleep. Opportunities for social comparison (e.g., class discussions, polls on Instagram) and tailoring of materials to the school context (e.g., picture of a teacher on poster) were appreciated by students. Contextual factors, including staff workload and lack of structural support, negatively affected implementation.

Implementers reported a lack of adequate information to implement intervention components, which resulted in low dose delivered for some intervention components (e.g., mobile application, classes about sleep). For sustained integration, clear roles, adequate support, and motivated staff are essential.

Conclusions: The intervention was generally well received. The participatory approach ensured that intervention components matched adolescents' living environment and the school context, but involving implementers earlier in the participatory process of implementation planning could optimize implementation.

Acknowledgments: I would like to thank the participating schools, students, school personell, and parents.

Proposal of a Novel Sleep Evaluation Index Utilizing Metabolic Dynamics During Sleep

K. Oyama¹, T. Kikuchi², S. Imazu², K. Yamamoto¹, M. Nokata¹, K. Kishimoto¹, M. Makikawa¹, N. Shiozawa¹, S. Okada¹

¹Ritsumeikan University, Shiga, Japan, ²INOAC CORPORATION, Living Business Division Planning departmant, Nagoya, Japan

Introduction: Recent studies have highlighted the impact of sleep quality on physical performance and quality of daily life (QOL). High-quality sleep, in particular, is essential for muscle repair, fatigue recovery, health maintenance, and enhancement of athletic performance (Charest J et al., 2020). However, conventional sleep research has mainly assessed sleep quality through sleep depth measured by polysomnography, leaving actual metabolic processes and concrete degrees of physical recovery largely unexplored. This study focuses on metabolic change as a core indicator of bodily recovery, aiming to quantitatively analyze metabolic dynamics during sleep and to propose metabolic indices that complement conventional sleep evaluation.

Materials and methods: Nine healthy adult men participated. Two mattress types—selected for their potential influence on sleep quality and physical recovery—were tested: (i) the FACET mattress, manufactured by INOAC Corporation and featuring a hexagonal-slit structure reported to promote efficient rolling, improve pressure distribution, and maintain posture during sleep (FACET condition); and (ii) a control mattress of identical material but without slits (standard condition). Each participant underwent two nights of sleep experiments under each condition. The measured parameters were heart rate, autonomic nervous system indices, metabolic rate, and body movement; we compared the effects of mattress type on each parameter and on the interrelationships among these parameters.

Results: Under the FACET condition, heart rate and metabolic rate decreased and body movement was suppressed during N3 sleep. The reduction in metabolic rate was especially pronounced, and both decreases were statistically significant according to the Mann-Whitney U test ($p < 0.01$). During N2 sleep, heart rate was comparable to the standard condition, whereas metabolic rate fell significantly ($p < 0.01$) and body movement increased significantly ($p < 0.01$). In REM sleep, where bodily activity is commonly suppressed, heart rate rose significantly ($p < 0.01$), while metabolic rate and body movement both decreased significantly ($p < 0.01$). Autonomic nervous system indices—often used as conventional sleep indicators—showed no substantial differences between mattress conditions.

Conclusions:

Under the experimental condition of using different mattresses, metabolic indices captured changes in sleep state during the N2 and N3 stages more sensitively than heart-rate or autonomic nervous-system indices. The simultaneous reduction in metabolic rate and body movement during REM sleep under the FACET condition likely reflects better posture maintenance and reduced antigravity muscle activity afforded by the hexagonal-slit structure. The accompanying rise in heart rate and the absence of change in autonomic indices suggest that conventional bio-signal-based metrics may overlook certain metabolic responses. These findings indicate that integrating metabolic indices with traditional

methods could enable more direct evaluation of recovery processes, offering a new perspective for assessing factors—such as mattress mechanical properties—that physically interact with the body.

Proposing a definition for sleep disorders

J.-A. Micoulaud-Franchi¹, J. Wakefield², C. Gauld³

¹Bordeaux University, Neurosciences, Bordeaux, France, ²New York University, Bioethics, New York, United States, ³Université Claude Bernard Lyon 1, Child and Adolescent Psychopathology, Lyon, France

Introduction: To establish an overarching definition of what constitutes a sleep disorder, it is essential to know which health conditions should be included in the classifications of sleep disorders and to better distinguish the normal from the pathological in sleep medicine. This would bring together several professional organizations in their understanding of this hitherto heterogeneous concept. However, no consensus regarding a general definition of a sleep disorder currently exists.

Materials and methods: We explore two of the main frameworks used in medical epistemology that could be used to define sleep disorders rigorously: harmful dysfunction analysis (HDA) and symptom network theory.

Results: For each framework, we detail the conceptual background, the method for applying it to the establishment of a general definition of a sleep disorder, the application to main sleep disorders of the ICSD-3-TR (with an emphasis on insomnia disorder) and a discussion of the main aspects of these two general definitions in the context of sleep medicine.

Conclusions: The complementarity between the two definitions could then be considered as an "epistemic hub" which could serve to clarify the debate about what sleep disorders are, so that our understanding of them and their clinical management improve.

Psychosocial determinants of sleep health among university students: a structural equations modeling approach

S. Fakroune^{1,2}, H. Ivers¹, S. Van den Broucke², C. Morin¹

¹Laval University, Centre d'étude des troubles du sommeil, Québec, Canada, ²Université Catholique de Louvain, Psychological Sciences Research Institute, Louvain-la-Neuve, Belgium

Introduction: Students are more at risk to develop sleep difficulties which could impact their health, mental health and academic performances. To address sleep issues before they reach clinical threshold, studying sleep health, an emerging concept in the literature, seems relevant. It considers sleep as a multidimensional construct which varies along a continuum, bringing nuance to the interpretation of individual sleep. This study aims to explore psychosocial determinants of sleep health among university students, using a socioecological approach.

Materials and methods: An online survey was sent to students (aged from 18 to 30 years old) registered at Laval University during the autumn semester. Those with a major medical condition or using medication to help them sleep were excluded from the study. The data were collected outside exam periods. This survey included questionnaires collecting information about sociodemographic, sleep health, sleep hygiene, sleep beliefs (using the Theory of Planned behavior), mental health (i.e. anxiety, perceived stress), health literacy, and social support. Prior to the statistical analyses, the data were weighted to be representative of the student population. Statistical analyses were then carried out to verify the goodness of fit of the proposed theoretical model, as well as a more in-depth analysis of the predictive and moderating factors.

Results: Valid data were provided by 524 participants. The model demonstrated a good overall fit to the data, and several hypothesized trajectories were supported. Specifically, poor sleep hygiene significantly predicted sleep health ($\beta = -.29, p < .01$), anxiety predicted sleep health as well ($\beta = -.26, p < .01$), behavioral control predicted both behavioral intention ($\beta = .30, p < .01$) and poor sleep hygiene ($\beta = -.28, p < .01$), behavioral intention predicted poor sleep hygiene ($\beta = -.13, p < .05$), and attitude predicted behavioral intention ($\beta = .14, p < .01$). Conversely, some expected associations were not confirmed: perceived norms and their importance did not predict behavioral intention; and perceived stress was not a direct predictors of sleep health. However, three unexpected significant pathways emerged: behavioral intention directly predicted sleep health ($\beta = .18, p < .01$), perceived stress predicted behavioral intention ($\beta = .25, p < .01$), and anxiety predicted poor sleep hygiene ($\beta = .39, p < .01$). In addition, moderation effects were observed. Employment status moderated the relationship between anxiety and sleep health, with stronger effects among students who had a job. Health literacy moderated the model with stronger perceived stress and anxiety effects for students with low literacy and stronger behavioral control effect for students with high literacy.

Conclusions: The psychosocial determinants examined in this study play a key role in students' sleep health. Anxiety has both direct and indirect effects, particularly among students combining work and studies, while perceived stress mainly strengthens intentions without directly improving sleep. Behavioral control strongly shapes intentions and sleep hygiene, whereas attitude and social norms play a limited role. Health literacy enhances the protective role of behavioral control and reduces the negative impact of stress and anxiety, especially among students with lower literacy. These findings highlight the relevance of interventions targeting both anxiety and sleep hygiene, while promoting students' perceived control. Finally, as intention poorly predicted sleep hygiene, futures studies should focus on specific sleep-related behaviors.

Quadratic Effects of Harsh Parenting on Changes in Children's Sleep During the Transition to Early-Adolescence

M. Thompson¹, B. Ache Akua¹, R. Kelly², M. El-Sheikh¹

¹Auburn University, Department of Human Development and Family Science, Auburn, United States,

²University of New Mexico, Department of Individual, Family and Community Education, Albuquerque, United States

Introduction: The family context is proposed to play a critical role in creating an optimal sleep environment (high levels of security, low arousal) (Worthman & Melby, 2002). Although harsh parenting has been identified as a risk factor for children's sleep problems, this work has strictly examined linear associations (Bell & Belsky, 2008; Kelly et al., 2014). Emerging work in the broader family risk literature indicates that effects of harsh parenting may be nonlinear (Hidalgo et al., 2023). Risk saturation (Morris et al., 2010) and family risk models (Davies et al., 2022) suggest prolonged exposure to intense levels of harsh parenting may activate processes designed to prevent sustained arousal in ways that decouple risk and development. Advancing this area of research, we utilized a two-wave longitudinal design to examine linear and quadratic effects of harsh parenting on change in children's actigraphy-derived sleep during the transition to early-adolescence.

Materials and methods: Children ($N=339$; Wave1: $M_{age}=9.44$ years, 48% girls, 65% White, 35% Black) and their parents, from socioeconomically diverse backgrounds in the southeastern USA, participated in two waves of data collection spaced two years apart. Harsh parenting was assessed via mothers' and fathers' report on the well-established Parent-Child Conflict Tactics Scale (Straus, 1999). Sleep is a multifaceted construct and while sleep parameters may overlap (Buysse, 2014; Sadeh, 2015), they represent distinct facets with differing developmental and clinical implications (Boatswain-Jacques et al., 2023; Park et al., 2019). Accordingly, we assessed several well-recognized sleep parameters. Sleep was measured objectively with actigraphy over one week to derive measures of sleep minutes (total number of minutes scored as sleep between sleep onset and wake time), efficiency (percentage of sleep time between onset and wake time), and activity (percentage of epochs during the night with activity). Children also self-reported on sleep-wake problems over the past two weeks (School Sleep Habits Survey; Wolfson & Carskadon, 1998).

Results: We examined effects of harsh parenting on changes in children's sleep over two years controlling for race, sex, body mass index, family income, and marital problems. No linear effects of harsh parenting emerged. There were significant quadratic effects of harsh parenting on sleep minutes

($p=.05$), efficiency ($p=.02$), and activity ($p=.04$). Increases in harsh parenting from low to moderate levels corresponded with decreases in sleep minutes and efficiency. As harsh parenting reached high levels, declines in sleep minutes and efficiency plateaued. Increases in sleep activity corresponded with increases in harsh parenting from low to moderate levels. Negative effects on sleep activity plateaued as harsh parenting reached high levels.

Conclusions: Novel findings illustrate that prospective relations between harsh parenting and children's sleep may be quadratic. At low to moderate levels of harsh parenting, sleep worsened. At high levels of harsh parenting, associations with less-optimal sleep attenuated; this pattern is consistent with risk saturation perspectives suggesting that prolonged exposure to intense levels of familial risk may activate processes designed to prevent chronic arousal. Findings highlight the importance of considering nonlinear associations in investigations between family risk and sleep.

Racial Disparities in Perceived Social Support and Sleep Quality Among College Students

E. Arana¹, C. Chovanes², A. Spaeth²

¹Rutgers Cancer Institute, Medicine, New Brunswick, United States, ²Rutgers University School of Arts and Sciences, Kinesiology and Health, New Brunswick, United States

Introduction: Insufficient sleep is a public health problem among college students. Approximately 71% of college students sleep less than eight hours per night, and one-third of students have trouble falling asleep at least once a week. Social support has been posited as a contributor to sleep quality. This study aims to determine whether perceived social support correlates with sleep quality among college students and whether these relationships differ by racial group.

Materials and methods: This is an observational, cross-sectional survey study. Traditional college-age students (18-23 years) who attend a large, public university were recruited in the lobbies of classroom buildings and student centers, Sunday through Saturday. Participants completed the Personal Resource Questionnaire (PRQ) and Pittsburgh Sleep Quality Index (PSQI) on a tablet. Higher scores on the PRQ indicate stronger social support while lower scores on the PSQI indicate better sleep quality. Descriptive statistics, chi-square tests, and Spearman's rho correlations were conducted.

Results: A total of 296 participants were enrolled in this study (51.7% White, 24.3% Asian, 24.0% Black). The mean age was 19.6 (SD=1.3). Most participants were female (63.8%), non-Hispanic (88.2%), and lived on campus (55.7%). Most participants shared a room (58.4%), were on financial aid (59.8%), and were unemployed (51.9%). Black and Asian students had lower perceived social support compared to White students (mean scores=136.1, 134.5, and 141.6, respectively, $p=0.04$), with no significant differences between Black and Asian students. Among the entire sample, perceived social support correlated with sleep quality such that higher perceived social support was associated with better sleep quality ($r=-0.28$, $p<0.001$). Black students had the strongest negative correlation between perceived social support and sleep quality ($r=-0.38$, $p<0.005$) compared to the correlation among White students ($r=-0.33$, $p<0.001$) and Asian students ($r=-0.20$, $p<0.11$). Black students were significantly less likely to report sleeping at least 7 hours/night than Asian or White students (25.7% vs 40.0% vs 47.9%, respectively; $p=0.002$).

Conclusions: This study highlights significant racial disparities in perceived social support and its association with sleep quality among college students. Colleges should consider offering programs to increase social support, particularly for Black students, as one way to potentially improve sleep quality.

Acknowledgments: This study was funded by the Aresty Research Center, Rutgers University, New Brunswick, NJ.

Real-World Observation of a Multi-Modal Smart Sleep Wellness Device: Sleep Quality Changes in a Consumer Population

L. Wai Nan¹, D.L. Geng Yan²

¹AM LIFE INTERNATIONAL SDN BHD, Product Department, Puchong, Malaysia, ²Jasper Lodge Nursing homes, Petaling Jaya, Malaysia

Introduction: This observational study evaluated the real-world effects of a smart sleep wellness device from Japan, developed by AmLife. The device, referred to as an Electric Potential Therapy (EPT) Device, integrates three key modalities—electric potential therapy, thermal therapy, and natural environmental sounds (such as ocean waves and bird calls)—along with calming audio frequencies, all embedded within a mattress designed to naturally enhance sleep comfort and overall well-being. The study was sponsored by AmLife and conducted in natural home environments.

Materials and methods: Sixty adults with mild sleep disturbances (PSQI > 5) were enrolled through rolling recruitment cycles, with each participant using the device nightly for 10 consecutive days. Subjective outcomes included the Pittsburgh Sleep Quality Index (PSQI), Epworth Sleepiness Scale (ESS), and Perceived Stress Scale (PSS). Objective outcomes were obtained from the Go2Sleep wearable device, with sleep efficiency analyzed as the primary parameter.

All data were anonymized and securely stored. Trend and correlation analyses will be conducted using paired t-tests or generalized linear mixed models (GLMM), implemented in Python 3.11.9 or SAS 9.4.

Results: Participants reported notable improvements in specific areas of their sleep experience as captured by the Pittsburgh Sleep Quality Index (PSQI). These included feeling less cold at night, experiencing fewer bad dreams, rating their overall sleep quality more positively, and having less difficulty staying awake during daily activities (all $p < 0.01$). ESS scores decreased significantly (from 9.74 to 8.76, $p = 0.044$), particularly in passive or sedentary contexts such as reading, watching television, taking an afternoon rest and after lunch. PSS scores also declined significantly (from 23.7 to 22.4, $p = 0.03$), especially in domains related to emotional regulation and coping with unpredictability. Mean sleep efficiency on day 10 was 98.43% (SD, 0.92), compared with 97.84% (SD, 2.35) on day 1 ($p = 0.07$), with notable inter-individual variability.

Conclusions: This real-world user observation study demonstrated that the EPT device improved selected aspects of sleep experience, including greater thermal comfort, fewer night-time disturbances, and better overall sleep ratings. Users also experienced a significant reduction in daytime sleepiness (ESS) and a notable decrease in stress levels (PSS), especially in terms of emotional balance and coping with daily challenges. These findings highlight the potential role of multi-modal non-pharmacological interventions in enhancing sleep, emotional stability, and well-being in daily life.

Acknowledgments: We thank AmLife International for kindly providing the excellent technology of the EPT device and funding support. We are also grateful to the study volunteers for their participation.

Reduced sleep quality and decreased executive performance in patients with psoriasis

S. Malloggi¹, G. Argenziano², A. Balato², F. Conte³, O. De Rosa^{2,3}, R. Di Caprio², G. Ficca³, G. Gronchi¹, L. Marigliano², F. Prignano⁴, E. Rosi⁴, F. Giganti¹

¹University of Florence, Department of Neuroscience, Psychology, Drug Research and Child Health (NEUROFARBA), Florence, Italy, ²University of Campania Luigi Vanvitelli, Dermatology Unit, Department of Mental and Physical Health and Preventive Medicine, Naples, Italy, ³University of Campania Luigi Vanvitelli, Department of Psychology, Caserta, Italy, ⁴University of Florence, Department of Health Sciences, Section of Dermatology, Florence, Italy

Introduction: Psoriasis is a widespread dermatological disease with frequent multiple comorbidities. In its pathogenesis and maintenance, sleep impairments seem to play a crucial, albeit underestimated, role. Here, our main aim is to provide an in-depth analysis of psoriatic patients' objective sleep features - whose clear and full description is still lacking - also addressing their association with cognitive functioning.

Materials and methods: Psoriatic patients were recruited from Dermatology Units based on the following criteria: 18–65 years, mild symptom severity (PASI < 10; DLQI < 5), no systemic treatment (topical only), absence of comorbid medical conditions (including psychiatric and sleep disorder diagnoses), no history of drug or alcohol abuse, limited caffeine (no more than 150 mg/day) and alcohol (no more than 250 mL/day) consumption. Control participants were recruited via social media and advertisements following the same inclusion criteria except for the presence of psoriasis.

All participants underwent 7 days of actigraphy (Camtech, UK). Sleep during the final two nights was also monitored using SomnoArt (PPRS, FR), a validated wearable device. Cognitive performance was assessed with the Rey-Osterrieth test, Rey Auditory Verbal Learning Test (RAVLT), Finger Tapping Test (FTT), 2-back test, and Go/No-Go task.

Results: Nineteen patients (12M, 7F; age = 37.89 ± 12.93) and 53 controls (14M, 39F; age = 28.33 ± 13.29) were recruited. Psoriatic patients showed reduced total sleep time ($p=.013$), higher sleep latency ($p=.023$), NREM ($p=.050$) and REM sleep duration ($p=.024$) compared to control participants. In addition, patients' sleep showed reduced number of sleep cycles ($p=.041$) and frequency of short awakenings (< 2 minutes; $p=.049$), as well as a higher number ($p=.005$) and frequency (per hour of sleep) ($p=.003$) of functional uncertainty periods (FUP; i.e. periods with three or more state transitions, separated by no more than 90 seconds). As for the cognitive assessment, patients committed more errors on the Go/No-Go Task ($p=.041$), obtained higher scores at the Rey Figure immediate test ($p=.004$) and less correct responses on the 2-back test ($p=.043$).

In the overall sample, positive correlations emerged between sleep efficiency and the number of correct responses on the FTT ($p=.353$; $p=.003$) and total responses to the 2-back test ($p=.242$; $p=.042$). Sleep cycle number correlated positively with performance at the Rey Figure Delayed Recall ($p=.301$; $p=.011$) and RAVLT ($p=.257$, $p=.012$) and negatively with Go/No-Go response time ($p=-.338$; $p=.004$).

Conclusions: Despite the mildness of symptom severity, psoriatic patients display significant impairments in their sleep features. Specifically, patients' sleep turns out to be shorter and more fragmented and notably shows reduced organization in NREM-REM cycles, a well-established indicator of sleep quality. Psoriatic patients' sleep also appears less stable than controls, as reflected by data on FUPs. These changes are negatively correlated with performance at executive tasks, highlighting an interesting interplay between sleep and cognitive functioning. The present data suggest that specific interventions to improve sleep quality could have an impact on patients' psychophysiological state and even on the very same course of psoriatic disease.

Reducing Evening Screen Time with REST-O: A Randomised Pilot Trial to Address Bedtime Procrastination

V. Hill¹, S. Ferguson¹, A. Rebar², H. Meaklim³, G. Vincent¹

¹Central Queensland University, Adelaide, Australia, ²University of South Carolina, South Carolina, United States, ³University of Melbourne, Melbourne, Australia

Introduction: Bedtime procrastination, the voluntary delay of going to bed without external reasons, is increasingly recognized as a contributor to insufficient sleep and associated health risks. Formative work indicates that pre-sleep electronic device use, a ubiquitous bedtime procrastination behaviour, may be targeted using a behaviour change approach. This pilot study aimed to examine (1) the acceptability and feasibility of the Reducing Evening Screen Time online program (REST-O) in new career starters, and (2) the preliminary effect of the program on daily pre-sleep electronic device use and sleep duration, as well as weekly measures of bedtime procrastination, excessive device use, and sleep quality and duration.

Materials and methods: A total of 59 participants (mean age: 23.3 years) were randomly assigned to one of three conditions: (1) self-compassion intervention, (2) sleep hygiene intervention, or (3) waitlist control. Each intervention consisted of a single 45-minute online session, followed by a one-week period during which participants were encouraged to apply the strategies learned. Assessments were conducted at baseline and after the one-week intervention period, measuring bedtime procrastination, sleep quality and sleep hygiene behaviors.

Results: All groups experienced a reduction in daily pre-sleep device use ($M = 23.4$ min per day) and an increase in daily sleep duration ($M = 12.7$ min per day) post-intervention. Continued reductions in bedtime procrastination, excessive device use, and improvements in sleep quality and duration were observed at followup. Improvements in sleep quality and sleep hygiene behaviors were also observed in the control group. The program appears feasible and acceptable to participants with a high daily completion rate ($M = 84.7\%$).

Conclusions:

Reductions in habit strength and hedonic motivation suggest that changes in automatic routines and the desire for short-term rewards may explain the improvements in bedtime behaviour. These findings offer early evidence that brief, self-guided behaviour change interventions can help reduce pre-sleep screen use and bedtime procrastination—behaviours linked to poor sleep. Participants found the

interventions practical and easy to follow, reporting high satisfaction and strong engagement. This study shows that targeting sleep hygiene in simple, accessible ways may support better sleep routines. Larger studies are needed to confirm these results and to better understand how these interventions work over time.

Acknowledgments: We would like to acknowledge all the participants who took part in this trial.

Relationship between stress, depression, anxiety, coping strategies, and sleep hygiene practice among Chinese employed adults: A cross-sectional study

Y. Luo¹, Z. Li¹, X. Ji¹, Y. Zhang¹, L. Mao¹, X. Shi¹, R. Yin¹

¹The First Affiliated Hospital of Soochow University, Suzhou, China

Introduction: As the current economic environment gets worse and worse, the pressure faced by employed adults is also increasing. The different ways employed adults deal with mental status may affect their sleep health. However, the interactions of these variables were scarcely examined in the cultural context of China. This study aims to explore the relationship between coping strategies, mental health, and sleep hygiene practice among Chinese employed adults.

Materials and methods: A total of 192 employed persons from Physical Examination Center of a tertiary hospital were recruited in this study from August 2024 to February 2025. An online questionnaire survey was conducted using the general information questionnaire, Sleep Hygiene Practice Scale (SHPS), Depression Anxiety Stress Scales (DASS), and Simplified Coping Style Questionnaire (SCSQ). SPSS was applied to perform descriptive and regression analysis.

Results: This study found that Chinese employed adults suffered from medium level of sleep hygiene practice, 41.7% experienced depression, 40.6% for anxiety, 22.4% for stress, and 45.3% applied positive coping strategies. Sleep hygiene practice was negatively related to coping strategies ($r=-0.275$, $P<0.001$), and positively associated with depression, anxiety, and stress ($r=0.598$, 0.695 , 0.662 , respectively, all $P<0.001$). Multiple line regression analysis found that stress ($\beta=0.239$, $P=0.024$) and anxiety ($\beta=0.487$, $P<0.001$) were the positive predictor of poor sleep hygiene practice.

Conclusions: Chinese employed adults are experiencing mixed psychological emotions and have poor sleep hygiene behaviors. To enhance the sleep health of adults, it is necessary to take measures to reduce their anxiety and personnel stress, so as to promote the sleep health of patients.

Relationship of sleep duration and sleep quality with Cardio metabolic Health, Inflammation, Oxidative stress and Antioxidants in night shift workers

A.P. Kaur¹, I. Saxena¹, B. Khulbe², A.K. Sriwastava¹, P. Kharya³, A.K. Gangwar⁴, S. Kaur⁵

¹All India Institute of Medical Sciences, Biochemistry, Gorakhpur, India, ²All India Institute of Medical Sciences, MBBS Student, Gorakhpur, India, ³All India Institute of Medical Sciences, Community and Family Medicine, Gorakhpur, India, ⁴KING GEORGE MEDICAL UNIVERSITY, PHYSIOLOGY, Lucknow, India, ⁵Heorlytics Pvt. Limited, Statistics, Mohali, India

Introduction: Human circadian rhythm is naturally aligned with the day-night cycle, promoting wakefulness during daylight hours and sleep during the night. However, night shift work forces individuals to sleep during the day, often in suboptimal conditions, resulting in shorter sleep duration, increased sleep fragmentation, and decreased sleep efficiency. Night shift workers often experience disrupted sleep patterns, leading to compromised sleep quality and associated health risks. Poor sleep quality among night shift workers has been linked to various adverse health outcomes, including increased risk of cardiovascular disease, metabolic disorders, and impaired cognitive function. The purpose of this study is to explore the relationship of sleep quality and duration with inflammation, oxidative stress, and antioxidants and cardio metabolic health in night shift workers.

Materials and methods: After approval from institutional ethics committee, 110 adults, were recruited and were divided into day workers and night shift workers. The volunteers were subject to anthropometric, chronobiological and sleep evaluations (by a questionnaire based on Pittsburgh sleep quality index), as well as to blood collection. Cardiometabolic health markers which were assessed by evaluating Blood pressure, Fasting triglyceride (TG) level, Fasting high-density lipoprotein (HDL)

cholesterol level and Fasting blood glucose. Markers of inflammation- C-Reactive Protein (CRP), IL-6, IL-1 β and TNF- α); marker for oxidative stress- γ Glutamyl Transferase (GGT) and markers for antioxidant status- Bilirubin, Uric acid, Vitamin A, C, D and E were measured in blood samples.

Results: This study found significant health differences between adults working day and night shifts, particularly regarding sleep quality, inflammation, and cardiometabolic health indicators. Key results include: 1. **Cardiometabolic Indicators:** Night shift workers exhibited higher body weight, systolic blood pressure, and triglycerides compared to day workers. Poor sleep quality was associated with increased diastolic blood pressure. 2. **Inflammation:** Elevated C-reactive protein (CRP) levels were observed among night shift workers, suggesting a link to chronic inflammation. However, other inflammatory markers did not show significant differences. 3. **Oxidative Stress and Antioxidants:** Surprisingly, individuals with poorer sleep quality had significantly lower GGT levels (16.72 ± 6.59) compared to those with better sleep quality (31.86 ± 15.58 ; $p < 0.001$), indicating that GGT may not reliably reflect oxidative stress in this context. Additionally, vitamin A levels were higher in night shift workers, suggesting a potential compensatory response to oxidative stress. 4. **Correlation Analysis:** Longer sleep duration positively correlated with serum bilirubin levels and negatively correlated with IL-1 β levels, indicating that adequate sleep may help reduce inflammation. Notably, poor sleep quality was associated with lower uric acid levels, reflecting a potential relationship between antioxidant levels and sleep quality. 5. **Ethnic Considerations:** The study also highlights the need for further exploration of ethnic differences in sleep health and its impact on health outcomes, as this could influence the observed relationships.

Conclusions: These findings underscore the complex interplay between sleep quality, health indicators, and shift work, emphasizing the need for targeted public health strategies to address the unique health challenges faced by night shift workers.

Acknowledgments: We acknowledge ICMR, India, New Delhi for funding this project

Relationships between childhood sleep health and mental health at 12-years: Findings from the *Growing Up in New Zealand* study

D. Muller¹, TL. Signal¹, D. Neumann², T. Akter³, L. Howe⁴, M. Shanthakumar⁵, S.-J. Paine²

¹Massey University, Sleep/Wake Research Centre, Wellington, New Zealand, ²University of Auckland, Faculty of Medical and Health Sciences, Auckland, New Zealand, ³Massey University, School of Health Sciences, Auckland, New Zealand, ⁴University of Bristol, Bristol Medical School, Bristol, United Kingdom, ⁵Massey University, Environmental Health Intelligence NZ, Wellington, New Zealand

Introduction: Poor sleep health is associated with poor mental health, however limited research has focused on these relationships in late childhood, and examined independent contributions of multiple facets of sleep health, or explored potential influences of sleep at earlier ages. Using survey data from the *Growing Up in New Zealand* longitudinal study, we aimed to investigate how sleep at multiple timepoints across childhood relates to mental health at 12-years of age.

Materials and methods: Child-reported depression symptoms (CES-DC-10) and anxiety symptoms (PROMIS Pediatric Anxiety-SF8a) at 12-years were outcome variables in multiple linear regression models. Model 1 (cross-sectional) concurrently included 12-year sleep measures (maternally-reported sleep duration weekdays, sleep duration weekends, sleep problem; sleep consistency [weekday-to-weekend sleep duration difference]; child-reported sleep quality) as predictor variables, adjusted for sociodemographic variables at 12-years (child ethnicity, area-level socioeconomic deprivation, material hardship, rurality, gender). Model 2 (longitudinal) additionally included sleep at 8-years (maternally-reported sleep duration, night wakings, sleep problem), 4-years (maternally-reported sleep duration, night wakings, sleep problem), and 2-years (maternally-reported sleep duration, night wakings) as predictors.

Results: The sample ($n = 3,715$) included 22% Māori (Indigenous peoples of Aotearoa New Zealand), 14% Pacific, 13% Asian, 4% 'other' ethnicities and 56% European 12-year-old children. Cross-sectional (Model 1) independent associations were identified between short sleep (<9 hrs) on weekdays, inconsistent sleep patterns (weekday-to-weekend duration difference >1 hr), poor quality (fairly/very bad), and problematic (small or moderate/large problem) sleep at 12-years and higher depression symptoms; and between short sleep on weekdays, poor quality, and problematic (small or moderate/large problem) sleep at 12-years and higher anxiety symptoms. Additional adjustment for sleep health at earlier ages (Model 2) fully attenuated associations (β [95% CI]) between

moderate/large sleep problems and anxiety symptoms (Model 1 1.63 [0.27-3.00], Model 2 0.85 [-0.79-2.49]) but there was minimal attenuation for associations between sleep problems and depression symptoms (small problem: Model 1 0.49 [0.13-0.86], Model 2 0.46 [0.06-0.86]; moderate/large problem Model 1 0.97 [0.36-1.58], Model 2 0.84 [0.16-1.52]), short sleep and anxiety symptoms (Model 1 1.27 [0.29-2.25], Model 2 1.17 [0.11-2.23]) and small sleep problems and anxiety symptoms (Model 1 1.19 [0.37-2.01], Model 2 1.16 [0.28-2.05]).

Conclusions: Results provide evidence of concurrent independent relationships between multiple facets of sleep health at 12-years and depression and anxiety symptoms at 12-years, indicating that sleep and mental health are tightly connected in late childhood. Strengths of association were greatest for sleep quality, the one child-report measure, highlighting the importance of asking children about their sleep experiences which may differ from caregiver perceptions. Findings suggest that the relationship between sleep at younger ages and mental health at 12-years of age is likely complex. This warrants further investigation, alongside exploring sleep and mental health relationships over time as children continue to develop.

Relationships between sleep and daily step count examined using large-scale, home-based, health monitoring data

J. Fitton¹, P. Nguyen¹, B. Lechat¹, H. Scott¹, B. Toson¹, J. Manners¹, C. Dunbar¹, K. Sansom¹, L. Pinilla¹, A. Hudson¹, G. Naik¹, A. Vakulin¹, A.C. Reynolds¹, P. Catcheside¹, P. Escourrou², D.J. Eckert¹

¹Flinders University, Flinders Health and Medical Research Institute: Sleep Health, Adelaide, Australia,

²Centre Interdisciplinaire du Sommeil, Paris, France

Introduction: Sleep and physical activity are two vital health behaviours, though the relationship between them remains poorly understood. Furthermore, previous research on this topic is often limited by relatively small or geographically constrained samples and an over-reliance on cross-sectional or self-reported data. To help advance knowledge of the sleep-activity relationship, we explored non-linear bidirectional associations between objective sleep parameters and daily step count in approximately 28-million person-days ($N = 70,963$; 244 regions) of large-scale health monitoring data.

Materials and methods: Data were attained using two FDA-cleared consumer health devices. Sleep parameters (sleep duration [mins], sleep onset latency [mins], and sleep efficiency [%]) were derived from the Withings Sleep Analyser, a validated under-mattress sleep sensor. Daily step count was measured using tri-axial accelerometry from the Withings ScanWatch. First, we performed a descriptive analysis to determine the proportion of the sample that routinely attained the National Sleep Foundation's sleep duration recommendations (adults 7-9hrs; older-adults 7-8hrs) alongside research-informed daily step count thresholds (adults 8,000 steps/day; older-adults 6,000 steps/day). Generalised additive mixed models (GAMMs) were used to produce exposure-response curves for the temporal association between sleep parameters and next-day step count, and vice versa. GAMMs were adjusted for demographic, temporal, and geographical factors.

Results: Only 12.9% of the sample routinely achieved 7-9 hours of sleep per night and >8,000 steps/day. 16.5% of participants slept <7 hours per night on average and lead a sedentary lifestyle (i.e., <5,000 steps/day). An inverted-U-shaped exposure-response curve indicated the optimal sleep duration for next-day step count was approximately 6 hours per night (e.g., +339 steps vs 8 hrs/night), though this increased to around 7 hours per night when adjusting for the duration of the wakefulness period. Greater sleep efficiency was associated with increased next-day step count in an exposure-dependent manner (25th to 75th sleep efficiency percentile: +282 steps/day). The association between sleep onset latency and next-day step count was inverse and near-linear (25th to 75th sleep onset latency percentile: -209 steps/day). Conversely, associations between step count and next-night sleep parameters were small and likely lack practical significance. All effect sizes were reduced when accounting for duration of wakefulness.

Conclusions: These data provide a novel insight into the relationship between sleep and physical activity at a multi-national level. Poor routine attainment of sleep recommendations alongside prominent step count thresholds highlights the need for public health initiatives that reduce barriers to both adequate sleep and physical activity, perhaps by better considering their interrelatedness.

Relaxation of social time pressure affects subjective sleep quality and its associations vary depending on chronotype

Y. Komada¹, K. Kondo¹, S. Kitamura², V. Tkachev³, T. Roenneberg⁴, M. Korman⁵

¹Institute of Science Tokyo, Tokyo, Japan, ²National Institute of Mental Health, Tokyo, Japan,

³Independent Researcher, Ariel, Israel, ⁴LMU Munich, Munich, Germany, ⁵Ariel University, Ariel, Israel

Introduction: Modern societal factors frequently impede the attainment of good sleep quality by many healthy adults. We investigated the chronotype-specific predictors of changes in subjective sleep quality following the relaxation of social time pressure during COVID-19 pandemic social restrictions in Japan.

Materials and methods: The internet-based Global Chrono-Corona Survey (GCCS) study received approval from the Ariel University Human Research Ethics Committee, Faculty of Health Sciences (AU-HEA-MK-20200629). A total of 1,649 participants completed the Japanese version of this study during the initial COVID-19 social restrictions. The final sample for analysis were 1,252 (34.6 ± 13.8 years, 67% female). Logistic regression analyses were used to assess changes under modified social time pressure in sleep quality by chronotype group (early, intermediate or late) from changes in patterns of daily behaviors.

Results: During social restrictions, subjective sleep quality deteriorated with decreased sleep duration and delays in sleep timing in the intermediate chronotype, while late chronotypes' reduction in sleep quality was associated with delayed sleep timing. Improved subjective sleep quality was associated with increased sleep duration and minimal sleep timing delay in the early and intermediate chronotypes. In late chronotypes, improved sleep quality was also associated with longer outdoor light exposure. These findings indicate that the determinants of changes in subjective sleep quality under modified social time pressure are at least partially chronotype-specific. Maintaining sleep timing may universally enhance subjective sleep quality during perturbations of social schedules. Moreover, in late chronotypes, the exposure to daylight may improve sleep quality, regardless of changes in sleep behaviors.

Conclusions: These insights may contribute to the development of effective strategies for promoting better sleep quality in modern societies where insufficient sleep is becoming increasingly widespread.

Reliability and validity of the Chinese version of Global Sleep Assessment Questionnaire in adult patients with sleep disorders

M. Sun¹, B. Zhou¹, L. Wu¹, X. Dong¹, F. Han¹

¹Peking University People's Hospital, Beijing, China

Introduction: Global Sleep Assessment Questionnaire(GSAQ) is a comprehensive screening tool to assess the presence of sleep disorders in the general population. Nowadays, Sleep disorders are estimated to affect 40% of adults worldwide, estimated nearly the same in China. This, in combination with a consistent association between lower or poor sleep quality and higher burden of multi-morbidity, underscores the need for translation and validation on the Chinese version of GSAQ to screening sleep disorders in China.

Materials and methods: We first translated GSAQ by two native Chinese speakers independently and back translated by two native English translator who had no access to the original English version of GSAQ. Secondly, we recruited a convenience sample of 55 patients complained with sleep disorders to assess the Chinese GSAQ scale's internal consistency and split-half reliability. Then, additional 55 patients were collected for exploratory factor analysis (EFA). Moreover, we obtained more 91 fulfilled questionnaires to perform confirmatory factor analysis (CFA) with total 201 samples. Finally, The Chinese version GSAQ were tested for criterion validity.

Results: The Chinese version of the GSAQ exhibited a Cronbach's α of 0.718 and a split-half reliability of 0.747. The KMO and Bartlett test confirmed that it was fit for applying this technique to this sample (KMO=0.601, Bartlett's Test of Sphericity $\chi^2=395.142$, $p<0.01$), EFA analysis defined four components of the GSAQ items considering the method of the eigenvalues >1 with 68.893% explained variance.

The CFA showing the goodness of fit of the GSAQ: $\chi^2=77.559$, $P<0.001$, $\chi^2/df=2.041$, $RMSEA=0.072$, $GFI=0.932$, $IFI=0.916$, $CFI=0.913$, indicating an acceptable model fit.

To verify criterion validity in the OSA population, correlations between GSAQ and Apnea Hypopnea Index (AHI) were analyzed. The results showed that the overall GSAQ had positive correlation with AHI ($r=0.312$, $p<0.001$). For insomnia, positive correlation was observed between the total GSAQ score with PSQI ($r=0.340$, $p<0.027$).

Conclusions: Chinese version of the GSAQ is a reliable tool for screening sleep disorders, especially for the most common ones, such as insomnia and OSA.

Restless Nights, Troubled Bodies: The Impact of Sleep Quality and Insomnia on Somatic Complaints in Psychosomatic Rehabilitation Patients

J. Faber¹, P. Bommersbach², A.A. Schlarb¹

¹Bielefeld University, Bielefeld, Germany, ²Eifelklinik Manderscheid, Manderscheid, Germany

Introduction: Sleep disturbances, particularly insomnia, are highly prevalent amongst patients in psychosomatic rehabilitation clinics. Impaired sleep quality or insomnia is not only a frequent comorbidity but also a potential aggravator of somatic symptoms, including pain, fatigue, and gastrointestinal complaints. Research suggests a bidirectional relationship between insomnia and somatic symptom complaints. However, this association has not been investigated in patients in psychosomatic rehabilitation clinics.

Materials and methods: From a total of 2,179 admissions to a psychosomatic rehabilitation clinic, a randomized sample of 356 patients (mean age = 49.04 years, SD = 9.96; 51.2% female) was selected. Patients completed standardized questionnaires assessing sleep quality, insomnia symptoms, somatic complaints, and a medical history form. Furthermore, ICD-10 diagnoses for mental and somatic disorders were determined using structured clinical interviews conducted by trained clinicians.

Results: Impaired sleep quality was significantly associated with more somatic complaints ($r = .337$, $p < .001$), and marginally significant with a greater number of somatic diagnoses ($r = .100$, $p = .09$), indicating a broad link between subjective sleep disturbance and somatic symptoms. Poor sleep quality was correlated with decreased general well-being, less appetite, more irregular bowel movements, problems urinating (including frequent urination in small amounts and increased nocturnal urination), and respiratory difficulties at rest and under exertion. Additionally, associations were found with nausea, excessive sweating, chills, and allergies.

Patients who met criteria for insomnia reported significantly more somatic complaints compared to those without insomnia ($t = -4.051$, $p < .001$); however, no significant differences were found regarding the number of somatic diagnoses. Patients who met criteria for insomnia reported significantly reduced general well-being, less appetite, frequent urination in small amounts, respiratory issues, excessive sweating, and chills.

Conclusions: The findings highlight the association between impaired sleep quality, insomnia, and somatic complaints in patients in psychosomatic rehabilitation clinics. Consistent with existing research, our results suggest that sleep quality and insomnia are linked to different somatic symptoms. While insomnia was associated with more self-reported symptoms, it did not correspond with a higher number of somatic diagnoses, suggesting that the quality rather than the quantity of somatic symptoms might have more impact. The results of this study highlight the importance of systematically assessing and treating sleep disturbances in psychosomatic settings, as doing so may improve both psychological and somatic outcomes.

Role of Deglycation molecules,ammino acid,phytonutrients,vitamin and mineral in Good quality sleep management

S. Somsup^{1,2}, V. Kuharattanakorn²

¹Robert Debre Hospital, Neuropediatrics, Paris, France, ²IVIVA POLYCLINIC, Nakhon Pathom, Thailand

Introduction: Sleep quality are global health concerns. Poor sleep quality has significant adverse health outcomes. Sleep quality is defined as an individual's self-satisfaction with four attributes as sleep efficiency, sleep latency, sleep duration, and wake after sleep onset. Antecedents include physiological as age, circadian rhythm, body mass index, NREM, REM, psychological (e.g., stress, anxiety, depression), environmental factors (e.g., room temperature, television/device use), and family/social commitments. Good sleep quality has positive effects such as feeling rested, normal reflexes, and positive relationships. Poor sleep quality consequences include fatigue, irritability, daytime dysfunction, slowed responses, and increased caffeine/alcohol intake.

The recent study was conducted to systematically review the effect of the melatonin on sleep quality. Many nutritional supplements have been used trying to benefit sleep wellness. There was no clinical study in this field. This study provides clinical study in patients with insomnia and normal patients after taking combined nutritional supplements as Rosmarinic acid, Fish oil (Omega 3), L-theanine, Glycine, Tryptophan, GABA, Magnesium, Calcium, Iron, B -complex Vitamins (e.g., B1,2,3,5,6,12,) Vitamin D and Vitamin E. Awake and sleep EEG were performed for clinical evaluation in sleep latency, sleep duration, NREM, REM and wake after sleep onset.

Materials and methods: The clinical trial prospective study in insomnia patients and normal patients compare pre and post taking combined nutritional supplements as Rosmarinic acid, Fish oil (Omega 3), L-theanine, Glycine, Tryptophan, GABA, Magnesium, Calcium, Iron, B -complex Vitamins (e.g., B1,2,3,5,6,12,) Vitamin D and Vitamin E for duration of 1 month. Awake and sleep EEG were performed for clinical evaluation in sleep latency, sleep duration, NREM, REM and wake after sleep onset.

Results: There were 20 cases in this study, 10 cases with normal sleep and 10 cases with insomnia. Awake and sleep EEG were performed pre and post taking combined nutritional supplements as Rosmarinic acid, Fish oil (Omega 3), L-theanine, Glycine, Tryptophan, GABA, Magnesium, Calcium, Iron, B -complex Vitamins (e.g., B1,2,3,5,6,12,) Vitamin D and Vitamin E for 1 month.

There were significant decrease sleep latency in both normal sleep and insomnia ($p < 0.01$), significant increase of duration of sleep in both normal sleep and insomnia ($p < 0.01$), significant increase NREM and REM in both normal sleep and insomnia ($p < 0.01$), significant decrease number wake after sleep in insomnia. But there were not significant decrease number of wake after sleep in normal sleep. The positive effect as feeling rested and fresh up were reported in both groups.

Conclusions: Combined nutritional supplements as Rosmarinic acid, Fish oil (Omega 3), L-theanine, Glycine, Tryptophan, GABA, Magnesium, Calcium, Iron, B -complex Vitamins (e.g., B1,2,3,5,6,12,) Vitamin D and Vitamin E could be the major role for good quality sleep management.

Acknowledgments: I would like to express their sincere gratitude to all of patients who participated in this research. I also extend our appreciation to staff of our clinic for providing the necessary facilities and advocacy message to all patients. More over my parents who have been provided a guidance, encouragement and private fund for this study.

Role of preoptic area thermo transient receptor potential vanilloid type II (TRPV2) channel in sleep and thermoregulation

R. Yadav¹

¹Sharda University, Allied Health Sciences, Greater Noida, India

Introduction: The maintenance of body temperature is the major homeostatic function of the hypothalamus. The preoptic area of the anterior hypothalamus is one of the most crucial sites of body temperature regulation and sleep. The present study reveals the role TRPV2 ion channel in the regulation of sleep and temperature regulation.

Materials and methods: The study was conducted in 12 male Wistar rats. Surgical procedures were performed for implantation under thiopentone sodium anesthesia (40 mg/kg body weight, i.p.). Bilateral 24G guide cannulae with indwelling styli were implanted, targeting 2 mm above the preoptic area (POA) as outlined in De Groot's atlas. A radio transmitter (TA10TAF-40, Data Science International, USA) was implanted abdominally to telemetrically record body temperature. A K-type thermocouple wire was inserted near the hypothalamus to measure brain temperature, which was recorded at 15-second intervals using a Fluke digital thermometer. Body temperature was recorded telemetrically at the same interval. Temperature measurements were collected from 10 AM to 4 PM, with capsaicin or saline injections administered at noon. Temperature data was averaged over 15-minute epochs. Bilateral injections of 0.2 μ l (TRPV2 agonist) or saline control were delivered at a rate of 0.1 μ l/min via

an injector cannula aimed at the POA. Injection sites were histologically verified. Statistical comparisons were conducted between pre- and post-injection periods, as well as between capsaicin- and saline-treated groups.

Results: The body temperature recorded in 6 rats ranged between 37.00 ± 0.3 °C and 37.46 ± 0.2 °C and brain temperature 36.7 ± 0.3 °C and 37.2 ± 0.4 °C. The injection of TRPV2 agonist ($0.2 \mu\text{g}/0.2 \mu\text{l}$) into the preoptic area produced a prompt increase in body and brain temperature. Tbr significantly increased from 37.1 ± 0.3 °C to 37.8 ± 0.2 °C, 12:15 to 12:30 h, ($p < 0.05$), 36.9 ± 0.2 °C to 38.1 ± 0.5 °C, 12:45 to 13:0 h, ($p < 0.05$), 36.9 ± 0.3 °C to 38.2 ± 0.3 °C, 13:0 to 13:15 h, ($p < 0.05$) and Tb significantly increased from 37.2 ± 0.2 °C to 37.9 ± 0.6 °C, 12:30 to 12:45 h, ($p < 0.05$). In rats, the injection of capsaicin ($0.2 \mu\text{g}/0.2 \mu\text{l}$) into the preoptic area of the anterior hypothalamus produced a prompt increase in body and brain temperature. TRPV2 agonist ($0.2 \mu\text{g}/0.2 \mu\text{l}$) increases REM sleep.

Conclusions: The TRPV2 channel agonist injection in the POA brings about an increase in body and brain temperature by stimulating cold-sensitive neurons and increasing REM sleep.

Acknowledgments: I acknowledge to Sharda University for providing a platform for performing research.

Rotating shifts change gut microbiota and sleep in shift workers: an observational study

D. Zheng^{1,2}, Y. Li^{1,2}

¹Shantou University Medical College, Shantou, China, ²Shantou University Mental Health Center, City, China

Introduction: Shift work can adversely impact workers' sleep conditions and change gut microbiota composition. Meanwhile, a bidirectional relationship exists between gut microbiota and sleep regulation via the brain-gut axis. This study aimed to determine the associations between gut microbiota and sleep alterations in shift workers.

Materials and methods: A total of 31 shift workers and 44 controls were recruited from June 2018 to July 2021 (mean age= 27.71 ± 4.38 years, female%=77%). Shift work was defined as workers involved in 8-hour rotations for more than 3 years. Subjective and objective sleep were assessed via questionnaires and polysomnography (PSG), respectively. Poor sleep efficiency (SE) was defined as $\text{SE} < 85\%$ assessed by PSG. The fecal samples were collected during the PSG recording day and immediately stored at -80°C until 16S rRNA sequencing. Linear and logistic regressions were used to examine the relationship between shift work, microbiota and sleep. All statistical analyses were performed using IBM SPSS 27.0. A p -value < 0.05 was used to determine statistical significance.

Results: Compared to controls, shift workers exhibited lower subjective ($87.27 \pm 11.31\%$ vs. $93.72 \pm 6.00\%$, $p=0.004$) and objective ($86.07 \pm 11.01\%$ vs. $91.66 \pm 4.33\%$, $p=0.013$) SE. Furthermore, we found that the reciprocal-transformed abundance of *Collinsella* was significantly lower in shift workers compared with controls (0.82 vs. 0.93 , $p=0.029$). After adjusting for age and sex, shift work was associated with both the reciprocal-transformed abundance of *Collinsella* ($\beta=-0.11$, $p=0.033$) and poor objective SE ($\text{OR}=9.30$, $p=0.005$), while the reciprocal-transformed abundance of *Collinsella* was significantly correlated with poor objective SE ($\text{OR}=0.05$, $p=0.018$). The association between shift work and poor objective SE was diminished by the reciprocal-transformed abundance of *Collinsella* ($\text{OR}=7.70$, $p=0.012$), though the mediating effect was insignificant.

Conclusions: Shift workers showed changes in gut microbiota composition and lower sleep efficiency. *Collinsella* may be the potential key microbiota linking the relationship between sleep and shift work. Microbiota might be a beneficial therapeutic targeting of sleep disturbances in shift workers.

Acknowledgments: I sincerely thank Shantou University Medical College, Shantou University Mental Health Center, Professor Yun Li, and her Sleep Medicine Research Team for their expertise and unwavering support.

Self-Injury-Related Psychosocial Characteristics and Sleep Health in Adults

S. Kim¹, Y. Lee¹, S. Chung², S. Suh¹

¹Sungshin Women's University, Seoul, Korea, Republic of, ²Department of Psychiatry, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of

Introduction: Self-injury is linked to various sleep problems, such as short sleep duration, difficulty maintaining sleep, and poor subjective sleep quality. This study aimed to investigate how sleep health differs among adults aged 20 to 69 based on their history of self-injury, and to explore four psychosocial factors of self-injury—perceptual (pain perception), situational (being alone), behavioral (latency from urge to action), and volitional (desire to stop)—linked to sleep health.

Materials and methods: A total of 124 adults with a history of self-injury were age- and gender-matched with 248 controls (N=372). Insomnia Severity Index (ISI), Sleep Health Index (SHI), Inventory of Statements About Self-Injury (ISAS), Depressive Symptom Inventory–Suicidality Subscale (DSI-SS), Generalized Anxiety Disorder-7 (GAD-7), and Patient Health Questionnaire-9 (PHQ-9) were assessed. The Sleep Health Index (SHI) is a 14-item self-report questionnaire designed to assess overall sleep health, including three subscales (sleep quality, sleep duration and sleep disorders). In this study, the behavior section of the ISAS (7 items) was used to assess self-injury methods and frequency. Correlations explored associations between self-injury and sleep health indices. Group differences between the self-harm group and controls were analyzed using ANCOVA adjusting for age, gender, suicidal ideation, anxiety, and depression. Additionally, four psychosocial characteristics relevant to self-injury – pain perception, being alone, latency from urge to action, and desire to stop – were assessed as separate variables.

Results: The sample consisted of 372 adults (mean age = 41.6 ± 13.8 years, 48.9% male). Among the self-injury group (n = 124), the most common methods were hitting oneself (16.7%), hair pulling (15.1%), and cutting (14.1%). Most engaged in self-injury alone (75%), within one hour of the urge (70%), and 80.6% expressed a desire to stop. Compared to matched controls, the self-injury group showed significantly poorer outcomes of overall sleep health and associated domains (all $ps < .01$) – even after controlling for covariates. Among the self-injury group, self-injury characteristics (pain perception, being alone, latency from urge to action, desire to stop) were significantly associated with multiple sleep health difficulties measured by the SHI ($r = .20-.30, p < .01$).

Conclusions: Compared to controls, individuals with self-injury reported greater insomnia and poorer sleep health across all sleep health domains. Self-injury psychosocial characteristics—pain perception, being alone, latency from urge to action, and desire to stop—were also associated with increased sleep disruption and greater reliance on medical support for sleep problems. These findings suggest that self-injury is linked not only to poor sleep outcomes but also to psychosocial characteristics that interact with multiple aspects of sleep health.

Sensationalising sleep: A research agenda for understanding and interpreting sleep-related discourses in the media

R. Gibson¹

¹Massey University, School of Psychology, Palmerston North, New Zealand

Introduction: The importance of sleep is well recognised, yet around a third of adults report suboptimal or disordered sleep. Common medicalised approaches to sleep seldom align with the reality of people's lives. Sociological perspectives acknowledge how (in our modern accelerated society) sleep is quantified, digitalised, and commercialised. Familial sleep arrangements and the regulation of sleep within the constructs of school and/or work are also key concerns which are shaped by social and cultural expectations regarding rest and productivity.

Sleep-related research has predominantly been from clinical and physiological perspectives. However, more recent epidemiological work has highlighted social disparities in sleep health including by age, gender, economic status, and ethnicity. Nevertheless, nuanced sociological considerations of sleep have seldom been explored. This is particularly important for bicultural countries such as Aotearoa New Zealand where mainstream discourses and health promotion have been colonised and Indigenous Māori are underrepresented.

Materials and methods: Media provides a platform for shaping beliefs and attitudes concerning sleep. Media messaging contributes to definitions of 'normal sleep' and sensationalised messages around sleep(lessness) and disease. These seldom account for nuanced differences across the lifespan or Indigenous knowledge and practices concerning sleep and wellbeing. How sleep-related messages are

delivered, interpreted, and resisted varies and warrants exploring - particularly among populations predisposed to sleep disturbances.

This presentation will outline a suite of research and preliminary findings from a sociological sleep enquiry in New Zealand. This includes the sleep-related themes and discourses present in freely accessible media sources. Followed by an investigation into the beliefs and practices of key groups/audiences in response to such discourses. Including studies using focus groups and interviews as well as creative writing and arts workshops.

Results: Discourse and responses are covered from key groups. For example, in the news media, adolescents sleep issues were presented as both 'a phase' and 'serious business'; pregnant women's sleep was presented as 'doomed' alongside instructions for becoming a safe sleeper and 'perfect mother'; and for older adults - sleep was presented as a 'magic bullet' for avoiding dementia or early death, alongside being something that would inevitably decline with ageing and also challenging to remedy. Finally, sleep was represented via Māori media as a time for communal and cultural connection as well as spiritual wellbeing. Preliminary findings from the audience response phase will be presented to help platform the reality of their sleeping lives and inform sleep messaging that is relevant and appropriate for contemporary New Zealand.

Conclusions: Ultimately, this work is contributing to new and innovative theories on sleep and society. Including, for example, perceptions of sleep as an experience; understandings of sleep disorders and treatments; as well as broader constructs of time, and the role of Māori knowledge in relation to the discourses, practices, and influences of sleep.

Acknowledgments: "Sensationalising Sleep: Discourses and practices of sleep in Aotearoa" is a programme of qualitative research supported by the New Zealand Royal Society Marsden Fast Start Fund (2023-2026).

Serial Mediating Effects of Insomnia and Nightmare in the Relationship between Self-Compassion and Non-Suicidal Self-Injury Among Hong Kong Adolescents

Y.Y. Ho¹, M.L. Wong¹

¹City University of Hong Kong, Department of Social and Behavioral Sciences, Kowloon, Hong Kong, SAR of China

Introduction: Non-suicidal self-injury (NSSI) has been increasingly gaining attention in adolescent mental health due to its association with mental health disorders, such as depression and anxiety disorders and a higher overall mortality rate when compared to their peers, particularly in relation to suicide. While much research has explored the association between self-compassion and NSSI in Western contexts, this association in Chinese culture remains underexplored. Meanwhile, despite growing evidence linking the two variables, the underlying mechanism remains unclear. In particular, notwithstanding the high co-occurrence of self-compassion, sleep disturbances, and NSSI, the potential roles of sleep disturbances remain largely unexamined. Further investigation is warranted to better understand their associations with each other. Thus, it is crucial to explore the abovementioned associations among Hong Kong adolescents. To the best of our knowledge, this is the first study investigating insomnia severity and nightmare distress as sequential mediators in the association between self-compassion and NSSI. We hypothesized the following: 1) Self-compassion is negatively associated with NSSI (H1); 2) Insomnia severity and then nightmare distress serially mediate the association between self-compassion and NSSI (H2).

Materials and methods: A total of 176 adolescents (73% female, $M_{age} = 16.9$, $SD = 1.18$) aged 12 to 18, living in Hong Kong and without a diagnosis of mental illness or a suicide attempt in the past month participated in the study. Participants completed online surveys on QuestionPro, which was disseminated via social media. The survey included socio-demographic information and published scales: the Self-Compassion Scale for Youth, the Insomnia Severity Index, the Nightmare Distress Questionnaire, and the Functional Assessment of Self-Mutilation Questionnaire.

Results: Pearson or Spearman rank correlation analyses indicated a negative correlation between self-compassion and NSSI ($r_s = -0.42$, $p < 0.001$), supporting H1. A serial mediation analysis (model 6) revealed a significant indirect effect of self-compassion on NSSI through the sequential pathway of insomnia severity and nightmare distress ($\beta = 0.02$, $logit = 0.02$, $OR = 1.02$, $SE = 0.01$, $BCa\ 95\% CI = 0.01, 0.03$), giving support to H2.

Conclusions: The present study highlights the significance of self-compassion to NSSI behaviors among Hong Kong adolescents, demonstrating a consistent association between the two variables across different cultural contexts. Nevertheless, due to cultural differences, the contributing factors underlying this association among Hong Kong adolescents warrant further investigation. Additionally, our findings suggest that self-compassion potentially plays a protective role in reducing NSSI engagement, especially in the presence of insomnia and nightmares. The present study shows that adolescents with lower self-compassion may be at greater risk for more severe insomnia, accompanied by nightmare distress, which then possibly increases their NSSI engagement. Future research could explore how self-compassion influences different stages of NSSI, particularly in the context of sleep disturbances, to gain a more comprehensive understanding of this complex interplay.

Acknowledgments: We would like to express our gratitude to all the participants who generously contributed their time to participate in this study.

Sex differences in bidirectional associations between dimensions of Fitbit-derived sleep and emotional health across one year in American Life in Realtime, a nationally representative sample of U.S. adults

R. Chaturvedi¹, G. Matthew², W. Troxel³, L. Hale⁴

¹USC, Los Angeles, United States, ²SUNY, Stony Brook, United States, ³RAND Corporation, Pittsburgh, United States, ⁴SUNY, Program in Public Health, Department of Family, Population, and Preventive Medicine, Renaissance School of Medicine, Stony Brook, United States

Introduction: We examined sex differences in within-person bidirectional and between-person associations between dimensions of Fitbit-measured sleep and multiple self-reported emotional health measures among a large sample of U.S. adults across ~1 year.

Materials and methods: Data were from American Life in Realtime (ALiR), a probability-based cohort representative of U.S. adults. Participants wore Fitbits to measure nighttime sleep and answered monthly questionnaires on depression, anxiety, and stress symptoms. Linear mixed models examined bidirectional associations of Fitbit sleep measures [mean and SD of total sleep time (TST), sleep onset, and sleep efficiency] across 14-day intervals that immediately preceded or succeeded each monthly report of emotional[WT1] health and between-person associations. Analyses adjusted for sociodemographic variables and examined gender differences.

Results: The analytical sample (n=733-754) had mean age of 47.1±14.6 and 48.7% female. Generally, within-person findings indicated that shorter and longer TST, poorer sleep efficiency, and greater variability in both sleep onset and efficiency than one's average predicted higher depression, anxiety, and stress scores in the subsequent monthly report. In reverse, worse than average emotional health predicted poorer sleep health in the succeeding 14 days, but findings were more consistent with sleep predicting emotional health. In consistent and strong between-person results, those with later sleep onset and more sleep variability had poorer average emotional health. Findings were generally stronger in females.

Conclusions: Poor sleep predicts worse emotional health and vice versa in a large representative sample, particularly among females, highlighting the need for tailored intervention strategies that consider gender-specific patterns in sleep-emotional health dynamics.

Sharper Minds Better Sleep: Effectiveness of a sleep focussed educational and skills building program for improving sleep and mental health in university students

K.R. Rossa¹, S.L. Edmed¹, D.L. Mann², G.A. Dingle³, C.L. Pattinson¹, S. Kalmadka¹, S.S. Smith¹

¹University of Queensland, Child Health Research Centre, Brisbane, Australia, ²University of Queensland, School of Electrical Engineering and Computer Science, Brisbane, Australia, ³University of Queensland, School of Psychology, Brisbane, Australia

Introduction: The transition to university is a critical period often marked by significant changes in living circumstances, academic demands, and social relationships. These shifts often lead to elevated stress and disrupted sleep, placing students at heightened risk for psychological distress. Sleep and mood share well-established bidirectional links, suggesting that improving one may positively influence

the other. University-led mental health promotion programs offer a key opportunity to equip students with skills and knowledge to proactively manage wellbeing. This study evaluated the effectiveness of a sleep-health focused, skills-building educational prevention program, called *Sharper Minds Better Sleep*, on improving sleep and mental health outcomes in university students.

Materials and methods: A quasi-experimental, between-groups, pre-post design was used. Participants were young adult university students enrolled in *Sharper Minds Better Sleep* (intervention group), or a control group (students completing surveys only). The intervention included 4x45 minute weekly online group learning sessions (6-8 people per session) delivered via Zoom by trained Provisional Psychologists. Sessions focussed on sleep and circadian health principles, and encouraged practical behaviour change through 'homework' tasks between sessions. All participants completed standardized questionnaires on sleep (duration, disturbance, daytime impairment, regularity), and mental health, while intervention participants also wore an actigraph for 7 days pre- and post-program, and completed additional sleep-related questionnaires (i.e., insomnia severity, bedtime procrastination).

Results: 81 students participated in the intervention group (71% female; $Mage=21.1$, $SD = 4.6$), and 149 in the control group (69% female; $Mage = 19.9$, $SD = 4.03$). Mixed repeated-measures ANOVA's revealed a significant Group $\times$ Time interaction for sleep disturbance [$F(1, 86) = 6.77$, $p = .01$, $\eta^2 = .073$], with the intervention group reporting greater reductions in sleep disturbances than controls from pre-to post-program. In contrast, no significant differences were found for sleep duration [$F(1, 77) = 1.815$, $p = .182$], daytime impairment [$F(1, 78) = 2.318$, $p = 0.132$], or subjective sleep regularity [$F(1, 77) = 3.378$, $p = 0.070$]. A Mann-Whitney U test indicated a significant difference in mental health change scores between groups ($U = 3260.00$, $Z = 2.03$, $p = .042$), with the intervention group demonstrating greater improvement. Within-group analyses of actigraphy data from the intervention group showed significant improvements in actigraphy-derived sleep regularity (Cohen's $d = -.75$), intradaily variability (Cohen's $d = .37$), as well as self-reported insomnia severity (Cohen's $d = .40$) and bedtime procrastination (Cohen's $d = .38$).

Conclusions: Participation in the *Sharper Minds Better Sleep* program was associated with significant reductions in sleep disturbance and improvements in sleep regularity, insomnia symptoms, and bedtime procrastination. These changes were accompanied by greater overall improvements in mental health reports compared to controls. While not all sleep metrics showed significant between-group differences, the results suggest that a skills-focussed sleep intervention can support meaningful changes in student wellbeing. University-delivered preventive programs targeting modifiable behaviours like sleep may offer a scalable pathway to reduce psychological distress and promote resilience in young adults.

Acknowledgments:

Shotgun metagenomics reveals alteration of gut microbiota and metabolic pathways in adults with poor sleep quality

S.-Y. Kim¹, H.-N. Kim¹

¹Ewha womans university, college of medicine, Psychiatry, Seoul, Korea, Republic of, ²Sungkyunkwan university, Seoul, Korea, Republic of

Introduction: Emerging evidence suggests that the gut microbiome plays a role in sleep disturbance. This study explored the characteristics of the gut microbiome and the functional metabolic pathways related to sleep quality.

Materials and methods: A total of 588 participants were recruited. Sleep quality was assessed using the Pittsburgh Sleep Quality Index, employing a cutoff score of 8.5. Based on this criterion, 42 individuals with poor sleep quality (PSQ) and 546 healthy controls with good sleep quality (GSQ) were identified. The fecal microbiome was analyzed using shotgun whole-metagenome sequencing, and groups were compared based on diversity metrics, differentially abundant species, metabolic pathways and metabolites.

Results: No significant differences in alpha and beta diversity indices were observed between individuals experiencing subjective sleep disturbances and those who did not. *Klebsiella pneumoniae* was more abundant in the PSQ group ($b = 0.476$; $q = 0.017$). Additionally, the following metabolic pathways were enriched in the PSQ group: octane oxidation (coefficient = 0.495, $q = 0.033$), the superpathway of acetyl-CoA biosynthesis (coefficient = 0.377, $q = 0.025$), superpathway of (Kdo)₂-lipid A biosynthesis (coefficient = 0.367, $q = 0.026$), petroselinic acid biosynthesis (coefficient = 0.353, $q =$

0.034), and superpathway of histidine, purine, and pyrimidine biosynthesis (coefficient = 0.349, $q = 0.042$). When metabolites levels associated with poor sleep quality were inferred using MelonnPan, higher xanthine levels were observed in the PSQ group (coefficient = 0.018; $q = 0.025$).

Conclusions: In summary, this study poses significant questions regarding the relationship between the gut microbiome and poor sleep quality.

Should School Start Times Be Delayed? A Narrative Review

T. Danisious¹

¹University of Oxford, Oxford, United Kingdom

Introduction: Adolescent sleep deprivation has emerged as a significant public health issue worldwide. The American Academy of Sleep Medicine recommends that adolescents aged 13–18 years obtain 8–10 hours of sleep each night to support optimal health (Paruth. However, many middle and high schools commence before 08:30 AM, conflicting with adolescent circadian rhythms. These early start times contribute to insufficient sleep, impairing academic performance, mood, and overall wellbeing.

Materials and methods: A narrative review methodology was used to synthesize current literature from high- and low-resource settings regarding adolescent sleep patterns and the impact of school start times. Sources included peer-reviewed journals, expert consensus guidelines, and public health data, with particular attention to circadian biology, school operations, and sociocultural contexts.

Results: Adolescents naturally experience a delay in their sleep-wake cycles due to hormonal influences on circadian rhythms. External factors such as screen use, academic demands, and caffeine intake exacerbate delayed sleep onset. Studies from high-income countries have shown benefits of delayed school start times, including longer sleep duration, improved academic performance, and reduced absenteeism. However, most studies are observational, and implementation challenges—such as transportation, scheduling conflicts, and climate considerations—limit generalizability, especially in countries like Sri Lanka.

Conclusions: Delaying school start times aligns with adolescent circadian physiology and has the potential to improve sleep health, academic outcomes, and overall wellbeing. However, implementation must be context-sensitive, especially in resource-limited settings. Complementary strategies such as sleep hygiene education, screen-time regulation, and exploration of dual-shift models aligned with chronotype may enhance effectiveness.

Acknowledgments: The author thanks the global sleep research community for their continued efforts in understanding adolescent sleep health, and acknowledges institutional guidance from the University of Oxford.

Sleep and Arousal in Adult Survivors of Chronic Childhood Trauma

A.S.Y. Ng¹, W.S. Chan²

¹The Hong Kong Polytechnic University, Department of Applied Social Sciences, Hong Kong, Hong Kong, SAR of China, ²The University of Hong Kong, Department of Psychology, Hong Kong, Hong Kong, SAR of China

Introduction: Childhood trauma survivors often report sleep disturbances, but the nature and characteristics of their sleep disturbances are understudied, especially in individuals without posttraumatic stress disorder (PTSD) (Kajeepeeta et al., 2015). Chronic trauma affects the autonomic nervous system, which could lead to altered arousal and subsequent sleep disturbances. However, previous studies examined sleep disturbances primarily in trauma survivors in clinical populations, making it difficult to evaluate whether altered sleep and arousal were consequences of trauma exposure or concomitants of current distress. This study investigated subjective and objective sleep and arousal parameters in chronic childhood trauma survivors without PTSD. Specifically, given the lack of previous data on both the sympathetic (SNS) and parasympathetic nervous system (PNS) activity, this study examined skin conductance levels (SCL) and high-frequency heart rate variability (HF-HRV) to fully understand arousal regulation in trauma survivors.

Materials and methods: Fifty survivors of chronic childhood trauma and 50 age-and-gender-matched controls with no history of childhood trauma were recruited (66% women; age = 26.09 ± 5.53). Participants completed the Pre-Sleep Arousal Scale and sleep diaries for 7 days. On the eighth day, they completed psycho-physiological assessments at the laboratory, including Pittsburgh Sleep Quality Index and Depression Anxiety Stress Scale. Three sets of SCL and HF-HRV recordings were obtained at baseline: when participants were at rest for 5 minutes; neutral: when participants read a neutral news story (2 minutes) and listened to a clip of relaxing music (2 minutes); and under distress: when participants read a news story about child abuse (2 minutes) and listen to a clip of child crying (2 minutes). Then, participants' sleep was measured by polysomnography.

Results: Relative to controls, trauma survivors had lower sleep quality (SQ) ($F = 24.70, p < .001, \eta^2 = .34$), longer diary-assessed sleep onset latency and wakefulness after sleep onset (WASO) ($F = 2.90, p = .026, \eta^2 = .11$) even after controlling for psychological distress. Objective differences were not significant in multivariate analyses ($F = 1.24, p = .30, \eta^2 = .05$), although univariate results showed that trauma survivors had greater WASO ($F = 4.54, p = .04$) and lower sleep efficiency ($F = 4.92, p = .03$). Trauma survivors reported higher pre-sleep arousal [$F(1, 82.3) = 31.1, p < .001, \eta^2 = .31$]. They also exhibited lower HF-HRV across all conditions [$F(1, 98) = 3.42, p = .05, \eta^2 = .03$], but SCL of the two groups was comparable. Finally, HF-HRV was associated with subjective SQ, total sleep time, and WASO and objective WASO.

Conclusions: This study found evidence for subjective but not objective sleep disturbances in childhood trauma survivors. Trauma survivors exhibited hyperarousal, indicated by heightened pre-sleep arousal and reduced HF-HRV. Our findings added to the literature that hyperarousal in trauma survivors was substantiated by decreased PNS rather than increased SNS activity, suggesting impaired autonomic downregulation. Finally, correlational findings underscored the potential mediating role of compromised PNS activity in the relationship between childhood trauma and sleep. Future research should explore how altered arousal may play a role in understanding and treating sleep disturbances in childhood trauma survivors.

Sleep and circadian knowledge in Australian undergraduate university students

Y.S. Bin^{1,2}, M. Shin³, K. Melehan⁴, G.R. Yamakawa⁵, C.M. Chow⁶, P. Cistulli^{1,2}

¹University of Sydney, Charles Perkins Centre, Sydney, Australia, ²University of Sydney, Faculty of Medicine and Health, Northern Clinical School, Sydney, Australia, ³University of Sydney, Brain and Mind Centre, Youth Mental Health & Technology, Sydney, Australia, ⁴University of Sydney, Faculty of Medicine and Health, Discipline of Sleep Medicine, Sydney, Australia, ⁵University of Sydney, Faculty of Medicine and Health, School of Medical Sciences, Sydney, Australia, ⁶University of Sydney, Faculty of Medicine and Health, Sydney School of Health Sciences, Discipline of Exercise and Sports Science, Sydney, Australia

Introduction: University students are particularly vulnerable to sleep loss and circadian disruption. Although 7-9 hours of sleep are recommended, up to 11 hours may be required and appropriate for young adults aged 18-25 years. However, sleep is often curtailed by the need to juggle study, paid employment including shift work, and social obligations. This is exacerbated by the circadian delay of adolescence, which continues to the mid- to late-20s. University students are also often engaged in shiftwork. Understanding students' levels of knowledge around sleep and circadian health is critical for designing effective sleep education and health promotion programs.

Materials and methods: Undergraduate students enrolled in an introductory elective subject on sleep and circadian rhythms at the University of Sydney during 2020 to 2025 were asked to complete a pre-course survey as a participation activity. Knowledge was assessed using: 5 multiple-choice questions (MCQs) aligned with key learning outcomes of the subject; a 15-item Sleep Knowledge Questionnaire (SKQ) developed by Gallasch & Gradisar (2007); and the 15-item Sleep Alertness & Fatigue Education in Residency (SAFER) Knowledge Questionnaire from the American Academy of Sleep Medicine. Demographic data, reasons for enrolment, stage of behavioural change, and previous sleep education was also collected.

Results: N=7,287 students responded (67% response, 63% female, mean age 20.2 years, SD 2.5 years). Students endorsed goals of enrolment as increasing knowledge of sleep (88%), improving or changing sleep habits (88%), in addition to completing degree requirements (87%). Consistent with this, most students were in the contemplation (35%) and preparation (42%) stages of behavioural change around

making lifestyle changes to improve sleep. Most students (69%) reported no previous sleep education.

Students scored 2.5 (SD 1.1) out of 5 on MCQs testing key learning outcomes, indicating a lack of understanding of the two-process model of sleep regulation, the circadian delay in adolescence, and the use of light for circadian phase shifting. Mean score on the SKQ, was 10.9 (SD 2.4) out of 15, indicating some understanding of sleep hygiene but a lack of knowledge around bed restriction for insomnia. On the SAFER, students scored 8.2 (SD 2.4) out of 15 demonstrating a lack of practical knowledge around managing fatigue and sleep loss, the use of naps, and shift work. No significant differences were observed for students with and without previous sleep education on any of the knowledge scores (MCQ $t_{7285}=0.95$, $p=0.34$; SKQ $t_{6347}=1.20$, $p=0.23$; SAFER $t_{6175}=0.01$, $p=0.99$).

Conclusions: Undergraduate students possess a basic understanding of sleep hygiene but lack practical knowledge around circadian rhythms and how to manage shift work and sleep loss. Results from this self-selected sample (together with enrolment numbers in this elective subject) indicates a high level of interest in learning about and improving sleep, and points to areas that should be taught more widely. Future research should evaluate the effectiveness of targeted education and health promotion programs for improving knowledge and changing sleep and circadian behaviours.

Acknowledgments: With many thanks to the students of OLET1510 Health Challenges: Sleep & Circadian Rhythms who participated in this study.

Sleep and longevity: insights from sleep macroarchitecture and nocturnal heart rate variability

I. Filchenko¹, J. van der Meer¹, C. Bernasconi¹, M.H. Schmidt¹, C.L.A. Bassetti¹

¹Bern University Hospital (Inselspital) and University of Bern, Department of Neurology, Bern, Switzerland

Introduction: Healthy aging is priority in the international public health (Bassetti et al., 2022). Emerging evidence indicates that sleep-wake disorders and alterations are causally linked to adverse health outcomes, suggesting that sleep represents a key preventive target for longevity (Mander et al., 2017; Sun et al., 2024). As such, low electroencephalographic delta and sigma power during sleep was linked to cardiovascular risk (Berger et al., 2022), whereas altered sleep spindle amplitude and high theta, alpha, and sigma power were associated with cognitive decline (Djonlagic et al., 2019). Considering the paucity of the current evidence, we aimed to identify sleep phenotypes associated with selected incident comorbidities using real-world data from a university sleep center.

Materials and methods: This is an analysis of the Bernese Sleep-Wake Registry ($n \approx 11000$). Using clinical polysomnography, we quantified sleep macroarchitecture according to AASM criteria and nocturnal heart rate variability (HRV; 21 parameters representing time domain, frequency domain, and non-linear measurements) as the marker of autonomic functioning. Per study participant, we identified incident comorbidities (i.e., a diagnosis was not mentioned at the time of polysomnography but was mentioned at the later assessment point) from the clinical records. 36 incident comorbidities were classified into eight major groups (incident proportion [IP]: neurologic, 24.58%; psychiatric, 16.32% [i.e., depression in 92% cases]; cardiovascular, 19.24%; endocrine, 9.78%; metabolic, 8.49%; pulmonary, 3.71%; infectious, 11.91%; neoplastic, 4.81%). Associations between incident comorbidities and sleep parameters were explored with multiple logistic regression adjusted for age and sex. Only significant ($p < 0.05$) associations were reported.

Results: 4170 participants were included in the analysis (age: 48 ± 19 years; 63% men; total sleep time: 339.34 ± 91.79 minutes; cumulative observation time: 13217 person-years). Sleep macroarchitecture showed limited associations with incident comorbidities, with sleep-disordered breathing being moderately associated with cardiovascular, endocrine, and metabolic diseases and with low duration of slow-wave sleep being weakly associated with endocrine diseases. In contrast, HRV was associated with many of the incident comorbidities. Specifically, neurologic diseases were related to high and complex HRV. In a subanalysis focused on neurologic diseases, stroke (IP: 6.60%) was strongly associated with high and complex HRV, whereas cognitive dysfunction (IP: 10.06%) was moderately associated with a high very low frequency component. Neurodegeneration and neuroinflammation (IP: 1.63%) were strongly associated with low HRV with high sympathetic drive. Psychiatric diseases were strongly associated with low HRV, accompanied by reduced complexity and parasympathetic dominance. Metabolic diseases were moderately linked to high HRV with a high very low-frequency component. Neoplastic diseases were moderately associated with high HRV predictability.

Conclusions: These findings highlight the association of specific aspects of sleep physiology with incident comorbidities in a longitudinal analysis. Notably, nocturnal HRV seemed to provide stronger predictive value compared to sleep macroarchitecture, suggesting that altered autonomic functioning, reflected in HRV, may represent a prodromal phase preceding more overt changes in sleep macroarchitecture. These results underline the potential of nocturnal HRV for early risk stratification and targeted interventions, particularly for neurologic and psychiatric diseases, emphasizing its relevance for brain health. We will further explore the link between health outcomes and sleep microarchitecture.

Acknowledgments: None

Sleep and Nap habits within professional rugby club: SoSleep® Program. From prevention and coaching to performance optimization

A. Aranda^{1,2,3,4}, L. Aranda², A. Lamonzie⁵, P. Izard⁵

¹Ramsay Santé, Clinique de l'Union, Sleep Unit, St Jean, France, ²ALDV Consulting & Holding, Toulouse, France, ³Santé Cité Clinique Rive Gauche, Sleep Unit, Toulouse, France, ⁴Clinavenir Clinique des minines, Sleep Unit, Toulouse, France, ⁵Stade Toulousain, Medical Department, Toulouse, France

Introduction: Elite Athletes are susceptible to sleep inadequacies especially poor sleep quality and short sleep habits. Poor Sleep and sleep habit are associated to decreased athlete performance, increased injuries and less team success. 2021 expert consensus and clubs medical department were searching for assessment, program and more research on this field. We assessed a 360° sleep program on club request in prospective follow-up upon individual volunteer athlete to sensitize, evaluate and coach for sleep goals to improve individual and collective player's sleep for recovery and performance optimization upon elite rugby team.

Materials and methods: 72 rugby players athletes from professional teams were proposed for educational and voluntary sleep program (SoSleep®) over last 3 seasons in prospective study. The program was consisting in 360° sleep's evaluation directly at club's training field area with education briefing, sensibilization programs, on-line questionnaires, individual sleep assessment, in-board nap room, wearable polysomnography (Dreem® head band), medical sleep clinic evaluation with full home polysomnography test on requirements of club medical department.

Results: We had 47 sensibilization program forms, 36 players with several medical interviews, 106 questionnaire sets, 29 head band nights, 6 medical assessment pathways. Sensibilization program results showed that 52% were exposed to bad sleep prior to program then 89% to individual sleep better knowledge and 98% better sleep management intention after completion. Nap's habits results found that 46% to 91% of all players between 5 specific time period outcomes. We showed also that 91% of athletes will have nap habit during training week more than 75% during rest week (p-value = 0.0625) or 46% during day after match (p-value = 0.002569). Wearable polysomnography results showed 7h52 mean sleep time (26% REM-sleep, 17% deep-sleep, 49% light-sleep, 8% WASO). Average satisfaction program level was 4,53/5.

Conclusions: Sleep education program and our results with specific follow-up and polysomnographic evaluation at training field bedside seem of great interest and very promising. Results deserve to be discussed and confirmed subsequently, notably the low polysomnography deep sleep's proportion. Main explanation up to date would be that evaluations were made during the regular or final phase season when physical training is adjusted, likely different from pre-season trainings with modified sleep needs. Point of interest was the players' napping habits within week preparation and on day match. Player nap results indicate that this behavior seems more associated with an element of preparation and optimization than recovery. Sleep banking usefulness may also be considered and recommended. More data and specific outcome are needed for this specific population.

By the way, associated with competition results over the last 3 seasons with 3 consecutive victories in main national ligue TOP14 and 2 continental victories in European Champions cup, sleep optimization within a sports club seems a required element both for the individual recovery and performance for the player and the collective performance for the team.

Acknowledgments: We thank the Stade Toulouse SASP and SOS oxygen for institutional and financial support.

Sleep and Scuba Diving: Prevalence of Sleep Disorders and Their Potential Links with Decompression Illness in Recreational Divers

J.B. Maldent¹, E. Saguin², C. Louvrier³, D. Attias⁴, A. Pathak⁵, J. Pichon⁴

¹Clinique Ambroise Paré, Sleep and ENT medicine department, Toulouse, France, ²Hôpital d'instruction des Armées Bégin, Department of Psychiatry, Saint-Mandé, France, ³Clinique Ambroise paré, Sleep and ENT medicine department, Toulouse, France, ⁴Clinique Pasteur, Department of Pneumology, Toulouse, France, ⁵Princess Grace Hospital, Department of Cardiology, Monaco, Monaco

Introduction: Scuba diving requires sustained cognitive and physical performance and carries inherent risks. While fatigue and sleep disorders are known contributors to errors in high-risk environments, their impact on diving safety remains underexplored. Data linking sleep disorders to decompression illness (DCI) are scarce, particularly among recreational divers. This study aimed to assess the prevalence of sleep disturbances and their possible association with DCI in a large cohort of civilian recreational divers.

Materials and methods: We conducted a descriptive, cross-sectional study using anonymous, self-administered questionnaires distributed to recreational divers across metropolitan and overseas France, as well as Belgium. All questionnaires were disseminated institutionally via affiliated diving clubs. Professional and military divers were excluded. Data included demographics, diving history (number of dives and certification level), medical and accident history, and sleep-related factors. We used validated instruments: the Berlin questionnaire for OSA risk, the Pichot fatigue scale (cut-off >14), and a general sleep disorders questionnaire. Participants also reported insomnia, habitual snoring, and sleep quality the night before dives. DCI was defined as any incident with neurological, vestibular, or cardiopulmonary symptoms self-reported as a prior diving accident.

Results: A total of 572 complete responses were analyzed. The mean age was 49 ± 13 years, and 363 participants (65%) were male. The median number of lifetime dives was 250 [90–800]. Regarding certification level, 167 divers (29%) were level 1–2, 200 (35%) were level 3–4, and 189 (33%) were certified instructors. A total of 75 divers (13%) reported a prior diagnosis of obstructive sleep apnea (OSA), and 331 (58%) habitual snoring. The Berlin questionnaire identified 160 participants (28%) as high risk for OSA. Among the 75 divers with diagnosed OSA, 43 (57%) were untreated, 9 (12%) used a mandibular advancement device, and 23 (31%) were treated with continuous positive airway pressure (CPAP). Thirty-nine divers (7%) reported at least one episode of DCI. Among all divers, 486 (85%) reported having previously dived after a poor night's sleep, compared to 379 out of 533 divers without DCI (71%) ($p=0.07$). Among the 39 divers who had experienced DCI, 20 (53%) reported sleeping poorly the night before the incident. A positive Berlin score was found in 14 out of 39 divers with DCI (36%), compared to 128 out of 533 without DCI (24%) ($p = 0.1114$). Insomnia was reported by 74 divers (13%), and 35 (6%) had significant fatigue based on the Pichot scale (score >14).

Conclusions: Sleep-related risk factors are frequent among recreational divers. Trends suggest a possible link between poor sleep and DCI vulnerability. The proportion of untreated OSA and reported pre-dive fatigue underlines the value of including sleep screening in diver medical evaluations. These findings pave the way for future prospective studies and call for the integration of sleep health into diver medical assessments.

Sleep Apnea Monitoring with a Consumer-Grade Wearable: Performance of the Samsung Galaxy Watch

H. Jung¹, D. Kim², J. Choi¹, J.W. Seo¹, H. Lee¹, D. Lee¹, E.Y. Joo³

¹Samsung Electronics, Suwon, Korea, Republic of, ²Ewha Womans University Seoul Hospital, Ewha Womans University, College of Medicine, Seoul, Korea, Republic of, ³Sungkyunkwan University School of Medicine, Departments of Neurology, Samsung Medical Center, Seoul, Korea, Republic of

Introduction: Obstructive sleep apnea (OSA) is a common but significantly underdiagnosed sleep disorder associated with various adverse health outcomes, including cardiovascular disease, cognitive impairment, and reduced quality of life. The gold standard for diagnosing OSA is in-laboratory polysomnography (PSG), which, despite its diagnostic accuracy, presents challenges in terms of

accessibility, cost, and user burden. Wearable devices have emerged as promising alternatives for sleep apnea screening due to their convenience and potential for continuous, at-home monitoring. The Samsung Galaxy Watch (GW), a wrist-worn wearable device equipped with optical sensors for SpO₂ measurement, recently received FDA approval as a Software as a Medical Device (SaMD) for sleep apnea screening. This study aims to validate the AHI estimation performance of the Galaxy Watch6 and Watch7 models in comparison to PSG.

Materials and methods: A total of 326 valid sleep datasets were collected from participants undergoing overnight PSG at Samsung Medical Center. Each participant wore two identical Galaxy Watch devices—either GW6 or GW7—on both wrists during sleep to assess device and wrist-based variability. The devices collected multi-wavelength photoplethysmography (PPG) signals at 25 Hz and calculated SpO₂ values every second. AHI was estimated using a machine learning algorithm applied to one-minute epochs of SpO₂-derived features. Only sleep sessions with $\geq 70\%$ SpO₂ coverage and ≥ 4 hours of duration were included. PSG AHI values served as the reference standard for evaluation. Agreement metrics included Pearson correlation, intraclass correlation coefficient (ICC), Bland-Altman analysis, and diagnostic accuracy using AHI ≥ 15 as the clinical threshold.

Results: The estimated AHI from the Galaxy Watch showed strong correlation with PSG AHI (Pearson $r = 0.9$; ICC = 0.87; 95% CI: 0.84–0.90). Bland-Altman analysis revealed a mean bias of -1.9 events/h, indicating slight underestimation. For detecting moderate-to-severe OSA (AHI ≥ 15), the Galaxy Watch achieved 80% sensitivity, 87% specificity, 92% positive predictive value (PPV), and 70% negative predictive value (NPV). AHI estimation error varied by OSA severity: slight overestimation in normal cases and increasing underestimation in mild, moderate, and especially severe OSA groups (-4.77 events/h in severe cases). A significant negative correlation was found between AHI error and the PSG hypopnea index ($r = -0.47$), suggesting that errors were primarily driven by hypopnea detection, whereas no correlation was observed with the apnea index. SpO₂ coverage and estimation performance were similar between GW6 and GW7 (92.82% vs. 94.21%). Wrist-to-wrist AHI variability was minimal overall, but greater in severe OSA cases and under low SpO₂ coverage conditions, emphasizing the need for high-quality signal acquisition.

Conclusions: The Galaxy Watch demonstrates high accuracy in estimating AHI and effectively identifies moderate-to-severe OSA, aligning with previously reported FDA performance claims. Despite some limitations in hypopnea detection, the device offers a reliable and accessible screening solution for sleep apnea, supporting its broader use in home-based sleep health monitoring. High SpO₂ signal coverage is essential for optimal performance, especially in severe OSA cases. These findings highlight the potential of wrist-worn wearables as scalable tools for public health screening of sleep-disordered breathing.

Sleep Apnea Syndrome in Cardiology: Inaugural Experience of a Sleep Laboratory in Sub-Saharan Africa

O. Dieye^{1,2}, I.B. Diop², A.M. Dieye¹, K. Ba²

¹Centre de médecine du sommeil SAKINA, Dakar, Sénégal, Dakar, Senegal, ²Clinique Cardiologique CHU Fann Dakar Sénégal, Dakar, Senegal

Introduction: Les laboratoires du sommeil sont quasi inexistants en Afrique subsaharienne, malgré la prévalence croissante du syndrome d'apnée du sommeil (SAS), un facteur de risque cardiovasculaire indépendant. Nous rapportons la première expérience d'un laboratoire dédié au sommeil à Dakar, au Sénégal, en nous concentrant sur les caractéristiques cliniques, paracliniques et polysomnographiques des patients évalués pour un syndrome d'apnée obstructive du sommeil suspecté (SAOS) dans un cadre de cardiologie.

Materials and methods: We retrospectively analyzed 186 patients (October 22, 2020 – January 15, 2025) who underwent overnight polysomnography: attended video-polysomnography (n=139) or ambulatory recording (n=47). Standardized questionnaires (Epworth Sleepiness Scale, Pichot Fatigue Scale) were administered. Demographics, cardiovascular risk factors, clinical symptoms, and polysomnographic indices were assessed. OSAS was defined as an apnea-hypopnea index (AHI) $> 5/h$.

Results: Mean age was 48 ± 28 years; 54% male (sex ratio 1.18), mean BMI 27 kg/m^2 . Cardiovascular risk factors were common: hypertension 52%, type 2 diabetes 21%, dyslipidemia 19%. Predominant symptoms were snoring (81%) and morning fatigue (71%). Frequent cardiology referral reasons included recurrent malaise (n=90) and nocturnal palpitations (n=96). Epworth score > 10 occurred in

66% (n=123), mean Pichot score was 12. OSAS was diagnosed in 177 patients (95%): mild (n=43), moderate (n=60), severe (n=91, 49%). Obstructive predominance was noted in 66% (n=123), mixed with central predominance in 34% (n=63). Mean polysomnographic parameters: AHI 29/h, oxygen desaturation index 17/h, microarousal index 61/h, snoring events 222/h, periodic limb movements 47/h. Severe OSAS patients had reduced sleep efficiency (49% vs. 81% overall). Associated findings included periodic limb movements (n=130), Cheyne–Stokes respiration (n=2), obesity hypoventilation syndrome (n=1), and restless legs syndrome (n=3). **Figure 1** presented the main results.

Conclusions: In this inaugural Sub-Saharan African sleep laboratory, OSAS prevalence among cardiology referrals was extremely high (95%), predominantly in middle-aged, non-obese men with cardiometabolic comorbidities. Our data highlight the urgent need to integrate sleep diagnostics into cardiovascular care pathways in the region.

Introduction: Sleep disturbances are a significant public health concern, linked to diminished quality of life and various somatic and mental disorders. Despite high prevalence, systematic data on sleep in Russia's vast, geographically diverse population remain limited. The SleepStudyRU project, encompassing 11 time zones and diverse climatic regions, offers unique scale and fundamental significance for sleep epidemiology in such a heterogeneous environment. Our objective was to examine sleep characteristics, ascertain disturbance prevalence, and identify associated factors among the Russian population.

Materials and methods: This multicenter SleepStudyRU project surveyed 3,529 adults across all Russian Federal districts, ensuring robust sample representativeness. Data were collected via a custom questionnaire covering demographic, somatic, somnological, and chronobiological profiles. Analysis used frequency characteristics (proportion, %), median, and interquartile range (IQR). Multivariate logistic regression identified associated factors, calculating adjusted odds ratios (aORs) with 95% confidence intervals (95% CIs)

Results: Our sample comprised 3,529 respondents (66.2% women; 33.8% men) from diverse age groups (14–60+ years) and socioeconomic strata across all Federal districts. A striking 67.0% reported sleep quality disturbances. Primary issues included difficulties with sleep onset (38.6%), early morning awakenings (19.8%), and sleep maintenance challenges (13.9%). Daytime sleepiness was reported by 68.1%. Median self-assessed sleep quality was 7 (IQR 5–8) out of 10. For duration, 31.5% slept 7

hours, 25.9% slept 6 hours, and 15.2% slept under 5 hours.

Multivariate regression identified these independent factors significantly associated with increased likelihood of sleep quality disturbances: female sex (aOR 1.26; 95% CI 1.08–1.47); age over 60 years (aOR 1.49; 95% CI 1.07–2.08), presence of comorbidities (aOR 2.15; 95% CI 1.82–2.54), mobile phone use before sleep (aOR 1.56; 95% CI 1.32–1.85), watching TV before sleep (aOR 1.27; 95% CI 1.06–1.51), divorced or widowed marital status (aOR 1.90–1.91; 95% CI 1.38–2.63 and 1.19–3.07), residence in Volga (PFD), Siberian (SFD), or Southern (YFD) Federal Districts (aOR 1.62–2.52 vs. Central (CFD)), suggesting regional specificities. Conversely, moderate regular physical activity (1–2 times/week) was associated with reduced disturbance likelihood (aOR 0.74; 95% CI 0.62–0.89).

Conclusions: These preliminary SleepStudyRU data confirm an exceptionally high prevalence of sleep quality disturbances (67.0%) in Russia. Identified modifiable factors like pre-sleep gadget/TV use and comorbidities indicate promising targets for preventive/therapeutic interventions. Results spanning 11 time zones and diverse climatic zones critically underscore their importance for future investigations into geographical/chronobiological influences on national-scale sleep. Developing large-scale educational programs on sleep hygiene and behavioral impact is unequivocally necessary for improving Russian public health. Further research will clarify regional specificities.

Acknowledgments: The authors extend their sincere gratitude to all participants of the SleepStudyRU project for their valuable contribution and to the research assistants for their dedicated work in data collection

Sleep Concordance and Discordance in Dyads of Cancer Patients and Bed-Partner Caregivers: A Systematic Review on Patterns, Health Impacts, and Dyadic Interventions

J. Zhong¹, W. Liang², B. Ho¹, C.-C. Lin¹

¹The University of Hong Kong, Hong Kong, China, ²Nanjing Medical University, Nanjing, China

Introduction: Optimal sleep is composed of adequate sleep duration (seven to eight hours) that is easily initiated (less than 20 min of sleep onset latency [SOL]) and maintained without disruptions (less than 20 min of wake after sleep onset [WASO]). Non-optimal, disturbed sleep has been seen at an alarming high level in cancer patients and caregivers. The context of coping with cancer together as a relational system makes the cancer patient-partner dyads unique in the phenomenon of sleep and sleep disturbance. Therefore, this systematic review aimed to synthesize evidence on sleep concordance and discordance in the dyads of cancer patients and bed-partner caregivers.

Materials and methods: We conducted the systematic review following the JBI Manual for Evidence Synthesis on conducting systematic reviews of effectiveness. Searches were conducted the four medical databases, including PubMed, CINAHL Plus, Web of Science, and EMBASE. Studies were included if they focused on sleep in adult cancer populations, and included the perspectives on dyadic patterns, health impacts, and interventions of sleep among cancer patient-caregiver dyads. A narrative synthesis was conducted based on our three research questions: Dyadic patterns (sleep concordance and discordance), Health impacts (actor and partner effect on physical and psychosocial health), and Dyadic interventions. Meta-analyses were performed to determine the pooled effect of dyadic intervention on sleep outcomes.

Results: A total of 3810 studies imported for screening. Twenty-eight studies were included in the narrative synthesis with 19 observational studies and 9 interventional studies. Majority of caregivers reported the relationships with patients as spouses or partners. Observational studies identified significant actor and partner effects between sleep and health outcomes, including physical functioning, anxiety and depression, quality of life, and relationship satisfaction. Mindfulness practices were the most used intervention strategies in dyads. Psychological interventions, including family resilience therapy and acceptance and commitment therapy, have been applied in cancer patient-caregiver dyads. Eight studies reported the effectiveness of dyadic interventions on cancer patients' and caregivers' sleep disturbances. Dyadic interventions yielded a significant effect on decreasing patients' sleep disturbances (SMD=-0.53, 95%CI [-0.91, -0.15]) with a medium level of heterogeneity indicated by $I^2=48\%$ as well as a significant effect on decreasing caregivers' sleep disturbances (SMD=-0.52, 95% [-0.84, -0.19]) with a low heterogeneity indicated by $I^2=0\%$.

Conclusions: This review acknowledged the interdependent nature of sleep among cancer patients and caregivers. Our results could have significant implications in sleep management for healthcare professionals working with dyads impacted by cancer, particularly bed-sharing couples.

Sleep disorders after mild traumatic brain injuries in young male patients

N. Syrmos¹

¹Aristotle University, Thessaloniki, Greece

Introduction: Aim of this study was to present cases of sleep disorders after mild traumatic brain injuries in young male patients(<30 years old).

Materials and methods: 10 cases are presented. 10 young male patients. Range of age 18-30 years old. Some common symptoms were: 3 of patients have insomnia, 3 patients have sleep apnea, 2 have hypersomnia, and 2 have narcolepsy.

Results: All of them received :Cognitive behavioral therapy (CBT), Natural sleep-inducing remedies, Pharmacotherapy and continue Neurological, Psychological and Psychiatric Support. Good results in 8 patients (80%) and moderate in 2 (20%).

Conclusions: Multidisciplinary approach is essential to achieve optimal results for our patients.

Sleep Disorders in Chronic Kidney Disease Patients

C. Biswas¹, M. Begum Mony², D. Das³, E. Haque⁴, R.M. Talukder⁴

¹Medical college for Women's and Hospital, Psychiatry, Dhaka, Bangladesh, ²Medical college for Women's and Hospital, Nephrology, Dhaka, Bangladesh, ³Gazaria Heath Complex, Medicine, Munsigang, Bangladesh, ⁴Medical college for Women's and Hospital, Medicine, Dhaka, Bangladesh

Introduction: Chronic kidney disease (CKD) is associated with a variety of comorbidities, including sleep disorders, which significantly impact patients' quality of life. Sleep disturbances in CKD patients are underreported and poorly managed, despite their potential to exacerbate CKD-related complications.

Aim of the study: This study aims to assess the prevalence and types of sleep disorders among CKD patients and explore their clinical characteristics

Materials and methods: A cross-sectional study was conducted on 50 CKD patients at conducted at the Department of Nephrology, Medical College for Women& Hospital, Dhaka Bangladesh. During 1 year from January 2024 to December 2024.

Sleep disorders were evaluated using the Pittsburgh Sleep Quality Index (PSQI) and Epworth Sleepiness Scale (ESS).

Clinical and demographic data were also collected.

Results: The study revealed that 40% of participants experienced insomnia, 30% had obstructive sleep apnea (OSA),

20% suffered from restless legs syndrome (RLS), and 10% reported excessive daytime sleepiness. A total of 80% of the participants exhibited poor sleep quality based on the PSQI score, and 30% showed excessive daytime sleepiness according to the ESS. The majority of patients were in advanced stages of CKD (stage 5D), with a high prevalence of comorbidities such as hypertension and diabetes mellitus

Conclusions: In our study, sleep disorders were highly prevalent in CKD patients, significantly affecting their quality of life. The findings underscore the need for routine screening and management of sleep disturbances in this population. Further research is needed to explore the mechanisms linking CKD and sleep disorders, as well as the efficacy of targeted interventions to improve sleep quality in these patients.

Sleep Disturbance and Stressor-Specific Cortisol Dysregulation in Temporomandibular Disorder

H. Altier¹, J. Leoutsakos¹, A. Sharma¹, C. Campbell¹, R. Edwards², J. Haythornthwaite¹, L. Buenaver¹

¹Johns Hopkins University School of Medicine, Department of Psychiatry and Behavioral Sciences, Baltimore, United States, ²Brigham and Women's Hospital, Harvard Medical School, Boston, United States

Introduction: Nearly 60% of individuals with temporomandibular joint disorders (TMD), chronic pain conditions affecting the jaw joint and muscles, report sleep disturbances and daytime sleepiness. Further, sleep disruption alters hypothalamic-pituitary-adrenal (HPA) axis functioning in chronic pain. Salivary cortisol reactivity to pain-related (quantitative sensory testing; QST) and social-evaluative (Trier Social Stress Test; TSST) stressors in TMD patients and healthy controls was measured. We hypothesized that sleep disturbance would differentially influence cortisol trajectories, with TMD patients showing impaired regulation and healthy individuals exhibiting more flexible responses.

Materials and methods: TMD patients ($N=33$; $M_{age}=33.5\pm10.1$ years, 70% female, 64% white) recruited from a facial pain clinic and matched pain-free community controls ($N=20$; $M_{age}=27.9\pm7.7$ years, 60% female, 55% white) underwent QST and TSST on separate afternoons, with testing order randomized. Salivary cortisol was collected at baseline, immediately post-testing, and 15-, 20-, 25-, 30-, and 45-minute intervals post-testing. Participants completed psychosocial measures, including the Pittsburgh Sleep Quality Index (PSQI) and Epworth Sleepiness Scale (ESS), at baseline. Separate linear mixed-effects models evaluated log-transformed cortisol trajectories after each task in R, testing 3-way interactions between group (healthy vs. TMD), collection time, and sleep variables (PSQI total and subscales, ESS total), controlling for baseline cortisol. Natural splines modeled cortisol trajectories across time (spline 1=early phase up to 20 minutes post-stressor; spline 2=recovery phase). Likelihood ratio tests supported using 2 degrees of freedom for modeling time.

Results: After QST, significant 3-way interactions emerged for PSQI total (spline 1: $b=0.17[0.00, 0.34]$, $t(324)=1.99$, $p=.047$), sleep quality (spline 1: $b=1.23[0.53, 1.93]$, $t(324)=3.44$, $p<.001$), sleep latency (spline 1: $b=0.69[0.12, 1.26]$, $t(324)=2.37$, $p=.019$), sleep duration (spline 1: $b=0.89[0.15, 1.63]$, $t(324)=2.37$, $p=.019$), sleep disturbance (spline 2: $b=0.58[0.04, 1.12]$, $t(324)=2.12$, $p=.035$), daytime dysfunction (spline 1: $b=-0.68[-1.34, -0.02]$, $t(324)=-2.01$, $p=.045$), sleep efficiency raw score (spline 1: $b=-0.05[-0.09, -0.01]$, $t(324)=-2.68$, $p=.008$), and ESS total score (spline 1: $b=0.10[0.01, 0.19]$, $t(318)=2.10$, $p=.036$). Overall, greater sleep dysfunction was associated with elevated early cortisol responses in TMD patients and steeper early declines in healthy controls.

After TSST, significant 3-way interactions were found for PSQI total (spline 2: $b=-0.15[-0.25, -0.05]$, $t(318)=-2.86$, $p=.004$), sleep latency (spline 2: $b=-0.35[-0.70, -0.01]$, $t(318)=-2.02$, $p=.045$), sleep disturbance (spline 1: $b=-1.41[-2.21, -0.61]$, $t(318)=-3.48$, $p<.001$), daytime dysfunction (spline 2: $b=-0.59[-0.98, -0.19]$, $t(318)=-2.93$, $p=.004$), sleep efficiency raw score (spline 1: $b=0.05[0.01, 0.09]$, $t(318)=2.55$, $p=.011$; spline 2: $b=0.03[0.01, 0.06]$, $t(318)=2.83$, $p=.005$), and ESS total score (spline 1: $b=-0.10[-0.19, -0.01]$, $t(312)=-2.29$, $p=.022$). Overall, greater sleep dysfunction was associated with blunted cortisol in TMD patients and stronger cortisol increases in healthy controls.

Conclusions: These findings suggest stressor-specific HPA axis patterns. Following pain-related stress, sleep-disturbed healthy controls demonstrate intact cortisol downregulation, while TMD patients show sustained activation. Conversely, social-evaluative stress elicits stronger cortisol responses in poor-sleeping healthy controls, possibly due to heightened threat sensitivity after impaired sleep, whereas TMD patients exhibit blunted responses, potentially reflecting HPA exhaustion or chronic stress habituation. Future research with larger samples and objective, longitudinal sleep measures is needed to replicate these patterns and clarify mechanisms linking sleep and HPA regulation in TMD.

Acknowledgments: This research was supported by the Johns Hopkins Medicine Blaustein Pain Research Fund Grant.

SLEEP HEALTH AMONG MEDICAL STUDENTS IN ABAKALIKI NIGERIA: A DESCRIPTIVE STUDY

C. Eze¹, F. Okoro¹, O. Afolabi¹, U. Kalu¹

¹Alex Ekwueme Federal University Teaching Hospital Abakaliki, Internal Medicine, Abakaliki, Nigeria

Introduction: Sleep health focuses on those measurable characteristics of sleep that are most clearly associated with physical, mental, and neurobehavioral well-being, and not necessarily the absence of sleep disorder. Sleep health is characterised by subjective satisfaction, appropriate timing, adequate duration, high efficiency, and sustained alertness during waking hours. Adequate and restful sleep is particularly crucial for medical students, who face unique challenges due to the demanding nature of their academic and clinical responsibilities. There is limited data on sleep health among medical students in Nigeria. This research study investigated the pattern of sleep health among medical students in Abakaliki Nigeria.

Materials and methods: This cross-sectional observational study was undertaken among the medical students of 2 public institutions in Abakaliki Nigeria from 16th to 23rd June 2023. The data collection was done using SATED Questionnaire.

Results: Out of the 288 medical students (males- 53.1%, females- 46.9%), good sleep health was recorded in 6.6%. The mean SATED sleep score was 4.9 ± 1.7 (male- 4.9 ± 1.8 , female- 4.9 ± 1.6) (p -value = 1) and it was significantly lower among the final-year students. Age difference, sex difference and presence of chronic headache did not significantly affect the SATED sleep score. The mean sleep duration was 6.1 ± 1.5 hours (male- 6.1 ± 1.6 , female- 6.0 ± 1.4). Sleep duration (54.5%) had the best rating while sleep efficiency (44%) had the lowest rating among the assessed sleep domains.

Conclusions: Sleep health as measured with the SATED sleep health score is poor among medical students in Abakaliki Nigeria. It is significantly poorer among final-year medical students.

In view of the attendant consequences of poor sleep health, interventions like education about sleep hygiene, the formation of support groups, the use of cognitive behavioural therapy (CBT), and the provision of resources to manage anxiety could help improve sleep health among medical students and ensure that they are well-rested and ready to learn and practice medicine.

Acknowledgments: We acknowledge the staff of the Medical Records Department of AEFUTHA for the help in data collection

SLEEP HEALTH AMONG PATIENTS ATTENDING ADULT NEUROLOGY CLINIC IN ABAKALIKI NIGERIA

C. Eze¹, F. Okoro¹, O. Afolabi¹, U. Kalu¹

¹Alex Ekwueme Federal University Teaching Hospital Abakaliki, Internal Medicine, Abakaliki, Nigeria

Introduction: Sleep health indicates how well an individual or population sleeps. Good sleep health is characterized by subjective satisfaction, sustained alertness during waking hours, appropriate timing, high efficiency, and adequate duration. Poor sleep health is associated with many short-term and long-term health consequences. There are limited data on the pattern of sleep health in Nigeria. Against this backdrop, we embarked on this study to determine the Pattern of Sleep Health among patients attending the Adult Neurology clinic in a Federal Teaching Hospital, in Abakaliki, Nigeria.

Materials and methods: This was a cross-sectional observational hospital-based study undertaken from July to September 2022 at the Adult Neurology clinic of the Alex Ekwueme Federal University Teaching Hospital Abakaliki, Nigeria.

Results: Out of the 267 (Male- 146) patients recruited for the study, 19% had good sleep health with SATED scores of 8 to 10 while 81% had poor sleep health. The absence of alcohol abuse, cigarette smoking, and neurological diagnosis were statistically associated with poor sleep health with no sex and age predilection. The mean sleep duration was 7.47 ± 1.50 hours (male= 7.63 hours, female= 7.28 hours, 18- 64years= 7.43 hours, ≥ 65 years =7.88 hours). **Timing** of sleep (mean= 0.97) was the least rated while sleep **satisfaction** (mean= 1.54) was the best-rated sleep dimension.

Conclusions: Sleep health is poor among patients attending the adult Neurology clinic at Abakaliki Nigeria and it is associated with smoking, absence of alcohol abuse, and neurological diagnosis. Self-reported Sleep duration may not be a sensitive measure of sleep health and should always be used in combination with other sleep health dimension measures as contained in the SATED questionnaire. Sleep health should be assessed routinely at the outpatient clinics with the SATED questionnaire and appropriate treatment should be instituted promptly to forestall the adverse consequences of poor sleep health.

Acknowledgments: We acknowledge the staff of the Medical Records department for their help in data collection

Sleep Health in Type 2 Diabetes: The Role of Sleep Variability in Glycemic Control

S. Reutrakul¹, J.J. McNany¹, J.C. Park¹, F.Y. Chau¹, E. Van Cauter², J. Law¹, A. Cross¹, S. Pannain², S. Sintetas², K.K. Danielson¹, B. Prasad¹, E.C. Hanlon²

¹University of Illinois Chicago, Chicago, United States, ²University of Chicago, Chicago, United States

Introduction: Sleep health is now recognized to be at a level playing field as other lifestyle behaviors in managing people with diabetes. Sleep health consists of multiple dimensions (e.g. duration, timing, regularity/ variability, efficiency) which may contribute differently to glycemic control in persons with type 2 diabetes (T2D). This study aimed to comprehensively evaluate the associations between sleep health dimensions and glycemic control in T2D.

Materials and methods: Seventy-four persons with T2D participated in this study. They were recruited in a study exploring sleep in T2D with and without diabetic retinopathy (DR), NCT 04547439. Sleep duration, sleep efficiency, sleep midpoint and sleep variability (standard deviation, SD, of sleep duration) were obtained from 14-day actigraphy recordings. Sleep satisfaction and daytime sleepiness (Epworth Sleepiness Scale, ESS) were obtained from questionnaires. Multidimension sleep health (MSH) score was created from a sum of sleep scores in each dimension (range 0-6, with higher score reflecting better sleep). Obstructive sleep apnea was assessed using an overnight home monitor (WatchPAT300). Hemoglobin A1C (A1C) and high sensitivity C-reactive protein (hs-CRP) were obtained. Correlation and multiple regression analyses were performed to establish an independent association between sleep measures and A1C.

Results: Mean (SD) age was 54.0 (6.0) years, body mass index of 34.3 (7.0) kg/m², diabetes duration of 13.4 (8.4) years, 58.0% of the participants were female, and 68.9% had DR. Their median (IQR) A1C was 7.6 (6.6, 8.8)%, 58.1% were taking insulin and the mean (SD) number of non-insulin antihyperglycemic medications was 1.85 (0.8). For objectively measured sleep dimensions, mean (SD) sleep duration was 6.2 (1.0) h with 75% of participants sleeping <7h, median sleep efficiency was 82.1 (77.1, 86.6)% with 68.9% of the participants had sleep efficiency <85%, mean sleep midpoint was 03:18 (01:22) AM, SD of sleep duration was 69.2 (56.6, 89.3) minutes with 62.2% having values ≥60 minutes. Mean ESS was 8.2 (5.2) with 24.3% of participants reporting excessive daytime sleepiness, and 71.6% reporting that their sleep quality was “very good” or “fairly good”. The mean MSH score was 3.41 (1.13). Median apnea hypopnea index (AHI) was 14.8 (6.6, 25.0). Bivariate analyses suggested that SD of sleep duration ($p<0.05$), AHI and insulin use ($p<0.1$), hs-CRP/ sleep efficiency/ DR status (all $p<0.2$) might be related to A1C. Other sleep dimensions and MSH score were not related to A1C. Stepwise regression analysis adjusting for insulin use, hs-CRP and DR status revealed that SD of sleep duration (natural-log transformed), but not sleep efficiency or AHI, was independently associated with A1C (natural-log transformed), $B=0.148$, $p=0.016$.

Conclusions: Participants with T2D in this study exhibited poor sleep in multiple dimensions. However, among them, irregular day-to-day sleep duration appeared to be a significant predictor of glycemic control. Interventions to enhance sleep regularity could potentially be beneficial in improving glucose control in persons with T2D.

Sleep Health of Preschool Children in Bangladesh

S. Ameen¹, A.T. Hossain¹, A. Hossain¹, N. Pini², M. Ordway³, W.P. Fifer², S.E. Arifeen¹, A. Sania²

¹International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, ²Columbia University Irving Medical Center, New York, United States, ³Yale University School of Nursing, Orange, United States

Introduction: Sleep affects a range of physical and neurodevelopmental outcomes, including executive function, growth, and obesity risk, which are public health priorities in low- and middle-income countries (LMICs). However, most data on children's sleep health come from high-income countries, and their recommendations may not apply to LMICs. Despite the importance of childhood sleep and emerging evidence of cross-cultural variation in early childhood sleep, little is known about children's sleep health in Bangladesh, a lower middle-income country in South Asia experiencing rapid urbanization and growing socioeconomic inequality.

Materials and methods: We collected sleep health data from 433 preschoolers in Dhaka, Bangladesh, using the Brief Infant Sleep Questionnaire Short Form (BISQ-R-SF) to assess children's sleep patterns and parental perceptions and behaviors. Additionally, we conducted qualitative research through two

focus group discussions (6 participants each) and seven in-depth interviews to explore maternal knowledge and attitudes toward children's sleep needs, co-sleeping, and potential sleep health interventions.

Results: Children aged 3–4 years slept an average of 10.3 hours per day (SD 1.5 h), with 40% sleeping less than the recommended duration (10–13 hours). Only 17.5% of children meet WHO's recommendation for maximum screen use (1h/day); mothers reported an average of 3.2 h (SD 1.9) of daily screen use for their preschoolers. Night-waking was common, only 30% of children slept through the night, while 66% woke 1–2 times at night, and 10% woke 3 or more times. Children went to bed on average at 10:30 p.m. (SD 1.2 h), about two hours later than the Western norm of 8:30 p.m. Screen time was positively associated with later bedtimes (p for trend < 0.001). Children of more educated mothers also had later bedtime and longer daytime naps. Co-sleeping was nearly universal. During in-depth interviews and FGDs, mothers expressed strong reluctance to allow children to sleep alone before age seven. Some linked their child's night-waking to their own sleep disturbances and daytime fatigue. Most mothers were unaware of recommended sleep durations, and the concept of a bedtime routine was unfamiliar. Although sleep interventions were described as “foreign”, mothers actively sought advice on best practices.

Conclusions: Preschool children in Bangladesh sleep less than recommended and frequently wake at night. Higher screen time is linked to poorer sleep outcomes. These findings, along with limited parental knowledge about healthy sleep practices, highlight the need for culturally adapted sleep promotion interventions in Bangladesh.

Sleep Health Profile In Early Infancy Is Associated With Emerging Executive Function Development

N. Pini^{1,2}, A. Sania^{1,2}, L. Chen¹, K.A. Donald³, M. Zieff³, S. Lee^{1,2}, D. Amso⁴, W.P. Fifer^{1,2,5}

¹Columbia University Irving Medical Center, Psychiatry, New York, United States, ²New York State Psychiatric Institute, Developmental Neuroscience, New York, United States, ³University of Cape Town, Paediatrics and Child Health, Cape Town, South Africa, ⁴Columbia University, Psychology, New York, United States, ⁵Columbia University Irving Medical Center, Pediatrics, New York, United States

Introduction: Infant sleep health is increasingly recognized as a key component of brain maturation and executive function (EF) development in early childhood. Data from low-resource settings remain scarce, where environmental and cultural factors may uniquely shape sleep patterns.

Materials and methods: Data were collected from 200 mother-infant dyads in a prospective cohort study in Gugulethu, Cape Town, South Africa. Infant sleep was assessed using the Brief Infant Sleep Questionnaire at 2–5, 6–10, 12–15, 16–19, and 20–24 months. At 24 months of age, executive function was assessed using the Spin the Pot (STP) task for both inhibitory control and working memory. Nonparametric K-means clustering identified sleep profiles of bedtime, night and day sleep duration and night-waking frequency. Multiple linear regression models were used to examine associations between sleep clusters at each time point and EF outcomes. Models were adjusted for maternal education, anxiety, depression, family income, and age at EF assessment.

Results: Four sleep profiles emerged: (1) Optimal (25.4%) with early bedtime, long night and total sleep, and few night-wakings; (2) Good (26.1%) with later bedtime, long day and total sleep, and frequent night-wakings; (3) Poor (26.3%) with shorter total sleep and longer day sleep; and (4) Poorest (28.3%) with latest bedtime and shortest total sleep. A dose-response relationship between sleep profiles during 2–5 months of age and STP scores (P for trend = 0.01) was observed. The poorest sleepers scored 2.1 points lower (95% CI: -3.6, -0.63) than optimal sleepers in the STP task. Sleep clusters at later ages were not associated with STP scores.

Conclusions: Sleep health in early infancy may critically influence EF development, particularly working memory and inhibitory control. Findings emphasize the need for culturally tailored interventions to promote healthy sleep habits in infancy.

SLEEP-HOPE: Evaluating Sleep Quality and Quantity in Menopausal Patients living with Hypothyroidism Using Hormonal, Pharmacological, and Complementary Therapies in Canada

A. Zarruk¹

¹West Island Metabolic Unit, Dollard des Ormeaux, Canada

Introduction: Sleep disturbances are common in menopausal and hypothyroid patients, significantly impairing quality of life. While hormonal replacement therapies, pharmacological interventions, and complementary and alternative medicine (CAM) approaches are available, their comparative effectiveness in improving sleep quality in real-world Canadian settings remains underexplored. This study aims to evaluate improvements in subjective sleep quality, measured by the Sleep Quality Scale (SQS), in menopausal and hypothyroid patients undergoing various therapeutic interventions. Secondary outcomes include changes in quality-of-life metrics assessed using the Pittsburgh Sleep Quality Index (PSQI), Epworth Sleepiness Scale (ESS), Thyroid-Specific Patient-Reported Outcome Measure (ThyPRO), and Short Form-8 Health Survey (SF-8).

Materials and methods: The SLEEP-HOPE study is an observational, longitudinal study conducted across three private endocrinology practices in Montreal, Canada. Female patients with menopause and hypothyroidism reporting unsatisfactory sleep were recruited. Participants completed standardized questionnaires, including PSQI, ESS, ThyPRO, and SF-8, at baseline and three-month follow-ups. Treatment modalities included hormonal therapies (e.g., thyroid hormone replacement, menopausal hormone therapy), pharmacological interventions (e.g., hypnotics, antidepressants), and CAM therapies (e.g., melatonin, ashwagandha, yoga). Additional data on comorbidities, medication adherence, and lifestyle factors were collected.

Results: Descriptive statistics will summarize participant characteristics and treatment distributions. Paired t-tests and ANOVA will compare pre- and post-intervention scores, while multivariate regression analyses will explore associations between treatments and outcomes, adjusting for confounders such as age and BMI.

Conclusions: This study aims to provide valuable insights into the effectiveness of hormonal, pharmacological, and CAM therapies in addressing sleep disturbances among menopausal patients with hypothyroidism. Findings are expected to show moderate benefits of hormonal therapies while emphasizing the unmet need for optimizing sleep quality. These results will support the development of evidence-based, holistic management strategies to improve sleep and overall quality of life in this patient population.

Sleep Hygiene Awareness and Behavior Among Young Adults in Urban India Background

N. Nagalla¹

¹Arete Hospital, Pulmonary & Sleep Disorders, Hyderabad, India

Introduction: With India's growing youth population and rising prevalence of insomnia and sleep-related complaints, understanding the level of sleep hygiene awareness and behaviour is essential for early interventions and public health strategies.

Objectives: To assess the awareness and practices related to sleep hygiene among urban Indian young adults aged 18–23.

Materials and methods: Survey conducted on Sleep Hygiene Awareness & Practices. Received 1076 responses from students in the age group of 18-23 yr. (54% of respondents are male & 46% are female).

Results:

- Sleep Hygiene is average/ poor for 92% of the respondents – in line with global data of 70-95% non-ideal sleep hygiene practices
- Only 20% of individuals with poor sleep hygiene are seeking help – in line with global data, but very sub-optimal from overall health & wellness perspective
- 38% feel sleepy during the day & 30% have noticed memory/ concentration issues - Clear correlation between daytime sleep and memory/ concentration loss.
- 66% of the respondents mentioned “strongly agree” & 28% mentioned “agree” to the question, “Do you think sleep quality affects your performance?” – but people seeking help is minimal

Conclusions: The study highlights a critical gap in sleep hygiene awareness among urban Indian youth, exacerbated by lifestyle choices, academic pressures, and digital overuse. This behavioural and knowledge disconnect calls for targeted public health interventions – including curriculum-based sleep education, social media awareness campaigns, and digital sleep health tools tailored for youth.

Sleep in Context: How Activities During Waking Hours Shape Sleep in First-Year University Students

Y. Lepcha¹, K. Chong¹, A. Willoughby¹, M. Chee¹

¹National University of Singapore, Singapore, Singapore

Introduction: Sleep is shaped by a combination of internal processes that regulate sleep and wake, and external influences that modulate these systems. Our waking hours are filled with activities that affect our sleep in different ways, including those that directly influence our bed and wake times. In the present study, we used time-use diaries to capture the timing of a wide variety of daily activities in combination with sleep metrics from the Oura ring to examine how the structure and content of daily activities are associated with sleep in a sample of first-year undergraduate university students.

Materials and methods: 608 incoming first-year university students completed daily time-use diaries for up to three weeks using our custom-made app, Z4IP (8,356 days in total). Activities were reported in 15-minute intervals for the full 24 hours. 11 categories were used to capture different aspects of student life, including major university activities (Lessons, Self-study, Co-curricular Activities), leisure (Social, Digital Leisure, Exercise), and other essential daily activities (Sleep, Meals, Self-care, Transport, Other). Latent class analysis (LCA) was used to identify the underlying patterns of activity in students' daily lives. In addition, objective measures of bedtime, wake time, sleep duration and wake period duration were collected using the Oura ring.

Results: LCA revealed eight categories with distinct daily activity patterns: AM Lessons, PM Lessons, Self-study, Evening Co-curricular Activity (CCA), Evening Social, Day Social, Late Digital Leisure and Other.

Average wake times ranged from 07:31 to 11:01, with AM Lessons being the earliest and Late Digital Leisure the latest. Wake times were approximately 08:30-09:00 for the other categories. Average bedtimes ranged from 00:43 to 02:59. Late Digital Leisure days had the latest bedtime, followed by Evening Social and Evening CCA days at 02:50 and 01:42 respectively. Categories with morning or evening activities showed the longest wake period durations. The AM Lessons, Evening CCA and Evening Social categories all had wake periods of over 17 hours, whereas days with less structure, Self-study and Late Digital Leisure days, had wake period durations under 16 hours.

Engagement in digital leisure regularly preceded sleep in all but two categories (Evening CCA and Evening Social), suggesting it was a common pre-sleep activity when there were no other competing evening activities.

Conclusions: In the present study, LCA effectively identified characteristic patterns of time-use data to produce eight interpretable day categories from 8,356 days. Morning lessons, evening CCA activities and socialising significantly affected wake and bedtimes, compromising students' sleep duration. While extended evening digital leisure activity was associated with much later sleep timing, shorter periods of digital leisure activity were also observed prior to sleep on days with both earlier and later bedtimes.

Acknowledgments: This work was supported by funds from the Yong Loo Lin School of Medicine and the Lee Foundation, awarded to Dr Michael W.L. Chee.

Sleep Irregularity, Anxiety and Depressive Symptoms in Young Adults with Delayed Sleep Wake Phase Disorder and Insomnia

K. Nguyen¹, N. Lovato¹, G. Micic¹, A. Phillips¹, C. Dunbar¹, J. Fitton¹, G. Robertson¹, A. Montero¹, K. Loffler¹, K. Sansom¹, A. Vakulin¹, R. Adams¹, A. Reynolds¹

¹Flinders Health and Medical Research Institute: Sleep Health, Adelaide, Australia

Introduction: In the general population, irregular sleep-wake patterns are associated with poor mental health outcomes. However, there is a lack of research on the relationship between sleep irregularity and mental health in young adults with unmanaged sleep disorders. Sleep irregularity likely mediates the relationship between sleep disorders and daytime functioning and may increase the risk of negative mental health outcomes. This study aimed to: (i) explore the association between unmanaged sleep disorders, sleep irregularity, and mental health outcomes; and (ii) determine whether sleep irregularity explains effect heterogeneity in the association between sleep disorders and mental health.

Materials and methods: The sleep-wake timings of 60 young adults (60% female, mean±SD age=25.1±4.6y) were recorded through sleep-wake diaries for up to three weeks. Validated questionnaires (e.g., Insomnia Severity Index, Epworth Sleepiness Scale), structured clinical interviews and in-laboratory polysomnography (PSG) were used to determine diagnoses. Sleep irregularity was measured using the Sleep Regularity Index (SRI). The General Anxiety Disorder (GAD-7), and Patient Health Questionnaire (PHQ-9) were used to assess anxiety and depression symptom severity, respectively. Bootstrapped regressions were used to determine the associations between SRI and mental health symptoms, with an interaction term of sleep disorder*SRI included to explore effect heterogeneity in the relationship between sleep disorders and mental health symptoms.

Results: 78% of participants had unmanaged Insomnia or Delayed Sleep Wake Phase Disorder (DSWPD) (43% Insomnia and 35% DSWPD) while 22% did not meet diagnostic criteria for a sleep disorder ('healthy sleepers'). The SRI was lower, reflecting greater irregularity, in young adults with unmanaged DSWPD (Median SRI(IQR) = 75.3(66.0-79.2); B = -8.96, 95% CI [-16.03, -2.55], $p=0.08$), than in healthy sleepers (79.4(76.0-85.0), 95% CI [76.46, 84.86]), while SRI scores were not significantly different for those with unmanaged insomnia (78.2(69.8-82.3); B = -2.59, 95% CI [-7.42, 2.16], $p=0.29$). Having either DSWPD or insomnia was independently associated with an increase in depressive symptoms (B = 2.48, 95% CI [1.22, 3.59], $p<0.01$), but not anxiety symptoms (B = 0.37, 95% CI [-1.20, 1.75], $p=0.62$). Preliminary moderation analyses were conducted given prior evidence that SRI is associated with mental health. SRI did not modify the association between sleep disorders and depressive symptoms (Insomnia: B = -0.01, 95% CI [-0.32, 0.23], $p=0.89$; DSWPD: B = -0.09, 95% CI [-0.38, 0.11], $p=0.35$) or anxiety symptoms (Insomnia: B = -0.03, 95% CI [-0.40, 0.45], $p=0.93$; DSWPD: B = -0.04, 95% CI [-0.43, 0.42], $p=0.89$).

Conclusions: Young adults with DSWPD had less regular sleep than healthy sleepers. This likely reflects the known sleep patterns of those with DSWPD, where they need to wake earlier to meet early morning commitments despite delayed bed and wake times when their schedule permits. Sleep irregularity did not modify the association between sleep disorders and mental health symptoms. Sleep disorder symptom severity or the type of sleep disorder may have a greater influence on mental health than sleep irregularity. Future research examining the relationship between sleep irregularity and long-term health outcomes is needed.

Acknowledgments: The authors would like to acknowledge the Lifetime Support Authority (Australia) for funding this study.

Sleep latency and sleep duration association with depression symptoms among US adolescents and young adults: A NHANES 2005 – 2018 analysis

D. Bancovsky¹, A. Gileles-Hillel^{2,3}

¹Safra Children's Hospital - Sheba Medical Center, Pediatric Neurology Unit, Ramat Gan, Israel, ²The Hebrew University of Jerusalem, The Faculty of Medicine, Jerusalem, Israel, ³Hadassah Medical Center, Pediatric Pulmonology and Sleep Unit, Jerusalem, Israel

Introduction: Sleep and mental health are deeply intertwined and impose a substantial public health and economic burden globally. Neurobiological mechanisms may include disruptions in circadian rhythms, sleep architecture, and neurophysiological markers such as reduced sleep spindle activity. Numerous studies indicate that both insufficient and excessive sleep are associated with depression, suggesting a complex bidirectional relationship. More specifically, sleep problems can precede, exacerbate, or result from depressive episodes, with short sleep duration being linked to increased loneliness, anxiety, and affective disorders. In this study, we aimed to provide a measurable effect size for the association of sleep duration and sleep latency with depression. We assessed depression symptoms and sleep among US adolescents and young adults using 14 years of NHANES pooled cross-sectional data.

Materials and methods: We conducted a pooled cross-sectional analysis using data from the U.S. National Health and Nutrition Examination Survey (NHANES), cycles 2005–2018. Participants aged 18–25 years were included. Primary outcomes were self-reported sleep duration (minutes/night) and sleep latency (minutes to fall asleep). Depressive symptoms were assessed via the Patient Health Questionnaire-9 (PHQ-9) and categorized as none, mild, moderate, or severe. ANCOVA with Tukey post hoc tests controlling for cycle compared group means. A multivariable linear regression model was then adjusted for gender, age, race/ethnicity, BMI, and snoring complaints or other comorbidities. NHANES sampling weights were incorporated to ensure national representativeness.

Results: The sample included 6,506 participants for sleep duration and 2,064 participants for sleep latency. Mean sleep duration was 438.9 ± 93.3 minutes, and mean sleep latency was 23.3 ± 19.0 minutes. A statistically significant difference was observed between depression groups in mean sleep duration ($F=14.8$, $p < 0.0001$) and sleep latency ($F=25.4$, $p < 0.0001$) with a dose-dependent response. Sleep duration decreased with any depression severity (mild -16.6 min, $p < 0.0001$; moderate -18.6 , $p < 0.001$; severe -21.0 , $p=0.053$ compared to no depression). Sleep latency increased in a dose-dependent manner with depression severity (mild 6.7 min, $p < 0.001$; moderate 11.6 min, $p < 0.001$; severe 15.2 min, $p < 0.001$). In a fully adjusted model, depression remained independently associated with shorter sleep duration ($\beta=-12.8$, 95% CI= $-23.6 - -1.9$, $p=0.02$) and longer sleep latency ($\beta=8.4$, 95% CI= $4.8-12.0$, $p < 0.0001$).

Conclusions: In this nationally representative sample of US adolescents and young adults, depression was associated with ~16-21 minutes shorter sleep duration and with a ~6-15 minutes longer sleep latency. In other words, depressive symptoms were associated with shorter subjective sleep duration and increased difficulties in sleep initiation, both consistent with insomnia symptoms. Our findings highlight the intricate relationship between sleep and mental health, underscoring the importance of early sleep-focused interventions among adolescents and young adults to mitigate the burden of mental health in this population. Further trials exploring the temporal relationship between sleep and mental health are required to elucidate the results of this exploratory analysis.

Sleep Myths and Student Health: Exploring the Link Between Misbeliefs, Sleep Hygiene, and Sleep Quality in Indian Youth

M. Sharma¹, S. Paliwal²

¹Sleep Moksha, Panchkula, India, ²Hislop College, Nagpur, India

Introduction: Sleep deficiency has become an alarmingly common phenomenon among college students with negative consequences on their physical, cognitive, and emotional well-being as well as academic performance. Specifically, the prevalence of sleep-related myths and the influence of these myths on their sleep quality and sleep practices remains unknown in Indian college students. The study explored associations between sleep-related beliefs and their self-reported sleep hygiene and quality of sleep.

Materials and methods: The cross-sectional study comprised of 200 college students (83% females) between the ages of 18 to 25 years (mean 22.5 years). Sleep beliefs were assessed in six different domains using 20 statements identified by the experts as sleep myths. A higher score indicated more sleep myths. Sleep Hygiene Index was used to assess the practice of sleep hygiene behaviors, with a higher score representing poorer sleep hygiene. Sleep quality was examined using the Pittsburgh Sleep Quality Index. Data was analysed using frequencies, percentages and Linear correlation.

Results: In all 38% of the participants either agree or strongly agree with the sleep myths. The PSQI of 83 % of participants is poor, more than 60% have just fair sleep hygiene, 28% have poor sleep hygiene. None of the participants showed excellent sleep hygiene. Correlation analysis suggests that sleep beliefs are positively associated with poor sleep quality ($r= .516$; $p < .01$) and poor sleep hygiene ($r= .433$; $p < .01$). The beliefs, hygiene and quality of sleep remained the same across the demographics indicating the poorer sleep practices amongst all participants despite their educational, cultural or socio-economic backgrounds.

Conclusions: This study highlights a critical concern regarding the prevalence of sleep-related myths and their significant association with poor sleep hygiene and sleep quality among Indian college students. A substantial proportion of participants endorsed inaccurate beliefs about sleep, which were strongly correlated with suboptimal sleep practices and poor sleep outcomes. Alarmingly, none of the respondents reported excellent sleep hygiene, and the vast majority exhibited poor sleep quality. The

findings may be useful in developing sleep health campaigns to promote sleep health of college students by correcting myths and maladaptive sleep health practices.

Keywords: India, Sleep health campaigns, Sleep hygiene behaviors, Sleep practices, Sleep Quality, Students Health, Indian Youth

Acknowledgments: we would like to extend our heartfelt gratitude to all the participants who took part in this study.

Sleep N' Quit: an EMA Study on Daily Sleep and Smoking among Lower Socioeconomic Smokers Who Want to Quit Smoking in the U.S.

C.K. Ra¹, M. Steinberg², M. Businelle³, K. Gamble⁴, D. Hedeker⁵, A. Spaeth⁶, N. Pehlivan⁷, A. Villanti²

¹Rutgers University/ Cancer Institute, Oncology, RWJ Medical School, New Brunswick, United States,

²Rutgers University, Rutgers Institute for Nicotine & Tobacco Studies, New Brunswick, United States,

³University of Oklahoma Health Sciences Center, TSET Health Promotion Research Center, Stephenson Cancer Center, Okc, United States, ⁴University of Alabama at Birmingham, Behavioral Neurobiology, Psychiatry, School of Medicine, Birmingham, United States, ⁵University of Chicago, Department of Public Health Sciences, Chicago, United States, ⁶Rutgers University, Department of Kinesiology and Health, Piscataway, United States, ⁷Seoul National University, School of Public Health, Seoul, Korea, Republic of

Introduction: Cigarette smoking is the leading preventable cause of morbidity and mortality in the United States, and is highly concentrated among individuals with lower socioeconomic status (SES). Previous studies have shown that lower SES is associated with higher rates of poor sleep, and poor sleep is associated with lower likelihood of smoking cessation. However, the temporal associations between daily sleep and smoking remain poorly understood. Therefore, the current study aimed to assess the feasibility and compliance of a real-time data capture approach of sleep and smoking among lower SES smokers who are attempting to quit.

Materials and methods: Participants were lower SES smokers who sought treatment at the 11 state-funded tobacco quit centers across New Jersey. Eligibility criteria included: 1) household income <200% of the federal poverty line, 2) a score ≥ 4 on the Rapid Estimate of Adult Literacy in Medicine-Short Form, 3) willingness to quit smoking 14 days after the baseline visit, 4) ≥ 18 years of age, 5) an expired CO level ≥ 7 ppm, 6) currently smoking ≥ 5 cigarettes per day, 7) no overnight shiftwork, and 8) not currently using potentially sedating medications. This study was conducted 100% remotely. Study participation lasted 6 weeks (2-week pre-quit and 4-week post-quit) and included 4 virtual visits. Participants were provided with a study phone, Actiwatch and Bluetooth breathalyzer with detailed instructions regarding the use of the phone, Actiwatch, and EMA procedures via mail. Participants completed questionnaires at the baseline visit, including assessment of sleep, other tobacco use, past/current medical history. Subjects wore an Actiwatch and used the study app and Bluetooth breathalyzer to record daily sleep and smoking-related behaviors for the entire 6-week study period. At the end of the study, participants returned the Actiwatch and study phone via mail.

Results: Since April 2024, 28 participants have completed the six-week EMA study. Participants were 70% White, 30% Black, and 64% female, with a mean age of 51.3 years. EMA compliance averaged 80% during Pre-Quit and 77% during Post-Quit. Biochemically confirmed abstinence rates were 30% on the quit date and 19% at the end of the study virtual visits. Participants' daily smoking abstinence rates were 22.6% (131/580 days) during Pre-Quit and 32.9% (279/847 days) during Post-Quit ($p < .001$). Most participants (23 out of 28) wore the Actiwatch on more than 90% of study days. Self-reported EMA sleep data showed a mean sleep onset latency of 45 minutes, waking up an average of 1.6 times per night, with an average of 1 hour of wake-time during the night, and spending 3 hours and 15 minutes in bed awake on average.

Conclusions: Collecting real-time data via devices over 6 weeks was feasible and acceptable among individuals with lower SES who want to quit smoking. The role of sleep health and circadian rhythms has been understudied in smoking cessation interventions. This is the first known study to elucidate associations between daily sleep dysregulation and smoking cessation using mHealth technology. Findings from this project will inform the development of future tailored sleep interventions in smoking cessation programs for this underserved population.

Sleep, physical activity and mental health among French business leaders: a cross-sectional study

V. Bourlois¹, P. Baron¹, C. Elsworth-Edelsten², S. Levillain³, C. Bonduelle¹, Y. Roussel¹, T. Pezé¹, R. Hurdie¹

¹Univ. Littoral Côte d'Opale, Univ. Artois, Univ. Lille, ULR 7369 - URePSSS - Unité de Recherche Pluridisciplinaire Sport Santé Société, Dunkerque, France, ²School of Human and Life Sciences, Canterbury Christchurch University, Kent, United Kingdom, ³IESEG School of Management, Paris, France

Introduction: Recent studies revealed that more than half of French business leaders are at risk of burnout, they sacrifice sleep, physical activity and often work over 60 hours weekly. Poor sleep and lack of exercise contribute to major health issues in general population. To date, no study explored the variations in health status among business leaders across different types and sizes of companies. This study aims to assess health among French business leaders, focusing on sleep quality, physical activity, anxiety, and stress levels across their different organizational contexts. We hypothesized that hierarchical positions and level of responsibility was associated with severity of health issues

Materials and methods: 361 business managers (158 women and 203 men) comprising 37.4% of Large Enterprises and Intermediate-Sized Enterprises and 62.6% of Very Small Enterprises and Small and Medium-sized Enterprises, agreed to complete questionnaires including: Pittsburg Sleep Quality Index, Perceived Stress Scale, Global Anxiety Disorder and International Physical Activity Questionnaire. RStudio software was utilized for descriptive statistics and analyses.

Results: Results revealed that 67.3% of them have poor sleep, 47.8% are highly stressed, and 22.5% have very low levels of physical activity. Women exhibit worse mental health and top leaders of small enterprise experience more stress, practice less physical activity and have poorer sleep

Conclusions: Our findings reveal the critical need for immediate action to support leaders and managers health. The intrinsic distinctive characteristics of a leader's lifestyle might require the creation of specific programs to enable them to engage long term in healthier self-care practices that take into consideration sex and organizational context.

Sleep, PTSD, and Eating Disorders: A Longitudinal Study on Sleep and Mental Health in a Community Sample Following Collective Trauma

Y. Latzer¹, Z. Spivak-Lavi², O. Tzischinsky³

¹University of Haifa, Faculty of Social Welfare and Health Sciences, Haifa, Israel, ²Max Stern Yezreel Valley College, Department of Social Work, Emek Yezreel, Israel, ³Academic Western Galilee College, The Department of Criminology, Akko, Israel

Introduction: Sleep disturbances are a common and persistent consequence of trauma exposure, but their role as a pre-existing vulnerability factor for post-traumatic stress disorder (PTSD) and eating disorders (EDs) remains almost underexplored. Sleep is increasingly recognized as a critical component of mental health, influencing emotional regulation, physiological stress responses, and susceptibility to psychopathology. Night eating syndrome (NES), characterized by excessive food intake during the evening and nighttime hours, has been associated with both trauma and poor sleep quality. This longitudinal study examined how poor sleep quality prior to a collective trauma event predicts later PTSD symptoms and disordered eating patterns in a community sample.

Objectives and Hypotheses:

We hypothesized that: (1) poor sleep quality at baseline, T1 (August 2023) would predict greater PTSD symptoms at T2 (five months after the October 7th); (2) PTSD risk at T2 would predict increased severity of NES and other ED symptoms at T3 (a year after the October 7th); and (3) PTSD symptoms would mediate the relationship between sleep quality and later eating-related psychopathology.

Materials and methods: A community sample of 240 Israeli adults (Mean age = 41.37, 58% female) participated in a three-wave longitudinal study. Participants completed validated self-report questionnaires online at three time points. Measures included: Pittsburgh Sleep Quality Index (PSQI), (at T1), the PTSD risk (PCL-5) (at T2), the Night Eating Questionnaire (NEQ), and the SCOFF questionnaire for general ED symptoms (at T3). Sociodemographic data, including age, gender, education, marital and employment status, were also collected. Structural equation modeling with

bootstrapped confidence intervals was used to test the hypothesized mediation model, controlling for demographic variables. Group comparisons were conducted based on a PSQI cutoff score (>5).

Results: Preliminary analyses showed all variables were positively and significantly correlated. Poor sleep quality at T1 predicted higher PTSD symptoms at T2 ($\beta = .429$, $p < .001$). PTSD symptoms at T2 significantly predicted NEQ scores ($\beta = .461$, $p < .001$) and SCOFF scores ($\beta = .390$, $p < .001$) at T3. Mediation analyses indicated that PTSD symptoms significantly mediated the relationship between sleep quality and both NES (indirect $\beta = .197$) and ED symptoms (indirect $\beta = .167$). A direct effect was observed between sleep disturbances and NES ($\beta = .219$, $p < .01$), but not with general EDs. Clinically, participants with poor sleep quality at T1 (PSQI > 5) had significantly higher PTSD, NEQ, and SCOFF scores at follow-ups ($p < .001$).

Conclusions:

The present study provides important insights into the relationship between sleep quality or sleep disturbances, PTSD risk, and various types of EDs within a community sample. By utilizing a three-wave design, this study uniquely captured how pre-existing sleep difficulties contribute to psychological distress following trauma exposure. The findings emphasize that poor sleep quality is not merely a consequence of trauma but may act as an independent risk factor, heightening vulnerability to PTSD symptoms and subsequent disordered eating patterns. In the context of collective trauma, such as the recent and ongoing war in Israel, identifying at-risk populations and modifiable risk factors is crucial for preventive interventions.

Sleep Quality among University Students in Lebanon during War Conflicts: A Cross-Sectional Study

M.A. Labaki¹, H. El Haddad¹, M. Estanom¹, M. Gergi¹, C. Khalil¹, R. Youssef¹, S. Assaad¹

¹School of Medicine and Medical Sciences, Holy Spirit University of Kaslik (USEK), Jounieh, Lebanon

Introduction: Sleep is a vital component for cognitive function, emotional well-being, and overall health, yet it is frequently disrupted by external stressors, such as war and conflict. University students, particularly those in conflict zones, face increased risks of poor sleep quality due to academic pressure, psychological stress, and trauma exposure. This study aims to assess the prevalence of poor sleep quality, sleep latency, and sleep efficiency among university students in Lebanon during the 2023-2024 war conflicts, and the direct and indirect effects of war exposure.

Materials and methods: A cross-sectional study was conducted on 631 university students in Lebanon using the Pittsburgh Sleep Quality Index (PSQI) to evaluate sleep quality. Sociodemographic characteristics and the type of war exposure (direct or indirect) were also assessed. Inferential statistical tests were performed to identify correlations between sleep quality and sociodemographic factors, as well as sleep quality and war exposure. The Prevalence Rate Ratio (PRR) was calculated to identify risk and protective factors for poor sleep quality in each socio demographic group. A binary regression model was applied to predict the most significant risk factors for compromised sleep quality.

Results: 73.5% of Lebanese university students had poor sleep quality (PSQI > 5), with a mean Global PSQI score of $8.20 (\pm 3.95)$. Students with direct war exposure had the highest mean score of 10.57 ($p < 0.001$), compared to 8.04 for those with indirect exposure. The average sleep latency PSQI score was 1.46 ± 1.04 , and the average sleep efficiency PSQI score was 1.00 ± 1.00 . Compared to no exposure, indirect exposure resulted in a 22% higher prevalence (PRR=1.22) of poor sleep, while direct exposure showed a 60% higher prevalence (PRR=1.60). The binary exposure showed that female gender increased the odds of poor sleep by 2.71 ($p=0.035$), and direct war exposure increased the odds by 19.76 times ($p = 0.001$).

Conclusions: This study highlights the profound impact of war exposure on sleep quality among Lebanese university students, with direct exposure having the greatest risk. Poor sleep quality in war-affected zones can lead to severe disruptions in academic performance, cognitive function, and overall mental and physical health. The findings underscore the need for targeted interventions, including mental health support and stress management programs, to limit sleep disturbances in conflict-affected populations. Further research is warranted to explore effective coping mechanisms and long-term sleep health in similar contexts.

Acknowledgments: N/A

Sleep quality and hypertension: correlation between Pittsburgh Sleep Quality Index (PSQI) scores and the prevalence of hypertension and blood pressure reduction patterns

K. Ma¹, X. Gao¹, X. Fu¹

¹Peking University School of Stomatology, Beijing, China

Introduction: This study investigated the association between sleep quality and hypertension, evaluating the correlation of Pittsburgh Sleep Quality Index (PSQI) scores with hypertension prevalence and blood pressure dipping patterns.

Materials and methods: From anonymized subjective and objective sleep and blood pressure data collected via commercial wearable health devices from over 150,000 volunteers, we screened and included 17,462 participants with complete blood pressure data, among whom 5,490 had PSQI scores. Participants were stratified into "high sleep quality" (PSQI ≤ 5) and "low sleep quality" (PSQI ≥ 6) groups. Chi-square tests were used to compare hypertension prevalence between the two groups. Further analysis was conducted on 926 hypertensive patients, categorized into "dipper" and "non-dipper/reverse-dipper" groups, with chi-square tests performed to assess sleep quality differences.

Results: Among 17,462 participants, 3,882 (22.2%) had hypertension. In the 5,490 participants with PSQI scores, the hypertension prevalence was higher in the "low sleep quality" group (17.9%) compared to the "high sleep quality" group (13.9%), indicating that poor sleep quality was associated with an increased risk of hypertension (99.9% CI, * $p = 0.0008617$). However, among the 926 hypertensive patients, no statistically significant difference in subjective sleep quality was observed between dippers and non-dippers/reverse-dippers.

Conclusions: Higher PSQI scores (worse sleep quality) were associated with an elevated risk of hypertension. However, subjective sleep quality did not significantly differ between dippers and non-dippers/reverse-dippers, suggesting that abnormal blood pressure circadian rhythms may not directly contribute to perceived sleep disturbances. Further research incorporating objective sleep monitoring is warranted.

Sleep, shift work disorder and risk for depression in South African ambulance emergency care personnel

L.M. Motaung¹, K. Scheuermaier¹, J.G. Davimes¹

¹University of the Witwatersrand, School of Biomedical Sciences, Johannesburg, South Africa

Introduction: Ambulance emergency care personnel (ECP) have long working hours, a rotating shift schedule and a high workload. They are also at risk of developing sleep and mental health issues, such as shift work disorder and depression, due to the stressful nature of the job. In a country with exceptionally high violent crime and motor vehicle associated injuries and fatalities, such as South Africa, ECP are exposed to a high workload while being under-resourced and understaffed; and the related trauma may further enhance sleep and mental health issues. Thus, this study investigated self-reported subjective sleep, risk for depression and shift work disorder in South African ECP.

Materials and methods: Ambulance ECP working for a private medical and emergency care provider were recruited around Gauteng, South Africa. The two typical shift structures in South Africa (2Day2Night4Off and Long-Short) were investigated. Demographics, BMI, years of rotating shift experience and self-rated overall health were collected. Participants completed questionnaires which investigated sleep quality (Pittsburgh Sleep Quality Index (PSQI)), depression symptoms (Patient Health Questionnaire-2 (PHQ-2)) and risk for shiftwork disorder (SWD) (Shift Work Disorder Questionnaire (SWDQ)).

Results: A total of 65 ambulance ECP (58.5% male, 33.6 ± 8.4 years, $BMI = 29.4 \pm 6.7$ kg/m²) participated in the study. The mean ($\pm$ SD) years' experience of rotating shifts was $8.7 (\pm 6.8)$ years. The mean ($\pm$ SD) PHQ-2 score was $1.5 (\pm 1.4)$ and 21% ($n=14$) of the participants were at risk of higher depressive symptoms (PHQ-2 ≥ 3). The participants had poor sleep quality with the mean global PSQI score at $7.8 (\pm 3.7)$ and 70.8% ($n=46$) of the sample being poor sleepers (PSQI > 5). ECP with poor sleep quality had higher depressive symptoms ($p = 0.002$). There was a significant difference between shift type and PSQI components for sleep latency ($p = 0.005$) and sleep disturbances ($p = 0.037$), with the long-short shift having more sleep disturbances and a longer sleep latency than 2day2night4off shift. No significant differences in PHQ-2, PSQI and SWD were found between shift types. A high risk for SWD occurred in

40% (n=24) of the participants and was associated with poor sleep quality ($p<0.001$) and higher depressive symptoms ($p=0.015$). Female participants had a higher PSQI score compared to males (8.9 ± 3.0 vs 7.1 ± 3.9 , $p=0.019$). When adjusting for age and shift type (β estimate =1.92, SE= 0.89; $p=0.036$) women had higher odds to be classified as poor sleepers (92.6% vs 55.3%, $p=0.001$) and at high risk for SWD compared to men (OR= 3.69, 95% Wald CI 1.09-12.49).

Conclusions: South African ambulance emergency care personnel have a high risk for shift work disorder and poor sleep quality. Poor sleep quality was associated with higher depressive symptoms and women reported worse sleep compared to men. We found no difference according to shift type. Interventions are warranted to improve sleep and mental health of emergency care personnel, especially for women.

Acknowledgments: The authors would like to thank all of the participants of this study and National Research Foundation of South Africa (NRF) Thutuka grant for funding the study.

Sleep Stage Classification over Continuous Positive Airway Pressure Signals with Multi-Period Convolutional Neural Network

H.-Y. Chen¹, H.-T. Wu², A. Husain³, S. Pokusa³, C.-Y. Chen¹

¹PranaQ Pte. Ltd, Singapore, Singapore, ²New York University, Mathematical Sciences, New York, United States, ³Duke University Medical Center, Durham, United States

Introduction: Continuous Positive Airway Pressure (CPAP) therapy is the standard treatment for obstructive sleep apnea (OSA), yet its potential for passive sleep monitoring remains underexplored. Polysomnography (PSG), the clinical gold standard for sleep staging, is resource-intensive and impractical for routine home use. To address this gap, we developed a deep learning-based framework that classifies sleep stages using only CPAP signals.

Materials and methods: We propose the **Multi-Period Convolutional Neural Network (MP-CNN)**, a novel architecture specifically designed to extract temporal features from CPAP-derived respiratory signals. Unlike conventional CNNs that rely on fixed receptive fields, MP-CNN incorporates multiple period-specific convolutional kernels ($p=3$, $p=9$, and $p=21$) to simultaneously capture short- and long-term respiratory dynamics. The model processes 630-second input windows with subject-normalized input features, including **CPAP flow (Cflow)**, **positive airway pressure (PAP)**, and **instantaneous respiratory rate (IRR)**. We augment features by reducing redundancy while preserving temporal information. Specifically, every 25 samples are downsampled to 1 Hz, and four statistical descriptors (mean, standard deviation, maximum, minimum) are computed within each window to capture local dynamics. This multi-period design allows MP-CNN to more effectively uncover the intrinsic relationships between CPAP signals and sleep stages, which may be overlooked by standard CNN architectures. The model was evaluated on split-night PSG sleep studies, where CPAP titration began midway through the recording. Data from 32 subjects with moderate to severe OSA were included, with ground truth sleep stages annotated by trained technicians according to AASM guidelines. A 3-fold cross-validation protocol was applied to ensure robust evaluation.

Results: Our proposed MP-CNN achieved a **macro F1-score of 0.685** and a **Cohen's Kappa of 0.523** in three-stage classification, with **per-stage sensitivity/specificity of 0.693/0.908 (Wake)**, **0.520/0.930 (REM)**, and **0.818/0.669 (NREM)**. These results demonstrate competitive or superior performance compared to existing approaches that rely on more intrusive signals. Feature ablation studies further revealed that downsampled statistical features were essential for improving model performance, particularly in REM detection. In addition, the model showed a strong correlation with ground truth sleep metrics, such as **total sleep time (Pearson's $r = 0.85$)**. We also assessed demographic effects by stratifying subjects by gender, BMI, and age. No statistically significant differences in performance were observed across subgroups, although females and younger subjects exhibited slightly higher agreement in some cases. Overall, the model generalized well across demographic factors, indicating that demographic variability was not a primary source of cross-dataset performance differences.

Conclusions: Our results demonstrate the feasibility of leveraging CPAP-derived respiratory signals for unobtrusive sleep stage classification. The MP-CNN architecture enables accurate sleep staging without the need for additional sensors, offering a scalable and cost-effective solution for home-based sleep monitoring. Future work will focus on extending the framework to include deep sleep detection and adaptive integration with automatic positive airway pressure (APAP) systems.

Acknowledgments: We thank the **Duke Hospital Sleep Center** for providing access to the CPAP titration dataset and the sleep technicians **Aatif Husain** and **Shirah Pokusa** for their expert manual annotations and support.

Sleep Temporal Entropy: A Novel Sleep Fragmentation Biomarker Predicting Cardiometabolic Disease and Mortality Risk

J. Chen¹, C. Cavaillès², H. Sun³, H. Zhao¹, Y. Gao⁴, D. Xie^{5,1}, X. Chen⁶, W. Huang^{7,8,9}, H. Yi^{7,8,9}, S. Hong^{5,1}, S. Gao¹, Y. Leng²

¹Peking University Health Science Center, Institute of Medical Technology, Beijing, China, ²University of California, San Francisco, Department of Psychiatry and Behavioral Sciences, San Francisco, United States, ³Harvard Medical School, Beth Israel Deaconess Medical Center, Department of Neurology, Boston, United States, ⁴University of Oxford, Nuffield Department of Population Health, Oxford, United Kingdom, ⁵Peking University, National Institute of Health Data Science, Beijing, China, ⁶Beijing Wuji Medical Technology Co., Ltd., Beijing, China, ⁷Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Department of Otorhinolaryngology Head and Neck Surgery, Shanghai, China, ⁸Shanghai Key Laboratory of Sleep-Disordered Breathing, ShanghaiChian, China, ⁹Shanghai Jiao Tong University, Otolaryngology Institute, ShanghaiChina, China

Introduction: Sleep fragmentation involves frequent arousals and irregular sleep stage transitions, which impair physiological recovery and contribute to increased cardiometabolic and mortality risk. Conventional fragmentation metrics such as Wake After Sleep Onset (WASO), Sleep Efficiency (SE), and Arousal Index (Arl) rely on arbitrary thresholds and fail to capture the temporal complexity of sleep transitions. Advanced EEG-derived indices offer deeper insights but are less practical for long-term monitoring and have rarely been evaluated against serious outcomes. To address these limitations, we developed a novel metric—Sleep Temporal Entropy (STE) which quantifies variability in the duration derived from the hypnogram. This study aimed to evaluate STE's ability to predict adverse health outcomes, compare its performance with traditional and existing metrics, and examine its relationship with mortality and cardiometabolic disorders.

Materials and methods: We analyzed data from the Shanghai Sleep Health Study Cohort (SSHSC, n=3,219, clinic-based) and the Sleep Heart Health Study (SHHS, n=4,862, community-based). STE was calculated by applying Shannon entropy to the temporal distribution of each sleep stage (Wake, N1, N2, N3, REM), yielding both whole night and stage-specific. In both cohorts, five machine learning models including Extreme Gradient Boosting (XGBoost) were trained to predict cardiometabolic conditions and mortality. SHapley Additive exPlanations (SHAP) were used to assess the relative importance of each feature. In SHHS, survival analysis was conducted using Cox proportional hazards regression models. STE values were categorized into quintiles, and hazard ratios (HRs) with 95% confidence intervals (CIs) were calculated across unadjusted and adjusted models. Proportional hazards assumptions were tested, and restricted cubic splines were used to evaluate non-linearity.

Results: In both cohorts, STE—especially REM and N3-stage STE—ranked consistently among the most important predictors in SHAP analysis, surpassing conventional fragmentation metrics. In SSHSC, XGBoost achieved the highest predictive performance (AUC = 0.84, accuracy = 0.81), with STE contributing more than WASO or ArI in predicting hypertension, diabetes, and hyperlipidemia. In SHHS, machine learning models confirmed STE's relevance in predicting all-cause and cardiovascular mortality. Cox regression revealed a U-shaped association between STE and mortality risk. Compared to the reference quintile (Q3), participants in the lowest quintile of REM STE had a significantly elevated risk of all-cause mortality (HR = 1.58, 95% CI: 1.16–2.15) and cardiovascular mortality (HR = 2.83, 95% CI: 1.66–4.80). Similarly, participants in the highest REM STE quintile also showed increased CVD mortality risk (HR = 2.13, 95% CI: 1.14–3.96). Overall STE showed similar U-shaped patterns, whereas Wake STE exhibited a linear positive association with both outcomes.

Conclusions: STE provides a more comprehensive quantification of sleep fragmentation and irregularity than traditional metrics, offering a multidimensional assessment of sleep quality. Our findings demonstrate that STE is a robust predictor of cardiometabolic disorders and mortality, as evidenced by its performance in both machine learning models and Cox regression analyses. Notably, the U-shaped risk association for STE suggests an optimal range of STE for better health.

Sleep Timing and Cardiovascular Events: A Systematic Review & Meta-Analysis

T. Suri¹, B. Bansal¹, S. Mittal¹, A. Mohan¹

¹All India Institute of Medical Sciences, New Delhi, Pulmonary, Critical Care & Sleep Medicine, New Delhi, India

Introduction: Cardiovascular disease risk is associated with multiple aspects of sleep health. There is a large body of evidence linking short and long sleep durations as well as sleep disorders like obstructive sleep apnea and insomnia with the occurrence of cardiovascular events. However, the risk of cardiovascular events with circadian factors such as sleep timing is less well studied. We performed a systematic review to determine the effect of bedtime or sleep onset timing on the risk of cardiovascular events (acute coronary events and stroke) and mortality.

Materials and methods: We performed a systematic search of the MEDLINE, Embase, Scopus, and Cochrane Central Register of Controlled Trials (CENTRAL) databases. Two authors independently screened the titles/abstracts and the full texts to identify studies that observed the risk of cardiovascular events and mortality based on bedtime or sleep onset timing. The risk of bias among the included studies was adjudged using the ROBINS-E tool. Meta-analysis was performed using a random effects model to estimate the pooled hazard ratios of cardiovascular mortality with early and late sleep timings. The review protocol was prospectively registered in PROSPERO.

Results: A total of seven studies were included. The exposure was measured either as bedtime using a questionnaire (five studies) or as sleep onset timing using actigraphy over one week (two studies). The outcomes included cardiovascular mortality (three studies), cardiovascular events (three studies), coronary events (two studies), and stroke (one study). All studies had some concerns of risk of bias. All studies adjusted for confounders, including age, sex, smoking status, socioeconomic status, and various clinical risk factors. Among three studies comprising of 95,764 subjects, meta-analyses revealed increased risk of cardiovascular mortality among both early sleepers (bedtime/sleep onset before 10 or 11 PM; HR = 1.23, 95% confidence intervals: 1.07 – 1.42, $I^2 = 0\%$) and late sleepers (bedtime/sleep onset after 12 AM; HR = 1.37, 95% CI: 1.12 – 1.68, $I^2 = 25.3\%$) compared to those with intermediate sleep timings. Meta-analyses could not be performed to assess the risk of cardiovascular events due to the variable definitions of the outcome. All three studies found an increased risk of cardiovascular events with early sleep timing (before 9 or 10 PM), whereas two out of three studies found an increased risk of cardiovascular events with late sleep timing (after 12 AM) compared to intermediate sleep timings. One out of two studies found that late sleep timing increased the risk of acute coronary events. The sole study that reported on stroke found an increased risk with both early (at/before 9 PM) and late (after 12 AM) bedtime.

Conclusions: We found that both early and delayed bedtime/sleep onset timings can increase the risk for cardiovascular events and mortality compared with intermediate sleep timings. Public health interventions to improve sleep health should incorporate measures to optimize both sleep duration and timing.

Sleep timing, sleep duration and serum metabolites in healthy adults

C. Sørensen¹, I. Dudka², A. Virel³, I. Kåreholt^{4,1}, L. Jt Balter^{5,6,7,8}, J. Axelsson^{8,7}, G. Kalpouzos⁹, S. Sindri^{1,10}

Introduction: Short and long sleep duration as well as poor sleep quality have been linked to higher prevalence of metabolic disorders. However, it is still unclear how diverse sleep variables relate to

different metabolic pathways. This study examines how different features of sleep health relate to serum metabolites.

Materials and methods: The study used data from 197 healthy individuals aged 20-79 (Females n=103) from the IronAge study performed at Karolinska Institutet in Sweden. Sleep variables were assessed with the Karolinska Sleep Questionnaire, where the following variables were computed: sleep duration, sleep debt, midpoint, social jetlag (i.e., the discrepancy between midpoint on free and workdays), napping frequency and sleep quality. Morning fasting blood samples were collected and ^1H NMR spectroscopy was utilized for metabolomic analysis. The metabolites were categorized according to their major metabolic pathways: amino acid, lipid, carbohydrate, energy and gut microbiota. Linear regressions were performed to examine the relationship between each sleep variable and metabolite.

Results: Sleep duration, midpoint of sleep on free days, social jetlag and chronotype associated with eight metabolites at a significance level of $p < 0.01$. Notably, midpoint associated with most metabolites spanning multiple pathways. A later midpoint was associated with higher levels of metabolites in the lipid pathway, and lower levels in the amino acid and energy pathway.

Conclusions: These observations indicate that sleep timing features, *midpoint* and *social jetlag*, have a stronger relationship with morning metabolism than other sleep health dimensions. Following replication in larger samples, these complex relationships may hold potential for health promotion.

Acknowledgments: We thank the IronAge staff for their help with data collection and the participants for their contribution. We also thank KI Biobank for handling the blood samples, the Swedish NMR Center in Umeå (SciLifeLab) for NMR analysis, and finally Åldrecentrum and SNAC-K in Stockholm for giving access to their premises for data collection.

Sleep-Wake Classification Using Heart Rate and HRV Derived From Short PPG Signals

M. Kim¹, H. Lee¹, H.-G. Kim¹, K.-Y. Kim¹

¹Electronics and Telecommunications Research Institute (ETRI), Daegu-Gyeongbuk Research Division, Daegu, Korea, Republic of

Introduction: Accurate classification of sleep-wake states is essential not only for diagnosing sleep disorders but also for developing vigilance detection and alerting systems in high-risk environments, such as drowsy driving or critical occupational settings. While polysomnography (PSG) remains the gold standard for sleep staging, its high cost and complex measurement requirements limit its practical application in daily life. Therefore, there is growing interest in non-invasive simplified approaches based on physiological signals. This study proposes a method for classifying sleep and wake states every 30 seconds using only heart rate (HR) and heart rate variability (HRV) features derived from photoplethysmography (PPG), exploring the feasibility of implementing this approach using a single-sensor PPG system.

Materials and methods: This study utilized overnight PPG data from 1,680 subjects in the Multi-Ethnic Study of Atherosclerosis (MESA) dataset provided by the National Sleep Research Resource (NSRR). Each subject's PPG signal was segmented into 30-second epochs. Signal preprocessing, peak detection, and RR interval extraction were then performed for each epoch to compute HR and five HRV features (SDNN, RMSSD, pNN50, SD1, and SD2). Considering the dominance of parasympathetic activity during sleep, parasympathetically mediated features (RMSSD, pNN50, SD1) were emphasized, along with SDNN, representing overall autonomic activity, and SD2 indicating long-term variability. The dataset was divided into training and test set in a 7:3 ratio, stratified by subject, and undersampling was applied to address class imbalance. A Random Forest classifier was selected due to its computational efficiency. Optimal hyperparameters were identified through grid search, and the classifier was trained separately for four classification scenarios: binary (Wake/Sleep), three-class (Wake/NREM/REM), four-class (Wake/LS/DS/REM), and five-class (Wake/N1/N2/N3/REM).

Results: For Wake-Sleep classification, the model achieved an accuracy of 69.5%, with precision, recall, and F1-score of 74%, 60%, and 66%, respectively, for the wake class. These results indicate that reliable sleep-wake classification can be achieved even when using a limited set of physiological features. However, classification performance decreased as the number of sleep stages increased, achieving accuracies of 47.3%, 40.1%, and 32.8% for the 3-class, 4-class, and 5-class classifications, respectively. These results indicate that using only HR and HRV-derived features may not provide adequate discriminatory power for detailed sleep staging.

Conclusions: This study demonstrates the feasibility of classifying sleep-wake states using short PPG segments at a 30-second resolution, based solely on HR and HRV features. The independent processing performed at every 30 seconds highlights the potential for real-time implementation in embedded systems, such as wearable or portable monitoring devices. Furthermore, the proposed method could be extended to applications requiring continuous short-term monitoring of vigilance and fatigue.

Acknowledgments: This work was supported by Electronics and Telecommunications Research Institute (ETRI) grant funded by the Korean government. [25ZD1140, Regional Industry ICT Convergence Technology Advancement and Support Project in Daegu-Gyeongbuk(Medical)].

Social bedtime procrastination is associated with need to belong and results in shorter sleep and poorer next-day mood

V. Kok¹, J. Gooley¹

¹Duke-NUS Medical School, Singapore, Singapore

Introduction: Late-night social activities often compete with time for sleep. Socializing plays a key role in buffering stress and promoting feelings of enjoyment and belonging. However, social interactions can contribute to bedtime procrastination, defined as going to bed later than intended when there is no external need to do so. In this study, we investigated drivers and consequences of face-to-face social bedtime procrastination in residential college students. We hypothesized that instances of social bedtime procrastination would be associated with shorter sleep and poorer next-day wellbeing, and predicted by greater need to belong and extraversion.

Materials and methods: University students in a single residential college ($n=104$, 59 women) wore actigraphy watches and Bluetooth proximity beacons during the same 2-week period to track their nocturnal sleep and physical proximity to one another. Daily diaries recorded instances of social bedtime procrastination and the friend(s) involved in delaying bedtime, as well as next-day mood and daytime sleepiness. The Need to Belong Scale assessed individual differences in the desire for acceptance and belonging, and the Big Five Inventory was used to assess extraversion (score range=1-5 for both instruments). Mixed models were used to test associations of social bedtime procrastination with daily sleep behavior (onset, offset, duration), negative morning mood, positive affect, and daytime sleepiness. Diary-reported social interactions were analyzed to construct the social bedtime procrastination network. Exponential random graph models were used to test associations of psychological traits with membership and tie strength in the network.

Results: On nights when students engaged in face-to-face social bedtime procrastination, their sleep duration was more than an hour shorter compared to nights when they did not go to bed later than intended. ($\beta=-1.21$ h, 95% CI=-1.48 to -0.95 h, $P<0.001$). These nights were associated with a next-day increase in negative morning mood ($P=0.008$), decrease in positive affect ($P=0.004$), and higher odds of daytime sleepiness ($P=0.001$). Students' bedtimes were strongly correlated with the timing of their last objectively measured proximity event with the person who delayed their bedtime ($r=0.83$, $P<0.001$). The odds of a social bedtime procrastination event were nearly 2-fold higher for a 1-point increase in need to belong score (adjusted OR=1.88, 95% CI=1.49 to 2.36), and 1.3-fold higher for a 1-point increase in extraversion score (adjusted OR=1.30, 95% CI=1.06 to 1.57).

Conclusions: Social bedtime procrastination may be an important factor contributing to late bedtimes and short sleep among students living in residential colleges. Students who seek social opportunities to satisfy their drive to socialize or need to belong are more likely to engage in face-to-face social bedtime procrastination. These insights could inform interventions aimed at promoting healthier sleep habits within social contexts.

Acknowledgments: The work was funded by the Ministry of Education, Singapore (MOE2019-T2-2-074) and the National Research Foundation, Singapore (NRF2016-SOL002-001).

Socio-economic disparities in sleep duration and latency among U.S adolescents: 14 years pooled cross-sectional analysis of NHANES data

D. Bancovsky¹, A. Gileles-Hillel^{2,3}

¹Safra Children's Hospital - Sheba Medical Center, Pediatric Neurology Unit, Ramat Gan, Israel, ²The Hebrew University of Jerusalem, The Faculty of Medicine, Jerusalem, Israel, ³Hadassah Medical Center, Pediatric Pulmonology and Sleep Unit, Jerusalem, Israel

Introduction: Sleep is crucial to optimal health and quality of life. Nevertheless, recent data shows this fundamental right is not equitably distributed across racial and ethnic groups. To address the crucial gap in the association of youth's sleep with social, economic, and racial/ethnic variables, our study assesses 14 years of nationally representative sleep duration and latency data from the U.S. National Health and Nutrition Examination Survey (NHANES).

Materials and methods: We analysed pooled cross-sectional data from NHANES cycles 2005–2018, including participants aged 16–18 years. Self-reported sleep loss (<7 hours) and short sleep latency (<10 minutes) were the primary dependent variables. Race, ethnicity, income, education, and household reference marital status were the main independent variables. Both univariable and multivariable logistic regression models were used, adjusting for gender, age, physical activity, BMI, and other health comorbidities.

Results: We included 3,766 participants in the sleep loss, and 1,346 participants in the sleep latency analysis. Sleep loss was positively associated with the Black non-Hispanic ethnicity group (OR 1.8, 95% CI: 1.4-2.3, $p<0.001$) and at least some high-school education (OR 1.7, 95% CI: 1.1-2.6, $p<0.01$), while negatively associated with being married (OR 0.6, 95% CI: 0.5-0.9, $p<0.01$). After adjusting for covariates, independent associations with sleep loss persisted for Black non-Hispanic (aOR 2.0, 95% CI: 1.3-3.0, $p<0.001$) and Hispanic ethnicities (aOR 1.7, 95% CI: 1.1-2.8, $p<0.01$); at least some high school (aOR 1.9, 95% CI: 1.1-3.3, $p<0.05$) and at least some college (aOR 2.4, 95% CI: 1.3-4.5, $p<0.01$).

Short sleep latency was associated with the Black non-Hispanic (OR 2.1, 95% CI: 1.4-3.2, $p<0.0001$) and the Hispanic (OR 1.6, 95% CI: 1.3-2.0, $p<0.0001$) ethnicities. These associations remained statistically significant after adjustment: Black non-Hispanic (aOR 2.8, 95% CI: 1.6-4.9, $p<0.01$) and Hispanic (aOR 3.3, 95% CI: 1.9-5.8, $p<0.001$).

Conclusions: Black non-Hispanic and Hispanic adolescents reported significantly shorter sleep durations and shorter sleep latency compared to their White non-Hispanic peers, even after adjustment for socio-demographic variables, suggesting a high prevalence of sleep deprivation in this population. Notably, marriage was protective against sleep loss, while higher parental education was associated with greater sleep loss, possibly due to earlier wake times, less bedtime supervision, or greater academic demands. Unmeasured factors likely contributing to these disparities include cultural sleep practices and environmental exposures such as noise and light pollution. Additionally, psychosocial stressors such as perceived discrimination, neighborhood safety, limited social support, and anxiety may mediate sleep loss among U.S. minorities. The findings underscore the need for greater ethnic diversity in sleep research to better address sleep health disparities and elucidate their contribution to increased morbidity and mortality among these vulnerable populations.

Structural Factors Impeding or Facilitating Freshmen Sleep Habits

C.S. Soon¹, X.Y. Chua¹, R.L.F. Leong¹, J.L. Ong¹, S.A.A. Massar¹, S. Qin¹, M.W.L. Chee¹

¹National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore

Introduction: Starting college is a time of transition that can be stressful. Developing healthy sleep habits in this period of relative autonomy is important for physical and mental wellbeing. We evaluated freshmen sleep, activity and wellbeing through different phases of the academic calendar using a wearable (Oura Ring) and a proprietary app (Z4IP). A comprehensive understanding of the structural factors that impede or facilitate freshmen sleep as they adapt to college life can inform programs to optimize student life and wellbeing.

Materials and methods: 638 freshmen underwent multi-factor evaluation across a 20-week semester using a combination of objective sleep measurements (Oura Ring), daily subjective reports of sleep and well-being (Z4IP), and periodic time-use diaries (Z4IP). We explored how sleep patterns were affected by the academic calendar, early morning classes, and staying on- versus off-campus.

Results: During instructional weeks, freshmen woke 49.8min earlier on weekdays compared to weekends ($t_{629}=24.14$, $p<0.0001$), especially when there were early morning classes. However, delaying

waketimes after the midterm break ($\beta=5.81$, $p<.0001$), often past the first class, resulted in increased sleep ($\beta=5.56$, $p<.0001$). In contrast, bedtimes were stably late across the semester, with minimal weekday-weekend differences (15.2min). Despite reduced needs for commuting, freshmen staying on-campus obtained less sleep than those staying off-campus ($t_{629}=-6.36$, $p<.0001$), even after accounting for naps ($t_{629}=-5.26$, $p<.0001$), due mainly to later bedtimes ($t_{629}=6.62$, $p<.0001$). Four hours before going to bed, on-campus students spent 60min on social and co-curricular activities, and compositional data analyses indicated that those spending more time on these activities slept later. Additional digital leisure activities showed similar effects for off-campus students.

Conclusions: Freshmen's sleep evolved across the semester as they adapted to college life. By the second half of the semester, more sleep was obtained by waking up later, often past early morning classes. Residential status also affected their sleep habits, and the type of activities that delayed when they went to bed. The mix of predicted and unpredicted findings underscores the utility of our minimally obtrusive, multi-factor, longitudinal behavioural and physiological phenotyping approach.

Acknowledgments: The authors report no financial conflicts of interests. Dr Michael WL Chee is on the Medical Advisory Board of Oura.

Structured Breathing Exercises as a Treatment for Insomnia, Anxiety, and Depression in Young Individuals: A Randomized Controlled Trial

P. Hjorth¹, A. Bick²

¹University of Southern Denmark, Psychiatry, Odense M, Denmark, ²University of Southern Denmark, Child psychiatry, Odense M, Denmark

Introduction: Insomnia is a prevalent and often debilitating condition among young individuals with anxiety and depression. Sleep disturbances, including difficulty initiating and maintaining sleep, are associated with emotional dysregulation, cognitive impairments, and an increased risk of chronic mental health conditions. Evidence suggests that structured breathing exercises (SBE) may enhance sleep quality by modulating autonomic nervous system activity, reducing hyperarousal, and promoting relaxation.

This study aims to evaluate the efficacy of SBE in improving sleep quality and reducing symptoms of insomnia, anxiety, and depression in young individuals aged 16–24 years.

Materials and methods: Methods

A randomized controlled trial (RCT) is currently in preparation and will be conducted during the summer and autumn of 2025. The study will recruit 100 participants from a mental health support program, who will be randomized into an SBE intervention group or a control group. The intervention consists of a four-week program including guided breathing techniques such as diaphragmatic breathing, box breathing, and Tummo breathing. Exercises will be practiced daily via an app, with weekly group sessions. Sleep outcomes will be assessed using the Insomnia Severity Index (ISI), and mental health measures will include the Hospital Anxiety and Depression Scale (HADS) and the General Health Questionnaire (GHQ-28).

Results: Expected Results

SBE is hypothesized to improve sleep quality by increasing parasympathetic activation, lowering cortisol levels, and reducing nocturnal hyperarousal. Controlled breathing techniques may enhance sleep onset, decrease nighttime awakenings, and improve overall sleep efficiency. If effective, this intervention could serve as a non-pharmacological, accessible approach for managing insomnia in young individuals with mental health concerns.

Conclusions: This study, set to begin in mid-2025 and findings could inform clinical practice by integrating breathwork as a complementary strategy for treating sleep disturbances in youth with anxiety and depression.

Subjective Sleep Parameters Associated with Anxiety and Depression in Mexican Young Adults: A Cross-Sectional Study

C. Olivera-López¹, V. Santiago-Ayala², M. Reséndiz-García², D. Roa-Cortés¹, M. Valencia-Flores^{1,2}

¹National Autonomous University of Mexico, Laboratory of Sleep Disorders, Faculty of Psychology, Mexico City, Mexico, ²Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Neurology Department, Sleep Disorders Clinic, Mexico City, Mexico

Introduction: A growing body of evidence supports a robust association between sleep disturbances and an elevated risk of mood disorders. However, the specific contribution of individual sleep parameters to the manifestation of mood-related symptoms, particularly within non-clinical populations, remains insufficiently explored. This study aimed to investigate the associations between subjective sleep parameters and self-reported symptoms of anxiety and depression in a cohort of young Mexican adults.

Materials and methods: A cross-sectional survey was conducted among a non-probabilistic sample of 198 participants aged 18 to 25 years, residing in Mexico City. The assessment protocol included self-reported measures of sleep duration, sleep latency, frequency of nocturnal awakenings, and daytime sleepiness, the latter rated on a Likert-type scale. Additionally, participants completed the validated Spanish versions of the Beck Anxiety Inventory (BAI) and Beck Depression Inventory (BDII). Multiple linear regression analyses were performed to evaluate the predictive value of sleep-related variables on anxiety and depression scores. Assumptions of homoscedasticity and absence of multicollinearity were verified prior to analysis. The study was approved by the Institutional Research and Ethics Committee (CEI/379/2024).

Results: The sample consisted of 49 males and 149 females, with a mean age of 19.7 years (SD = 1.5). The average reported sleep duration was 445.3 minutes per night (SD = 70.5), with a mean sleep efficiency of 89.9% (SD = 6.5) and an average sleep latency of 22.3 minutes (SD = 22.2). Excessive daytime sleepiness was reported by 18% of participants. Multiple linear regression analyses indicated that both excessive daytime sleepiness ($\beta = -0.255$, $p < 0.01$) and the number of nocturnal awakenings ($\beta = 0.219$, $p < 0.01$) were significant predictors of anxiety symptoms. These variables also significantly predicted depressive symptoms, although the association with nocturnal awakenings was weaker (daytime sleepiness: $\beta = -0.263$, $p < 0.01$; nocturnal awakenings: $\beta = 0.179$, $p = 0.014$). Other sleep parameters did not demonstrate statistically significant associations with mood symptoms.

Conclusions: Impairments in sleep maintenance and elevated levels of daytime sleepiness are significantly associated with mood symptoms in young adults, even when total sleep duration and sleep efficiency fall within normative ranges. These findings emphasize the clinical importance of identifying and addressing specific sleep disturbances, which may play a critical role in the development or exacerbation of affective symptoms in this population.

Subjective sleep quality in psoriatic patients and its association with symptoms severity

O. De Rosa^{1,2}, G. Argenziano¹, A. Balato¹, F. Conte², R. Di Caprio¹, G. Ficca², F. Giganti³, G. Gronchi³, S. Malloggi³, L. Marigliano¹, E. Rosi⁴, F. Prignano⁴

¹University of Campania Luigi Vanvitelli, Dermatology Unit, Department of Mental and Physical Health and Preventive Medicine, Naples, Italy, ²University of Campania Luigi Vanvitelli, Department of Psychology, Caserta, Italy, ³University of Florence, Department of Neuroscience, Psychology, Drug Research and Child Health (NEUROFARBA), Florence, Italy, ⁴University of Florence, Department of Health Sciences, Section of Dermatology, Florence, Italy

Introduction: Psoriasis is a prevalent dermatological condition frequently associated with sleep disturbances. Evidence suggests a bidirectional relationship between sleep impairment and psoriatic symptoms, creating a vicious cycle that significantly impacts quality of life. This study investigated the subjective quality of sleep among patients diagnosed with psoriasis with mild symptom severity. The main aim was to determine the relationship between self-reported sleep quality and the perceived severity of psoriasis symptoms.

Materials and methods: Psoriatic patients were recruited from Dermatology Units based on the following criteria: 18–65 years, mild symptom severity (PASI < 10; DLQI < 5), no systemic treatment (topical only), absence of comorbid medical conditions (including psychiatric and sleep disorder diagnoses), no history of drug or alcohol abuse, limited caffeine (no more than 150 mg/day) and alcohol (no more than 250 mL/day) consumption. Control participants were recruited via social media and advertisement following the same inclusion criteria except for the presence of psoriatic disease. Participants filled out the Pittsburgh Sleep Quality Index (PSQI), addressing habitual sleep quality

across seven subscales (i.e., subjective sleep quality, sleep latency, sleep duration, sleep efficiency, sleep disorders, sleep medication use, daytime dysfunctions due to sleepiness), with higher scores indicating poor sleep quality. Participants were also required to complete a 10-item Numeric Rating Scale for 7 consecutive days to report psoriasis-related levels of itch and pain at bedtime and upon awakening. Additionally, participants completed a set of questionnaires exploring anxiety (Beck Anxiety Inventory; BAI) and depression symptoms (Beck Depression Inventory; BDI), habitual sleepiness (Epworth Sleepiness Scale; ESS), and Quality of Life (SF-36 questionnaire).

Results: Nineteen patients (12M, 7F; age = 37.89 ± 12.93) and 53 controls (14M, 39F; age = 28.33 ± 13.29) were recruited.

No between-groups differences emerged in PSQI scores nor in BAI, BDI, ESS, and SF-36 scores.

Patients' PSQI total scores exhibited a positive correlation with the level of itch and pain referred at bedtime (itch: $p=.608$; pain: $p=.006$; pain: $p=.613$; $p=.005$) and risetime (itch: $p=.568$; pain: $p=.110$; pain: $p=.594$; $p=.007$).

As for PSQI subscales, level of itch and pain, both at bedtime and risetime, positively correlated with subjective sleep quality (bedtime: itch: $p=.019$; pain: $p=.023$; risetime: itch: $p=.040$; pain: $p=.021$), sleep latency (bedtime: itch: $p=.048$; pain: $p=.050$; risetime: itch: $p=.049$; pain: $p=.014$) and daytime dysfunction (bedtime: itch: $p=.046$; pain: $p=.044$; risetime: itch: $p=.015$; pain: $p=.016$).

Moreover, patients' PSQI total score correlated with the SF-36 subscale of Physical functioning ($p=.024$), Fatigue ($p=.014$), and emotional well-being ($p=.012$), and with BAI scores ($p=.019$).

Conclusions: This study explored subjective sleep quality in psoriatic patients, focusing on the level of itch and pain intensity as key indicators of self-reported disease burden. Our findings revealed that poorer subjective sleep quality was positively correlated with perceived psoriasis symptoms. This result highlights the relevance of addressing sleep quality in psoriatic patients, even when symptom severity is low. Optimizing sleep emerges as a key factor in overall patient well-being and potentially contributes to a more effective and comprehensive management of the disease.

Summertime bedroom overheating in un-airconditioned UK urban apartments during Heat Alert periods: thermal comfort and sleep outcomes

I. Hartescu¹, M. Ravikumar¹, K.J. Lomas², V. Haines³, A. Beizae², J. Barnes³, Z. Zambelli³, V. Rossi², K. Morgan¹

¹Loughborough University, School of Sport, Exercise and Health Sciences, Loughborough, United Kingdom, ²Loughborough University, School of Architecture Building and Civil Engineering, Loughborough, United Kingdom, ³Loughborough University, School of Design and Creative Arts, Loughborough, United Kingdom

Introduction: The increasing frequency of heatwaves associated with global warming has implications for urban sleep quality in temperate regions. Growing epidemiological evidence has linked higher night-time air temperatures to indices of subjective sleep disturbance. Less research attention, however, has focussed on the mediating impact of bedroom overheating on both subjective and objective sleep outcomes during periods of untypically hot weather. The ongoing UK Home Heat Health project monitored the bedroom climate and sleep outcomes in un-airconditioned London apartments during the summers of 2023 and 2024.

Materials and methods: Following recruitment and screening, the sleep of 123 healthy adults (mean age = 35; 82 female) living in separate un-airconditioned London apartments was continuously monitored using actigraphy (CamnTech Motionwatch 8; epochs=30s) and a phone app consensus sleep diary (which included daily ratings of bedroom thermal comfort and heat-related sleep disturbance). Participant bedrooms were fitted with HOBO MX1101 sensors recording temperature at half hourly intervals. Using a quasi-experimental design, outcomes from 5-7 days of continuous 'typical' temperatures (Baseline: BL) and the first night of periods covered by UK Met Office 'Heat Health Alert' warnings (Hot Nights: HN) were compared in repeated measures general linear models.

Results: Night-time (22.00-07.00) bedroom temperatures rose significantly during Heat Alert nights (mean/range BL = 22.4°C / 17.5 - 26.4°C ; HN = 25.5°C / 22.0 - 29.3°C , $p<0.001$) with the average number of 30min periods exceeding 26°C , the CIBSE TM59 threshold for bedroom overheating, increasing from (mean/SD) 0.5 per night/0.1 at BL to 6.5 per night/8.0 on HN ($p<0.001$). Relative to BL,

participant ratings of bedroom thermal discomfort ($p < 0.001$) and sleep disturbance attributed to bedroom temperature ($p < 0.001$) both increased significantly on HN. Actigraphy showed modest but significant reductions in Total Sleep Time (mean/SD BL = 389.4/53.3; HN 379.0/62.2, $p = 0.04$) and Time in Bed (mean/SD BL = 492.4/53.2; HN 478.1/75.1, $p = 0.04$). Average rise times were 21 minutes earlier following HN ($p < 0.001$).

Conclusions: In these un-airconditioned apartments typical of London housing stock, bedroom overheating and subjective bedroom thermal discomfort was common on hot nights. However, while ratings of sleep disturbance attributed to bedroom temperature also increased significantly, most sleep outcomes (sleep latency, wake after sleep onset, sleep efficiency, sleep fragmentation, mobility during sleep) showed no significant BL-HN change. All the Heat Alerts captured here received the lowest health risk classification of 'yellow'. For these lower range hot spells, the immediate impact of bedroom overheating appears to be reflected more in experience (subjective ratings) and behaviour (e.g. rise times) than sleep architecture. Monitoring for higher risk Heat Alerts, and longer term low-risk alerts is ongoing in the Home Heat Health project.

Summertime bedroom temperatures in un-airconditioned UK urban apartments: factors influencing subjective and objective sleep outcomes

I. Hartescu¹, K. Morgan¹, K.J. Lomas², V. Haines³, A. Beizaee², J. Barnes³, Z. Zambelli³, V. Rossi², M. Ravikumar¹

¹Loughborough University, School of Sport, Exercise and Health Sciences, Loughborough, United Kingdom, ²Loughborough University, School of Architecture Building and Civil Engineering, Loughborough, United Kingdom, ³Loughborough University, School of Design and Creative Arts, Loughborough, United Kingdom

Introduction: The increasing frequency of heatwaves associated with global warming has implications for urban sleep quality, with epidemiological evidence showing clear links between higher night-time air temperatures and subjective sleep disturbance (e.g. Obradovich et al, 2017; Khosravi et al, 2025). In understanding factors mediating these subjective reports, however, less research has focussed on the influence of bedroom temperatures or on individual differences in sleep reactivity. We examined actigraphic total sleep time (TST) and subjective sleep experiences in relation to bedroom temperatures and scores on the Ford Insomnia Response to Stress Test (FIRST) during periods of untypically hot London weather.

Materials and methods: The UK Home Heat Health project monitored bedroom climate and sleep outcomes during the summers (June-September) of 2023 and 2024. Following recruitment and psychometric profiling 123 healthy adults (mean age = 35; 82 female) living in separate un-airconditioned London apartments were continuously monitored using actigraphy (CamnTech Motionwatch 8) and a phone app Consensus Sleep Diary with additional 10-point ratings of bedroom thermal comfort and degree of heat-related sleep disturbance. Bedroom temperatures were monitored half-hourly using HOBO MX1101 sensors. Outcomes from 5-7 days of continuous 'typical' temperatures (Baseline: BL) and the first night of periods covered by UK Met Office 'Heat Health Alert' warnings (Hot Nights: HN) were first compared in general linear models. For ratings of thermal comfort, heat-related sleep disturbance, feeling 'rested' in the morning, and actigraphic total sleep time (TST), change scores (BL minus HN) were then computed and entered as dependent variables in 4 separate linear regression models with maximum bedroom temp (°C), age (years), gender (M/F) and FIRST scores as independent variables (IVs) in each.

Results: Night-time (22.00-07.00) bedroom temperatures rose significantly during HN (mean/range BL = 22.4°C /17.5-26.4°C; HN = 25.5°C/22.0-29.3°C, $p < 0.001$) with 46% of bedrooms exceeding the CIBSE TM59 threshold (26°C) signifying overheating. HN thermal comfort ($p < 0.001$), feelings of being 'rested' ($p < 0.001$) and actigraphic TST ($p < 0.05$) significantly decreasing, while ratings of heat-related sleep disturbance significantly increased ($p < 0.001$). In the regression models entering all IVs, only (increasing) maximum bedroom temperatures significantly predicted these negative changes in thermal comfort (standardized beta = - 0.2; $p = 0.037$), heat-related sleep disturbance (standardized beta = - 0.2; $p = 0.03$) and feeling 'rested' in the morning (standardized beta = - 0.23; $p = .012$). For actigraphic TST all IVs in the model were non-significant.

Conclusions: In these un-airconditioned apartments typical of London housing stock bedroom overheating was common on hot nights. However, while the magnitude of change indicating thermal discomfort, heat-related sleep disturbance, and morning feelings of being 'unrested' increased with bedroom temperature, the magnitude of objectively measured changes in TST did not. All outcomes were independent of sleep reactivity (FIRST) scores. For less severe hot spells in temperate climates, the linear impact of rising bedroom temperatures is reflected more in subjective experience than in sleep architecture. This has implications for inferences drawn from subjective reports, and will be examined further in the ongoing Home Heat Health project.

Targeting Sleep to Improve Risky Driving: Results from a Randomized Controlled Trial in Young Drivers

K.R. Rossa¹, C.L. Pattinson¹, D.L. Mann², J. Zhang², S.L. Edmed¹, M.A. Alam³, S.S. Soleimanloo⁴, K.A. Sullivan⁵, P.M. Salmon⁶, A.C. Allan¹, S.S. Smith¹

¹University of Queensland, Child Health Research Centre, Brisbane, Australia, ²University of Queensland, School of Electrical Engineering and Computer Science, Brisbane, Australia, ³University of Queensland, Poche Centre for Indigenous Health, Brisbane, Australia, ⁴University of Queensland, School of Psychology, Brisbane, Australia, ⁵Queensland University of Technology, School of Psychology and Counselling, Brisbane, Australia, ⁶University of the Sunshine Coast, Human Factors and Sociotechnical Systems, Brisbane, Australia

Introduction: Young adults are over-represented in sleepiness related road crashes. Given the critical role that sleep plays in risky driving in young people, addressing sleep loss through targeted interventions should be a priority. To date, no randomized controlled trials have assessed the effects of increased sleep on on-road driving risk. Addressing this gap, the current study examined the effectiveness of a community-based sleep extension and education intervention on 1) increasing objective sleep duration and reducing sleep restriction episodes, and 2) reducing on-road risky driving in sleepy young drivers.

Materials and methods: This pragmatic, parallel-group randomized controlled trial involved young Australian drivers who reported habitual sleep of <7 hours per night and <6 hours on at least two nights per week, with no diagnosed sleep disorders or overnight shift work. Participants were randomized to either a sleep extension and education intervention or a placebo control condition receiving nutrition information. Outcomes were assessed using wrist actigraphy and in-vehicle accelerometers during three, two-week naturalistic assessment periods: Baseline (weeks 1–2), Intervention Maintenance (weeks 6–7), and 6-Month Follow-Up (weeks 33–34). The intervention group received brief sleep health education and an individualized sleep extension plan, implemented over a 3-week period following Baseline assessment. Primary outcomes were changes from baseline in objective sleep duration, frequency of sleep restriction, and risky driving behaviours (harsh starts, stops, and rapid turns). Secondary outcomes included diary reported sleep duration, subjective sleep disturbance, and sleep related daytime impairment. Analyses were conducted on an intention-to-treat basis using mixed-effect linear models.

Results: Of 951 participants screened for eligibility, 115 were randomized, and 99 completed the study (*Mean* = 20.62, *SD* = 1.90, 73% female). Significant intervention effects were observed in objective risky driving (reduction in proportion of harsh starts/stops (β = -0.14, 95% CI: -0.27, -0.02, p = 0.024), and rapid turning (β = -0.07, 95% CI: -0.14, -0.005, p = 0.036) for participants in the sleep extension condition relative to the placebo condition during the intervention maintenance phase, but not during follow-up. Participants in the sleep intervention group reported a significant reduction in subjective sleep-related daytime impairment during the intervention maintenance phase (β = -5.64, 95% CI: -9.14, -2.14, p = 0.002). However, this effect was not sustained at follow-up. No significant intervention effects were observed in objective or subjective sleep duration or frequency of sleep restriction episodes between groups at maintenance, or follow-up assessment.

Conclusions: A behavioural sleep extension and education intervention led to short-term improvements in objective risky driving indicators and reductions in daytime impairment among young adult drivers, despite no significant change in objective sleep duration. Although effect sizes were modest, g-force events are strong predictors of crash risk and suggest a potentially meaningful

population-level impact. Our findings highlight the promise of sleep-focused interventions in road safety strategies, while underscoring the need for ongoing support to sustain behavioural change.

Temporal Dynamics of Sleep, Depression, and Fatigue During Pregnancy: A Multilevel Vector Autoregression Analysis

P. Chen¹, Y. Wang², J. Wang³, J. Zhang³, Q. Lin⁴, C. Park¹, B. Zhu³

¹University of Illinois Chicago, College of Nursing, Chicago, United States, ²The Hong Kong Polytechnic University, School of Nursing, Hong Kong, Hong Kong, SAR of China, ³Shanghai Jiao Tong University, School of Nursing, Shanghai, China, ⁴International Peace Maternity and Child Health Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China

Introduction: Pregnant women often experience complex and evolving physical and psychological symptoms including sleep disturbance, depression, and fatigue. Few studies have used person-centered longitudinal models that capture dynamic, reciprocal relationships among multiple symptoms. To address this gap, this study aimed to examine the temporal and between-subject associations of those symptoms across different trimesters.

Materials and methods: A prospective cohort design was used. Pregnant women (N=228) were followed up during the first, second, third trimester, and 6-month postpartum. At each time point, participants completed a sleep diary for seven consecutive days. Sleep parameters were calculated using the 7-day averages. According to previous literature on the operationalization of multidimensional sleep health, a composite score was calculated based on five indicators: early chronotype (defined as a 7-day average sleep mid-point < the median 3:26 AM), sufficient sleep duration (7-8 hours per night), absence of insomnia (Insomnia Severity Index ≤ 7), no loud snoring (one item from the STOP-Bang), and low daytime sleepiness (Epworth Sleepiness Scale < 10). One point was assigned for meeting each criterion, with a total score ranging from 0 to 5. Fatigue was assessed using a single item from the sleep diary (rated 0-10), and the 7-day mean was used. Depressive symptom was measured using the Edinburgh Postnatal Depression Scale. We used a multilevel vector autoregressive (MLVAR) model to examine temporal and between-person association and uncover potential feedback loops among the symptoms across time. The model was estimated using the mlVAR package (R v4.4.2), with participants as the grouping variable.

Results: Participants mean age was 31.7 years (SD 3.8, range 21-48). The temporal effects revealed several significant associations. Fatigue at the previous time point significantly predicted worse sleep health at the subsequent time point ($\beta = -0.142$, $p = 0.002$). Depressive symptom significantly predicted better sleep health ($\beta = 0.113$, $p = 0.024$) and lower fatigue ($\beta = -0.080$, $p = 0.027$) at the following time point. Both depressive symptom ($\beta = -0.122$, $p = 0.003$) and sleep health ($\beta = -0.092$, $p = 0.029$) demonstrated a significant negative autoregressive effect, indicating an inverse temporal association within depression or sleep across adjacent time points. All other temporal and autoregressive paths not reported were statistically non-significant. The between-subject results further revealed that individuals with higher fatigue reported higher depression (partial $r = 0.210$, $p = 0.001$) and poorer sleep health (partial $r = -0.316$, $p < 0.001$), and those with higher depression also reported lower sleep health (partial $r = -0.338$, $p < 0.001$).

Conclusions: Fatigue emerged as a robust predictor of subsequent declines in sleep health, highlighting its relevance as a potential intervention target. Negative autoregressive patterns indicated temporal instability in both sleep and depression. Temporal analyses showed that higher depressive symptoms predicted better subsequent sleep, whereas between-subject results indicated that greater depression was associated with poorer overall sleep health. These cross-level inconsistencies suggest that temporal effects may capture short-term, dynamics, while between-subject effects reflect stable individual differences—highlighting the need for intensive longitudinal designs to disentangle these processes.

Temporal profile of distal skin temperature change at sleep onset across multiple nights in adolescents and older adults

A. Jouvencel¹, A. Willoughby¹, R. Leong¹, M. Chee¹

¹National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore

Introduction: At sleep onset, there is a decrease in core body temperature and an increase in distal skin temperature (DST). However, most studies have focus on single night lab measurements in adults. There is a need for naturalistic studies over different age groups to understand the night-to-night variability of this physiological herald of sleep. We sought to determine temporal kinetics of peri-sleep DST increase using a wearable sleep tracker and the consistency of these measurements across multiple nights in adolescents and older adults.

Materials and methods: DST was measured using Oura rings (Gen 2 and 3) equipped with NTC thermistors sensitive to 0.01°C temperature changes. N2 sleep onset was determined via EEG (SOMNOtouch and Dreem band) over 8 to 10 nights and up to 5 naps for adolescents. DST measurement and analysis focused on the time between the Time Attempting To Sleep (TATS) and N2 sleep onset. A novel semi-automatic algorithm was developed to identify the rise in DST, calculating both the temperature delta and rate of increase. Mixed-effects models were employed to explore relationships between temperature rise characteristics and N2 sleep onset timing and temperature. All models were controlled for age and sex.

Results: Analyses included 42 adolescents (224 nights and 73 naps) and 45 older adults (197 nights), 52% of participants were female across both studies and mean age was 16.4±0.9 and 75.0±3.3 years respectively. Average temperatures at the start of the rise were 30.8±2.6 °C (adolescents, 30.0±1.9 for naps) and 33.6±1.2 °C (older adults) reaching 35.4±0.3 °C (35.2±0.9 °C for naps) and 35.6±0.8 °C at the end of the rise while N2 sleep onset temperatures were 35.2±0.6 °C (34.2±0.5 °C for naps) and 35.4±0.9 °C. The rates of change were 0.16±0.06 °C/min (0.29±0.08 for naps) and 0.10±0.06 °C/min, in adolescents and older adults. Weak associations were found between the timing of the rise in temperature and N2 sleep onset latency (adolescents nights: $\beta = 0.26$, $p < .001$; adolescents naps: $\beta = 0.29$, $p = 0.005$; adults: $\beta = 0.31$, $p < .001$). Stronger associations were found between the final DST of the rise and N2 sleep onset DST (adolescents nights: $\beta = 0.57$, $p < .001$; adolescents naps: $\beta = 0.71$, $p < .001$; adults: $\beta = 0.73$, $p < .001$). DST at the end of the rise is affected by bedtime. Interestingly, with later bedtimes, DST reached at end of the sleep onset ramp in DST was higher for adolescents ($\beta = 0.18$, $p = 0.005$) but lower for older women ($\beta = -0.25$, $p = 0.023$). This suggests an age x timing interaction of the temperature rise that needs to be further studied.

Conclusions: The Oura ring can detect a rise in DST around N2 sleep onset across populations. Even accounting for intra-individual variability of the starting DST, this rise consistently concludes proximate to (but not at) DST at N2 sleep onset, suggesting there is a DST threshold indicative of sleep initiation that is modulated by age differences in circadian timing.

The Association between Sleep Duration, Insomnia, Daytime Sleepiness, Health, Quality of Life, and Sociodemographic Factors in General Populations Across Africa, Asia, Europe, and the Caribbean: Findings from the Burden of Obstructive Lung Disease (BOLD) Study

B. Benediktsdóttir¹, J. Potts², E.H. Thorarinsdottir³, C. Jansson⁴, T. Gislason⁵, A.F.S. Amaral⁶

¹Faculty of Medicine, University of Iceland. Landspítalinn - The National University Hospital Iceland, Department of Sleep, Kópavogur, Iceland, ²National Heart and Lung Institute, Imperial College, London, United Kingdom, ³Primary Health Care of the Capital Area, Reykjavík, Iceland, ⁴Uppsala University, Department of Medical Sciences: Respiratory, Allergy and Sleep Research, Uppsala, Sweden, ⁵Faculty of Medicine, University of Iceland. Landspítalinn - The National University Hospital Iceland, Department of Sleep, Reykjavík, Iceland, ⁶National Heart and Lung Institute, Imperial College. NIHR Imperial Biomedical Research Centre, London, United Kingdom

Introduction: Sleep duration and quality are crucial determinants of health. Yet, few studies have examined their associations with cardiometabolic diseases and sociodemographic factors across diverse global settings using standardized tools. This study investigates how sleep duration, insomnia, and daytime sleepiness relate to health outcomes and social determinants across 18 sites in 15 countries.

Materials and methods: We analyzed data from 5,929 participants aged ≥50 years in the BOLD (<https://www.imperial.ac.uk/nhli/bold/>) follow-up study (2019–2021). Standardized questionnaires assessed sleep duration, insomnia (≥3 nights/week), daytime sleepiness (≥3 days/week), socioeconomic

status, and doctor-diagnosed cardiometabolic diseases. Associations were explored using mixed-effects logistic regression models adjusted for age, sex, BMI, smoking, and study site.

Results: Average sleep duration was 7.1 hours (SD: 1.4). Sleep duration was inversely associated with education and wealth, but unemployment was linked to longer sleep. Short sleep (<6 hours) was more prevalent in high-income countries (e.g., Norway, Iceland), while long sleep (>8 hours) was common in lower-income settings (e.g., Malawi, Jamaica). Higher-latitude countries in Northern Europe had shorter sleep durations and a higher proportion of short sleepers, and lower-latitude tropical regions had the longest sleep durations and fewer short sleepers. Western locations reporting longer sleep durations and fewer short sleepers and eastern longitudes with higher proportions of short sleepers.

Both short and long sleepers more often self-estimated their health as poor compared to normal sleepers. Short sleep alone did not show a statistically significant association with cardiometabolic diseases. Insomnia alone was significantly associated with an increased risk of hypertension (OR = 1.26), heart disease (OR = 1.33), and stroke (OR = 1.65). Among those with short sleep and insomnia the risk increased for heart disease (OR = 2.36) and diabetes (OR = 2.05). Daytime sleepiness is an independent predictor of cardiometabolic disease; hypertension (OR = 1.34), heart disease (OR = 1.48), diabetes (OR = 1.94) and stroke (OR = 1.49). Short sleepers with daytime sleepiness exhibited even greater risks, particularly for heart disease (OR = 1.95) and diabetes (OR = 3.30). Those with only long sleep had increased risk for stroke (OR = 1.92), but when long sleep was combined with daytime sleepiness, the stroke risk increased (OR = 2.38). Long sleepers with insomnia had increased risk for hypertension (OR = 2.75).

Conclusions: Our findings emphasize the role of poverty, education, and geography in shaping global sleep disparities. Sleep duration alone is an incomplete marker of health risk. Instead, sleep health should be evaluated multidimensionally—considering insomnia, daytime sleepiness and socioeconomic in context with sleep duration. Interventions targeting sleep quality and daytime functioning may be more effective in mitigating cardiometabolic risks than focusing on sleep duration alone.

The association between weekend catch-up sleep and the reduction of obesity and overweight risk in adolescents with insufficient weekday sleep

K.I. Yang¹, D.W. Kim², M.-R. Lee³, Y. Hwangbo³, J.H. Kim⁴, S.B. Hong⁵

¹Soonchunhyang University College of Medicine, Cheonan Hospital, Center for Sleep and Brain Health, Neurology, Cheonan, Korea, Republic of, ²Konkuk University Hospital, Neurology, Seoul, Korea, Republic of, ³Soonchunhyang University College of Medicine, Preventive Medicine, Cheonan, Korea, Republic of, ⁴Ewha Womans University Seoul Hospital, Ewha Womans University College of Medicine, Neurology, Seoul, Korea, Republic of, ⁵St. Peter's General Hospital, Epilepsy & Sleep Center, Neurology, Seoul, Korea, Republic of

Introduction: Some researches have emphasized the need to explore the relationship between sleep habits, particularly weekend catch-up sleep (CUS), and overweight/obesity outcomes in adolescents. However, the protective effect of compensatory sleep on weight remains controversial. This study investigates the association between weekend CUS and overweight/obesity in Korean adolescents, focusing on weekday sleep sufficiency.

Materials and methods: A nationwide cross-sectional study was conducted among 12,434 high school students in South Korea. Sleep patterns including total sleep duration and weekend CUS were assessed using self-reported questionnaires. Body mass index (BMI) was calculated and categorized into overweight/obese and normal weight groups based on age- and sex-adjusted Z-scores. Logistic and linear regression models were used to assess the associations between sleep variables and overweight/obesity.

Results: Students with 3 or more h of CUS had lower odds of being overweight/obesity (odds ratio = 0.67, 95% confidence interval: 0.57–0.80) compared to those with non-CUS. This protective effect remained significant in the subgroup with perceived insufficient weekday sleep. Furthermore, students with 3 or more h of CUS had significantly lower BMI z-scores ($\beta = -0.18, p < 0.001$), an association that was also observed in those with perceived insufficient sleep ($\beta = -0.16, p = 0.003$). The analysis showed a dose-dependent pattern, with greater weekend CUS being associated with a stepwise reduction in BMI z-scores.

Conclusions: Weekend CUS may serve as an important compensatory mechanism for adolescents to reduce the risk of being overweight or obese. However, no additional benefits of CUS were observed in adolescents with sufficient sleep quality.

The Association of Sleep Duration and Quality with Obesity-related Cancers: Results from the Health Examinees Study

S. Cho^{1,2}, S. Min¹, H. Lee^{1,3}, S.Y. Lee¹, A. Shin^{1,4}, Y.J. Lee⁵, D. Kang^{1,3}

¹Seoul National University College of Medicine, Preventive Medicine, Seoul, Korea, Republic of, ²Seoul National University Hospital, Family Medicine, Seoul, Korea, Republic of, ³Seoul National University Graduate School, Integrated Major in Innovative Medical Science, Seoul, Korea, Republic of, ⁴Seoul National University College of Medicine, Cancer Research Institute, Seoul, Korea, Republic of, ⁵Seoul National University College of Medicine, Department of Psychiatry and Center for Sleep and Chronobiology, Seoul, Korea, Republic of

Introduction: Sleep has emerged as a modifiable risk factor for metabolic dysfunction and cancer. However, prospective evidence linking sleep duration and quality to cancer risk remains inconclusive. This study aims to investigate the associations of self-reported sleep duration and quality with obesity-related cancer risk in a large-scale Korean population.

Materials and methods: This prospective cohort study utilized data from the Health Examinees-Gem (HEXA-G) cohort, comprising 67,910 adults aged ≥ 40 years who were recruited between 2004 and 2013. Sleep quality were self-reported at baseline and assessed based on multiple dimensions, including sleep duration (6–<8 hours), bedtime (20:00–24:00), difficulty initiating or maintaining sleep (not at all), sleep disturbance due to worries (not at all), nonrestorative sleep (not at all), daytime fatigue (not at all), habitual snoring (<3 times per week) and snoring with breathing interruptions (no) as reference. Each response was summarized into a composite sleep quality score (score range 0–14) and categorized into quartiles. This study adopted obesity-related cancers, defined by the International Agency for Research on Cancer. Cancer cases were identified through national cancer registration data from the Korea Central Cancer Registry of the Korea National Cancer Center. Cox proportional hazards models were applied to assess hazard ratios (HRs) and 95% confidence intervals (CIs) for the associations of sleep quality with risk of obesity-related cancer, with follow-up from baseline to first cancer diagnosis, death, loss to follow-up, or end of study.

Results: Among the individual components of the composite sleep quality score, significant associations of frequent daytime fatigue (HR: 1.53, 95% CI: 1.18–1.99, $p=0.003$), habitual snoring (HR: 1.24, 95% CI: 1.03–1.50, $P=0.025$), and snoring with breathing interruptions (HR: 1.40, 95% CI: 1.08–1.82, $p=0.011$) with obesity-related cancer risk were demonstrated in females. Sleep duration, bedtime, difficulties in initiating or maintaining sleep, sleep disturbances due to worries, and nonrestorative sleep were not significantly associated with obesity-related cancer risk. Furthermore, females in the highest quartile of the composite sleep quality score had increased risk of obesity-related cancer (HR: 1.17, 95% CI: 1.02–1.35); however, the effect size of this association was smaller compared to the associations observed for specific symptoms, including frequent daytime fatigue, habitual snoring, and snoring with breathing interruptions. In males, combined sleep quality without sleep duration was significantly associated with higher obesity-related cancer risk (HR: 1.47, 95% CI: 1.09–1.97, $p=0.010$), even in the absence of significant associations with individual sleep quality components.

Conclusions: In this large-scale prospective cohort study, higher composite sleep scores combining sleep duration with sleep quality were associated with elevated risk in females, and poor sleep quality without considering sleep duration was associated with elevated risk in males. These findings underscore the importance of multidimensional sleep quality assessment as a modifiable behavioral factor in the prevention of obesity-related cancer.

The association of sleep quality with post-surgery functional status and quality of life in patients with spinal degenerative diseases: A prospective study

P. Chen¹, Y. Mu², J. Yuan³, Y. Li⁴, H. Tan⁵, C. Park¹, B. Zhu², C. Shi⁶

¹University of Illinois Chicago, College of Nursing, Chicago, United States, ²Shanghai Jiao Tong University, School of Nursing, Shanghai, China, ³Songjiang Hospital Affiliated to School of Medicine,

Shanghai, China, ⁴The Hong Kong Polytechnic University, School of Nursing, Hongkong, Hong Kong, SAR of China, ⁵Shanghai Jiao Tong University School of Medicine, Clinical Research Institute, Shanghai, China, ⁶Changzheng Hospital, Department of Orthopedics, Shanghai, China

Introduction: Sleep plays an important role in individual well-being. Sleep quality of patients with spinal degenerative diseases (SDD) can be severely impaired. Few studies have explored whether sleep quality was associated with post-surgery recovery. This study aimed to examine the association between sleep quality with post-surgery functional status and quality of life among people with SDD.

Materials and methods: This prospective cohort study included 185 patients recruited between August 2022 and June 2023 from the spine center of a tertiary hospital in Shanghai, China. Sleep quality was assessed using the Pittsburgh Sleep Quality Index (PSQI). Functional status was measured by the Oswestry Disability Index or Neck Disability Index, while quality of life was assessed using the EuroQoL 5-Dimension 5-Level questionnaire. Potential confounders, e.g., depression and pain, were measured using validated instruments. Data was collected before the surgery and one-month post-surgery. Change in sleep quality before and after the surgery was calculated and used for the analyses. Minimal clinically important difference (MCID) for sleep quality was calculated as 0.5 times the standard deviation. Participants were classified into “Clinically improved”, “Clinically worsened”, or “No significant change.” Multivariate analysis of covariance (MANCOVA) was conducted to examine the association between sleep quality with the combined functional status and quality of life. Effect size was calculated using partial η^2 .

Results: Participants mean age was 46.8 years (SD=12.2), and 59.5% were males. The mean BMI was 24.4 kg/m² (SD=3.5). Lumbar surgery was performed in 67.0% of cases (N=124), while 33.0% underwent neck surgery (N=61). Based on MANCOVA, in addition to age, surgery site, changes in depression ($p=0.001$, partial $\eta^2=0.07$) and pain ($p=0.003$, partial $\eta^2=0.06$), change in sleep quality ($p=0.006$, partial $\eta^2=0.06$) was a significant predictor of the outcomes. The effect size was moderate. Additionally, the MCID for PSQI was 2.03. When sleep quality change was classified into “Clinically improved” ($\Delta\text{PSQI} \leq -2.03$, N=45, 24.3%), “Clinically worsened” ($\Delta\text{PSQI} \geq 2.03$, N=43, 23.2%), and “No significant change” ($-2.03 < \Delta\text{PSQI} < 2.03$, N=97, 52.4%), the association remained statistically significant ($p=0.004$, partial $\eta^2=0.040$).

Conclusions: In addition to traditional factors (e.g., age, surgery site, pain, depression), sleep quality was a significant predictor of post-surgery functional status and quality of life among patients with SDD. Change in sleep quality from pre- to post-surgery was not only statistically significant, but also clinically meaningful. Incorporating sleep assessment and management into peri-operative care may facilitate post-surgery recovery.

The Cost of Compromised Sleep: Links Between Sleep Health Dimensions and Daytime Sleepiness and Fatigue in healthy adults

M. L. Santos¹, C. M Marques-Dias², C. Reis^{1,2,3}

¹Faculty of Medicine, University of Lisbon, Lisbon, Portugal, ²GIMM - Gulbenkian Institute of Molecular Medicine, Lisbon, Portugal, ³CRCW - Faculty of Human Sciences, Catholic University, Lisbon, Portugal

Introduction: Sleep health dimensions include sleep duration, efficiency, timing, quality and regularity and have been studied both, individually and collectively, for their associations with various health outcomes. These dimensions can be reflected in metrics that can be assessed through self-report, behavioural measures like actigraphy, and physiological data. These metrics are easily interpretable and hold strong validity, making them useful to study both clinical and general population. Sleepiness, mental and physical fatigue, however distinct, are interrelated dimensions that can impact daytime activities. These symptoms are associated with different health outcomes and can occur not only in individuals with sleep disorders, but also in healthy individuals when sleep health dimensions are disrupted. This study aims to determine which actigraphy and questionnaire-based metrics best capture these daytime functioning aspects, in particular sleepiness assessed by the Epworth Sleepiness Scale (ESS), mental and physical fatigue assessed by the Multidimensional Fatigue Inventory (MFI).

Materials and methods: We analysed data from 143 healthy working-age adults (median age: 34 years; IQR: [23–49]; 53.15% female) who wore an actigraphy device (ActTrust or ActLumus, Condor Instrument™) for an average of 27 consecutive days (above 3700 days of actigraphy). Objective metrics included: transition probability from rest to activity during the main sleep bout (kRA), lowest five hours of activity (L5), highest ten hours of activity (M10), intradaily variability (IV), and interdaily stability (IS), derived using pyActigraphy Python package. MSFsc (“sleep chronotype”) was derived from the Munich Chronotype Questionnaire, while perceived sleep quality and duration were extracted from the Pittsburgh Sleep Quality Index (PSQI). General linear models adjusted for age and sex were used to evaluate associations between sleep metrics, fatigue and daytime symptoms were conducted using GraphPad Prism v.10.3.0 with significance set at $p < 0.05$.

Results: In the Poisson regression model predicting sleepiness ($R^2=0.31$), higher kRA ($\beta=1.98$, $p=0.011$), higher L5 ($\beta=0.001$, $p=0.011$), and lower IS ($\beta=-0.424$, $p=0.037$) were significantly associated with greater ESS scores. PF also showed a significant positive association ($\beta=0.037$, $p<0.001$). In the MF model ($R^2=0.24$), significant predictors included lower kRA ($\beta=-1.66$, $p=0.025$), younger age ($\beta=-0.006$, $p=0.016$), higher PF ($\beta=0.024$, $p=0.015$), and poorer perceived sleep quality ($\beta=0.132$, $p=0.031$). Regarding the PF model ($R^2=0.32$), higher ESS scores ($\beta=0.028$, $p=0.002$), higher mental fatigue ($\beta=0.021$, $p=0.024$) and lower IV ($\beta=-1.03$, $p=0.009$), were significant predictors. Male sex ($\beta=-0.140$, $p=0.031$) was also associated with greater PF. Additionally, lower perceived sleep quality was associated with greater PF ($\beta=0.134$, $p=0.018$).

Conclusions: Our findings reveal a divergence in how different aspects of sleep health relate to daytime symptoms in healthy adults. Sleepiness was more strongly associated with objective indicators of irregular and fragmented activity rhythms, not subjective sleep complaints, mirroring patterns observed in sleep apnea patients. In contrast, mental and physical fatigue were more closely linked to perceived poor sleep quality and general tiredness. These findings highlight the importance of distinguishing between sleepiness and fatigue when evaluating sleep health, as they may reflect different underlying mechanisms and intervention targets.

The Cross-cultural Application of the Peds B-SATED Model for Assessing Pediatric Sleep Health

B. Shen¹, P. Fan², X. Wang², C. Tu², X. Zhang², S. Qin²

¹Shanghai Children's Medical Center, Department of Nursing, Shanghai, China, ²Shanghai Jiao Tong University, School of Nursing, Shanghai, China

Introduction: Pediatric sleep health has a profound impact on children's physical growth, cognitive development, emotional regulation, and overall well-being. This study is grounded in the Peds B-SATED model developed by Meltzer et al. It systematically outlines six core dimensions of pediatric sleep health, including sleep satisfaction, alertness, timing, efficiency, duration, and related behaviors. Drawing on the socio-ecological systems theory, the paper further explores the multi-level interactive influences of family, school, culture, and the physical environment on children's sleep.

Materials and methods: Existing sleep assessment models have predominantly been developed within Western cultural contexts, which may limit their applicability to the distinct sleep patterns and sociocultural environments of Chinese children. To bridge this gap, this study outlines several key research directions: the integration of subjective and objective assessment methods (e.g., sleep diaries, the CSHQ, and wearable devices) to construct a pediatric sleep health evaluation framework tailored to China's socio-ecological context; the exploration of artificial intelligence applications in real-time monitoring and personalized interventions; and the advancement of the clinical and public health utility of the Peds B-SATED model through cross-cultural validation and interdisciplinary collaboration. These initiatives aim to generate contextually relevant, evidence-based strategies to support the promotion of pediatric sleep health in China.

Results: This study systematically reviews over 20 commonly used subjective and objective sleep assessment tools across both domestic and international contexts, including sleep diaries, the Children's Sleep Habits Questionnaire (CSHQ), actigraphy, and polysomnography (PSG). Subjective instruments, such as ISAS, TSAS, and ASHS, are user-friendly and accessible but are susceptible to bias from proxy reporting. In contrast, objective measures like PSG and wearable technologies offer high accuracy but are limited in scalability due to their cost and technical complexity. The study further explores emerging applications of artificial intelligence (AI) in pediatric sleep assessment, highlighting real-time monitoring systems and deep learning algorithms based on multimodal data sources—such as

actigraphy, environmental sensors, and sleep diaries—as well as the potential of wearable devices for enabling personalized interventions. In addition, the research identifies key challenges in the cross-cultural adaptation of the Peds B-SATED model. For example, prevalent practices in China, such as routine daytime napping and delayed bedtimes associated with academic demands, necessitate culturally sensitive modifications to the model. Accordingly, the inclusion of 'nap quality' as a component of sleep satisfaction is proposed as a contextually relevant optimization strategy.

Conclusions: The Peds B-SATED model, characterized by its systematic structure and developmental sensitivity, is redefining clinical approaches to pediatric sleep health. To enhance its applicability in the Chinese context, future research should prioritize multicenter validation, the development of culturally responsive assessment instruments, and the integration of artificial intelligence (AI) technologies into clinical practice. Moreover, incorporating stratified intervention strategies—such as adjusting school start times and enhancing synchronization of family routines—holds promise for advancing the comprehensiveness and precision of pediatric sleep health assessment in real-world settings.

The effectiveness of acupressure on sleep quality in cancer patients: A systematic review and meta-analysis of randomized controlled trials

C. Yang¹, Y. Huang¹, W. Ling¹, D.S.T. Cheung¹, J.J. Lee¹

¹The University of Hong Kong, School of Nursing, Hong Kong, Hong Kong, SAR of China

Introduction: Poor sleep quality is prevalent among cancer patients and significantly impacts their physical and psychological well-being and quality of life. Studies increasingly support the effectiveness of acupressure for improving sleep quality. However, it remains unclear whether the effect of acupressure on sleep quality can be generalized across various cancer conditions. The population-level and intervention-level characteristics of acupressure that are associated with sleep quality are also unclear. Hence, this meta-analysis aims to examine the effectiveness of acupressure on sleep quality in cancer patients and to identify the population-level and intervention-level characteristics associated with the intervention outcome of sleep quality.

Materials and methods: PubMed, EMBASE, APA PsycInfo, Web of Science, CINAHL, Cochrane Library, China National Knowledge Infrastructure, and WanFang were searched for eligible randomized controlled trials (RCTs) from inception to April 2024. Two reviewers independently conducted the searches, screened the retrieved studies, and extracted data from the eligible studies. Methodological quality was assessed using the Cochrane Risk of Bias Tool for Randomized Trials 2.0. A random-effects model was used for the meta-analysis. Subgroup analyses were conducted to examine the effects of cancer type, cancer treatment type, acupressure type, stimulation materials, acupressure provider, and control condition using Review Manager Software 5.4. Meta-regression analyses including sample sizes, number of acupoints, number of acupressure sessions, duration of each acupressure session, and overall duration of acupressure intervention were performed using R version 4.3.2. Both the subgroup analyses and the meta-regression aimed to investigate potential heterogeneity and identify characteristics that may be associated with more favorable acupressure outcomes.

Results: A total of 22 RCTs involving 2,113 participants from 8 regions were included in this meta-analysis. Compared with sham acupressure, usual care, patient education, and no intervention control groups, acupressure exhibited a significant beneficial effect on sleep quality in cancer patients at post-intervention (Standardized Mean Difference [SMD] = -1.38, 95% CI [-1.81, -0.95], $p < 0.001$, $I^2 = 94\%$) and at 4-week follow-up (SMD = -0.33, 95% CI [-0.56, -0.10], $p = 0.004$, $I^2 = 13\%$). Acupressure also showed statistically significant improvements in sleep efficiency (SMD = 0.77, 95% CI [0.27, 1.26], $p = 0.002$, $I^2 = 78\%$) and total sleep time (SMD = 0.68, 95% CI [0.15, 1.22], $p = 0.010$, $I^2 = 81\%$) at post-intervention. None of the characteristics significantly affected the overall effect size on sleep quality.

Conclusions: Acupressure appears to be a promising intervention for enhancing sleep quality among cancer patients. Future studies should focus on elucidating the long-term effects of acupressure on sleep quality, identifying the specific characteristics of acupressure that yield better intervention outcomes, and determining which types of cancer patients can benefit from this intervention.

The Effect of Continuous Positive Airway Pressure (CPAP) on Lower Urinary Tract Symptoms (LUTS) in Obstructive Sleep Apnea (OSA) patients with depression

A.E. Le¹, S.M. Wong², C.Z.S. Tseng¹

¹Wong Tai Sin Hospital, Department of Tuberculosis and Chest Unit, Kowloon, Hong Kong, SAR of China, ²Private practice, Hong Kong, Hong Kong, SAR of China

Introduction: There is a bidirectional connection between depression and LUTS⁽¹⁾. Moreover, OSA can contribute to LUTS⁽²⁾.

This study aimed to assess the immediate effect of CPAP on LUTS in patients with depression and OSA in Hong Kong.

Materials and methods: Patients referred for sleep studies were recruited from 15/02/2025 to 30/05/2025. The Patient Health Questionnaire-9 (PHQ-9) is a valid tool to evaluate depression and depression was defined as PHQ-9 score ≥ 4 ⁽³⁾.

In addition, the International Prostate Symptom Score (IPSS) has been validated to evaluate LUTS in female and male patients our locality⁽⁴⁾, and IPSS was assessed before and after one night of CPAP.

Results: A total of 94 patients were recruited, and among them 49 patients were depressive as defined by PHQ-9 score ≥ 4 (52.1%). There was no difference in age, body mass index, neck circumference or apnea-hypopnea index ($p>0.05$). Patients with depression presented with a higher IPSS than the control group ($p<0.05$). Additionally, there was a better response in LUTS among patients with depression.

Conclusions: This pilot study showed that the use of CPAP after one night significantly improves LUTS in obstructive patients with depression and sleep apnea.

CPAP may play a role in LUTS patients with depression and sleep apnea. However, due to sample size, a larger study with longer follow is required to reach any solid conclusion.

Acknowledgments: All authors declare that they have no conflicts of interest.

The effect of sleep hygiene education combined with Schroth exercises on sleep quality among adolescents with idiopathic scoliosis: A randomized controlled trial

M. Aldughmi¹, S. T. Lebzu¹

¹University of Jordan, Physiotherapy, Amman, Jordan

Introduction: Adolescent Idiopathic Scoliosis (AIS) is the most prevalent type of scoliosis affecting adolescents 10 to 18 years of age. Around 43% of individuals with AIS report poor sleep quality that negatively affect their quality of life. Schroth exercises are widely used among people with AIS, they consist of sensorimotor, postural and breathing exercises aimed to adjust normal postural alignment, static/dynamic postural control, and spinal stability. Although sleep hygiene education (SHE) is the most common used sleep management technique, no previous study explored the combined effects of performing Schroth exercises with SHE on sleep quality among individuals with AIS. Therefore, the aim of this study was to explore the combined effect of SHE with Schroth exercises on sleep quality, quality of life, and Cobb angle among individuals with AIS using a randomized control study design.

Materials and methods: Using a single-blinded randomized controlled design, 30 participants were randomly assigned using block randomization into two groups: Group A (SHE and Schroth) ($n=15$, mean age= 14.00 ± 2.24), and group B (Schroth alone) ($n=15$, mean age= 14.27 ± 2.76). Participants in both groups performed Schroth exercises twice a week for 12 weeks supervised by a certified Schroth physical therapist. Group A received SHE and were contacted once a week to monitor compliance to the SHE program. All participants completed the following assessments at baseline and post intervention: Pittsburgh Sleep Quality Index (PSQI) to assess global sleep quality, Sleep Hygiene Index (SHI) to assess sleep related behaviors, Scoliosis Research Society-22 revised (SRS-22r) to assess quality of life, and radiographic Cobb angle measurement to assess degree of spinal curvature. Ethical approval was received from the Institutional Review Board of the Royal Medical Services (472024//1).

Results: There was a significant difference in PSQI scores between the two groups post intervention, in which group A had lower scores compared to group B ($t = -4.039$, $p = 0.001$), SHI was also significantly different between the two groups post intervention, in which group A had lower scores compared to group B ($t = -3.393$, $p = 0.003$). Although both groups had lower Cobb angle degrees and higher scores in the SRS-22r post intervention, the change was not significantly different between the two groups.

Conclusions: This study demonstrates that a 12 week SHE program combined with Schroth exercises can significantly improve sleep quality and sleep hygiene among individuals with AIS. Findings from this study emphasizes the need to address poor sleep quality among individuals with AIS, in which the use

of SHE combined with Schroth exercises provides a non-pharmacological management approach to these issues among this population. Large scale future studies are needed to confirm these findings.

Acknowledgments: We would like to thank study participants, RMS spine clinic physicians, and physical therapist Dima Abu suod for their help in this study.

The effects of physical activity timing and adherence to physical activity guidelines on sleep in children with Attention-deficit/hyperactivity disorder

X. Liang^{1,2}, M. Zhao³, R.H. Xu², A.C.-Y. Tse¹, J.A. Haegele⁴, S.X. Li⁵

¹The Education University of Hong Kong, Department of Health and Physical Education, Hong Kong, Hong Kong, SAR of China, ²The Hong Kong Polytechnic University, Department of Rehabilitation Sciences, Hong Kong, Hong Kong, SAR of China, ³Lanzhou University, School of Public Health, Lanzhou, China, ⁴Old Dominion University, Department of Human Movement Sciences, Norfolk, United States, ⁵University of Hong Kong, Department of Psychology, Hong Kong, Hong Kong, SAR of China

Introduction: Regular physical activity (PA) has been shown to benefit sleep. However, the effects of PA timing and adherence to the WHO's recommended 60-minute moderate-to-vigorous physical activity (MVPA) guideline on sleep remain unclear, especially for children with Attention-deficit/hyperactivity disorder (ADHD) who often experience sleep problems. This study examined whether the timing of MVPA influenced objectively measured sleep, including sleep latency (SL), sleep efficiency (SE), total sleep time (TST), and wake after sleep onset (WASO), among children with ADHD.

Materials and methods: This cross-sectional study involved 253 children clinically diagnosed with ADHD (Mage=8.60 ± 1.31 years, 81% boys). MVPA timing was categorized as more than 8 hours before bedtime, 3–8 hours before bedtime, and less than 3 hours before bedtime. Meeting the MVPA guideline was defined as engaging in at least 60 minutes of MVPA daily. PA and sleep were recorded using an ActiGraph GT9X accelerometer for 7 consecutive days. A multivariate analysis of covariance (MANCOVA) controlling for age, sex, IQ, BMI, comorbidity, medication, and ADHD subtypes was carried out to compare the group differences in physical activity levels, timing of MVPA, and sleep parameters. Hierarchical regression models were used to examine the association of sleep parameters (i.e., SL, SE, TST, and WASO) with the timing of MVPA.

Results: Among the participants, 174 children (68.8%) met the WHO daily guideline of 60 minutes of MVPA, and, across all monitoring days, 77.94% of days met the MVPA guideline. These children had better sleep outcomes than those who did not meet the guideline, with shorter sleep latency ($F=50.98$, $\eta^2=.173$), higher sleep efficiency ($F=24.04$, $\eta^2=.090$), and less WASO ($F=17.54$, $\eta^2=.067$). Regarding PA timing, meeting the MVPA guideline and MVPA time more than 8 hours before bedtime were associated with reduced SL ($\beta=-.265$, $p=.001$), improved SE ($\beta=.268$, $p=.002$) and reduced WASO ($\beta=-.263$, $p=.002$). Conversely, MVPA time less than 3 hours before bedtime was associated with decreased SE ($\beta=-.211$, $p=.002$) and increased WASO ($\beta=.231$, $p<.001$).

Conclusions: The current study provides evidence that children with ADHD who have achieved the MVPA guideline have better sleep quality than those who have not. Attainment of the MVPA guideline and MVPA at 8 h before bedtime are associated with improved sleep. MVPA close to bedtime is related to decreased sleep efficiency and increased WASO. Future research should consider implementing PA intervention to determine the best timing of exercise for improving sleep in this clinical group.

Acknowledgments: We would like to acknowledge Dr. Ma, Dr. Wang, and Miss Feng Yan for their contributions to data collection, as well as all participants and their parents who participated in this study. This work was supported by the Research Institute for Sports Science and Technology, The Hong Kong Polytechnic University [P0050100].

The Effects of Sleep Extension on Emotion Regulation Among Chronically Sleep-Restricted Young Adults: The Moderating Role of Intervention Adherence

Y. Zheng¹, E.Y.Y. Lau^{1,2,3}, W. Wang^{1,2}, H.Y.D. Ma^{1,2}, C.h. Chan¹

¹The Education University of Hong Kong, Psychology, Hong Kong, Hong Kong, SAR of China, ²The Education University of Hong Kong, Analytics\Assessment Research Centre, Hong Kong, Hong Kong, SAR of China, ³The Education University of Hong Kong, Centre for Psychosocial Health, Hong Kong, Hong Kong, SAR of China

Introduction: Chronic sleep restriction in emerging adults is associated with altered emotion regulation (ER) including reactivity and regulatory capacity (Tomaso et al., 2021). One-week sleep extension (SE) interventions could improve affective states (e.g., increased positive emotions), but fail to alter conscious ER strategies (Parsons & Young, 2022). However, neuroimaging evidence suggests extended interventions may induce neuroplasticity: a 9-day SE protocol reduced amygdala activity and enhanced prefrontal-amygdala connectivity during rest, implicating implicit ER mechanisms (Motomura et al., 2017). Thus, the impact of over-one-week SE intervention on ER is worth further investigation, particularly for young adults, whose cognitive development is still ongoing (Benitez & Gunstad, 2012). Besides, a study found that higher adherence to a 5-week SE protocol correlates with greater sleep gains and emotional benefits (Dyk et al., 2017). This suggests that level of adherence may have a moderating effect on the impact of SE on emotions. However, there is still a gap in how adherence moderates the SE-ER relationship.

Therefore, this study aims to examine (a) how a two-week at-home SE protocol affects the ER capability of chronically sleep-restricted young adults, and (b) the extent to which adherence moderates the SE-ER relationship. It is hypothesised that: (1) the SE intervention will improve ER, and (2) greater adherence will amplify the efficacy of SE on ER.

Materials and methods: 110 participants (aged 18–29) with habitual sleep ≤ 7 hours/night) will be randomized into the SE group (n=55) and the sleep hygiene (SH) control group (n=55), after a 1-week baseline and 1-week SH education. By participating in an intervention interview, the SE group will receive a 2-week SE intervention (target: +60 mins/night). While the SH group will receive SH education only.

ER will be assessed through the Ecological Momentary Assessment (EMA): At least 3×/day prompts via PRO-Diary. The assessments involve:

1. Affective states: affective states on The Positive and Negative Affect Schedule, PANAS;
2. ER strategy use: 6 strategies (distraction, reappraisal, suppression, acceptance, avoidance, rumination) rated on 5-point Likert scales.

Adherence will be comprehensively measured based on the EMA/sleep diary completion rates, and the proportion of extended sleep, which is operationalized as $[(\text{intervention sleep duration} - \text{baseline duration})/60] \times 100\%$. Multilevel models will test whether adherence moderates the SE-ER relationship by examining the significance and directionality of the Group $\times$ Adherence interaction term.

Results: It is anticipated that the SE group will show greater improvement in adaptive strategy use (reappraisal and distraction). For the moderating role of adherence, high-adherence SE participants will exhibit more sustained emotional stability and larger ER gains than low-adherence peers.

Conclusions: This study could demonstrate the SE-ER relationship among sleep-restricted young adults. The benefits of intervention may be facilitated by personalized adherence support. The findings could inform future sleep education programs to target/find ways to increase protocol and goal adherence to facilitate behaviour change.

Acknowledgments: This research is supported by the Research Grants Council of the Hong Kong Special Administrative Region, China (EdUHK#18609423).

The experience of poor sleep of living with HIV in Indonesia: Toward an Intervention Development

H. Pujasari¹, P. Siahaan²

¹Universitas Indonesia, Basic Science and Fundamentals of Nursing, Depok, Indonesia, ²Universitas Indonesia, Bachelor of Nursing Program, Depok, Indonesia

Introduction: Poor sleep quality is a health problem primarily experienced by people living with HIV (PLHIV). The impact of poor sleep quality not only affects the HIV disease itself but also extends to many areas of life.

Objective: This study aimed to explore the experience of poor sleep quality in people living with HIV/AIDS (PLWHA) in Indonesia.

Materials and methods: The research method used was qualitative using semi-structured in-depth interviews with 12 PLHIV from a national peer support group. Approximately 60 minutes of interviews

were run through Zoom and recorded. The data was analyzed descriptively and interpretatively for 3 clusters of PLHIV that differ in the severity of sleep problems. These three clusters have been determined using an initial analysis based on Insomnia Severity Index (ISI) scores. Further data analysis was based on a hermeneutic form of PLHIV narratives

Results: three themes were developed: 1) I have a lot of things in my mind that prevent me from sleeping; 2) I would rather switch to TLD (Tenofovir Lamivudine Dolutegravir) so that I can have my sleep back; 3) When I can't sleep, I end up scrolling through my phone.

Conclusions: HIV-positive status and any HIV medication taken may affect PLHIV's sleeping pattern. However, there are many potentials to improve the sleep health of Indonesian PLHIV.

Acknowledgments: We would like to express our sincere gratitude to all the participants who shared their time and experiences with us, and to Hibah PUTI Q1 2023 Universitas Indonesia for providing the financial support that made this research possible.

The function and mechanism study of lncRNA LOC105**5 and its gene polymorphism on sleep fragmentation in OSA patients**

J. Shen¹, H. Yuan¹, W. Huang¹, K. Lai¹, Z. Gao¹, N. Li², S. Wang¹, J. Guan¹, F. Liu¹, S. Yin¹

¹Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai Key Laboratory of Sleep Disordered Breathing, Department of Otolaryngology-Head and Neck Surgery, Otolaryngology Institute, Shanghai, China, ²Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China

Introduction: Obstructive sleep apnea (OSA) is characterized by sleep fragmentation and disrupted sleep-wake architecture, though its underlying mechanisms remain poorly understood. Our previous large-scale genome-wide association study (GWAS) initially identified a significant association between the single nucleotide polymorphism (SNP) rs75****65 (G>A) and increased wake bouts in OSA patients. This SNP is located within the intron of gene lncRNA LOC105****5 whose function is unknown. How lncRNA LOC105****5 regulates sleep-wake and how rs75****65 affects the sleep-wake cycle in OSA patients via lncRNA LOC105****5 are not known.

Materials and methods: Materials: The GWAS analysis included 5208 patients with OSA diagnosed by standardized polysomnography (PSG) and 753 controls (AHI<5 beats/hour) selected from the Shanghai Sleep Health Study (SSHS) cohort, which provided genotypic and PSG-confirmed OSA phenotypes. Methods: QPCR, FISH, Western blot, RNA affinity chromatography, RIP, RNA Scope and other molecular technologies; AAV infection technology and CRISPR/Cas9 gene-editing technology; protein mass spectrometry, RNA sequencing and other multi-omics technologies; mouse brain stereotactic injection, EEG/EMG polysomnography monitoring technology, open field test (OFT), object recognition test (ORT) and patch clamp technique.

Results: lncRNA LOC105****5 exhibited high expression level in human central nervous system and base substitution of rs75****65, which was significantly associated with sleep fragmentation in our GWAS on OSA, markedly reduced its expression in cells. In mice, lncRNA LOC105****5 overexpression in nucleus accumbens (NAc) significantly reduced sleep-wake transitions and prolonged bout duration of each cycle. Further, integrated multi-omics approaches revealed a conserved GPCR as the downstream target of lncRNA LOC105****5. Neuronal conditional knockout of this GPCR recapitulated the LOC105****5 overexpression phenotype by reducing sleep-wake fragmentation. Moreover, mechanistic studies revealed that lncRNA-GPCR axis functions by affecting the neuronal excitability of NAc neurons.

Conclusions: Our study demonstrates that lncRNA LOC105****5 reduces sleep fragmentation in mice by affecting the excitability of NAc neurons, mediated through downregulation of a target GPCR. Additionally, the SNP rs75****65 may contribute to impaired sleep quality in OSA patients by suppressing the lncRNA LOC105****5 expression. These findings advance the physiological understanding of sleep regulation and highlight potential therapeutic targets for treating sleep fragmentation in OSA.

The impact of ambient temperature on sleep duration: findings from GRAPHS cohort

H. Romero Castillo¹, S. Kaali², R. Shah³, M. Mujtaba², I. Ayappa³, K. Ae-Ngibise², D. Jack⁴, T. Yussif², A. Lee³, A. Appiah², P. Donneyong², V. Kundel³, K. Poku Asante²

¹Icahn School of Medicine at Mount Sinai, Otolaryngology - Head and Neck Surgery, New York, United States, ²Kintampo Health Research Center, Kintampo, Ghana, ³Icahn School of Medicine at Mount Sinai, Pulmonary, Critical Care & Sleep Medicine, New York, United States, ⁴Columbia University, Mailman School of Public Health, New York, United States

Introduction: Higher environmental temperatures have been associated with poorer sleep outcomes. However, the impact of temperature on objective sleep metrics has been difficult to isolate due to the widespread use of temperature-modifying technologies such as heating and cooling systems. This study investigates the association between personal ambient temperature and actigraphic sleep duration in a pre-existing Ghana Randomized Air Pollution and Health Study (GRAPHS) cohort of post-partum women in the Kintampo North Municipality and Kintampo South District of Ghana, where such technologies are limited. Kintampo lies at a latitude of 8.1 degrees north of the equator and has a tropical climate with relatively stable temperatures year-round and distinct wet and dry seasons, rather than large seasonal variations in temperature or light duration. We hypothesize that higher personal ambient temperature is associated with decreased actigraphic sleep duration.

Materials and methods: The GRAPHS study enrolled pregnant women from 2013 to 2016. At 4- and 8-years post-partum, participants wore RTI MicroPEM V3.2 monitors over a 48-hour period, capturing personal ambient temperature, relative humidity, and fine particulate matter (PM_{2.5}) concentrations. Simultaneously, participants wore MicroMotionlogger actigraphy devices which recorded multi-night measures of sleep including total sleep time (TST), time in bed (TIB), wake after sleep onset (WASO), sleep efficiency, and number of nighttime awakenings. Sleep intervals were visually identified and scored using the Cole-Kripke algorithm. Linear regression models adjusting for age, BMI, and household size were used to assess associations between personal ambient temperature and sleep outcomes.

Results: A total of 115 participants, with a mean age of 34.5 ± 7.2 years and BMI of 24.0 ± 4.1 kg/m², contributed an average of 3.1 ± 2.0 nights of actigraphy data. The mean personal ambient temperature was 35.6 ± 2.0 °C and ranged between 28.6 – 42.9 °C. Average TST was 6.1 ± 1.2 hours, TIB was 7.6 ± 1.3 hours, WASO was 74.7 ± 36.9 minutes, sleep efficiency was $80.4 \pm 7.9\%$, and participants experienced an average of 19.1 ± 6.9 nighttime awakenings. Adjusted linear regression models showed that each 1 °C increase in ambient temperature was associated with reductions of TST by 12.2 ± 3.3 minutes ($p=0.007$) and TIB by 11.6 ± 3.5 minutes ($p=0.005$). No significant associations were identified between average ambient temperature and sleep efficiency, WASO, or number of nighttime awakenings.

Conclusions: In a tropical, rural Ghanaian setting with limited access to temperature-modifying technologies, higher personal ambient temperatures were significantly associated with reductions in objective total sleep time, time in bed, and sleep onset latency. These findings confirm our hypothesis and underscore that even modest heat elevations can materially erode sleep time. This effect may reflect the disruption of thermoregulatory processes essential to initiating and maintaining sleep. Given that shorter sleep duration has been linked to increased cardiovascular and metabolic health risks, our findings highlight the importance of addressing global warming as a public health priority. As global temperatures rise, interventions to improve thermal environments may be critical to safeguard sleep health and mitigate associated health disparities.

The impact of comorbid insomnia and sleep apnea (COMISA) on work ability: Results from population-based panel data in Korea

H. Ko¹, S.-S. Cho², D.-W. Lee³, J. Choi⁴, M.-S. Kim⁵, M.-Y. Kang¹

¹College of Medicine, The Catholic University of Korea, Department of Occupational and Environmental Medicine, Seoul, Korea, Republic of, ²College of Medicine, Dong-A University, Department of Occupational and Environmental Medicine, Busan, Korea, Republic of, ³Inha University Hospital, Department of Occupational and Environmental Medicine, Incheon, Korea, Republic of, ⁴Sungkyunkwan University, Department of Global Economics, Seoul, Korea, Republic of, ⁵H plus Yangji Hospital, Department of Occupational and Environmental Medicine, Seoul, Korea, Republic of

Introduction: Comorbid insomnia and sleep apnea (COMISA), represents a unique clinical phenotype associated with greater functional impairment than either condition alone. Despite growing interest,

the impact of COMISA on occupational functioning, particularly work ability (WA), remains understudied. This study aimed to evaluate the effects of COMISA on WA in the Korean working population using longitudinal panel data.

Materials and methods: Data were obtained from the Korean Work, Sleep, and Health Study, a population-based panel survey conducted between July 2022 and September 2024, including 10,086 wage-earning participants aged 19–70 years. COMISA was defined as the concurrent presence of high-risk sleep apnea (identified via the Berlin Questionnaire) and nocturnal insomnia symptoms (assessed using the Insomnia Severity Index). WA was assessed using the validated Korean version of the Work Ability Index (WAI). WA scores below 28 points were classified as “poor.” Generalized estimating equation models were used to assess associations between sleep disorder groups and WA, adjusting for age, gender, and occupation. Subgroup analyses were conducted by sex, age, occupational group, and shift work status.

Results: Participants with COMISA had markedly lower WA than those without sleep disorders. In fully adjusted models, the odds ratio (OR) for poor WA in the COMISA group was 5.742 (95% confidence interval [CI]: 4.715–6.993) compared to the normal group. The mean WAI score in the COMISA group was 4.377 points lower (95% CI: –4.593 to –4.161) than in the normal group. Individuals with insomnia and low-risk sleep apnea showed increased odds of poor WA (OR = 4.461; 95% CI: 3.598–5.531), although the association was weaker than that observed for COMISA. In contrast, isolated high-risk sleep apnea without insomnia demonstrated a limited association with reduced WA (OR = 1.145; 95% CI: 0.784–1.673). Significant associations between COMISA and poor WA were observed across all subgroups defined by sex, age, occupation, and shift work status, with stronger associations among men, white-collar workers, daytime workers, and individuals under 60 years of age.

Conclusions: COMISA is strongly associated with decreased WA among Korean workers, with certain populations demonstrating heightened vulnerability. These findings underscore the need for targeted workplace strategies and clinical interventions, such as routine screening, flexible work schedules for treatment and integrated treatment approaches that address both insomnia and sleep apnea.

Addressing COMISA may help mitigate productivity loss and promote workforce sustainability.

Acknowledgments: This work was supported by the National Research Foundation of Korea (NRF-2022R1F1A1066498).

The Impact of Problematic Smartphone Use on Sleep Duration and Quality

T. Wang¹

¹Charité – Universitätsmedizin Berlin, Berlin, Germany

Introduction: This systematic review and meta-analysis seek to comprehensively elucidate the impact of problematic smartphone use (PSU) on both sleep duration and sleep quality. This study aims to address existing research gaps, as prior studies have predominantly focused on either duration or quality in isolation.

Materials and methods: In accordance with PRISMA 2020 guidelines, a comprehensive search of 10 electronic databases, including PubMed and Embase, was conducted from their inception through August 20, 2024. Studies providing quantitative data on the effects of PSU on sleep duration and sleep quality were subjected to meta-analysis using Review Manager 5.4, while studies without specific effect sizes underwent descriptive analysis.

Results: A total of 28 studies published between 2015 and 2024 were included, involving 46,603 participants aged 13 to 41 years from countries such as Australia, Germany, China, Brazil, and Malaysia. The r/ρ subgroups were chosen to present the findings. The meta-analysis showed that PSU was slightly but significantly negatively associated with long sleep duration (SMD = -0.13, $p < 0.00001$, $I^2 = 23\%$), while no significant association was found with short sleep duration ($p > 0.05$). In contrast, PSU was moderately positively associated with poor sleep quality (SMD = 0.22, $p < 0.00001$, $I^2 = 42\%$) and significantly negatively associated with good sleep quality (SMD = -0.19, $p < 0.00001$, $I^2 = 50\%$).

Conclusions: This review underscores the adverse effects of problematic smartphone use, particularly its negative impact on sleep quality. While the effect on sleep duration appears small or non-significant, PSU can exacerbate other health issues such as depression, anxiety, cognitive impairment, and poor academic performance. These findings highlight the need for strategies aimed at mitigating PSU to promote healthier sleep patterns and overall well-being.

The impact of shift work and clinical paramedic scenarios on paramedics' sleepiness, fatigue and perceived workload: A novel simulation-based study

L. Hirello¹, A. Wolkow¹

¹Monash University, School of Psychological Sciences, Notting Hill, Australia

Introduction: Most paramedics work on a rotating shift schedule involving a combination of day and night shifts. Despite the known impact of shift work on sleep loss, and resultant performance and physiological impairments, few studies have examined the impact of rotating shift work on paramedics. The current study uses a simulated work rotation to explore the impact of rotating shift work and clinical work on paramedics' sleepiness, fatigue and perceived workload.

Materials and methods: In pairs, Australian paramedics complete a two 12-hour day shift, two 12-hour night shift simulated work rotation. Participants have an 8-hour sleep opportunity prior to the first day shift and between each subsequent shift. All sleep opportunities during the rotation occur in the Monash Sleep and Circadian Medicine Laboratory and are monitored with polysomnography. Simulated paramedic shifts take place in the Monash Paramedic Simulation Centre, where participants engage in four high-fidelity immersive paramedic clinical scenarios throughout each shift. Before and after each paramedic scenario, participants complete subjective assessments that monitor sleepiness (Karolinska Sleepiness Scale, KSS) and fatigue (Samn-Perelli fatigue Scale, SPS). After each scenario they also complete a multidimensional measure of perceived workload (NASA Task Load Index, NASA-TLX). Between scenarios, participants complete two cognitive and decision-making batteries per shift. Data was analysed via linear mixed models to compare within and between shift changes for participants.

Results: A total of 16 participants (69% female, mean age = 33.7 ± 8.0 years) have completed the simulated shift work rotation. Mean KSS scores increased between the first day shift (3.75) and the first (4.2, $p < 0.1$) and second night shifts (4.75, $p < 0.05$). Mean KSS scores also increased as the shifts progressed, increasing from 3.36 for the first clinical scenario of the shift to 4.32 ($p < 0.001$) for the third scenario and 4.94 ($p < 0.001$) for the last scenario. SPS values followed a similar trend to the KSS, with mean SPS values increasing from the first day shift to the last night shift (3.04 to 3.75, $p < 0.001$) and from the first scenario of the shift (2.66) to the third (3.34, $p < 0.001$) and fourth scenarios (3.95, $p < 0.001$). When NASA-TLX scores were deconstructed by subdimension, participants reported an increase in perceived physical demands between shifts, from 6.31 on the first day shift to 8.36 ($p < 0.01$), 8.34 ($p < 0.01$) and 8.29 ($p < 0.05$) on day shift two, night one and night two, respectively. Despite the increase in sleepiness, fatigue and physical demand, participants reported no change between or within shifts in any other subdimension or mean overall workload on the NASA-TLX.

Conclusions: This study is the first of its kind to examine the impact of a multi-day simulated shift work rotation on paramedics. Preliminary findings demonstrate that while participants experienced increased sleepiness, fatigue and physical demands throughout the rotation, their perception of overall workload did not significantly change. These findings provide valuable insight into the compensatory mechanisms present in populations regularly engaging in shift work and performing clinical work.

The Impact of Sleep Deprivation on Mental and Physical Functioning Among Medical Students: A Mixed-Methods Study

X. Nij¹, Q. Su¹, X. Wu¹, J. Ren¹, G. Chen¹, Y. Cai¹

¹Guangdong Provincial Hospital of Chinese Medicine, Guangdong Provincial Academy of Chinese Medical Sciences, The Second Clinical School of Guangzhou University of Chinese Medicine, Guangzhou, China

Introduction: Current research indicates that sleep deprivation induces significant neurocognitive impairments in healthy adults, including impaired synaptic plasticity, reduced brain volume, disrupted memory consolidation, and decreased alertness. Medical students typically experience shorter sleep duration and irregular sleep pattern, due to high-intensity academic tasks and clinical workload. This study aimed to assess the impact of sleep deprivation on mental and physical functioning as well as the daily life, among the medical students.

Materials and methods: This sequential explanatory mixed-methods study received ethical approval from the Ethics Committee of GPHCM (No. YE2022-266). All participants provided written informed consent prior to the enrolment. Phase 1 was a quantitative survey of medical students aged 18-26

years, interning in Guangzhou with self-reported average sleep duration ≤ 7 hours/night over the past week. Participants completed the Profile of Mood States (POMS), Epworth Sleepiness Scale (ESS), and Psychomotor Vigilance Task (PVT) to assess their emotional states, daytime sleepiness, and cognitive performance (reaction time, vigilance, and sustained attention). Based on the pilot study indicating cognitive impairment (defined as >10 PVT lapses) in 10% of participants, a sample size of 35 was expected. Phase 2 was a semi-structured qualitative interview, recruiting participants from the Phase 1, aiming at supplementing the quantitative findings. Data were analysed using statistics, thematic analysis, and triangulation validation between the quantitative and qualitative results.

Results: Quantitative analyses showed a significant negative correlation between sleep duration and PVT lapses ($p < 0.05$), indicating vigilance declined with reduced sleep duration. While sleep duration correlated negatively with PVT response speed, this relationship was not statistically significant ($p > 0.05$). Sex, body mass index, menstrual period, medical school and caffeinated beverages consumed did not significantly affected the PVT performance, POMS scores, or ESS scores ($p > 0.05$ for all).

Qualitative data revealed that all interviewees subjectively perceived sleep deprivation as negatively affecting their next-day work and study performance, including cognitive deficits, emotional instability, and uncomfortable physical symptoms. Common manifestations included reduced attention and psychomotor slowing (consistent with PVT results), alongside with impaired short-term memory, fatigue, and headaches, which was beyond the quantitative findings. Subgroup-analysis suggested that participants with mild sleep deprivation (6–6.5 hours/night) experienced appetite suppression and chest tightness, whereas severe deprivation (4–5 hours/night) had complaints about severe fatigue, excessive daytime sleepiness, memory impairment, and hyperarousal.

Conclusions: Even short-term sleep deprivation impairs brain functioning, causes discomfort and disrupts daily life in medical students. These findings underscore the urgent need to develop targeted healthcare interventions for medical students to mitigate these adverse effects, which may include sleep hygiene education, workload adjustments, and psychological support services.

Acknowledgments: This study was funded by Guangzhou University of Chinese Medicine, China (No. GZY2025GB0111), NATCM's Project of High-level Construction of Key TCM Disciplines (No. zyyzdxk-2023154) and College Students' Innovative/Entrepreneurial Training Plan Program (No.X202110572294).

The impact of urban transportation noise and bedroom temperatures on sleep quality during summertime

Z. Zambelli¹, V. Rossi², I. Hartescu³, M. Ravikumar³, K. Lomas², A. Beizaee², V. Haines¹, J. Barnes¹, K. Morgan³

¹Loughborough University, School of Design & Creative Arts, London, United Kingdom, ²Loughborough University, School of Architecture, Building and Civil Engineering, London, United Kingdom,

³Loughborough University, School of Sport, Exercise and Health Sciences, London, United Kingdom

Introduction: Heatwaves pose increasing risks to sleep health (Chevance et al., 2024), particularly in un-airconditioned apartments where high nighttime temperatures impair rest and thermal comfort. Equally, transportation noise, especially from road traffic, has been linked to sleep fragmentation and reduced sleep quality (Smith et al., 2022), yet its role in moderating heat-related sleep disturbances is not clear. This study integrated Department for Environment, Food and Rural Affairs strategic noise-map data (DEFRA, 2022) with continuous bedroom temperature logs and daily sleep-quality ratings, to understand whether road and rail noise independently predict the change in sleep quality experienced during UK summertime.

Materials and methods: The UK Home Heat Health project monitored bedroom climate and sleep in 123 healthy adults (mean age 35 years, 82 female) residing in un-airconditioned London apartments during June–September 2023–2024 (Lomas et al., 2024). Participants wore CamnTech actigraphs and completed a Consensus Sleep Diary with 10-point ratings of sleep quality, thermal comfort and heat-related sleep disturbance each day. Bedroom temperature was logged every 30 minutes via temperature sensors.

External night-time noise (11 pm–7 am) for road and rail sources was extracted from DEFRA strategic noise maps (35 dB cutoff), categorised in 5 dB bands (reference < 35 dB). Noise levels are modelled on a 10-metre grid at a receptor height of 4m above ground. Each participant apartment was assigned a

road noise level and rail noise level matching the exact location to the noise maps.

Analysis:

A multiple linear regression modelled change in sleep quality scores (baseline – hot spell night) as a function of maximum bedroom temperature, road- and rail-noise, controlling for age and sex. A total of 119 participants with complete data and noise mapping were included in the analysis.

Results: A multiple regression was conducted to predict the change in sleep-quality score (baseline minus hot-spell night) from maximum bedroom temperature, road-noise bands, rail-noise bands, age group, and sex. The overall model approached significance, $F(14, 104) = 1.75$, $p = .057$, and accounted for 19.0 % of the variance in sleep-quality change ($R^2 = .190$; adjusted $R^2 = .081$).

Examination of individual predictors showed that higher maximum bedroom temperature was associated with greater change in sleep quality, ($p = .042$). Among noise predictors, only the 65–70 dB road noise band significantly predicted change in sleep quality versus < 35 dB, ($p = .005$). No other road- or rail-noise bands, age, or sex reached significance ($p > .05$).

Conclusions: Although the model was only marginally significant, results indicate at possible interactive effects of overnight heat and traffic noise on sleep quality. These preliminary findings, based on noise-map estimates rather than direct measurements, highlight the importance of further research to clarify how thermal and acoustic stressors jointly influence sleep health in the context of urban apartments. Future studies should integrate primary noise monitoring, ventilation behaviour logs, and indoor climate data to explore these dynamics in depth.

Acknowledgments: We thank all the participants who took part in the Home Heat Health field trials of 2023 and 2024.

The Influence of Sleep Position and Pillow Height on Sleep Quality in Patients

P.T. Huang¹

¹Kaohsiung Armed Forces General Hospital, Medical Education and Research office, Kaohsiung City, Taiwan

Introduction: Sleep quality is an essential determinant of overall health, with sleep position and pillow height serving crucial functions in ensuring adequate spinal alignment and comfort during sleep. Inadequate alignment resulting from improper pillow height or less than ideal sleep positions may lead to musculoskeletal discomfort, disturbances in sleep patterns, and the aggravation of conditions such as sleep apnea and gastroesophageal reflux disease. The objective of this research is to assess the interactive influences of sleep position and pillow height on the quality of sleep among patients, emphasizing aspects such as physiological alignment, comfort, and subjective sleep experiences.

Materials and methods: A cross-sectional analysis was conducted involving adult participants who were assessed under various pillow heights and sleep positions. Objective measures included cervical spine alignment, head-neck pressure distribution, and muscle activity, while subjective comfort and sleep quality were evaluated using validated questionnaires. Participants experienced different pillow types and heights in both supine and side-lying positions.

Results: The experiment involved participants lying in a supine position and supine position for a duration of 10 minutes under same pillow conditions. Data analysis was performed using one-way repeated measures analysis of variance (ANOVA), with a significance threshold established at $p < 0.05$. Optimal pillow height was found to maintain the natural curvature of the cervical spine, reduce muscle activity in the neck, and improve pressure distribution, thus enhancing comfort and reducing morning stiffness. Research indicates that side and back sleeping positions, when accompanied by suitable pillow support, enhance spinal alignment and alleviate symptoms associated with sleep apnea and discomfort, in contrast to stomach sleeping or the use of inappropriate pillow heights. Hybrid pillows that incorporate supportive cores and possess sufficient fluffiness have been found to provide the greatest levels of subjective comfort and promote optimal cervical alignment.

Conclusions: The position in which one sleeps, as well as the height of the pillow used, are critical factors influencing sleep quality among patients. It is advisable to select pillow height based on individual preferences for sleep position in order to enhance spinal alignment, reduce discomfort, and facilitate restorative sleep. These results highlight the significance of ergonomic factors in sleep settings as a means to improve patient outcomes.

Acknowledgments: Keywords: Sleep, pillow heights, Sleep quality, Sleep position. Thanks supported by Kaohsiung Armed Forces General Hospital and series sleep study project.

The life style, sleep time and sleep duration of the people in different social stratus during previous four decades in Taiwan

S. Chen¹, C.-Y. Chen²

¹National Taiwan University, Department of Medicine, Taipei, Taiwan, ²Taipei Hospital, Ministry of Health and Welfare, Chest Department, New Taipei, Taiwan

Introduction: Nearly half of adults report poor sleep quality, though most do not meet diagnostic criteria for insomnia. The concept of “poor sleep” has been introduced to describe insufficiently restorative sleep or reduced satisfaction in the absence of a clinical disorder ([Leger et al.](#)). Risk factors include unmodifiable characteristics such as age and sex, as well as modifiable contributors like lifestyle and sleep habits.

We hypothesize that demographic and lifestyle factors influence self-reported sleep quality. This study aims (1) to summarize sleep epidemiology with respect to quality, duration, and time, and (2) to examine associations between sleep quality and demographic and lifestyle factors, including age, sex, social stratum, sleep time and duration, and habitual inactivity.

Materials and methods: The Taiwan Social Change Survey (TSCS) can be accessed on the Survey Research Database organized by the Institute of Sociology and the Center for Survey Research of the Academia Sinica in Taiwan ([Taiwan Social Change Survey](#)). It provides cross-sectional and panel study data that reveals Taiwan's economic, social, and cultural changes from 1984 till today.

Eight features were included in the analysis: year of survey, gender, age, social stratum, habitual inactivity, sleep time, sleep duration and sleep quality. The surveys spanned 1984–2022 and involved participants aged 19–97 (mean 44.3) years. Social stratum was classified into six levels, from core cities to less-developed towns. Habitual inactivity was categorized into four levels: often, sometimes, rarely, and never. Sleep time was grouped into four categories: (1) 18:00–22:00 (earlier–early), (2) 22:00–24:00 (later–early), (3) 00:00–02:00 (earlier–late), and (4) 02:00–05:00 (later–late). Sleep quality was defined by frequency of sleep loss (never, rarely, sometimes, often). After data cleaning, 30,902 records remained for analysis. Chi-square tests and ordinal logistic regression were applied to identify risk factors.

Results: Overall, $9.2 \pm 3\%$ of participants reported often experiencing poor sleep quality. Social stratum was excluded after chi-square test ($p > 0.10$). Female gender emerged as the strongest predictor (odds ratio [OR] = 1.39, $p = 0.031$), followed by habitual inactivity (OR = 0.91, $p = 0.045$). Later sleep time (OR = 1.19, $p = 0.36$) and shorter sleep duration (OR = 0.90, $p = 0.60$) showed nonsignificant associations, with fluctuating p-values among different years. Epidemiology demonstrates that earlier sleep time exhibits longer sleep duration. Age was not a significant factor; although prevalence of poor sleep was higher in individuals aged ≥ 70 years (7.8%), prior literature suggests this is more attributable to inactivity, limited social engagement, and comorbid conditions rather than aging itself ([Ohayon et al.](#)).

Conclusions:

1. Females are more likely to experience poor sleep.
2. Habitual inactivity is associated with poor sleep.
3. Good sleep quality may still be achievable with late sleep time or short sleep duration, awaiting further validation.

Acknowledgments: The authors acknowledge the contribution of public data from TSCS of Academia Sinica Taiwan.

The lived experience of sleep disorders: patient perspectives and priorities

J. Haycock¹, S. Taylor¹, N. Lovato¹, R. Adams^{1,2}, M. Junge³, A. Vakulin¹

¹Flinders University, Flinders Health and Medical Research Institute: Sleep Health, Adelaide, Australia,

²Southern Adelaide Local Health Network, SA Health, Respiratory and Sleep Services, Adelaide,

Australia, ³Sleep Health Foundation, Melbourne, Australia

Introduction: Sleep disorders have a significant impact on quality of life for millions of people, but the perspectives and priorities of people with lived experience of sleep disorders are not well understood. Understanding the impact of sleep disorders from the perspectives of people with lived experience is important for clinical care and research. This research project explores the impact of sleep disorders on quality of life, capturing the voices of people with lived experience of sleep disorders. Better understanding the lived experience is essential to ensure patient perspectives can help inform advocacy, education, research, policy and practice.

Materials and methods: In this qualitative research project, members of a lived experience advisory group were invited to answer four questions regarding their sleep disorder and treatment journey. This research includes the stories of 11 people with a broad range of sleep disorders (6 females and 5 males, aged between 27-72 years). Thematic analysis was used to look for patterns and themes in the data.

Results: Three different themes were identified in the data. Firstly, the personal impact of sleep disorders, including impacts on physical and mental health, relationships and productivity. Secondly, health system impacts including the long journey to treatment, which was often self-initiated and with many different health professionals. Thirdly, societal impacts including the low priority of sleep, public unawareness and sleep disorders are often overlooked. These themes all interact to make it difficult for people with sleep disorders to seek help and navigate complex treatment pathways.

Conclusions: This project provides valuable insight to understand the lived experience and impact of sleep disorders on quality of life. These impacts make it more difficult for people to navigate the challenges and barriers associated with diagnosis and treatment of sleep disorders. By investigating the personal impacts of sleep disorders, we can inform public health and advocacy messaging to create messages that are meaningful to people with sleep disorders. We can also improve education of health professionals by incorporating patient voices and perspectives into training programmes. Lived experience can also help inform research into treatment options and pathways, to ensure treatments are affordable, accessible and easy to navigate. This work highlights the importance of working with people with lived experience for advocacy, and collaboration and co-design in academic research.

Acknowledgments: Special thanks to all current and past Sleep Health Foundation Lived Experience Advisory Partners. This work was funded by Flinders University.

The longitudinal mediating role of sleep in the bidirectional relationship between depression and functional disability among older adults: A systematic review and conceptual framework

H. Wu^{1,2}, L. Wang^{1,2}, H. Chen^{1,2}, W. Gao^{1,2}

¹Nanchang University, Department of Epidemiology & Health Statistics, School of Public Health, Nanchang, China, ²Nanchang University, Jiangxi Provincial Key Laboratory of Disease Prevention and Public Health, Nanchang, China

Introduction: The increasing prevalence of depression and functional disability in older adults highlights the need for targeted interventions. Sleep, as a potentially modifiable factor, holds promise in addressing these challenges. Given that sleep health provides clues for understanding the potential causes that could mitigate the negative effects of depression and functional disability, a better understanding of the relationship between sleep, depression, and functional disability is crucial for crafting effective preventive strategies and personalized interventions for older adults.

Materials and methods: This review and conceptual framework aimed to examine the pairwise bidirectional associations between sleep, depression, and functional disability and identify the longitudinal mediating role of sleep in the bidirectional relationship between depression and functional disability in older adults. The academic databases PsycArticles, PubMed, MEDLINE, Science Citation Index, Social Sciences Citation Index, ProQuest Dissertations and Theses Global, Cochrane, and Scopus were searched for research published in English between January 2000 and June 2024. Systematic review and cohort study designs were eligible. All included studies were assessed for quality using the Critical Appraisal Skill Programme checklist (CASP 2024). A narrative synthesis approach will be applied to integrate the findings, including an analysis of variability in terms of setting, population, exposure/ intervention, and outcomes.

Results: 397,289 citations were identified, and 82 studies meeting the inclusion criteria were included. Cohort studies and reviews provide evidence that there is a dynamic reciprocal correlation between sleep, depression, and functional disability in the older population. The research identifies reciprocal

causal pathways—depression exacerbates functional disability through unhealthy sleep, while functional disability worsens depression via unhealthy sleep—highlighting a vicious cycle that accelerates health decline in aging populations. Sleep longitudinally mediates the bidirectional relationship between depression and functional disability in older adults, acting both as a result and a driver in this dynamic interplay. The proposed framework prioritizes sleep health as a modifiable target for breaking the depression-functional disability cycle, offering actionable strategies to mitigate adverse outcomes in older adults.

Conclusions: This review and conceptual framework highlight that sleep health can provide crucial insights for mitigating the adverse effects experienced by older adults due to depression and functional disability. For healthcare professionals and policymakers, it provides evidence about prioritizing sleep health as an accessible step to foster a healthy lifestyle.

Introduction: Biomarker profiling from biofluids such as blood are widely measured in clinical research, using for example Olink proteomics panels. One such research focus area is cardiovascular disease (CVD), for which chronic sleep restriction (SR) is a risk factor. However, it remains unclear whether blood levels of commonly measured CVD biomarkers are sensitive to acute dynamic factors such as SR, physical exercise (PEX), and time of day.

Materials and methods: 16 normal-weight, healthy men participated in a crossover design in which they underwent three highly standardized in-lab nights of sleep restriction (SR, 4.25 h/night) and normal sleep (NS, 8.5 h/night) in randomized order. Blood samples were collected in the morning, evening, and immediately before and repeatedly after 30 min of high-intensity exercise, with 88 cardiovascular disease protein biomarkers quantified using Olink technology and selected validation by ELISA.

Results: Significant time-of-day-dependent changes in several CVD biomarkers were identified. Whereas several proteins were exercise-induced across sleep conditions (such as the canonical exerkines IL-6 and BDNF), exercise-induced proteomic dynamics differed in response to recurrent SR, compared with following NS. Moreover, SR compared with NS resulted in a biomarker profile previously associated with increased prospective risk of several CVDs across large-scale cohorts (such as higher circulating levels of IL-27 and LGALS9).

Conclusions: Our findings highlight how dynamic physiology can modulate CVD biomarker levels. These results also underscore the need to consider sleep duration as a key determinant of cardiovascular health—an emphasis reflected in recent American Heart Association guidelines. Further studies in women, older individuals, and patients with prior CVD, and across different chronotypes and dietary schedules are warranted.

The Relationship between Digital Emotion Regulation and Bedtime Procrastination

Y. Lee¹, S. Suh¹

¹Sungshin Women's University, Seoul, Korea, Republic of

Introduction: Bedtime procrastination (BP) is defined as going to bed later than intended without having external reasons for doing so. BP has been shown to function as an emotional regulation strategy for many individuals. This study explores bedtime procrastination based on James Gross's Process Model of Emotion Regulation, proposing that the phenomenon represents a nuanced, often maladaptive, strategy to manage pre-sleep emotional states. We hypothesize that individuals engage in bedtime procrastination by implicitly or explicitly employing various regulation strategies: situation selection/modification, attentional deployment, and cognitive change. This framework allows for a deeper understanding of the underlying psychological mechanisms driving the delay of sleep.

Materials and methods: A total of 22 young adults with high levels of BP (scores of 33 or higher) participated in the study. Bedtime procrastination, Process Model of Emotion Regulation Questionnaire (PMERQ) and a 7-day sleep diary were assessed using self-report questionnaires. The PMERQ is a 45-item instrument assessing ten emotion regulation strategies across Gross's five-stage process model, with each strategy categorized as engagement- or disengagement-focused. To examine the relationship between BP and Gross's process model of emotion regulation, a nonparametric Spearman correlation analysis was conducted.

Results: Participants (mean age 21.95 ± 2.1 , 86.4% female) were mostly university students (77.3%). Participants showed a mean sleep onset latency of 11.1 minutes ($SD=7.11$), total sleep time of 397.8 minutes ($SD=52.6$), bedtime procrastination of 86.6 minutes ($SD=41.7$), and spent an average of 93.5 minutes ($SD=39.2$) using their phones within the 3 hours before bedtime. Correlation analyses were conducted to examine the associations between BP and items from the PMERQ. BP was positively correlated with the situation selection subscale of the PMERQ ($r = .457, p < .05$) and was particularly associated with the disengagement strategy within the situation selection domain ($r = .449, p < .01$). BP also showed a significant positive correlation with PMERQ item 26 ("negotiating to resolve conflict") ($r = .443, p < .01$).

Conclusions: BP was significantly associated with both engagement and disengagement items of situation modification, as well as with the situation selection subscale. Intentionally postponing bedtime could be interpreted as a strategy to exert control over the environment to reduce emotional burden or stabilize emotions. According to Gross's process model of emotion regulation, BP may particularly reflect early-stage regulation strategies such as situation selection and situation modification. This conceptualization highlights bedtime procrastination not merely as a failure of self-regulation, but also a complex interplay of emotional regulation attempts.

The role of physical activity in modulating weekday and weekend sleep duration among patients with newly diagnosed type 2 diabetes

S. Dai^{1,2,3}, L. Ye², J. Huang^{2,4}, F. Chen⁵, Y. Zhang^{2,6}, L. Zhang⁷, Y. Xue⁸, C. Yang⁹, F. Wang⁹, D. Shu¹⁰, X. Liu¹¹, M. Wang¹², X. Shen^{9,13}

Introduction: Sleep duration is a modifiable health factor closely linked to both physical and metabolic well-being. Its integration into chronic disease management has received increasing attention. However, the interplay between physical activity (PA), sedentary behavior, and sleep duration remains underexplored, particularly in individuals with newly diagnosed type 2 diabetes mellitus (T2DM).

Materials and methods: The current study investigated patterns of PA, sedentary behavior, and self-reported sleep duration on weekdays and weekends in patients with newly diagnosed T2DM. Participants were categorized into low, moderate, and high PA groups based on the International Physical Activity Questionnaire. Clinical, behavioral, and demographic data were collected and analyzed. Group comparisons and generalized linear models were used to examine the potential role of PA in modulating weekday and weekend sleep durations.

Results: A total of 340 participants (mean age 43.4 ± 10.2 years) were recruited from the endocrinology clinic of The Affiliated Hospital of Hangzhou Normal University. All patients were enrolled at the time of diagnosis and had not yet initiated hypoglycemic therapy. At baseline, the mean fasting plasma glucose was 9.19 ± 4.06 mmol/L, mean HbA1c was $8.51 \pm 2.60\%$, and the mean 2-hour postprandial glucose was 14.82 ± 7.86 mmol/L. Regarding sleep health, the average weekday sleep duration was 6.73 ± 0.81 hours, while weekend sleep duration averaged 7.39 ± 1.08 hours. Based on total weekly MET-minutes, 21.2% of participants were classified as having low PA, 49.7% as moderate PA, and 29.1% as high PA. To explore associations, our simple group comparisons revealed that participants in the high PA group had significantly longer sleep durations on both weekdays and weekends compared to those in the low PA group ($p < 0.01$). Furthermore, linear regression analysis showed that higher total PA ($B = 0.00003$, $p < 0.001$) and vigorous PA ($B = 0.000013$, $p < 0.001$) were independently associated with longer weekday sleep duration. In contrast, higher fasting plasma glucose was significantly associated with shorter weekday sleep ($B = -0.066$, $p = 0.011$). Notably, these associations were not observed when weekend sleep duration was used as the dependent variable.

Conclusions: In patients with newly diagnosed T2DM, insufficient physical activity is linked to reduced weekday sleep duration. These findings highlight the importance of incorporating sleep management and promoting physical activity into early lifestyle interventions for diabetes care.

The Role of Sleep Health in Glycemic Regulation Among Non-Diabetic Pregnant Women

G. Abu Irsheed¹, W. Ackerman¹, A. Steffen¹, L. Quinn¹, L. Burke¹, L. Borbas¹, G. Alameda¹, R. Maganurue¹, A. Virmanie¹, N. Nazeer¹, I. Buhimschi¹, B. Izci Balserak¹

¹University of Illinois Chicago, Chicago, United States

Introduction: Sleep plays a critical role in glucose metabolism during pregnancy, yet most prior research has focused on non-pregnant adults. Recent studies link sleep disturbances to increased risk of gestational diabetes, poor cardiometabolic health, and other complications, but often examine isolated aspects such as sleep quality or timing. Sleep health is a multidimensional construct, including quality, duration, efficiency, timing, and regularity, offers a more comprehensive understanding of sleep's impact on metabolic outcomes. This approach remains underexplored in pregnant populations,

particularly African American pregnant women (AAPW), who experience both sleep disparities and glycemic dysregulation. This study investigates between-person and within-person associations between sleep health and glycemic outcomes in non-diabetic AAPW.

Materials and methods: Data from 55 non-diabetic AAPW enrolled in the BETTER lifestyle counseling study (NCT05234125) were analyzed. Sleep health was assessed using the Pittsburgh Sleep Quality Index (PSQI) for sleep quality, and 7-day Fitbit-derived measures for sleep duration, efficiency, timing (sleep midpoint), and regularity (standard deviation of sleep midpoint). Glycemic outcomes were assessed through 7-day continuous glucose monitoring (mean glucose, SD, mean amplitude of glycemic excursions (MAGE), and coefficient of variation (%CV). Between-person associations were examined using multivariable regression, while within-person temporal associations were tested using mixed-effects models with day-level sleep and glucose data. All models were adjusted for maternal age, gestational age, BMI, average daily steps, and education.

Results: The analytic sample included 55 non-diabetic AAPW (mean age= 29.6 ± 5.5 years; gestational age= 17.7 ± 2.7 weeks; BMI= 33.2 ± 5.1 kg/m²). Among between-person associations, poorer sleep quality was significantly associated with greater glycemic variability. Specifically, higher PSQI scores were linked to higher glucose SD ($\beta = 0.42$, $p = 0.011$), %CV ($\beta = 0.44$, $p = 0.005$), and MAGE ($\beta = 1.10$, $p = 0.003$). For temporal (within-person) associations, daily sleep dimensions were lagged by one day to predict next-day glucose outcomes. Analyses included 51 participants with ≥ 3 days of matched sleep and CGM data; 4 were excluded due to insufficient data. In these models, higher sleep efficiency was associated with higher mean glucose the following day ($\beta = 0.22$, $p = 0.029$). This finding may reflect complex or bidirectional interactions between sleep and glucose metabolism during pregnancy on daily level. Notably, the sample exhibited high average sleep efficiency (mean= $88.8\% \pm 3.4$) with low within-person variability, which may limit the ability to detect typical temporal associations. No other sleep health dimensions were significantly associated with glycemic outcomes in either between-person or within-person models. Other Continuous Glucose Monitoring Metrics (e.g., Time-in-Range, Time-Below-Range and Time-Above-Range) were not significantly predicted by any of the sleep dimensions.

Conclusions: These findings highlight the importance of sleep health in glycemic regulation during pregnancy. Poorer sleep quality was associated with greater glycemic variability between individuals. Unexpectedly, higher daily sleep efficiency predicted higher next-day glucose levels within individuals. This may be influenced by the overall high sleep efficiency and low night-to-night variation observed in the sample. Together, these results suggest that both stable sleep patterns and night-to-night variations may influence glucose regulation in non-diabetic AAPW. Further research is needed to clarify these relationships.

Time-Frequency Representation Learning Based on PPG Signals for Sleep Staging

Y. Li^{1,2}, Z. Song³, M. Glos², Y. Zhang⁴, T. Penzel²

¹Zhengzhou University, School of Electrical and Information Engineering, Zhengzhou, China, ²Charité - Universitätsmedizin Berlin, Interdisciplinary Sleep Medicine Center, Berlin, Germany, ³Southwest University, College of Hanhong, Chongqing, China, ⁴Southwest University, College of Electronic and Information Engineering, Chongqing, China

Introduction: Sleep health is closely related to a range of chronic diseases, which has led to increased public awareness and the rapid development of consumer-grade sleep monitoring devices. At present, most wearable devices leverage photoplethysmography (PPG) signals in combination with accelerometer data to analyze sleep stages. However, existing PPG-based sleep staging methods suffer from two main limitations: a heavy reliance on manual feature engineering and the necessity of large-scale electrocardiogram data for pre-training. These limitations hinder the model's generalization ability and its practical applicability.

Materials and methods: This study introduces a U-shaped sleep staging framework based on PPG signals, which combines time-frequency domain transformation with sequential feature extraction to enhance the time-frequency representation capability of PPG signals. The model integrates convolutional neural networks with a symmetric connection mechanism, enabling effective local feature extraction while enhancing time series modeling capabilities, thus improving classification accuracy.

To preprocess the PPG signals, an 8th-order Chebyshev Type II filter was applied with a cutoff frequency of 8 Hz. This filtering step removed high-frequency noise while preserving low-frequency information, such as heart rate and blood flow, which are relevant to sleep stage classification. Subsequently, the filtered signals were downsampled to 32 Hz, a frequency selected to retain key physiological characteristics such as heart rate variability and respiration-related frequencies, while also reducing data volume.

The experimental data were collected from the Interdisciplinary Sleep Medicine Center at Charité – Universitätsmedizin Berlin, including fingertip pulse oximeter PPG signals from 42 healthy participants (average age 37.5 ± 14.5 years). The dataset comprises 120 sleep recordings, with each participant contributing data from at least two nights. The study systematically assessed the impact of input sequence length on model performance and employed various cross-validation strategies, including random 10-fold cross-validation, leave-subjects-out, and leave-one-night-out, to evaluate the model's stability and generalization performance across different data splits.

Results: The model demonstrated optimal performance in classifying the four sleep stages—Wake, Light sleep, Deep sleep, and REM sleep—with an F1-score of 0.76 ± 0.03 and a Kappa coefficient of 0.69 ± 0.02 . Mann-Whitney U tests revealed no significant differences between the various cross-validation strategies ($p > 0.05$), indicating good stability of the model. As the number of input epochs increased (1, 8, 32, 64, 128, 256), the Kappa values for 10-fold cross-validation were 0.57, 0.61, 0.62, 0.62, 0.65, and 0.68, respectively.

Conclusions: The time-frequency representation learning method based on PPG signals proposed in this study effectively distinguishes between the four sleep stages, with model performance improving as the input segment length increases. This suggests that the model can effectively capture long-term dependencies in PPG data. The results highlight the potential of using PPG signals for sleep stage recognition, offering a low-cost, non-invasive, and intelligent solution for home sleep monitoring.

Acknowledgments: We appreciate the dedication and efforts of Leonie Julia Alt from the Interdisciplinary Sleep Medicine Center, Charité – Universitätsmedizin Berlin, in collecting and organizing the data.

Timing Matters: Differential Associations of Pre-Bedtime vs. In-Bed Objective Phone Use with Sleep among University Students

Z. Pu¹, S. Massar¹, X.Y. Chua¹, C.S. Soon¹, M. Chee¹

¹National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore

Introduction: Despite recommendations to the contrary, smartphones have increasingly become integral to many people's bedtime routines. An array of recent studies reported negative sleep outcomes due to nighttime phone usage, however, most of these studies relied on self-report measures. It is not clear how these outcomes are reflected in objective sleep and phone usage records. The present study used high-resolution smartphone sensing, ecological momentary assessments, and wearable sleep tracking to follow a cohort of university students under free-living conditions over a semester-long monitoring period.

Materials and methods: First-year undergraduates ($N = 233$) reported daily timings of getting into bed and intention to sleep via ecological momentary assessment, corroborated by objective data measured by a sleep tracking wearable (Oura ring 3). To objectively measure participants' phone usage, an app installed on participants' Android phones continuously and anonymously recorded their phone use sessions through touchscreen interactions (taps) along with the timestamp and the most active app for each tap within the sessions. Nightly phone usage patterns were characterized in the three separate time windows: before bedtime (3-hours prior to getting into bed), in-bed prior to intention to sleep, in-bed after intention to sleep. A total of $>13,000$ nights with paired diary, wearable, and phone use data were recorded. Linear mixed models were used to examine within- and between-subjects associations between phone usage in different time windows and sleep outcomes.

Results: During the 3 hours before getting into bed, participants used their phone for $70.08 (\pm 25.67)$ minutes. While in bed but before intention to sleep (14.97 ± 15.85 minutes), participants used their phones for $8.61 (\pm 11.30)$ minutes. The average interval between intention to sleep and sleep onset was $23.28 (\pm 8.97)$ minutes, during which participants used their phones for $8.51 (\pm 6.46)$ minutes. Counter to our hypothesis, higher phone usage (by 1 min) before getting into bed was associated with

same-night earlier sleep onset (0.25 mins, $p < 0.001$) and increased total sleep time (0.22 mins, $p < 0.001$). Higher pre-bedtime phone use was also associated with increased wakefulness after sleep onset (0.01 mins, $p = 0.04$). In contrast, 1-min increase in in-bed phone usage (both before and after intention to sleep) was associated with same-night later sleep onset (before intention to sleep: 0.37 mins, $p < 0.001$; after intention to sleep: 0.52 mins, $p < 0.001$), later wake-up time (before intention to sleep: 0.39 mins, $p < 0.001$; after intention to sleep: 0.59 mins, $p < 0.001$), but no change in TST. In-bed usage was also related to increased sleep onset latency and reduced sleep efficiency ($ps \leq 0.03$).

Conclusions: Undergraduates continued to spend a significant amount of time using their phone while in bed, even after the first attempt to fall asleep. Strikingly, higher pre-bedtime phone use was associated earlier sleep onset and longer sleep duration, while higher in-bed phone use was associated with worse sleep outcome. This highlights the potential importance of distinguishing between different periods of nighttime phone usage when examining their associations with sleep outcomes.

Title: Relationship between initial pressure setting and continuous positive pressure therapy compliance

Y.W. Kim¹, M.J. Kang²

¹Haeundae Paik Hospital, Inje University College of Medicine, Department of Otolaryngology-Head and Neck Surgery, Busan, Korea, Republic of, ²Haeundae Paik Hospital, Inje University College of Medicine, Department of Hemato-Oncology, Busan, Korea, Republic of

Introduction: Various factors are known to affect continuous positive airway pressure (CPAP) therapy compliance. However, there is no consensus on its risk factors regarding compliance, since every study shows different results. Furthermore, there are no prior studies regarding initial CPAP pressure setting and CPAP compliance. This study focuses on initial pressure setting and clinical characteristics of patients using CPAP to investigate factors affecting CPAP adherence.

Materials and methods: We retrospectively reviewed the medical records of patients diagnosed with OSA and treated with CPAP at the Haeundae-Paik Hospital, between November 2019 and July 2023. Patients' demographics, BMI (body mass index), past medical history, CT 90 (percentage of time spent with SaO₂ below 90% of the total recording), AHI (apnea-hypopnea index), percentage of days used for at least 4 hours were gathered. The patients were divided into 2 subgroups. One group started CPAP with wide pressure range (4~15 cmH₂O) and changed to narrow range afterward. The other group was treated with narrow pressure range (commonly 8~11 cmH₂O) from start to end. Patients' clinical factors were compared. Using logistic regression analysis, factors associated with CPAP compliance were investigated.

Results: During the study period, 157 patients were treated with CPAP after diagnosed as OSA. After exclusion, 142 patients were included for data analysis (mean age 52.126, male : female 116 : 26). There were 45 (31.7%) patients in the wide to narrow range group, 97 (68.3%) patients in the narrow group. CPAP Adherence rates were 48.8% in the wide to narrow group, 77.3% in the narrow group respectively. Chi square test result showed $p=0.001$. Logistic regression showed that BMI, age, CT 90 had strong correlation with adherence rate.

Conclusions: Patients undergone treatment with narrow range initial pressure significantly showed higher rate of passing adherence test, compared with patients started with wide range. Also, BMI, age, CT 90 were associated with poor adherence rate of CPAP.

Title: Short-Term Effects of Daily Stress on Sleep and Physiological Markers: Resilience as a Moderator

M. Furutani¹, K. Sato¹, H. Fukuda¹, N. Kondo¹

¹Kobe University, Graduate School of Human Development and Environment, Kobe, Japan

Introduction: This study aimed to investigate the short-term effects of daytime stress on sleep quality and physiological indicators (salivary chromogranin A [CgA] and blood pressure) in full-time working adult males. Additionally, we examined the relationships between cumulative stress and psychological health indicators (perceived stress and sleep quality), and explored the role of individual resilience in moderating these associations.

Materials and methods: Twenty-four full-time employed adult males (mean age = 37.2, SD = 6.96) participated in a 15-day study. Participants recorded their daily stress levels (5-point scale; lower scores indicate greater stress) and sleep evaluations, including satisfaction with sleep onset and perceived depth of sleep (both on 5-point scales, with lower scores reflecting poor sleep). On days perceived as highly stressful and minimally stressful, salivary CgA samples were collected at bedtime, upon awakening, and 45 minutes post-awakening. Blood pressure was measured at bedtime and upon awakening. On the final day of the study, participants completed the Perceived Stress Scale (PSS) and Pittsburgh Sleep Quality Index (PSQI) to assess the previous two weeks. The Brief Resilience Scale (BRS) was also administered to evaluate individual resilience. This study was conducted with the approval of the Kobe university's ethics committee (No.684-2). The authors have no conflicts of interest to disclose.

Results: CgA levels were significantly higher on high-stress days compared to low-stress days ($F(1, 78) = 7.78, p < .01$), with the highest levels observed immediately after awakening ($F(2, 78) = 21.25, p < .001$). Subjective stress ratings were consistent, with significantly higher scores on high-stress days ($t = 4, df = 91, p < .001$). Linear mixed models revealed that daily stress was affected with lower satisfaction with sleep onset (Estimate = 0.12, SE = 0.04, $p = .003$) and reduced depth of sleep (Estimate = 0.11, SE = 0.04, $p = .004$). Daily stress also predicted higher systolic blood pressure at bedtime (Estimate = 1.21, SE = 0.53, $p = .002$). Multiple regression analysis, including BRS as a covariate, showed that cumulative stress scores were not significant predictors of either PSS or PSQI scores. However, higher resilience was significantly associated with lower perceived stress (Estimate = -0.43, 95% CI = -0.45 to -0.10, $p = .013$).

Conclusions: Day-to-day stress was linked to increased salivary CgA, elevated bedtime blood pressure, and decreased subjective sleep quality, indicating short-term physiological and behavioral responses. In contrast, cumulative stress did not significantly influence perceived stress or sleep quality over the two-week period. Rather, individual resilience played a protective role, being associated with lower perceived stress. These findings suggest that while daily stress manifests in short-term physiological responses, resilience may be a key factor in sustaining psychological well-being over time.

Towards Standardized Diagnostic Tools in Sleep Medicine: A Comprehensive Analysis of Reliability, Symptom Overlap, and Screening Questionnaires

J.-A. Micoulaud-Franchi¹, V. Martin², C. Gauld³

¹Bordeaux University, Neurosciences, Bordeaux, France, ²INRIA, Informatics, Nancy, France,

³Université Claude Bernard Lyon 1, Child and Adolescent Psychopathology, Lyon, France

Introduction: Sleep disorders, such as insomnia and obstructive sleep apnea (OSA), are defined by diagnostic criteria outlined in international classifications, including the ICSD and DSM. However, the reliability and clinical relevance of these criteria remain under discussion, partly due to the diversity and overlap of symptoms across assessment tools. This review synthesizes systematic analyses of screening questionnaires to better understand the complexity and limitations of current tools in sleep medicine.

Materials and methods: Four distinct methods were integrated:

1. A systematic review of studies evaluating the reliability of diagnostic criteria for sleep disorders using Cohen's kappa coefficient.
2. A content analysis of multiple sleep disorder screening questionnaires, assessing item overlap using the Jaccard Index.
3. A content analysis of insomnia questionnaires, focusing on their clinical dimensions and their ability to distinguish symptoms from related impairments.
4. A content analysis OSA questionnaires, examining the diversity and relevance of symptoms phenotypes covered by these tools.

Results: The systematic review of diagnostic criteria showed substantial reliability (mean kappa = 0.66), with a predominance of "test-retest" and "interrater" reliability methods. However, insomnia and parasomnia were overrepresented in the studies.

The analysis of multiple sleep disorder screening questionnaires revealed moderate similarity between symptoms (mean Jaccard Index = 0.44), with gaps in item harmonization. Insomnia questionnaires

identified 16 clinical manifestations but exhibited limited overlap (mean Jaccard Index = 0.409) and a lack of distinction between symptoms and impairments. Finally, the analysis of OSA questionnaires highlighted low content overlap (mean Jaccard Index = 0.224), with tools capturing heterogeneous phenotypic aspects of OSA and a risk of diagnostic biases.

Conclusions: These findings underscore significant gaps in the standardization of diagnostic criteria and screening tools for sleep disorders. The reliability of criteria is limited by an imbalance in studied disorders and the methods employed. Screening questionnaires suffer from heterogeneous content, low overlap, and poor differentiation between symptoms and consequences of disorders. These limitations call for the development of standardized tools that integrate broader clinical dimensions and differentiated approaches based on the phenotypes of sleep disorders. Greater harmonization of questionnaires and diagnostic criteria is essential to improve clinical validity and comparability across studies.

Transdiagnostic Effects of a Chinese Herbal Formula DEP-2306 on Improving Sleep in Adults with Depressive Episode with Insufficient Symptoms: A Real-World Study

H.T. Tang^{1,2}, H. Fang¹, R. Wang³, A. Yeung⁴, D.J. Yu^{1,2}, Z. Bian^{1,2,5,6}

¹Hong Kong Baptist University, School of Chinese Medicine, Kowloon, Hong Kong, SAR of China,

²Hong Kong Baptist University, Vincent V.C. Woo Chinese Medicine Clinical Research Institute, Kowloon, Hong Kong, SAR of China, ³The University of Hong Kong, Sleep Research Clinic and Laboratory, Department of Psychology, Hong Kong Island, Hong Kong, SAR of China, ⁴Massachusetts General Hospital, Depression Clinical and Research Program, Boston, United States, ⁵Hong Kong Baptist University, Centre for Chinese Herbal Medicine Drug Development Limited, New Territories, Hong Kong, SAR of China, ⁶The Chinese Medicine Hospital of Hong Kong, Kowloon, Hong Kong, SAR of China

Introduction: Sleep disturbances and depression frequently coexist, with most individuals experiencing depressive episodes reporting poor sleep quality, which can exacerbate mood dysregulation. Depressive Episode with Insufficient Symptoms (DEIS), characterized by symptoms that are subthreshold in severity or duration for a diagnosis of Major Depressive Disorder (MDD), represents a critical intervention window due to its heightened risk of progression to MDD and significant functional impairment. Pharmacological treatments, such as antidepressants, are often premature at this stage. Psychotherapy, although effective, faces barriers such as stigma and resource limitations. This highlights the need for effective, safe, and culturally acceptable alternatives. Leveraging thousands of years of holistic practice, Chinese herbal medicine has shown efficacy in alleviating depression in many clinical and preclinical studies. However, specific evidence for its transdiagnostic effects on sleep quality in DEIS is sparse. DEP-2306, a Chinese herbal formula designed to target DEIS treatment in mood, has demonstrated therapeutic potential in preliminary trials. This report extends prior work by analyzing its transdiagnostic effects on improving sleep in DEIS.

Materials and methods: A total of 67 DEIS patients received daily DEP-2306 for four weeks. The core ingredients include Curcuma Radix (Yujin), Paeoniae Radix Alba (Baishao), Triticum Aestivum (Fuxiaomai), and Acanthopanax Senticosus Radix et Rhizoma (Ciwujia). Main outcomes included sleep quality, measured by the Pittsburgh Sleep Quality Index (PSQI), and the 7 domains of PSQI, which include subjective sleep quality, sleep latency, sleep duration, habitual sleep efficiency, sleep disturbances, use of sleep medication, and daytime dysfunction. A linear mixed model was used to analyze treatment effects, with statistical significance defined as $p < 0.05$.

Results: Among the 67 participants (mean age 37.3 ± 13.4 ; 70.1% female), significant improvements were observed in PSQI total scores, which decreased from 10.3 to 7.9 ($p < 0.01$, Cohen's d (d)=0.76). Significant improvements were also seen in subjective sleep quality, with a large effect size (d =0.83), moderate-to-large effects on sleep latency (d =0.73), and moderate effects on daytime dysfunction

($d=0.51$). Small to moderate effects were noted on sleep duration ($d=0.37$) and sleep disturbances ($d=0.47$). The tolerability rate, defined as the dropout rate due to adverse events, was very low, reported as 1.49%.

Conclusions: This study demonstrated that a 4-week DEP-2306 intervention is effective and safe for improving sleep quality in participants with DEIS. While the mean PSQI score reduction of 2.45 after 4 weeks of treatment fell slightly below the recommended minimal clinically important difference of 2.5, the short treatment duration may have limited its full therapeutic potential. Future research should employ longer intervention periods, placebo-controlled designs, and objective sleep measures to further validate these findings.

Traumatic childhood experiences and objective sleep health in adults with insomnia symptoms

K.K.Y. Ng¹, M. Zhou¹, R.W.I. Ao¹, C.H. Sin¹, S. Xie¹, Y.K. Wing^{1,2}, C.X. Chen¹, N.Y. Chan¹

¹The Chinese University of Hong Kong, Li Chiu Kong Family Sleep Assessment Unit, Department of Psychiatry, Sha Tin, Hong Kong, SAR of China, ²The Chinese University of Hong Kong, Li Ka Shing Institute of Health Sciences, Faculty of Medicine, Sha Tin, Hong Kong, SAR of China

Introduction: Childhood trauma is a profound adverse factor that may have lasting effect on a child's development and health problems that may persist into adulthood. Sleep disturbance is one of the critical areas that could directly be affected by these early adverse experiences. Prior research has found that traumatic childhood experience was associated with poor sleep in adults, albeit the evidence were mainly relied on subjective sleep measurements. Notably, objective sleep measures, particularly REM and NREM sleep, play distinct roles in processing memory regarding adverse experiences and emotional regulation. We aimed to examine the impact of childhood adversities on objective sleep architecture in adults who had already developed insomnia symptoms.

Materials and methods: A total of 228 participants with insomnia symptoms (Difficulty initiating sleep, Difficulty maintaining sleep, and/or Early morning awakening) were included. All participants underwent clinical interview that included the Structured Clinical Interview for DSM-5 Disorders - Clinician version (SCID-CV) and Diagnostic Interview for Sleep Patterns and Sleep Disorders (D.I.S.P). They also completed questionnaires for childhood trauma (Childhood Trauma Questionnaire short form), and subjective sleep characteristics that included sleep reactivity (FIRST), pre-sleep cognitive and somatic arousal (PSAS), and insomnia severity index (ISI). Sleep macrostructures were measured by ambulatory polysomnography (Nox A1s or Nox SAS solutions). Comparisons of sleep macrostructures between childhood trauma groups were conducted by t tests. Sleep parameters that showed significant difference between childhood trauma groups were selected in regression model, to further examine the associations with childhood trauma events. Confounders including age, sex, family income, educational level, psychiatric illnesses, and apnea-hypopnea index were adjusted.

Results: A percentage of 90.4% ($n=207$) of participants had reported at least one type of traumatic childhood experience (TCE). Adults with TCE had greater REM sleep proportion (TCE- vs TCE+: 19.77% < 24.83%, $p=0.04$) and probably longer REM sleep duration (TCE- vs TCE+: 74.52 min vs 92.81 min, $p=0.09$), as compared to those without TCE. Adults with TCE also had higher proportion of diagnosed insomnia disorder according to the DSM-V criteria (TCE- vs TCE+: 57.1% < 88.5%, $p=0.02$). Subjective sleep characteristics (sleep reactivity, pre-sleep arousal, and insomnia severity) and other sleep macrostructures (total sleep time, sleep efficiency, wake time after sleep onset, NREM sleep percentages and duration, AHI) were comparable between groups. In regression models, the traumatic childhood experience was also associated with higher probability of increasing REM sleep percentage ($\beta=6.83$, 95%CI: 1.53-12.13), and longer REM sleep duration ($\beta=27.90$, 95%CI: 5.07-50.72), when confounders were fully adjusted.

Conclusions: Traumatic childhood experiences were associated with excessive REM sleep in adults with insomnia symptoms. Future studies are warranted to better understand the underlying mechanism in childhood trauma and REM sleep in poor adult sleepers, to develop effective interventions.

Uncovering Sleep-Linked Glucose Dynamics in Healthy Individuals Using Wearable Data

Z. Liang^{1,2}, N.H. Hoang¹, T. Karunarathna¹

¹Kyoto University of Advanced Science (KUAS), Faculty of Engineering, Kyoto, Japan, ²The University of Tokyo, Institute of Industrial Science (IIS), Tokyo, Japan

Introduction: Sleep plays an important role in metabolic regulation, yet the glycemic dynamics that occur during sleep and their relationship with daytime glucose patterns remain poorly understood, particularly in healthy individuals. Glucose homeostasis, when disrupted, is known to contribute to oxidative stress, systemic inflammation, and cardiovascular risk. While glycemic patterns in diabetes have been well documented, the prevailing assumption that healthy individuals maintain stable glucose control across the day is increasingly being challenged. Emerging evidence suggests that transient hyperglycemia and elevated glycemic variability (GV) can occur even in normoglycemic individuals. Daytime glucose is influenced by behavioral factors such as meals and activity, whereas nocturnal glucose regulation is primarily governed by endogenous, autonomic processes. Thus, examining how sleep-time glucose patterns interact with daytime fluctuations may yield valuable insight into circadian metabolic stability, and potentially flag early anomalies before clinical symptoms emerge.

Materials and methods: We conducted a retrospective analysis of 5,124 hours of 24-hour continuous glucose monitoring (CGM) and wearable sleep data collected in naturalistic conditions from 12 healthy adults (mean age: 32.7 years, 50% male). Glucose levels were recorded every 15 minutes using the FreeStyle Libre system. Sleep onset and offset were captured using Fitbit Charge 3 wristbands worn on the non-dominant wrist. The CGM data were segmented into individualized in-sleep (GsleeP) and awake-time (Gawake) intervals based on Fitbit measured sleep onset and offset. A comprehensive set of short-term GV metrics (e.g., mean, max, standard deviation, MGN, CV, HBGI, LBGI) was computed for each segment. We applied Mann-Whitney U tests for between-state comparisons, repeated-measures correlation (rmcorr) to assess intra-individual associations over time, and quantitative association rule mining (ARM) with a novel post-filtering method to uncover high-confidence glycemic patterns.

Results: GV was consistently higher during wakefulness, while LBGI was significantly elevated during sleep. Strong, time-lagged associations emerged: LBGI_{sleep} on day N was strongly correlated with LBGI_{awake} of both the same day and previous day (rmcorr = 0.68–0.75), and negatively correlated with prior daytime mean and MGN. Similar reciprocal patterns were observed between meansleep and daytime GV. ARM revealed clinically meaningful rules linking low nocturnal glucose (≤ 54 mg/dL) to elevated LBGI the following day. These rules demonstrated high confidence (0.75–0.88) and lift (4.1–11.5), exceeding previous applications of ARM in metabolic data.

Conclusions: This study revealed significant and reciprocal associations between glycemic variability during sleep and daytime in normoglycemic adults. By integrating continuous glucose monitoring with wearable sleep tracking, we demonstrate that nocturnal glucose dynamics are closely linked to glycemic stability across the 24-hour cycle. While causal direction cannot be inferred, the observed bidirectional associations across sleep–wake cycles highlight the potential of combining CGM and wearable sleep data to characterize individual glucose variability over time. This may inform future research on early metabolic changes prior to disease onset.

University students with classes before 8:30 AM exhibit short sleep and low attendance

J. Ma¹, V. Kok¹, J. Gooley¹

¹Duke-NUS Medical School, Singapore, Singapore

Introduction: Sleeping well and attending classes are important for learning performance in university students. However, many students struggle to obtain sufficient sleep. Early class start times may stand in the way of students reaching sleep and learning goals because they have to wake up much earlier than usual. Students may also skip early classes due to oversleeping or not wanting to wake up early. Here, we assessed the impact of early class start times on objective sleep behavior and daily self-reported class attendance in university students. We hypothesized that, for classes starting before 8:30

AM, (1) students would obtain shorter sleep on days they attended the class, and (2) students would be more likely to skip class compared with days when their first class started later.

Materials and methods: University students ($n=570$, 364 women) wore a wrist actigraphy device for 2 weeks during the school semester to track their sleep behavior. Daily diaries were used to record students' first class start time of the day, whether they attended the class, and their reasons for any absences. Mixed models were used to test associations of school start time with sleep duration (continuous variable) and class attendance (binary variable), adjusting for demographic variables, chronotype, commute time, and class format (i.e., in-person or online). The dataset used for analyses included 3,388 school nights and 4,551 non-school nights.

Results: On days when students attended their first class, their nocturnal sleep duration was more than an hour shorter ($\beta=-1.29$ h, 95% CI=-1.72 to -0.86 h, $P<0.001$) when class started before 8:30 AM ($M=5.87$ h, 95% CI=5.70 to 6.04 h) versus in the afternoon ($M=7.04$ h, 95% CI=6.97 to 7.12 h). When students skipped classes that started before 8:30 AM, however, their sleep duration ($M=7.42$ h, 95% CI=7.16 to 7.68 h) was comparable to non-school nights ($M=7.18$ h, 95% CI=7.14 to 7.23 h). Class attendance was about 20 percentage points lower when students' first class started before 8:30 AM (63.0%) compared with any time later in the day (ranging from 80.0% to 88.6%). The most common reasons cited for missing early morning classes were "I did not want to go" and "I overslept" (40.7% and 33.6% of skipped classes, respectively). The odds of being absent were 2-fold higher when students' first class started before 8:30 AM versus in the afternoon (adjusted OR=2.11, 95% CI=1.58 to 2.64).

Conclusions: In university students, early class start times were associated with short sleep and low class attendance. Students may face a trade-off where they either forego sleep to attend class, or skip class to obtain more sleep. Universities should consider avoiding mandatory classes that start before 8:30 AM in order to optimize sleep and learning.

Unpacking the Discrepancy Between Subjective and Wearable-Measured Sleep: A Neurophysiological Perspective Using fNIRS

Z. Liang^{1,2}

¹Kyoto University of Advanced Science (KUAS), Faculty of Engineering, Kyoto, Japan, ²The University of Tokyo, Institute of Industrial Science (IIS), Tokyo, Japan

Introduction: Discrepancies between subjective sleep experience and objective sleep metrics are well-documented in both clinical and consumer settings. While consumer sleep trackers like Fitbit provide convenient longitudinal monitoring of sleep structure using accelerometry and PPG, many users report that these data do not align with how they feel upon waking. These mismatches are often attributed to device inaccuracy, yet even gold-standard polysomnography (PSG) explains only a small fraction of the variance in subjective sleep quality. Despite this, little is known about the underlying neural basis of this divergence, particularly in the context of sleep-tracking technologies. This study aims to explore the neurophysiological correlates of subjective versus wearable-derived sleep assessments during the first sleep cycle, and to evaluate whether these reflect distinct patterns of prefrontal cortical activity.

Materials and methods: We conducted an N-of-1 pilot study with a healthy male in his 30s, free from diagnosed sleep or mental health conditions. Prefrontal cortical hemodynamics were recorded during the first 90 minutes of sleep using a 27-channel wearable fNIRS system (Brite 24, Artinis). Concurrently, sleep metrics were obtained from a Fitbit Sense (e.g., TST, WASO, sleep efficiency, light/deep/REM sleep ratios, and Fitbit's sleep score). Subjective sleep quality was self-rated on a 5-point Likert scale each morning. Eight hemodynamic features were derived from fNIRS data (i.e., mean, median, SD, skewness, kurtosis, total power, peak amplitude, peak ratio), and correlations were computed with both subjective ratings and Fitbit metrics.

Results: Subjective sleep ratings were moderately and positively correlated with median ΔO_2Hb and ΔHHb in specific prefrontal cortex (PFC) channels, suggesting that more stable or elevated hemodynamic activity during the first sleep cycle may support better perceived sleep. Negative correlations were observed between subjective ratings and the skewness and kurtosis of ΔO_2Hb , indicating that flatter or more symmetrical signal shapes may align with positive sleep perception. In contrast, Fitbit's sleep score showed strong negative correlations with the mean and standard deviation of ΔO_2Hb and ΔHHb in a different set of PFC channels ($r < -0.70$), implying that higher signal

amplitude or variability is linked to poorer device-rated sleep quality. Additional Fitbit metrics demonstrated distinct physiological signatures. Sleep continuity metrics—including sleep efficiency, WASO, wake ratio, and light sleep ratio—were positively associated with hemodynamic activity. Conversely, sleep quantity metrics like total sleep time and deep sleep ratio showed negative associations. REM sleep ratio exhibited weak or inconsistent correlations. Topographical analyses revealed little spatial overlap between channels linked to subjective ratings and those linked to Fitbit metrics.

Conclusions: Subjective and wearable-based sleep assessments appear to reflect different neurophysiological dimensions of early sleep cycle. The commonly observed mismatch is not merely a matter of device error but rather of measurement misalignment. These findings suggest a need to move beyond improving algorithmic accuracy and toward personalized, neuroscience-informed feedback in future sleep tracking technologies.

Upper Airway Sleep Health and its Physiology

K. Strohl¹

¹Case Western Reserve University, Medicine, Cleveland, United States

Introduction: Billions of animals, from fish to humans, depend on rhythmic activation of upper airway muscles to accomplish “breathing”- the regulation of appropriate exchange of oxygen and carbon dioxide with the environment. Breathing interrupted by swallows or with speech involves a highly integrated neural control system which can dynamically maintain nasopharyngeal, oropharyngeal, and hypopharyngeal airway size and/or stiffness using structural feedback and controlled elements of muscle tension/orientation to switch functions.

Materials and methods: A literature review was conducted to address to identify whether neuromechanical features required to keep the airway during sleep are incrementally described either as controller or mechanical, crucial throughout development, and ignored until it fails.

Results: Bothersome increases in resistance, and decreases in flow are the result of unintentional airway narrowing and collapse during sleep, not seen in such proportions in few species, except perhaps bulldogs and elephant seals. In the condition called obstructive sleep apnea, the predominant theory is one of airway collapse, which we propose is an example of a failure of a little appreciated putative control system based in the brainstem. Supporting this to some extent are the new drug targets, based on sleep-influenced receptors on CN XII.

Conclusions: We propose a broader and testable view of functional health and disease for not only CN XII but also the other motor nerves to the upper airway, like CN IX. The unconventional idea is that OSA occurs in the context of a failure of neuromechanical control involving the palatal muscles attached to the base of the skull from which the upper airway, as well as the trachea and lungs, hang.

Usage and effectiveness of sleep education apps among parents of infants in Japan

S. Tanaka¹, A. Yoshizaki², Y. Okanemasa¹, I. Mori³, M. Kikuchi⁴, M. Taniike⁵

¹Kanazawa University, Research Center for Child Mental Development, Kanazawa, Japan, ²Osaka University, Molecular Research Center for Children's Mental Development, United Graduate School of Child Development, Suita, Japan, ³Osaka University, Department of Environmental and Behavioral Pediatrics, United Graduate School of Child Development, Suita, Japan, ⁴Kanazawa University, Department of Psychiatry and Neurobiology, Graduate School of Medical Science, Kanazawa, Japan, ⁵Osaka University, Molecular Research Center for Children's Mental Development, United Graduate School of Child Development, Suita, Japan

Introduction: In Japan, the average duration of sleep for both children and adults is known to be shorter than many other countries in the world. It has also been pointed out that a lack of sleep during early childhood affects development and is a risk factor for later hyperactivity and impaired cognitive

function. Children's sleep disorders are also said to be related to parental stress and maternal depression, so early support of sleeping habits is necessary. Previous research in Japan has highlighted a lack of sleep education for parents, and therefore the necessity to provide sleep education to parents are raising young children. The sleep education app 'Nenne-navi' developed by Yoshizaki et al (2023; 2024) is being used in several municipalities in Japan, helping to create better sleep habits of parents and children, so that they can maintain improved lifestyles even after using the app. In previous studies reporting on the effectiveness of using such sleep education apps, the duration of use ranged from only a few times, to use for a whole year, and it is unclear what the most appropriate duration for use is. Therefore, in this study, we investigated the optimum duration for use for sleep education app use.

Materials and methods: Participants were recruited from infant health checkups and nursery schools targeting children aged 16 to 45 months in a countryside city in Japan. All participants installed the 'Nenne Navi' sleep education app on their mobile devices, entered their family's lifestyle habits, and their children's sleep challenges, and participated in pre- and post-surveys. The app provides participants with advice tailored to their lifestyle habits. The study was approved by the Ethical Research Review Committees of Osaka University and Kanazawa University on June 5th, 2020.

Results: Of the 56 participants who agreed to participate in the study, 20 used the app for 1 month, 16 used the app for between 2-5 months, and 20 used the app for between 6-12 months. The mean age of the participating mothers at the start was 27.56 with a range between 22-42 years. There was significant difference in variability of children's wake-up times, sleep onset latency, sleep duration, mothers' bedtimes, and SSR between the beginning and end of study. There was no correlation between age of children and duration of app use, however the presence of sleep challenges, such as late bedtime and a long time to fall asleep, had a slight effect on app-use continuation. On the other hand, those mothers who continued using for longer were more likely to show an improvement in anxiety.

Conclusions: The app may help reduce anxiety if used continuously by mothers of younger children. We will continue to collect data and analyze the relationship between continued use of the app and the knowledge of sleep and the confidence of mothers in their children and themselves to cope with sleep after using the app.

Acknowledgments: The authors would like to thank all the families who participated in the study and the staff of Healthcare Center at Kaga, Japan.

Using the learnings from general practice nurse-delivered models of care for chronic conditions to inform the design of models of care for chronic insomnia and obstructive sleep apnea: a mixed-methods systematic review

N. Grivell^{1,2,3,4}, B. Brown¹, J. Fuller⁵, C.L. Chai-Coetzer^{1,2,6}, R. McEvoy^{1,2}, E. Hoon^{2,7}

¹Flinders University, FHMRI Sleep Health/Adelaide Institute for Sleep Health, Flinders Health and Medical Research Institute, College of Medicine and Public Health, Adelaide, Australia, ²Flinders University, National Centre for Sleep Health Services Research, College of Medicine and Public Health, Adelaide, Australia, ³University of Melbourne, Department of Physiotherapy, Faculty of Medicine, Dentistry and Health Sciences, Melbourne, Australia, ⁴Austin Health, Institute for Breathing and Sleep, Melbourne, Australia, ⁵Flinders University, College of Nursing and Health Sciences, Adelaide, Australia, ⁶SA Health, Department of Respiratory, Sleep Medicine and Ventilation, Southern Adelaide Local Health Network, Adelaide, Australia, ⁷University of Adelaide, Discipline of General Practice and School of Public Health, Faculty of Health Sciences, Adelaide, Australia

Introduction: The potential for new general practice nurse-delivered models of care to address obstructive sleep apnea and chronic insomnia have been explored in response to long wait times for the assessment and management of OSA and limited access to cognitive behavioural therapy for insomnia. Despite randomised controlled trials demonstrating evidence of efficacy, these models of care have not yet been widely integrated into clinical practice. Understanding the barriers and facilitators to implementation can inform the translation of complex interventions, such as models of care, however there is a scarcity of research exploring the implementation of general practice nurse-delivered models of care for chronic sleep disorders. With many years of research investigating the implementation of general practice nurse-delivered models of care for other chronic conditions, a systematic review focussed on the implementation of these models of care for chronic conditions was conducted to inform the design and implementation of future general practice nurse-delivered models of care for chronic sleep disorders.

Materials and methods: A mixed-methods JBI convergent integrated systematic review was conducted. The review utilised a framework synthesis approach informed by a conceptual framework for the implementation of complex interventions into primary care. Data were identified that did not fit the chosen framework, necessitating the development of an amended determinant framework – Factors influencing the Implementation of models of care for Chronic Conditions in General Practice (FICC-GP).

Results: Eighty-five records, published between 1995 and 2025, reported barriers and/or facilitators to implementation of models of care and were included in the review. Facilitators included an awareness of the benefits of the model of care by both patients and clinicians, general practice staff practicing effective teamwork, a collaborative relationship between general practice clinicians and specialist services, alignment with current work practices, and patient capability, such as adequate literacy and time to commit to the intervention. Barriers to implementation included lack of clarity about the roles and responsibilities of general practice team members and the scope of practice of general practice nurses, insufficient or inappropriate funding, such as funding that does not support multi-disciplinary care, and models of care that do not offer individualised patient centred care.

Conclusions: This review informs our understanding of the factors that influence the implementation of general practice nurse-delivered models of care for chronic conditions. The findings may be used to inform the design of future studies testing the implementation of general practice nurse-delivered models of care for chronic sleep disorders. Establishing a collaborative relationship between general practices and sleep specialist teams, ensuring that approaches to care are patient centred, and collaborating with patients to co-design models of care may lead to greater success when implementing new models of care for chronic sleep disorders in general practice.

Utility of the General Practice Sleep Scale “GPSS” among women in childbearing age in comparison to existing OSA screening tools

L. Walters^{1,2}, T. Howarth^{1,3,4}, S.S. Heraganahally^{1,4,5,6}

¹Royal Darwin Hospital, Department of Respiratory and Sleep Medicine, Darwin, Australia, ²University of Queensland, Faculty of Medicine, Brisbane, Australia, ³University of Eastern Finland, Department of Technical Physics, Kuopio, Finland, ⁴Charles Darwin University, Faculty of Health, Darwin, Australia, ⁵Flinders University, College of Medicine and Public Health, Darwin, Australia, ⁶Darwin Private Hospital, Darwin Respiratory and Sleep Health, Darwin, Australia

Introduction: Background: The risk of developing obstructive sleep apnoea (OSA) increases during pregnancy. However, underdiagnosis of OSA during pregnancy continues and can have adverse maternal and fetal outcomes. Hence, it is vital in clinical practice to screen high risk women in childbearing age for presence of OSA.

Aims: In this study, we assessed the utility of the new OSA screening tool – the “GPSS” (General Practice Sleep Scale) among women in childbearing age in comparison to existing traditional OSA screening tools – the Epworth sleep scale (ESS) and STOP-Bang.

Materials and methods: Methods: This was a retrospective study including all women aged 18-35 years with either a completed GPSS/STOP-bang/ESS, or data available to retrospectively derive the GPSS/STOP-bang/ESS score, and who underwent diagnostic polysomnography (PSG) in the Northern Territory of Australia.

Results: Results: 30 women (median age 30.6 (IQR 26, 33.5), n=8 (26.7%) indigenous Australian, median apnoea hypopnea index (AHI) 9.5 (IQR 3.2, 12.9)) were included for analysis. 70% recorded OSA (50% mild, 6.7% moderate and 13% severe) with minor, non-significant differences in age and Indigenous status between those with OSA (median age 31.4 (IQR 26.6, 33.5), 28.6% Indigenous) and those without (median age 27 (IQR 26, 31), 22.2% Indigenous). Notably, the ESS was higher among patients without OSA than with (median 15 (IQR 12, 15) vs. 8 (IQR 6, 19), p=0.063) and frequency of a heightened ESS (ESS>8) was greater for those without OSA (77.8%) vs. those with (47.6%), showing a sensitivity and specificity of 47.6 & 22.2% respectively. The median STOP-bang score among those with OSA was 2 (IQR 2, 3) (47.6% moderate risk (score≥3)) vs. 1 (IQR 1, 3) (33.3% moderate risk) among those without, showing sensitivity and specificity of 47.6 & 66.7% respectively for a moderate risk score. The median GPSS score among those with OSA was 10 (IQR 7, 11) (76.2% moderate risk (score≥7)) vs. 8 (IQR 4, 10) (55.6% moderate risk) among those without, showing sensitivity and specificity of 76.2 & 44.4% respectively for a moderate risk.

Conclusions: This study illustrates a high prevalence of OSA in women of childbearing age. However, daytime symptoms appeared more commonly among those patients without OSA. The GPSS tool showed much higher sensitivity for OSA, while the STOP-bang showed higher specificity, indicating both may be of use in different clinical scenarios for this demographic. Further prospective studies are warranted to assess the performance of the GPSS amongst pregnant women.

Conflict of Interest: Nil to declare

Validation of the reliability and validity of the 3-Dimensional Sleep Scale (3DSS), Japanese version, a measure of sleep phase, quality, and quantity

Y. Matsumoto¹, N. Uchimura¹, T. Ishida¹, M. Ozone¹, K. Kumadaki², A. Hino², Y. Otsuka³, O. Itani⁴, Y. Kaneita³

¹Kurume University School of Medicine, Kurume, Japan, ²University of Occupational and Environmental Health, Kitakyusyu, Japan, ³Nihon University, Tokyo, Japan, ⁴International University of Health and Welfare, Tokyo, Japan

Introduction: The Pittsburgh Sleep Quality Index (PSQI) and the Athens Insomnia Scale (AIS) are scales for evaluating sleep. These scales can assess the quality (e.g., sleep latency, sleep maintenance) and quantity (e.g., sleep duration, daytime sleepiness) of sleep, but cannot assess phase (e.g., sleep regularity, chronotype). We developed the 3-Dimensional Sleep Scale (3DSS) in 2015 to assess sleep phase along with quality and quantity. However, we encountered some problems, such as the small sample size at the time of validation and the classical methods for establishing reliability and validity. We therefore aimed to increase the sample size and update the statistical methods, to again validate the reliability and validity of the 3DSS.

Materials and methods: We conducted a web-based survey of approximately three thousand dayshift workers at four companies in Tokyo, Japan, between 2021 and 2022. The 15 questions of the 3DSS were tested for reliability and validity according to the COSMIN checklist, an international standard for scale development. The maximum likelihood method and promax rotation were selected for exploratory factor analysis. Reliability was tested by calculating the intraclass correlation coefficient and McDonald's ω reliability coefficient. To verify reproducibility, participants were asked to respond again within 2 weeks to the 15 items of the 3DSS, and the intraclass correlation coefficient between the first and second responses was calculated. Convergent and discriminant validity were verified by multi-trait multi-method analysis. As sleep phase indicators for convergent validity, holiday wake-up times and social jetlag were used. As sleep quality indicator for convergent validity, the total AIS Q1–5 score used. As sleep quantity indicators for convergent validity, the total AIS Q6–8 score and weekday sleep duration used. Cutoff values were verified using ROC curves and AUCs. We used "social jetlag ≥ 1 h" as the outcome when validating the cutoff value for the phase score. An "AIS score of 6 points or more" was set as the outcome when validating the cutoff values of the 3DSS sleep quality score and sleep quantity score. The author received a Grant-in-Aid for Scientific Research from the Ministry of Education, Culture, Sports, Science, and Technology to conduct this research (grant no. 21K10507).

Results: A total of 2,605 participants (1,718 men, 887 women; mean age, 42.2 $\pm$ 11.7 years) were included in the analysis, after excluding non-responders, non-consenters, and absent employees. Exploratory factor analysis confirmed a three-factor structure of sleep phase, quality, and quantity, with reliability coefficients of 0.690, 0.786, and 0.710, respectively. The second dataset of responses was obtained from 402 participants to verify reproducibility. Intraclass correlation coefficients for reproducibility, close to or greater than 0.7, were observed for all items. For convergent and discriminant validity, ideal correlations were observed for all subscales, as hypothesized. AUCs for sleep phase, quality, and quantity were 0.747, 0.812, and 0.819, respectively.

Conclusions: The 3DSS demonstrated sufficient reliability and validity for use as a sleep assessment tool. As the world's first instrument to evaluate sleep phase, quality, and quantity within a single scale, the development of an English version is warranted.

Vascular Age Estimation Using a Consumer Wearable Sleep Tracker

G. Yilmaz¹, S. Ghorbani¹, J.L. Ong¹, H.A. Golkashani¹, C. Zhang¹, B.T.T. Yeo¹, M.W.L. Chee¹

¹National University of Singapore, Centre for Sleep and Cognition, Yong Loo Lin School of Medicine, Singapore, Singapore

Introduction: Arterial stiffening, a hallmark of vascular aging, increases with age and is a proven biomarker of cardiovascular risk. However, instruments for its measurement are not suited for high frequency longitudinal measurement and not easily accessible outside of specialist settings. Nocturnal deployment of photoplethysmography (PPG) embedded in wearable consumer health trackers is a potential solution for recurrent longitudinal assessment of vascular aging at scale. Here, we assessed the ability of a sleep-tracking wearable (Oura Ring Gen 3) to detect age-related differences in key PPG features, comparing it to data from a clinical-grade pulse oximeter concurrently collected from the fingertip. We evaluated ring derived vascular age prediction performance using a featureless deep learning algorithm.

Materials and methods: Healthy adults (N=160; 78 males (49%), median age 31 years (IQR: 23)) underwent overnight polysomnography (PSG) in a sleep laboratory, during which fingertip photoplethysmography (PPG) and wearable ring PPG data were collected simultaneously. Pulse waveforms were extracted from both clinical and wearable sensors using a custom algorithm. Key PPG waveform features, crest time (CT), time difference between systolic and diastolic peaks (dT), and reflection index (RI), were used to assess waveform similarity across devices. Vascular age was estimated directly from PPG waveforms using a featureless deep learning approach based on a convolutional neural network (CNN). Model performance was compared between the fingertip and ring devices.

Results: Sleep PPG waveforms from fingertip and ring devices showed high overall similarity, with a median (IQR) cross-correlation of 0.97 (0.02) between devices. Age-related waveform changes were most strongly marked by PPG crest time ($r = 0.64$ and 0.62 for fingertip and wearable ring sensors respectively). The deep learning model similarly showed comparable prediction performance with mean absolute errors (MAE (SD)) of 6.28 (1.48) and 7.25 (1.29) years, and r (SD) of 0.84 (0.07) and 0.80 (0.10) for clinical-grade and consumer-grade sensors.

Conclusions: These findings support the feasibility of using wearable consumer devices to assess vascular age conveniently and frequently. Given the strong link between arterial stiffness and cardiovascular morbidity, these tools hold great promise for allowing persons to discover lifestyle changes that result in improvement in vascular health.

Virtual Reality–Assisted Sleep Bundle Intervention for Enhancing Sleep Outcomes in Critically Ill Patients

H.-Y. Chiu¹

¹Taipei Medical University, School of Nursing, College of Nursing, Taipei, Taiwan

Introduction: Sleep disturbance is a main complaint reported by critically ill patients, with an estimated prevalence of 66%. However, an effective intervention is still lacking in the current settings of intensive care units (ICUs). This study aimed to evaluate the effects of the virtual reality–assisted Sleep Bundle, comprising Supports Clustering, Light and Noise Reduction, Emotional Distress Relief, Eye Mask Use, and Pain Monitoring and Management, on sleep quality and quantity in critically ill patients.

Materials and methods: A two-arm, assessor-blinded randomized controlled trial was conducted in a surgical intensive care unit between April 2022 and May 2024. The primary outcomes were subjective sleep quality, assessed using the Traditional Chinese version of the Richards-Campbell Sleep Questionnaire, and objective sleep metrics measured via actigraphy. Secondary outcomes included anxiety and stress levels, evaluated using visual analogue scales. Generalized estimating equations were used to assess treatment effects over time.

Results: A total of 100 surgical ICU patients were randomized 1:1 to receive either the SLEEP intervention or standard care. After three days, patients in the experimental group demonstrated significantly better sleep quality, reduced percentage of stage 2 sleep, and increased stage 3 sleep compared to the control group (all $p < 0.05$).

Conclusions: The virtual reality-assisted sleep bundle program significantly improved subjective and objective sleep outcomes in critically ill surgical patients, supporting its implementation as a nonpharmacological strategy in ICU settings.

Acknowledgments: This study is supported by the National Science of Technology Council, Taiwan.

Vision Transformer-based Per-Second Resolution Detection of Obstructive Sleep Apnea with Explainability

J. Hong¹, K. Jang¹, H. Lee¹, H.-W. Shin², H.-S. Kim¹

¹Seoul National University, Graduate School of Data Science, Seoul, Korea, Republic of, ²Seoul National University Hospital, Department of Otorhinolaryngology-Head and Neck Surgery, Seoul, Korea, Republic of

Introduction: Manual, second-by-second scoring of polysomnography (PSG) remains the gold standard for obstructive sleep apnea (OSA) diagnosis but is resource-intensive and subject to variability among scorers. Current automated methods typically analyze fewer than three biosignal channels, providing only the coarse Apnea-Hypopnea Index (AHI) without second-level annotation, thus compromising clinical detail and interpretability. To address these limitations, we propose VOSA, a Vision Transformer (ViT)-based deep learning model designed to replicate a sleep technologist's visual diagnostic workflow using comprehensive, standardized PSG images.

Materials and methods: VOSA processes standardized PSG images, each containing 21 distinct biosignals utilizing specialized patch design and transformer blocks. The model performs per-second labeling of normal, hypopnea, or apnea events, calculates the Apnea-Hypopnea Index (AHI), and classifies OSA severity into four levels. Additionally, the ViT architecture provides visual explanations through attention heatmaps and well-calibrated confidence scores. Training and validation were conducted using the KISS dataset, comprising PSG data from 7,745 patients collected across four clinical centers. Model robustness was further tested on the independent, publicly available Sleep Heart Health Study-2 (SHHS-2) dataset.

Results: VOSA demonstrated robust performance with a per-second macro-F1 score of 82.6% and a severity classification macro-F1 of 73.5% in the KISS dataset, significantly outperforming baseline model. Importantly, 99.2% of patients were correctly classified into their actual or adjacent severity categories. Attention heatmap visualizations highlighted model alignment with established American Academy of Sleep Medicine (AASM) guidelines, confirming the clinical relevance. Reliability of VOSA's confidence score was evaluated by ECE (expected calibrated error), demonstrating near-perfect calibration of 0.005.

Conclusions: VOSA, leveraging comprehensive PSG image data and Vision Transformer-based architecture, provides second-level respiratory event predictions. By integrating visual explanations and calibrated confidence scores, VOSA represents a significant step towards scalable, interpretable, and precise diagnostic workflows in sleep medicine.

Where You Live Shapes How You Sleep: Geographic and Cultural Influences on Sleep Duration in Global Data Measured by the Galaxy Watch

P. Song¹, J.J. Lee², H. Jung³, H. Lee³, E.Y. Joo⁴

¹Inje University College of Medicine, Ilsan Paik Hospital, Department of Neurology, Goyang, Korea, Republic of, ²Ewha Womans University, Department of Data Science, Seoul, Korea, Republic of, ³Samsung Electronics, Suwon, Korea, Republic of, ⁴Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Neurology, Seoul, Korea, Republic of

Introduction: Endogenous circadian rhythms regulate human sleep but are also influenced by environmental light exposure and sociocultural factors. The widespread adoption of wearable devices has enabled the acquisition of large-scale, population-level sleep data across diverse geographic and socioeconomic contexts, including regions previously underrepresented in sleep research. In this study, we analyzed sleep data collected globally from Samsung Galaxy Watch devices to examine variations in nocturnal sleep duration and timing, and their alignment with local sunrise and sunset times, in relation to latitude, season, and cultural context.

Materials and methods: We analyzed 475 million sleep records obtained in 2023 from users in 101 countries. Sleep metrics included sleep onset time (SO), total sleep time (TST), sleep offset time (SF),

and wake after sleep onset (WASO). Sleep timing was evaluated to local sunrise and sunset, assuming device registration reflected users' locations. Countries were classified into five latitude-based climate zones—tropical, dry, temperate/continental, and polar—based on the Köppen-Geiger climate classification.

Results: Total sleep time increased with latitude, with the shortest durations observed near the equator (15°N to 15°S) and the longest in Arctic regions (66.5°N to 90°N). Countries within the temperate and continental zones (approximately 30° to 60° latitude) exhibited consistently later sleep onset and offset times than countries in other climate zones. Sleep timing patterns were notably similar among culturally related or geographically adjacent countries, suggesting sociocultural influences on sleep behavior.

Conclusions: Sleep duration and timing can be shaped by a combination of latitude, seasonal variation in natural light, and cultural context. These findings underscore the importance of developing region-specific strategies for public health messaging and sleep education.

Why do people miss their optimal sleep window? Adherence to a personalized sleep-wake recommendation delivered with a mobile application

S. Suh¹, S. Shin¹, Y.M. Song², E. Joo³, S. Choi⁴, J.K. Kim^{2,5,6}

¹Sungshin University, Psychology, Seoul, Korea, Republic of, ²Institute for Basic Science, Biomedical Mathematics Group, Pioneer Research Center for Mathematical and Computational Sciences, Daejeon, Korea, Republic of, ³Sungkyunkwan University / Samsung Medical Center, Department of Neurology, School of Medicine, Seoul, Korea, Republic of, ⁴Sungkyunkwan University, Graduate School of Clinical Nursing Science, Seoul, Korea, Republic of, ⁵KAIST, Department of Mathematical Sciences, Seoul, Korea, Republic of, ⁶Korea University, Department of Medicine, College of Medicine, Seoul, Korea, Republic of

Introduction: The physiological benefits of aligning sleep with the body's natural circadian rhythms has been extensively documented in the literature. Despite this understanding, a substantial portion of the population struggles to adhere to a consistent sleep schedule that aligns with their internal chronotype. This study investigated the real-world application and adherence of SleepWake, a mobile application that recommends an individualized and optimal sleep-wake window.

Materials and methods: Participants in this study (n=77) received a real-time, personalized sleep recommendation delivered by the SleepWake mobile application. The SleepWake app implements a previously developed framework for dynamic tracking of sleep homeostasis and circadian rhythms using a mathematical model, provided to all participants after 14 days of monitoring sleep and wake times. Throughout the intervention period (14~28 days), the app continuously generated and delivered individualized sleep and wake recommendations based on accumulated sleep deficits and personalized sleep phase alignment optimized for individual sleep patterns. Sleep indices included sleep duration, sleep regularity, and sleep timing. Insomnia symptoms (measured by the Insomnia Severity Index; ISI) and excessive daytime sleepiness (Epworth Sleepiness Scale; ESS) were also measured. Sleep period agreement was calculated based on the proportion of observed sleep compared to suggested sleep, with values allowed to exceed 1 if the participant slept longer than the suggested sleep time.

Results: Participants (mean age = 33.7±7.1 years, 19.5% female, 44.2% shift workers). A total of 1,048 sleep records were analyzed. Sleep period agreement was on average 67% (range 45% – 96%). Among the analyzed sleep records, 41.3% (n=433) indicated participants slept more than one hour later than the suggested bedtime, with the average discrepancy being 67 minutes later (ranging from 90 minutes earlier to 287 minutes later). Smaller discrepancies between suggested and actual bedtime were associated with longer sleep duration (nocturnal sleep + naps; $r=.52$, $p=.001$). Discrepancies between suggested and actual bedtime were not associated with age, sex, shift work, ISI scores, or ESS scores.

Conclusions: Despite the promise of informing participants of their biologically aligned sleep timing, adherence to the recommended sleep-wake schedule was moderate. Notably, a large proportion of users delayed their bedtime beyond the suggested window, underscoring the persistent gap between ideal and actual sleep behavior, even when armed with real-time, individualized guidance. Future research should explore strategies to enhance user engagement and behavioral compliance, as well as assess long-term outcomes associated with adherence to biologically informed sleep schedules.

Acknowledgments: This work was supported by the Institute for Basic Science IBS-R029-C3 (to J.K.K.).

“You need to be better than this” : Using an intersectional lens to examine sleep and healthcare access in marginalised communities in Australia

A. Sam¹, R. Lane², T. Sletten¹, L. Jobson¹, S. Verma¹, L. Nguyen³, A. Yaghobi⁴, J. Wiley¹, P. Varma¹

¹Monash University, School of Psychological Sciences, Melbourne, Australia, ²Sutter Health, Sacramento, United States, ³Swinburne University, Melbourne, Australia, ⁴Independent Researcher, Melbourne, Australia

Introduction: Sleep health disparities are under-recognised, yet are a critical marker of health inequities. Marginalised and underrepresented communities often experience unique and compounded barriers to healthy sleep. Interactions between racial discrimination, gender, socioeconomic factors, housing stability, and cultural misalignment with Western sleep norms are some factors that can contribute to these sleep disparities. However, intersectional approaches, such as the compounded effects of multiple personal, social, financial, environmental and cultural identities are not meaningfully incorporated in sleep research and practice. This exploratory study used an intersectional lens to: a) examine prevalence of sleep disorders in multicultural communities; b) explore contextual narratives and perspectives surrounding sleep and healthcare accessibility.

Materials and methods: The study used a mixed-methods approach. A cross-sectional, weighted survey of 1829 individuals representing key multicultural communities in Australia (e.g. South Asians, Southeast Asians, East Asians, Middle Eastern communities) captured quantitative data on demographics, work patterns (including shift work), sleep health (Insomnia Severity Index or ISI, Shift Work Disorder Questionnaire or SWDQ), mental health (Patient Health Questionnaire – 4), and experiences of discrimination (Intersectional Discrimination Index). In-depth interviews were conducted with 25 individuals representing a subset of community members and key stakeholders (clinicians, educators, researchers, policy makers) to examine facilitators, barriers and culturally embedded perspectives on sleep.

Results:

Over 52% of participants from multicultural communities screened positive for insomnia, a rate that is double the general population estimates 5. 37.6% were shift workers, double general population, with 1 in 2 meeting the criteria for Shift Work Disorder. Elevated anxiety ($r = 0.57$), depression symptoms ($r = 0.54$), and experiences of intersectional discrimination ($r = 0.31$) were correlated with greater insomnia symptoms (all $p < .001$). Greater resilience was correlated with decreased insomnia symptoms ($r = -0.34$, $p < .001$). Interviews identified complex multilevel influences on sleep across individual, familial, community, clinician, and systemic domains:

1. Sleep norms – Dominant sleep narratives were described as Western-centric, overlooking communal and integrative sleep practices, and collectivistic values. Sleep was often stigmatised as ‘laziness’, reinforcing extended wakefulness for productivity.
2. Minority Stress – Interviewees described sleep as being impacted by unique stressors, including loneliness, familial disconnection, racism, and migration processes and trauma.
3. Sleep is a Privilege – Sleep was identified as a privileged experience, with broader systemic barriers, such as overcrowded housing, cost of living, public transportation and infrastructure deficits, long and irregular work schedules, knowledge inaccessibility, and tokenistic political support.
4. Clinician Awareness – Clinicians-cited inadequate training and tools. Community members reported experiences of discrimination and emphasised the value of clinician self-disclosure and shared lived experience in fostering trust.
5. Community-led Strategies – Peer advocacy and culturally grounded supports, particularly through local government, were considered key facilitators of good sleep.

Conclusions: Improving sleep health requires a shift in narrative: from individual responsibility to system-level support. Embedding an intersectional lens in research, practice and policy making can address compounded impacts of marginalisation. Community-led interventions, investment in culturally-safe, accessible services, and delivery of integrative, holistic clinical education can promote more inclusive health outcomes for our communities.

Acknowledgments: We thank our participants and community consultants for their generosity and support.

Technology/Technical

Actigraphy from sensor-level acceleration measurement

J.Y. Chua¹, P. Ridgway¹, A. Williams¹, J. Langford^{1,2}

¹ActivInsights Ltd, Kimbolton, United Kingdom, ²University of Exeter, Exeter, United Kingdom

Introduction: As actigraphy advances, standardised reporting methods become essential. Transitioning from traditional counts per minute to sensor-level, raw acceleration (m/s^2) enhances data transparency, reproducibility, and consistency across disciplines. However, maintaining backward compatibility remains essential to preserve continuity with decades of legacy data from now-discontinued devices. We developed an open-access web tool that processes and analyses sleep data in the Actiwatch-compatible AWD file format. This allows data from devices like GENEActiv to be converted and analysed in a historical format, facilitating cross-device compatibility and supporting long-term data integration.

Materials and methods: The core of the system is an open AWD conversion algorithm designed to approximate AWD-equivalent outputs from raw GENEActiv acceleration and light data. The algorithm was implemented independently in R and C# for cross-verification. Validation was conducted by collecting GENEActiv and Actiwatch data simultaneously, converting GENEActiv files to AWD format, and comparing the results.

We built a web-based application incorporating Actiware's open sleep scoring algorithm. Usability was assessed through moderated sessions with sleep clinicians. Clinicians completed task-based evaluations while narrating their experience, focusing on familiarity to existing workflows, ease of navigation, and value of individual features.

Internal validation compared rest intervals marked using the web toolkit with those analysed in Actiware. Validation efforts included determining the best GENEActiv and web toolkit configuration for closest equivalence to Actiwatch outputs.

Clinicians with prior experience using Actiware and performing sleep scoring were recruited for usability testing. To assess cross-platform compatibility, the group included two Mac and four Windows users.

Results: Clinicians responded positively to the toolkit, describing it as intuitive, quick, easy to navigate, and convenient for its web-based nature. The interval mark-up feature was considered straightforward and well-suited to their analytical needs, contributing to an overall efficient user experience.

Validation of the AWD conversion demonstrated a strong equivalence between the converted GENEActiv data and Actiwatch AWD files. Zero-count rates for the data from the two systems differed by only a few percent of each other and a linear regression of time-matched non-zero epochs yielded a slope near 1, confirming high alignment. GENEActiv data sampled at 50 Hz analysed at a wake threshold of 60 counts provided the closest match to Actiwatch outputs. This configuration slightly overestimated total sleep time by 4.91 minutes and sleep efficiency by 0.80%, while underestimating sleep onset latency by 4.23 minutes, wake after sleep onset (WASO) by 0.09 minutes, and number of awakenings by 1.95. Although based on a single participant, these results support the potential of this approach for future validation with larger datasets.

Conclusions: This project addresses the challenges of the discontinuation of legacy actigraphy systems. By developing an AWD file conversion algorithm and a user-friendly, web-based toolkit, we enable clinicians to maintain continuity between historical data and new data from modern GENEActiv devices. Clinician feedback highlighted the tool's accessibility and ease of use, and early validation results demonstrate strong equivalence between converted and original datasets. Together, these tools offer a scalable solution for cross-platform sleep data analysis and establish a foundation for expanded validation studies involving more diverse populations.

Adenosine-Mediated Sleep Enhancement via Transcranial Near-Infrared Photobiomodulation: Translational Evidence from Animal and Human Studies

J. Jung^{1,2}, C. Yeo², J.G. Kim¹, T. Kim¹

¹Gwangju Institute of Science and Technology, Biomedical Science and Engineering, Gwangju, Korea, Republic of, ²TEDi MEDi, Co., Ltd., Research, Gwangju, Korea, Republic of

Introduction: Adenosine is a well-established neuromodulator implicated in sleep homeostasis, particularly in the promotion of non-rapid eye movement (NREM) sleep. However, modulation of adenosine itself has not yet been successfully developed as a therapeutic modality for insomnia. Near-infrared (NIR) photobiomodulation (PBM) enhances mitochondrial activity and ATP production, potentially leading to increased extracellular adenosine levels. Based on this mechanistic hypothesis, we conducted a translational investigation comprising both animal and human studies to evaluate the sleep-promoting effects of NIR PBM.

Materials and methods:

In the animal study, mice were implanted with a fiberoptic cannula on the skull surface fixed with dental cement, allowing localized delivery of 810 nm filtered NIR light. EEG recordings were obtained to assess sleep architecture. Intracerebral levels of adenosine were measured by microdialysis and cytochrome c oxidase activity of the illuminated area of brain was quantified. For a randomized sham-controlled double-blind clinical trial (RCT), a wearable PBM device consisting of 32 NIR LEDs (810 nm) was developed for application to the forehead. Forty participants with subthreshold insomnia (defined by Insomnia Severity Index, ISI) were randomly assigned to either PBM or sham stimulation groups. Following a 2-week baseline period, participants received 1 week of nightly intervention. Subjective sleep quality was evaluated using the ISI, Pittsburgh Sleep Quality Index (PSQI), and Epworth Sleepiness Scale (ESS). Objective sleep parameters were monitored via actigraphy using a wearable watch and a data collection system (Labfront Research Tool: www.labfront.com). A two-way repeated measures ANOVA was employed to analyze the main effects of Time, Group, and Time × Group interaction.

Results:

In the animal study, NIR PBM significantly increased NREM sleep duration and delta power on EEG. Biochemical assays confirmed elevated adenosine levels and enhanced cytochrome c oxidase activity, supporting increased mitochondrial function. In the RCT, the PBM group demonstrated statistically significant reductions in ISI, PSQI, and ESS scores after the intervention with large effect sizes (Cohen's $d = 1.08$ and 0.78 for ISI and PSQI, respectively), while the sham group showed non-significant changes. Notably, ISI and PSQI scores exhibited significant Time × Group interactions ($P = 0.007$ and 0.011 , respectively), indicating a differential improvement in the PBM group over time. Actigraphy-based sleep analysis is ongoing.

Conclusions: This translational study provides converging preclinical and clinical evidence that transcranial NIR photobiomodulation enhances sleep, potentially via increased adenosine signaling. The findings support the feasibility of NIR PBM as a non-pharmacological intervention for sleep enhancement and warrant further trials in patients with clinically diagnosed insomnia.

AI-Based Contactless Sleep Monitoring for Early Detection of Mood Dysregulation in Hospitalized Patients

H.-R. Lin^{1,2}, C.-H. Chuang¹, Y.-K. Lee³

¹National Sun Yat-sen University, Institute of Medical Science and Technology, Kaohsiung, Taiwan,

²Kaohsiung Armed Forces General Hospital, Nursing Department, Kaohsiung, Taiwan, ³Kaohsiung Armed Forces General Hospital, Medical Education and Research Center, Kaohsiung, Taiwan

Introduction: Sleep disturbances are both a symptom and an early warning sign for mood disorders, including depression and bipolar disorders. Poor sleep quality not only impairs recovery but is also associated with increased risks of emotional instability, aggression, and suicide. These sleep-related issues are often underrecognized in psychiatric wards. Early and continuous monitoring of sleep may provide crucial opportunities for proactive intervention in vulnerable patients. This study aims to

develop a contactless, AI-driven sleep monitoring system based on smart mattress technology to detect physiological changes associated with mood disorder exacerbation. The goal is to enhance early detection of emotional dysregulation and support timely psychiatric intervention.

Materials and methods: This study consists of two phases. In the first phase, the smart mattress system (Huijia Health Life Corporation) will be calibrated against gold-standard polysomnography (PSG) in healthy individuals to evaluate its validity and sensitivity for sleep stage detection and physiological signal reliability. In the second phase, psychiatric inpatients diagnosed with depression or bipolar disorder will undergo continuous overnight monitoring using the smart mattress, which captures heart rate, respiration, and body movement. Supervised machine learning algorithms will be used to model the association between sleep dynamics and clinical indicators of mood instability. SHAP will be applied to interpret model outputs and determine key contributing features.

Results: We anticipate developing a validated supervised learning model capable of detecting early changes in sleep patterns that indicate deterioration of mood disorders. The system is expected to provide real-time insights to assist clinical teams in decision-making and intervention planning.

Conclusions: Integrating AI-assisted, contactless sleep monitoring into psychiatric care may significantly improve early detection and clinical management of mood disorders. This approach has the potential to enhance patient safety, support timely treatment, and improve the overall quality of psychiatric care.

Acknowledgments: We sincerely thank the Kaohsiung Armed Forces General Hospital for providing clinical resources and institutional support. We also acknowledge Huijia Health Life Corporation for supplying the smart mattress system used in this study. Special thanks to Bo-Sheng Chen for his technical expertise in AI model development and implementation.

AI-based Prediction Model of Alzheimer's Disease From Polysomnographic Records: A Preliminary Study

S. Oh¹, J. Key¹, S. Park², S.-H. Kim², E. Urtnasan³

¹Yonsei University, Department of Biomedical Engineering, Wonju, Korea, Republic of, ²Yonsei University Wonju College of Medicine, Department of Internal Medicine, Wonju, Korea, Republic of, ³Yonsei University, Division of AI Semiconductor, Wonju, Korea, Republic of

Introduction: Alzheimer's disease (AD) is a progressive neurodegenerative disorder and the most common cause of dementia, primarily affecting memory, cognitive function, and behavior. Thus, a convenient and accurate screening method is critical for the early detection of AD. This study aimed to develop an AI-based prediction model for prescreening Alzheimer's disease using nocturnal polysomnographic (PSG) recordings.

Materials and methods: Real-world clinical PSG data were collected from 150 subjects (100 controls and 50 with AD) from the MrOS sleep study. We proposed a hybrid deep learning model that combines convolutional and recurrent neural network architectures, optimized through dropout and batch normalization. The model extracted and analyzed complex patterns from nocturnal EEG signals. PSG data were preprocessed, segmented into 30-second intervals, and evaluated using 5-fold cross-validation.

Results: The AI-based prediction model showed promising performance, achieving an accuracy of 76.19%, a sensitivity of 77.35%, and a specificity of 74.73% in screening for AD.

Conclusions: Our preliminary results demonstrate the feasibility of using AI-based PSG analysis for AD prescreening. The proposed model has potential as a practical and non-invasive tool for early detection and monitoring of neurodegenerative disorders.

Acknowledgments: none

An innovative solution to positional therapy for obstructive sleep apnea - Pilot Study

T.Z.J. Teng¹, C.Y.-H. Chu¹, C.A.S.M. Chua¹, T.C. Charn¹, C.Q. Phua¹

¹Sengkang General Hospital, Singapore, Singapore

Introduction: Obstructive sleep apnea (OSA) is a prevalent global health issue, with a significant subset, positional OSA (POSA), affecting up to 60% of patients. While continuous positive airway pressure

(CPAP) is the gold standard treatment, poor compliance due to discomfort remains a major limitation. Existing positional therapies often act as aversive stimuli, leading to suboptimal long-term adherence. This pilot study evaluated a novel, comfort-focused approach using a commercially available G-shaped maternity pillow as a positional therapy device for POSA, hypothesizing that its supportive design would effectively maintain lateral sleep positioning and improve respiratory outcomes.

Materials and methods: In this prospective pilot study, 18 adult patients with confirmed POSA (per Cartwright's criteria) were enrolled. The study protocol involved: (1) a baseline inpatient polysomnography (PSG) without intervention; (2) a two-week actigraphy period to establish baseline sleep patterns; (3) a subsequent inpatient PSG with the G-shaped maternity pillow; (4) Psychomotor Vigilance Task (PVT) testing pre- and post-intervention; and (5) validated sleep questionnaires (Karolinska Sleepiness Scale, Samn-Perelli Fatigue Scale, PANAS) to assess subjective sleep quality, alertness, and mood. Respiratory indices, sleep architecture, and sleep position data from the two PSGs were compared using paired statistical tests.

Results: Use of the maternity pillow resulted in a significant improvement in respiratory parameters. The median apnea-hypopnea index (AHI) decreased from 17.5 to 8.92 events/hour ($p<0.01$) and the oxygen desaturation index (ODI) from 14.8 to 6.41 events/hour ($p<0.01$). The pillow was highly effective in enforcing lateral sleep, increasing the median lateral sleep time from 19.7% to 84.2% of total sleep time ($p<0.01$). Although total sleep time and sleep efficiency decreased during the single-night intervention, participants demonstrated improved morning alertness on PVT testing (faster response times, $p=0.03$) and reported less fatigue ($p=0.02$). Patient acceptance was notably high, with 83.3% preferring the pillow over CPAP and 61.1% continuing its use post-study.

Conclusions: These preliminary findings suggest that a G-shaped maternity pillow is an effective and well-tolerated positional therapy for POSA, significantly reducing AHI and ODI by successfully promoting lateral sleep. Its high acceptance rate highlights its potential as a comfortable and accessible alternative for CPAP-intolerant patients. This study introduces a promising new category of positional therapy based on positive support rather than aversion. Larger, long-term trials with an acclimatization period are warranted to confirm these efficacy and compliance findings in a real-world setting.

An Integrated EEG-Respiratory Home Sleep Monitoring System for Sleep Staging and Arousal Detection in Obstructive Sleep Apnea Screening

W.-K. Lin¹, K.-Y. Chen², C.-W. Li², Y.-T. Sun³, C.-Y. Lin^{4,1}, S.-F. Liang²

¹Sleep Medicine Center, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan, ²Department of Computer Science and Information Engineering, National Cheng Kung University, Tainan, Taiwan, ³Institute of Medical Informatics, National Cheng Kung University, Tainan, Taiwan, ⁴Department of Otolaryngology, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan

Introduction: Obstructive sleep apnea (OSA) has a high prevalence and is associated with serious health risks, yet patients in Taiwan often face waiting periods exceeding six months for a polysomnography (PSG) test due to limited bed availability at sleep centers. Home sleep test offers an alternative approach to address this issue; however, current devices typically measure only respiratory parameters. The absence of EEG signals prevents the detection of arousal events, leading to an underestimation of the Apnea-Hypopnea Index (AHI). Moreover, without EEG data, it is difficult to objectively assess sleep quality impacted by OSA. Therefore, a home sleep monitoring system that integrates EEG and respiratory signals is highly desirable.

Materials and methods: We developed an integrated home-based sleep monitoring system combining a self developed EEG eye mask to capture Fp1, E2, and F3 channels with ApneaLink Air to measure airflow, respiratory effort, and oxygen saturation. This system enables synchronized, high-quality recording of both brain and respiratory signals over eight hour sleep periods. A scoring platform was also developed that integrates a web based scoring interface and assisted labeling of events and wave candidates for manual scoring. A validation study was conducted at National Cheng Kung University Hospital and the data from 21 participants (aged 25-67 years, AHI range: 5.8-72.6 events/hour) undergoing simultaneous overnight recordings using both our system and standard PSG. Sleep staging and arousal events were manually scored by clinical technicians. Agreement between the scoring results of the eye masks and the PSG was evaluated using mean differences for key sleep indices: Total Sleep Time (TST), Wake After Sleep Onset (WASO), Sleep Onset Latency (SOL), and Sleep Efficiency

(SE), kappa and average agreement for sleep staging, and correlation analysis for the arousal Index. These metrics were used to assess measurement consistency and potential bias.

Results: The mean differences between our system and PSG measurements were SOL = 0.07 minutes, WASO = 6.26 minutes, SE = -1.72%, and TST = -6.90 minutes. For sleep staging between our system and PSG, kappa = 0.81 with an agreement of 90.3%, based on a four-stage classification: Wake, Light sleep (combining N1 and N2), N3, and REM. A strong correlation ($r = 0.83$) was also observed for the arousal index. Furthermore, our system demonstrated significantly higher AHI and HI values compared to ApneaLink ($p < 0.001$), as the integration of EEG-based arousal detection enabled more accurate identification of respiratory-related events.

Conclusions: We propose an integrated EEG-respiratory home sleep monitoring system to enable synchronized, high-quality recording of brain and respiratory signals over eight-hour sleep periods. The validation experiments demonstrated high agreement between the proposed system and standard PSG across subjects with varying AHI severities. In addition, the EEG signals support the detection of arousal events, leading to more accurate AHI estimation. This system is expected to improve the quality of sleep diagnostics and help reduce wait times for sleep testing in the near future.

Acknowledgments: This study is supported by National Cheng Kung University Hospital (NCKUH-11407005) and the National Science and Technology Council (NSTC 113-2221-E-006-168), Taiwan.

A novel ECG-Based Machine Learning Pipeline for Screening Major Depressive Episodes in Sleep Disorder Patients

A. Defillo¹, M. Grassi^{1,2,3}, S. Dacco^{1,2,3}

¹Medibio Limited, Savage, United States, ²Humanitas University, Rozzano, Italy, ³Villa San Benedetto Menni, Albese con Cassan, Italy

Introduction: Major Depressive Episodes are a significant global health challenge, often co-occurring with sleep disorders. Accurate and efficient screening for current MDE (cMDE) in patients undergoing evaluation for sleep disturbances could improve diagnostic efficiency and treatment outcomes. Traditional diagnostic methods for cMDE, such as clinical interviews and questionnaires, are resource-intensive and require significant clinical expertise.

Advances in machine learning (ML) and physiological data analysis have opened new avenues for leveraging objective signals like ECG to screen for cMDE. Polysomnography routinely captures ECG signals, providing a unique opportunity to explore their potential in identifying autonomic and sleep-related patterns indicative of depressive symptoms.

This project aims to investigate the accuracy of a pipeline of ML algorithms that allow screening for cMDE using only ECG as a physiological signal in subjects undergoing in-patient polysomnography.

Materials and methods: 296 subjects from a recently completed prospective, single-arm, non-randomized cohort study have been used to investigate the screening performance of the cMDE determination pipeline compared to the MINI neuropsychiatric interview. All subjects recruited in this study were referred for inpatient polysomnography due to suspected sleep disorders.

The cMDE determination pipeline begins with a deep learning algorithm that classifies sleep stages using only the lead-II ECG signal. Subsequently, heart rate (HR) and heart rate variability (HRV) metrics are computed across the identified sleep stages, and macrostructure indices derived from the ECG-based sleep staging are calculated. Finally, HR and HRV metrics and macrostructure indices are combined with the responses to items 1 and 2 of the PHQ-9 questionnaire and used as input for an ML algorithm to perform the final cMDE determination.

Results: The observed sensitivity relative to the MINI cMDE determination was 80.85% (95% CI: 66.74%-90.85%), the specificity was 71.37% (95% CI: 65.31%-76.91%), the positive predictive value was 34.86% (95% CI: 25.99%-44.58%), and the negative predictive value was 95.16% (95% CI: 91.01%-97.76%).

Conclusions: The proposed machine learning pipeline leveraging the ECG as a physiological signal demonstrates promising potential as a screening tool for cMDE in patients undergoing polysomnography for suspected sleep disorders.

A novel, wearable, in-ear EEG technology to assess sleep and daytime sleepiness

P. Saini¹, J.B. Berent², S.-H. Hsu², M. Joyner², J. Dwyer², A. Specht², C. Dong¹, K. Borodin², S. Martin², P. Crum², D. Buhl³, D. Rye¹

¹Emory University, Department of Neurology, Atlanta, United States, ²Nextsense, San Francisco, United States, ³Sage Therapeutics Inc, Boston, United States

Introduction: In laboratory polysomnography (PSG) is the gold standard for assessing sleep and excessive daytime sleepiness (EDS), but is time, labor, and cost intensive and has limited diagnostic utility. Thus, a substantial unmet clinical need persists for measures that are more readily accessible and accurate for detecting sleep and EDS. Here, we describe the usability and validity of an in-ear electroencephalogram (Ear-EEG) device alongside PSG and maintenance of wakefulness testing (MWT) in healthy participants (NCT05114616), and participants with narcolepsy (NT) or idiopathic hypersomnia (IH), both on and off their wake-promoting medications (NCT05066009).

Materials and methods: Eight clinic patients with NT/IH underwent standard MWTs during two visits while wearing NextSense's Ear-EEG device, one during a site-blinded, randomized drug holiday to assess treatment effect. Sixteen healthy participants underwent 4-hour sleep-restricted PSG to assess increased sleep pressure during MWT. Subjective sleepiness (Karolinska Sleepiness Scale) was assessed post-MWT, whereas objective vigilance and working memory were assessed only after sessions 1 and 3 by Psychomotor Vigilance Task (PVT) and NBack Trials, respectively. Device comfort and usability were assessed by questionnaire. PSG and Ear-EEG recordings were scored for sleep stages independently by three scorers blind to subject and condition. Within-and-between rater agreement between PSG and Ear-EEG-based sleep staging was in accordance with AASM standards. Pre-trained SleepTransformer model was adapted to Ear-EEG via direct transfer and fine-tuning, with performance evaluated using Macro-F1 (MF1) and Cohen's Kappa. Mixed models were used to analyze sleep-related and treatment-related outcomes.

Results: There was high agreement between the accuracy of the 3 raters (82.7%) in healthy controls. The Nextsense Ear-EEG device demonstrated robust agreement with PSG for Wake (90%) and N2 (83%); moderate agreement for REM-sleep (74%), N3 (66%), and slightly lower for N1 (56%). Automatic scoring using the Sleep Transformer adapted to Ear-EEG resulted in a MF1 score of 80.0%, a Kappa coefficient of 85.8% with human scorers, and an accuracy (90.9%) superior to human annotators. Most metrics (SOL, TST, REM, N2/N3 durations and latencies, WASO, and SE) were similar between PSG-EEG and Ear-EEG (all $p > 0.05$), except that 5.63 min more N1 sleep was derived via Ear-EEG ($p = 0.0025$). The mean difference in SOLs during MWTs was small (-0.68 min, $p = 0.7321$), and even lower for overnight SOLs in healthy participants (-0.16 min, $p = 0.9034$). SOLs did not differ significantly between PSG-EEG or Ear-EEG, $p > 0.05$. In NT/IH, SOL was greater On-Drug compared to Off-Drug (21.49 ± 15.24 vs 7.93 ± 7.96 , $p = 2 \times 10^{-16}$). Vigilance was greater and less variable On-Drug than Off-Drug with these changes being associated with SOL (Interaction with Slowest 10% $p = 0.0003$ and Lapses $p = 0.003$). Working memory was faster but less accurate On-Drug than Off-Drug and associated with SOL (Interaction with Accuracy $p = .002$ and Correct RT $p = 2.59 \times 10^{-12}$). Participants reported the Ear-EEG as very comfortable on a 10-point scale (Healthy: 7.9 ± 1.3 , NT/IH: 8.7 ± 1.1).

Conclusions: NextSense's Ear-EEG device advances the collection of accurate sleep-wake state metrics reflective of clinically relevant signs and symptoms (e.g., sleepiness, vigilance, and memory). It offers a comfortable, accurate alternative to PSG for assessing sleep and daytime sleepiness.

Acknowledgments: The study was supported by Sage Therapeutics, Inc. and Nextsense.

Apnea Detector Across Multiple Cohorts Reaches Expert Level Performance

M.R. Kjaer^{1,2,3}, U. Hanif^{1,2,3}, A. Brink-Kjaer¹, M. Olsen^{1,2,3}, O. Sum-Ping³, O. Carrillo³, S.A. Sands⁴, S. Redline⁴, P. Jennum², E. Mignot³

¹Technical University of Denmark, Health Technology, Kongens Lyngby, Denmark, ²Danish Center for Sleep Medicine, Glostrup, Denmark, ³Stanford University, Stanford Center for Sleep Sciences and Medicine, United States, ⁴Harvard Medical School, Boston, United States

Introduction: Sleep disordered breathing (SDB), the repeated occurrence breathing events like obstructive apneas (OA), central apneas (CA), and hypopneas (HYPO), affects millions globally and contributes to significant morbidity. Diagnosing SDB requires manual scoring of polysomnography (PSG) recordings, a labor-intensive process marked by high inter-rater variability and inconsistent application of scoring rules. Despite the availability of automated scoring tools, most have limited

generalizability due to training on single-center datasets and an inability to distinguish among event subtypes. We developed the Apneic Breathing Event Detector (ABED), a deep learning-based tool designed to detect and classify OA, CA, HYPO, and isolated respiratory events without arousals or desaturations (IREs). ABED aims to increase accuracy, reduce scoring burden, and enable more consistent, scalable SDB evaluation across centers.

Materials and methods: ABED was trained on 5,456 full-night PSGs from four large cohorts available through the National Sleep Research Resource. An independent test set of 1,099 PSGs, spanning all four cohorts, was used for evaluation. In addition, ABED was tested on two external datasets including 113 subjects scored by multiple independent experts. Input channels included cannula flow, oral thermistor, thoracic and abdominal effort, SpO₂, and probabilities of wake and arousal derived from previously validated EEG-based models. Each PSG was processed in overlapping 240-second windows. ABED's deep learning architecture combined convolutional layers (based on a modified ResNet50), bi-directional LSTMs, and YOLO detection heads for event classification and localization.

Results: Across all test cohorts, ABED achieved a mean F1 score of 0.78 for apnea event detection, with specific F1 scores of 0.71 for OA, 0.51 for CA, and 0.65 for HYPO. The model also detected IREs, capturing events with clear respiratory effort reductions but no associated desaturations or arousals. Predicted apnea-hypopnea index (AHI) values strongly correlated with expert annotations ($R^2 = 0.84$), and ABED correctly classified sleep apnea severity in 75.3% of cases. In external, expert-scored datasets, ABED performed comparably or better than individual scorers, matching human-level detection accuracy across event types. Performance was robust to differences in scoring criteria and generalizable across sites and populations. Signal quality analysis revealed ABED maintained stable performance across a range of signal conditions, with mild degradation only for poor-quality thoracic excursions and EEG signals.

Conclusions: ABED is a robust and generalizable deep learning model for expert level automated detection and classification of SDB events, including less commonly recognized IREs. Its performance is consistent across diverse cohorts, hypopnea scoring definitions, and expert annotations, offering a scalable solution to address the current challenges of manual PSG scoring.

Apnea-Hypopnea Event Detection from 10-Second Sleep Audio Clips: A Machine Learning Model

E. Ma¹, C.-Y. Tsai², P.-Z. Wang³

¹Taipei American School, Taipei, Taiwan, ²Taipei Medical University, Taipei, Taiwan, ³Imperial College London, London, United Kingdom

Introduction: Sleep apnea is a prevalent sleep disorder with serious health consequences, underscoring the need for accurate and accessible detection methods. Current diagnostic standards, such as overnight polysomnography (PSG), are expensive and inconvenient. We propose a novel machine learning approach that utilizes pre-trained large audio models to analyze raw audio waveforms—such as 10-second segments of breathing or snoring sounds—for apnea detection. To enhance performance, we introduce a multi-task learning framework that addresses both apnea detection and sleep stage classification, leveraging the physiological relevance of sleep stages. This combination of a pre-trained audio encoder and multi-task learning is designed to improve generalization and robustness in identifying apnea events.

Materials and methods: The proposed framework comprises two main components: a pre-trained audio encoder and a multi-task classifier. We use HuBERT, a state-of-the-art self-supervised audio model, to convert raw 10-second waveform segments into compact feature embeddings. These embeddings serve as input to a downstream classifier consisting of a shared feature extractor ("bottom" network) followed by two task-specific branches: one for binary apnea classification (apnea vs. no-apnea) and another for sleep stage classification (Wake, REM, NREM). Each branch includes a lightweight task-specific encoder and prediction head built atop the shared representation. The model is trained end-to-end in a multi-task learning (MTL) setup, optimizing a combined loss from both tasks.

Incorporating sleep stage information provides important physiological context—for example, certain sleep stages may correlate with higher apnea occurrence—thereby guiding the model to learn more robust features that improve apnea detection.

Results: Preliminary evaluation on a held-out test set yielded promising performance. The proposed multi-task model achieved an accuracy of 84.8% and an area under the curve (AUC) of 0.810 for binary apnea classification. These results demonstrate that our model can reliably distinguish apnea events from normal breathing using only short audio segments. Importantly, incorporating sleep stage classification as an auxiliary task improved overall apnea detection performance compared to a single-task baseline, confirming the benefits of multi-task learning. We also employed a dynamic loss weighting strategy to balance optimization between the two tasks, which further enhanced training stability and performance. The current model architecture—comprising a HuBERT-based audio encoder and a shared-bottom, task-specific multi-task classifier—proved effective in learning generalizable audio features and context-aware physiological representations.

Conclusions: In conclusion, this study demonstrates that combining pre-trained large audio models with multi-task learning offers a promising approach for automatic sleep apnea detection. By leveraging HuBERT as an acoustic feature extractor and jointly training on apnea detection and sleep stage classification, the model captures both general audio patterns and context-specific physiological cues. The resulting accuracy and AUC indicate that this audio-based method can serve as a non-invasive, efficient tool for sleep apnea screening in both clinical and home settings. Future work will explore alternative foundation audio models, incorporate additional physiological signals, and validate the approach on larger and more diverse populations to support real-world deployment.

A randomized controlled trial to evaluate digital cognitive behavioral therapy for insomnia (CBT-I) with artificial intelligence chatbot for youth with insomnia: Preliminary results

T.M.H. Li¹, C.C.W. Cheng¹, R.W.L. So¹, N.Y. Chan¹, S.X. Li^{2,3}, J.W.Y. Chan¹, Y.K. Wing^{1,4}

¹The Chinese University of Hong Kong, Li Chiu Kong Family Sleep Assessment Unit, Department of Psychiatry, Hong Kong, Hong Kong, SAR of China, ²The University of Hong Kong, Department of Psychology, Hong Kong, Hong Kong, SAR of China, ³The University of Hong Kong, The State Key Laboratory of Brain and Cognitive Sciences, Hong Kong, Hong Kong, SAR of China, ⁴The Chinese University of Hong Kong, Li Ka Shing Institute of Health Sciences, Hong Kong, Hong Kong, SAR of China

Introduction: Digital cognitive behavioral therapy for insomnia (CBT-I) has shown to be effective in improving insomnia among youths. Research suggests that digital interventions are more effective when they incorporate interactive elements. Artificial intelligence (AI) chatbots have the potential to transform digital CBT-I into an interactive, conversational tool. This randomized controlled trial aims to evaluate the efficacy of an app-based CBT-I with an AI chatbot in alleviating insomnia symptoms in youths compared to an app-based CBT-I without an AI chatbot.

Materials and methods: The study was a randomized controlled trial that recruited participants aged 18-25 years with moderate to severe insomnia, as indicated by a score of 14 or higher on the Insomnia Severity Index (ISI), and meeting DSM-IV-TR criteria for insomnia disorder. Exclusion criteria encompassed a history of sleep disorders other than insomnia, mental retardation, serious suicidality, current pharmacological treatment, structured psychotherapy, or recent shiftwork/trans-meridian travel. Eligible participants were randomly assigned to either the intervention group, receiving an app-based CBT-I with AI chatbot, or the control group with an app-based CBT-I without AI chatbot, in a 1:1 ratio using permuted block randomization with block sizes of 2, 4, or 6 participants, stratified by gender and insomnia severity. Both interventions lasted for 28 days, with participants progressing through four CBT-I modules (28 daily units) sequentially. In the intervention group, participants interacted with the chatbot through free-text input or predefined response options, with the chatbot providing standardized statements and follow-up questions. Assessments were conducted at baseline (T0), 2-week interim (T1), post-intervention (T2), 3-month follow-up (T3), and 6-month follow-up (T4). An intent-to-treat analysis using a mixed-effects model for repeated measures was utilized to evaluate the effect on the primary outcome, the ISI.

Results: Among the 87 participants recruited, 44 participants (mean age=21.3±2.24 years; 61.4% female) were assigned to the intervention group, while 43 participants (mean age=21.0±2.29 years; 60.5% female) were allocated to the control group. Both groups exhibited significant improvements in

ISI scores at post-intervention ($d=2.15-2.41$, $p<.001$). However, the intervention did not yield a better treatment outcome compared to the control group ($d=0.37$, $p=.36$). Over the follow-up periods, the effect in the control group remained stable ($d=2.30-2.74$, $p<.001$), while the effect in the intervention group continued to increase ($d=3.53-3.71$, $p<.001$). By T4, a significant difference emerged between the control group (mean ISI= 12.0 ± 6.16) and the intervention group (mean ISI= 6.00 ± 4.83), indicating that the intervention group had more significant improvement (effect size $d=1.47$, $p=.04$). A significant time x group interaction effect ($\beta=-4.80$, 95% CI: -9.59 to -0.01 , $p=.04$) were observed.

Conclusions: The study is currently in progress with the goal of recruiting 168 participants. Preliminary findings suggest that utilizing an AI chatbot as a new tool to deliver digital CBT-I shows potential by providing interactive features and enhancing efficacy. This approach may increase service accessibility at a lower cost, potentially alleviating the worldwide impact of insomnia.

Are different Transcutaneous Carbon Dioxide (TcCO₂) monitor brands in positive correlation and agreement?

D. Slater¹, S. Sigauke¹, J. King¹, M. Urban¹, D. Wang¹

¹Canberra Hospital, Department of Respiratory and Sleep Medicine (DRSM), Garran, Australia

Introduction: Transcutaneous carbon dioxide (TcCO₂) measurement is essential for the diagnosis of nocturnal hypoventilation. These measurements however have a wide margin of error, with the literature stipulating the clinically acceptable range of TcCO₂ measurement being $\pm 7.5\text{mmHg}$ ($\pm 1\text{kPa}$). Sleep laboratories largely utilise the Sentec SDM™ or Radiometer TCM5™ for TcCO₂ measurement. To date, there are no studies that have investigated the agreement of these devices against each other. In this study, we investigated whether the TcCO₂ values derived from the Sentec SDM™ monitor correlated with the Radiometer TCM5, and comparing these measures to PCO₂ derived from Capillary Blood Gas (CBG). We also assessed how well these values agreed with each other. We hypothesised that there would be strong positive correlations between TcCO₂ measurements and PCO₂, and agreement would be observed between these measures.

Materials and methods: 59 patient measurements of TcCO₂ from Sentec™ and Radiometer™ probes were collected. The measurement site for the TcCO₂ probes was inferior to the clavicle, as recommended by Sentec™ and Radiometer™. PCO₂ was sampled via lancet prick at the earlobe for confirmation of TcCO₂ readings once stabilised prior to sleep study commencement (PM), and immediately on termination of the sleep study (AM). Data was assessed for normality. Correlation between metrics was assessed via Pearson and Spearman correlation coefficients. Agreement was assessed via Bland-Altman plots.

Results: Strong positive correlations were demonstrated between metrics (Correlation values ranged from 0.741-0.888, all p values < 0.001). Close agreement was demonstrated across all metrics.

Conclusions: This study demonstrated that TcCO₂ measured via Sentec SDM™ and the Radiometer TCM5™ were in strong positive correlation with each other and PCO₂, with these measurements showing agreement within the sleep laboratory context. This provides confidence to sleep laboratories that TcCO₂ monitor choice should not affect the quality of the data being collected. Most samples collected in this study however were normocapnic. Further investigation of agreement between these devices in cases of nocturnal hypoventilation is required to ensure condition diagnosis is consistent irrespective of the TcCO₂ monitor being used.

Acknowledgments: Thanks to Sentec for the provision of their SDM monitors for the study.

A Screening Alternative for Depressive Episodes in COMISA: A Comparative Evaluation of a Novel Software Compared to Neuropsychometric Assessments

A. Defillo¹, M. Grassi^{1,2,3}, S. Dacco^{1,2,3}

¹Medibio Limited, Savage, United States, ²Humanitas University, Rozzano, Italy, ³Villa San Benedetto Menni, Albese con Cassan, Italy

Introduction: In recent years, numerous studies have focused on enhancing the understanding of sleep disorders within military, veteran, and civilian populations. Among these, insomnia and obstructive sleep apnea (OSA) have emerged as the two most prevalent sleep disorders affecting both military personnel and civilians.

The term COMISA was introduced to describe the co-occurrence of insomnia and OSA, highlighting the significant burden associated with this dual condition. Research has shown that COMISA is associated with more severe mental health challenges compared to insomnia or OSA alone.

The aim of this study is to investigate the agreement between the determination for current Major Depressive Episodes (cMDE) made by the MEB-001 software (Medibio Limited) and the MINI's cMDE diagnosis across specific clinical subgroups. These include individuals with suspected insomnia but no confirmed sleep apnea, individuals with confirmed sleep apnea but no suspected insomnia, and those with COMISA.

Materials and methods: This study analyzes data from the recently completed prospective, single-arm, non-randomized cohort study. The subjects recruited in this study were referred for an inpatient polysomnography for suspected sleep disorders.

Results: In a preliminary analysis, in the subgroup of subjects with insomnia but no confirmed sleep apnea (n=55), the observed sensitivity relative to the MINI cMDE determination was 90.91% (95% CI: 58.72%-99.97%), the specificity was 61.36% (95% CI: 45.50%-75.64%), the PPV was 34.17% (95% CI: 9.69%-53.48%), and the NPV was 96.43% (95% CI: 81.65%-99.91%). Instead, in the COMISA subgroup (n=147), the observed sensitivity relative to the MINI cMDE determination was 88.46% (95% CI: 69.85%-97.55%), the specificity was 71.07% (95% CI: 62.13%-78.95%), the PPV was 39.66% (95% CI: 27.05%-53.36%) and the NPV was 96.63% (95% CI: 90.46%-99.30%).

Conclusions: The MEB-001 software demonstrated strong sensitivity and high negative predictive value for detecting current Major Depressive Episodes (cMDE) across clinical subgroups, particularly in individuals with COMISA and insomnia without sleep apnea.

A Smartphone-based Intervention to Improve Light Exposure in Young Adults

D. Mahfoud^{1,2}, Z. Tang¹, T. Vicknaswari¹, R. P. Najjar^{1,2,3}

¹National University of Singapore, Eye N' Brain Research Group, Department of Ophthalmology, Singapore, Singapore, ²Singapore Eye Research Institute, Visual Neurosciences, Singapore, Singapore, ³National University of Singapore, Department of Biomedical Engineering, Singapore, Singapore

Introduction: Light exposure patterns play a critical role in regulating circadian rhythms and promoting optimal sleep quality. Modern lifestyles often involve insufficient daytime sunlight exposure and excessive artificial light at night, disrupting sleep-wake cycles and impairing alertness and cognitive performance. Smartphone-based behavioural interventions offer a promising scalable approach to optimize individual light exposure and health. In this study, we introduce a novel, digital, smartphone-based intervention that tunes behaviour to optimize light exposure—enhancing daytime light intake while reducing nighttime exposure—with the goal of improving sleep quality and daytime functioning in young adults.

Materials and methods: Seventeen healthy young male adults (average age $\pm$ SD = 28.1 $\pm$ 4.5 years) participated in this study comprising a baseline and an intervention phase (10–14 days each). Light exposure was measured using wearable sensors with a 1-min sampling rate, for the continuous quantification of illuminance, spectral composition of light, and melanopic Equivalent Daylight Illuminance (mEDI). Daytime outdoor time (7AM–7PM) was estimated using a machine learning model trained to classify light data as indoor or outdoor. Sleep quality and duration were monitored using the same devices and sleep diaries. Baseline sleep quality and daytime sleepiness were assessed using the Pittsburgh Sleep Quality Index (PSQI) and the Epworth Sleepiness Scale (ESS), respectively. During the intervention phase, participants received personalized WhatsApp nudges encouraging greater daytime exposure and reduced evening exposure to light. Evening nudges were sent three hours before baseline average bedtime. Outcome measures included time spent outdoors and above the recommended 250 mEDI (in minutes and as a percentage of wear time), average mEDI levels during daytime, as well as sleep metrics (e.g. Bed time, Get up time, Time in bed, Sleep efficiency, number of awakenings, etc.).

Results: At baseline, participants reported a mean PSQI score of 5.6 $\pm$ 3.3 and an ESS score of 7.2 $\pm$ 3.3. The digital intervention successfully enhanced outdoor time in 14 out of 18 participants (77.8%).

That increment ranged between 4 to 78 minutes of outdoor time per day with improvements being more pronounced on weekdays compared to weekends. On average, on weekdays, daily outdoor time was increased from 84.6 ± 48.9 (at baseline) to 100.5 ± 51.7 minutes ($p = 0.03$). Accounting for the sensor's wear time, this translated to an increase from $12.6 \pm 7.2\%$ to $15.6 \pm 7.1\%$ ($p = 0.01$) of outdoor time during daytime. Time spent above 250 mEDI was also increased from $15.0 \pm 8.9\%$ to $18.7 \pm 9.2\%$ ($p = 0.008$). Additionally, mEDI levels increased marginally from 350.6 ± 280.2 lx to 470 ± 272.7 lx ($p=0.07$) during waketime. These outcome measures were not different between baseline and intervention on weekends. Nighttime mEDI levels and most sleep metrics were comparable between conditions, with fewer maximum awakenings during the intervention ($p=0.04$).

Conclusions: Our findings demonstrate the potential of a scalable smartphone-based intervention to enhance weekday light diets in young adults living busy, modern lifestyles. By significantly increasing daytime light exposure and mEDI, our approach holds promise for enhancing circadian alignment, reducing daytime sleepiness and performance, and improving nighttime sleep.

A technical and clinical validation of ElvySense Medical for sleep apnea diagnostics

S. Kainulainen^{1,2}, M. Vainikka¹, S. Häkkinen¹, M. Hiltunen¹, T. Laitinen¹, M. Rusanen^{1,3}

¹University of Eastern Finland, Department of Technical Physics, Kuopio, Finland, ²Kuopio University Hospital, Clinical Research Center, Kuopio, Finland, ³Kuopio University Hospital, Diagnostic Imaging Center, Kuopio, Finland

Introduction: Sleep apnea is a highly prevalent but underdiagnosed disease. Sleep registrations needed to confirm sleep apnea diagnosis require a high amount of manual labour, and currently these methods do not allow continuous follow-up measurements. In this study, we performed a technical and clinical validation for ElvySense Medical system that is a self-applied stand-alone device for sleep apnea detection. The device consists of a pressure-sensitive electromechanical film-like sensor placed under the mattress, an oximeter, a separate control device and an automated analysis software. It aims to fill current diagnostic gaps providing respiratory and associated event scoring and the possibility to use the device as an easy-to-use diagnostic and screening tool as well as a follow-up monitor.

Materials and methods: We recruited and measured 56 individuals (34.0% female, mean (SD) age = 51.6 (12.1), mean (SD) BMI = 30.8 (5.5)) based on clinical home sleep apnea test (HSAT) done at Kuopio University Hospital aiming at equal number of volunteers for each sleep apnea severity group. Based on baseline HSAT, 9 had no, 16 had mild, 16 had moderate and 15 had severe sleep apnea based on apnea-hypopnea index (AHI). The volunteers underwent type I polysomnography (PSG) at SmartSleep Laboratory (University of Eastern Finland, Kuopio, Finland) and simultaneous ElvySense Medical measurement before their possible treatment initiation. After scoring, the performance of ElvySense Medical was evaluated by first comparing the number of scored events and estimated sleep time. Second, we utilized Pearson's r and Wilcoxon's signed-rank to test the agreement of the PSG AHI and ElvySense Medical AHI. Third, we calculated the sensitivity and specificity of the ElvySense Medical in detecting moderate-to-severe sleep apnea.

Results: Measurements had 95% success rate: three measurements out of the total 56 failed due to a technical issue in the ElvySense Medical, leaving 53 recordings for the data analyses. Based on in-lab PSG, 6 had no, 12 had mild, 12 had moderate and 24 had severe sleep apnea. The median PSG AHI and ElvySense Medical AHI did not differ significantly (25.5 vs. 23.3, $p=0.13$) and the correlation between them was 0.79 ($p<0.01$). The ElvySense Medical differentiated those with $AHI \geq 15$ with a sensitivity of 94.3% and specificity of 72.2%. On average, ElvySense Medical scored 40.2 apneas more and 7.9 hypopneas less than was scored to PSG, utilizing 2.02 hours longer estimated sleep time than PSG-based total sleep time.

Conclusions: The ElvySense Medical system shows high sensitivity and acceptable specificity in differentiating individuals having moderate-to-severe sleep apnea from those being healthy or having mild sleep apnea with only a few failed measurements. The strong positive correlation between the AHI's indicates diagnostic accuracy comparable to standard HSAT with considerably less manual labour.

Acknowledgments: This validation study was funded by eLive Ecosystem Oy (ElvySense). The sponsor did not participate in the study design, recruitment, analyses, interpretation, or writing of this abstract.

Automated distinctive apnea type analysis from pulseoximetry signal only

N. Netzer¹, C. Schöbel², C. Siebenmann¹, D. Krefting³

¹Eurac Research, Institute of Mountain Emergency Medicine, Bozen, Italy, ²Ruhrland Klinik Universität Essen, Zentrum für Schlaf- und Telemedizin, Essen, Germany, ³University Göttingen, Medizinische Informatik, Göttingen, Germany

Introduction: The use of pulseoximetry and the signal of arterial oxygen saturation for early detection and screening of sleep disordered breathing based on the number of oxygen desaturations (ODI), the mean oxygen saturation and the time of oxygen saturation below 90% is widely acknowledged since the 1990's. In 2001 we presented in an overview in the journal Chest with figures of the different shapes of the oxygen saturation curve with the different types of apneas and hypopneas. At this time this was meant as an add on for the manual visual analysis of apneas and hypopneas. Now, with the increasing possibilities of AI supported automated analysis even in wearables it was time to consider using the findings of 2001 for a much advanced automated analysis of the oxygen saturation curve. The idea arose to use the angle of the uprising leg of the oxygen curve after the apneic dip to determine a mathematical value usable for further automated calculation.

Materials and methods: We put an angle on the visually recorded 50 each consecutive central, complex, and obstructive apneas as well as hypopneas from the polysomnographs (Sleep Doc Porti, Fenyves und Gut, Rangendingen, Germany) of five different male patients (mean age 62,4 years) and analyzed the mean difference of the angles of the different apnea types via T-test in MS Excel as well as we calculated the mean angles for the different apnea type.

Results: The angles of the uprising leg after desaturation dip of the different apnea types and hypopneas differ significantly ($p < 0.05$). The mean of the angle on the uprising leg of the oxygen saturation curve after a desaturation dip of central apneas is the most flat with an average of 27°. The average angles of obstructive apneas was the steepest with 79°, complex respectively mixed apneas had an average angle of 65° and hypopneas an significantly flatter angle of 33°.

Conclusions: The differentiation of the angles of the uprising leg of the oxygen saturation curve after a desaturation dip can most likely be used for an analysis of different apnea types without the need of the respiratory curves of respiratory belts or the the flow from a nasal thermistor or nasal pressure recording. With the help the learning possibilities (generative pretraining) of artificial intelligence and the use of such a technology built in wearables the distinction of central and obstructive sleep apnea, so far not possible without polygraphy or polysomnography, could be possible in the near future.

Automatic Nap Detection During MSLT and MWT Using Wearable Sensors in Patients with Sleep Disorders

O. Gnarra^{1,2}, N. Scherrer¹, J. Warncke³, J. van der Meer³, D. Paez-Granados^{1,2}, M. Schmidt³

¹ETH Zurich, Health Sciences and Technology, Zurich, Switzerland, ²Swiss Paraplegic Research (SPF), Nottwil, Switzerland, ³Inselspital, Bern University Hospital, University of Bern, Sleep-Wake Epilepsy Center, NeuroTec, Department of Neurology, Bern, Switzerland

Introduction: Short daytime sleep episodes, or naps, are increasingly recognized as valuable biomarkers for hypersomnolence and neurodegenerative conditions. Their accurate detection is important for diagnosis and disease monitoring. In clinical settings, naps are assessed via polysomnography (PSG) during the Multiple Sleep Latency Test (MSLT) and Maintenance of Wakefulness Test (MWT). While well-established, these procedures are labor-intensive and limited to single-day hospital-based recordings. Wearable devices offer a promising alternative for nap detection in real-life conditions. However, most existing algorithms are optimized for long-duration nocturnal sleep and perform poorly on shorter naps than one hour. This study aims for automatic short nap detection using data from a wristband (Empatica E4) recorded in parallel with PSG during MSLT and MWT in sleep patients with sleep disorders.

Materials and methods: Patients were recruited at the University Hospital of Bern, Switzerland. The dataset includes 188 Empatica recordings from 35 individuals with suspected or diagnosed sleep disorders, amounting to approximately 80 hours of raw signal data, including manual sleep staging by

clinical experts. The wristband provided 32 Hz accelerometer data and 1 Hz heart rate data, which were downsampled and combined to simulate the lower-resolution inputs typical of consumer-grade devices. To classify 30-second epochs as sleep or wake, we implemented a compact Temporal Convolutional Network. Inputs were structured into 270-second windows with a 30-second stride, and the network processed 1 Hz activity and heart rate signals through seven residual blocks using dilated convolutions, batch normalization, rectified linear unit activation function, and dropout. A time-distributed linear layer outputs a sleep probability for each epoch. The model was trained against manual sleep staging using class-weighted binary cross-entropy, the Adam optimizer, and early stopping. A 10% holdout set was reserved for final evaluation, while the remaining 90% was used for 5-fold cross-validation and hyperparameter tuning.

Results: On the independent holdout set, the model achieved an accuracy of 0.75, a precision of 0.67, a recall of 0.78, and an F1 score of 0.72 for the detection of short naps with an average duration of 15 minutes. These results demonstrate a clear improvement over naive baselines ("always wake," "always sleep," and class-balanced random), whose F1 scores ranged from 0 to 0.55. Performance was robust across participants, with the model successfully identifying short naps despite the subtle physiological changes and minimal movement typical of MSLT and MWT sessions.

Conclusions: The dataset poses inherent challenges: during MSLT and MWT, participants often remain physically still while awake, making activity-based sleep detection difficult; furthermore, heart rate changes may be subtle. Nevertheless, the model achieved strong performance under these conditions, suggesting good potential for generalization. Importantly, this approach uses only low-resolution features from widely used consumer wearables, making the model easily transferable to large datasets collected outside clinical settings. These encouraging results support future testing on larger, more diverse populations and in free-living conditions, with the potential to enhance large-scale nap detection from commercial devices. This model lays the foundation for real-world ambulatory monitoring of hypersomnolence and related disorders using wearable technologies.

A Web3-Based System for Decentralized Sleep and Circadian Health Data Sharing

N. Maeda-Nishino¹, M. Haas², N.-M. Ceornea²

¹Stanford University, Psychiatry, Stanford, United States, ²Freedom Factory, Newark, United States

Introduction: Sleep research is increasingly powered by wearable technology, yet data privacy, siloed storage, and limited participant agency remain challenges. We introduce a Web3-based platform that encrypts and decentralizes wearable-derived sleep data, allowing individuals to retain ownership while contributing anonymized datasets to collaborative research.

Materials and methods: We designed a pilot framework integrating wearable sleep tracking (commercial and custom devices) with decentralized storage via IPFS and public blockchain indexing. Users access personalized insights through AI-generated dashboards while retaining control over data-sharing permissions via smart contracts. A simulated cohort of 10 individuals was used to test feasibility, with live-user recruitment underway.

Results: System-level testing demonstrated successful data encryption, indexing, and retrieval across platforms. Users were able to view circadian alignment feedback and authorize selective data access. Early user feedback suggests interest in both the privacy-preserving model and personalized insights, though usability testing is ongoing.

Conclusions:

This technology demonstrates the feasibility of integrating Web3 infrastructure with sleep and circadian monitoring. While full-scale deployment is in progress, this prototype points to a future of participant-driven research ecosystems with increased transparency, scalability, and trust. We anticipate expanding to real-world trials and open-science collaborations in 2025–2026.

Acknowledgments: We thank the Stanford Sleep and Circadian Neurobiology Lab for scientific input and Freedom Factory for development support. Additional thanks to early testers and advisors in digital health and decentralized technologies.

Benchmarking Reveals Shared Biases in Sleep-Staging Algorithms and Points to Age-Aware Solutions

M. Bechny^{1,2}, A. Dei Rossi³, M. Metaldi², J. van der Meer⁴, M. Schmidt⁴, C. Bassetti⁴, A. Tzovara¹, F. Faraci², L. Fiorillo^{2,5}

¹University of Bern, Bern, Switzerland, ²SUPSI-MeDiTech, Lugano-Viganello, Switzerland, ³Università della Svizzera Italiana, Lugano-Viganello, Switzerland, ⁴Inselspital, Universitätsspital Bern, Bern, Switzerland, ⁵Ente Ospedaliero Cantonale, Lugano, Switzerland

Introduction: Deep learning (DL) algorithms (models) hold promise for automating the labor-intensive task of sleep-staging. Yet, clinical adoption remains limited due to inter-scorer variability, partly stemming from ambiguities in AASM guidelines¹, which constrains model performance and hinders translation. Debates over optimal DL architectures are further complicated by heterogeneous datasets and inconsistent validation protocols. While standardized benchmarking is key, it must be paired with subgroup-specific performance analysis. To address this, we trained state-of-the-art DL-models within a harmonized, large-scale benchmarking framework and evaluated them using a robust, distribution-aware approach to quantify systematic biases.

Materials and methods: We leveraged DL-models from the SLEEPYLAND² benchmarking platform (U-Sleep³, DeepResNet⁴, SleepTransformer⁵), pre-trained on over 27,000 harmonized PSGs from 17 public datasets using standardized pipelines to ensure comparability. These models were then evaluated on 6,633 out-of-distribution PSGs from the Bern Sleep-Wake Registry⁶, spanning ages 0-88 and diverse clinical conditions. To assess bias in individual sleep-scoring models, we applied a GAMLSS-based framework^{7,8} that quantifies the full distribution of both model performance metrics (e.g., macro- or stage-specific F1-score) and errors in prediction-derived clinical markers (e.g., sleep-stage durations, number of stage-transitions). This approach captures non-linear effects of age while adjusting for covariates such as gender, AHI, and PLMI, characterizing individual health status. Beyond mean trends, it quantifies variability and extremes, and enables formal testing of how these variables shape model behavior, offering a comprehensive view of clinically relevant, variable-driven biases.

Results: Despite architectural differences, all models showed similar average performance (macro-F1 $\approx$ 0.75) and exhibited consistent bias patterns. Performance declined markedly at age extremes, especially in children, reflecting underrepresentation in training data and differences in AASM scoring rules. Non-linear age-related biases were observed across all performance metrics and prediction-derived clinical markers. Higher AHI and PLMI were associated with greater errors and variability, likely due to fragmented sleep and signal artifacts. Among stages, N1 remained the most challenging (F1 $\approx$ 0.45), while REM and wake were the most reliable. All models consistently overestimated WASO, and consequently the number of awakenings, and underestimated N3 duration, with the strongest biases observed in younger and high-AHI subgroups. Notably, stage transitions were systematically undercounted, producing overly smoothed hypnograms, likely a result of loss functions used during DL-model optimization.

Conclusions: Our analysis shows that performance and marker biases in DL-based sleep-staging are consistent across architectures and primarily driven by demographic and clinical factors, rather than model design. These findings underscore the need for structured validation of algorithm behavior across real-world subgroups. Our GAMLSS-based framework supports this by quantifying full distributions of performance and marker errors, and identifying sources of systematic bias. Strong non-linear age effects, likely reflecting AASM scoring differences between pediatric and adult populations, suggest that future DL-models could benefit from incorporating age as their input. Additionally, training strategies such as targeted upsampling of underrepresented groups may help mitigate imbalance-driven bias. Given the consistency of bias patterns across models, future progress in automated sleep-staging should prioritize subgroup-aware mitigation strategies over further architectural innovation, to ensure fair and clinically reliable deployment.

Beyond Conventional Sleep: Modelling Diverse Sleep Behaviours Using Personalized Sleep Probability

C.S. Soon¹, X.Y. Chua¹, M.W.L. Chee¹

¹National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore

Introduction: Traditional sleep research has largely focused on the assessment of a single, consolidated nocturnal sleep period. While mostly effective for individuals with conventional sleep patterns, current data pre-processing / processing approaches are often unsuitable for persons with irregular or unconventional sleep schedules, such as shift workers or those with polyphasic sleep habits who often do not have a well-defined “main” sleep period. To more accurately capture such non-canonical sleep in community dwelling individuals, we propose a novel method that utilizes a personalized sleep probability model for identifying main sleep periods across individuals.

Materials and methods: For each individual, a 24-hour mean sleep probability profile is first constructed using multiple days of wearable-derived sleep-wake data, i.e., the likelihood that someone is asleep at any time of the day (15min resolution), including main sleep and naps. The mean sleep probability captures an individual's sleep habit over time. Sleep episodes detected are then weighted according to the individual's mean sleep probability profile, matched to the time-of-day at which they occur. Sleep episodes separated by short wake gaps during typical sleep periods (i.e., high mean sleep probability) are concatenated. For each day, the sleep episode occurring between 1800h the previous day and 1759h the current day with the highest cumulative sleep probability weighted TST is then identified as the main sleep period. This method accounts for both intra- and inter-individual variability in sleep patterns without assuming a fixed circadian timing.

Results: This approach was validated in a diverse sample of 2351 individuals (1268 female, 53.9%) across varying age groups, from 18 to 80 years old (mean 52.0, S.D. 23.8), including university students, working adults, and older adults. Here, our method demonstrated robustness in identifying main sleep periods across heterogeneous sleep patterns, with preference given to sleep episodes during an individual's typical sleep hours, but also accommodating deviations on irregular days. Multiple sleep episodes may be detected within an individual's typical sleep window, particularly among older adults experiencing high sleep fragmentation. The sleep probability model effectively identified and merged these fragmented episodes, capturing them as components of a single, extended sleep period.

Conclusions: This personalized 24-hour sleep probability framework provides a standardized yet adaptable method for identifying main sleep periods in wearable- or nearable- based sleep studies. It enables comparability of main sleep periods across individuals with irregular sleep behaviours to support the characterization of sleep in a broader and more diverse population. While the current evaluation focused on retrospective analyses, the approach can be readily adapted for prospective applications. For example, baseline or moving-window sleep probability can inform wearables when to increase sensor sensitivity to facilitate detection of the Time an individual is Attempting to Sleep (TATS Start Time), or to distinguish between transient wakefulness and the true end of a sleep episode. Sleep probability modelling can also be used to track seasonal shifts in sleep timing.

Bright White Light Reduces Early Afternoon Alertness Decline in Healthy Adults

S. Lou¹, S. Hu¹, Y. Chen¹, Y. Zhou¹, J. Hou², L. Liang², H. Sun¹

¹Peking University Sixth Hospital, Peking University Institute of Mental Health, NHC Key Laboratory of Mental Health (Peking University), National Clinical Research Center for Mental Disorders (Peking University Sixth Hospital), Beijing, China, ²Peking University Health Science Center, Beijing, China

Introduction: Decreased alertness impairs individual judgment, leading to more human errors, decreased work efficiency, and even increased risk of accidents. Light exposure has been shown to

modulate alertness, but the optimal intensity for afternoon settings remains unclear. This study aimed to examine the effects of different light intensities on afternoon alertness in healthy adults.

Materials and methods: 82 healthy subjects aged 18 to 45 years were enrolled and block-randomly assigned to four light intensity groups: 2500 lux group (n = 21), 5000 lux group (n = 20), 7500 lux group (n = 21), and 10000 lux group (n = 20). Two subjects who violated the protocol were excluded, and finally 80 subjects (20 in each group) were included in the statistical analysis. The experiment was completed within two consecutive days (baseline day and intervention day). On the baseline day, the starting time point of the subjects' afternoon sleepiness was set as the 0 minute. During the subsequent 90 minutes, subjective alertness scoring (Karolinska Sleepiness Scale, KSS), objective alertness testing (10-minute Psychomotor Vigilance Task, PVT) and saliva cortisol collection were carried out every 30 minutes. On the intervention day, continuous light exposure for 30 minutes was given starting from the 0th minute. The procedures for collecting subjective and objective alertness and saliva cortisol were exactly the same as those on the baseline day.

Results: Statistical analyses were performed using two-way repeated measures ANOVA to assess the effects of light intensity and time on alertness. Results showed significant between-group differences in the slowest 10% reaction speed of the PVT ($F(3, 76) = 4.100, p = 0.009$). Post hoc analysis revealed that the reaction speed in the 10000 lux group was significantly lower than that in the other three groups, and the group×time interaction effect was significant ($F(3, 76) = 2.056, p = 0.031$). No significant differences were observed in KSS scores or cortisol levels among groups. Subsequently, using paired t-tests, the study found that compared with the baseline day: In the 2500 lux group, the KSS scores decreased significantly at 90 min ($t = 2.595, p = 0.018$). In the 5000 lux group, the KSS scores decreased significantly at 30 min ($t = 2.223, p = 0.039$), and the slowest 10% PVT reaction speed decreased significantly at 30 min ($t = 3.399, p = 0.003$) and 90 min ($t = 2.602, p = 0.018$). In the 10000 lux group, the KSS scores at 30 min ($t = 2.517, p = 0.021$) and 90 min ($t = 3.559, p = 0.002$) were significantly decreased, and the slowest 10% PVT reaction speed at the onset of light exposure ($t = 3.216, p = 0.005$) was significantly decreased.

Conclusions: The study concludes that 2500 lux, 5000 lux, and 10000 lux light exposure reduce subjective alertness decline, and the higher the intensity, the faster the effect. The 10000 lux light exposure has the most pronounced impact on objective alertness in the early afternoon. Future research should explore the underlying mechanisms and long-term effects of high-intensity light exposure.

Can Large language models be used to perform clinical evaluation for patients reporting sleep disorders ? A proof of concept comparing human versus LLM performed medical diagnosis

F. Pecune¹, X. Blanc², J. Coelho^{1,3}, P. Philip^{1,3}

¹University of Bordeaux, CNRS, Sanpsy, UMR6033, Bordeaux, France, ²University of Bordeaux, CNRS, LaBRI, UMR5800, Talence, France, ³CHU de Bordeaux, Sleep Medicine Service, Bordeaux, France

Introduction: Sleep related disorders are increasingly prevalent worldwide, yet there remains a significant gap between clinical needs and physicians availability. To help address this, advances in Large Language Models (LLMs) offer promising tools for supporting sleep doctors in clinical diagnosis. LLMs have been successfully applied to clinical tasks such as information extraction and patient report summarization. The DSM-5 R criteria provide a structured and standardized system for diagnosing sleep related disorders, with clear guidelines on symptom classification across various syndromes or pathologies. A diagnostic tool that incorporates DSM-5 R criteria and LLMs could theoretically assist clinicians in identifying sleep related symptoms and disorders more efficiently and consistently.

Materials and methods: We collected clinical interviews of 67 patients performed by 2 sleep specialists from the sleep department of the University Hospital of Bordeaux. The interviews were de-identified, transcribed, and independently analyzed by both clinicians, who assigned diagnoses following a list of twelve sleep-related disorders defined by the DSM-5 R classification. We developed a total of 36 large language model (LLM)-based systems to generate diagnostic hypotheses from clinical interview transcripts. Each system integrates one of 12 distinct LLMs—ranging from the smallest (LLaMA 3.1 with 8 million parameters) to the largest (GPT-4o)—and implements one of three prompting strategies. These include: (1) zero-shot prompting, which directly poses the diagnostic question to the model; (2) chain-of-thought prompting, which guides the model through a structured reasoning process; and (3) prompt chaining, which simulates a multi-agent dialogue. This experimental design allows for a robust

comparative analysis of both the diagnostic capabilities of the LLMs and the impact of the prompting strategies. To evaluate performance, we compared each system's diagnostic outputs with clinical assessments provided by human specialists.

Results: Our preliminary findings demonstrate a clear influence of LLM size on the diagnostic performance of our systems. Small-scale models (approximately 8 million parameters) yield poor results, frequently producing hallucinations by suggesting pathologies not identified by clinicians. In contrast, medium-sized models (ranging from 24 million to 70 million parameters) achieve sensitivity and specificity scores exceeding 70%. The largest models, such as GPT-4o, attain scores above 90% for both metrics. Interestingly, our initial analysis indicates that the choice of prompting strategy has a minor impact on diagnostic accuracy. Contrary to expectations, the most straightforward approach—zero-shot prompting—consistently outperforms more complex methods. This suggests that allowing the LLM to operate with minimal guidance may be more effective in this context.

Conclusions:

Our proof of concept demonstrates that large language models can approach or even match specialists-level performance in diagnosing sleep disorders from transcribed patient interviews. While prompting strategy has a limited effect, model size plays a critical role in diagnostic accuracy. These findings raise important ethical questions. While larger LLMs show superior diagnostic performance, their reliance on cloud-based infrastructure poses challenges for clinical deployment. This trade-off between performance and privacy highlights the need for further development of high-performing models that can run securely in local clinical environments.

Can the alpha power of the electroencephalogram (EEG) signal during the eyes-closed calibration of the Multiple Sleep Latency Test (MSLT) first nap predict daytime hypersomnolence?

J. Eritaia¹, D. Pazeski¹, S. Gyulay¹, D.B. Brew^{2,3}, D.V. George^{1,3}, D.S. Pradeepan^{1,3}

¹John Hunter Hospital, Respiratory and Sleep Medicine, New Lambton Heights, Australia, ²University of Newcastle, School of Medicine and Public Health, Newcastle, Australia, ³Hunter Medical Research Institute, Asthma and Breathing, New Lambton Heights, Australia

Introduction: Hypersomnolence poses significant medical risks, including driving risks. A sleep latency of 8 minutes or less, as measured by the Multiple Sleep Latency Test (MSLT), indicates clinical sleepiness. However, MSLT is time-consuming and resource intensive. An alternative, simple method would be valuable.

This study evaluates whether EEG total alpha power (TAP) from the 20-second eyes closed calibration exercise conducted before the start of nap 1 of the MSLT can predict sleep latency (MSL) as a measure of daytime hypersomnolence

Materials and methods: We retrospectively collected data from 400 consecutive polysomnography (PSG) and MSLT sleep studies conducted between January 2022 and February 2025 at an Australian tertiary hospital. Participants were prohibited from alcohol and caffeine during the tests as per the laboratory standard procedure. Exclusions included PSG reports with an Apnea-Hypopnea Index (AHI) ≥ 15 , Total Sleep Time (TST) < 6 hours, or Sleep Efficiency (SE) $< 75\%$ ($n=156$), and MSLT data with poor EEG quality and different montages ($n=37$).

We extracted alpha frequency components of EEG from the occipital (O1 & O2) and frontal (F3 & F4) lobes using digital filtering (filter settings of 8 Hz for the low pass and 12 Hz for the high pass).

To calculate total alpha power (TAP), alpha waves were transformed using a Fast Fourier Transformation algorithm (LabChart8, ADInstruments) before generating TAP values from each of the 4 signals using the 20-second segment of the eyes-closed manoeuvre at the start of nap 1. We averaged, then categorized TAP values from the frontal channels (F-TAP) and occipital channels (O-TAP) into 3 groups of low TAP ($< 20 \mu V^2$), medium TAP ($20-40 \mu V^2$), and high TAP ($> 40 \mu V^2$). Mean sleep latency

was compared to the 3 groups using a one-way ANOVA and post hoc tests ($p < 0.05$). Analyses were conducted using IBM SPSS Version 30.

Results: After exclusion, PSG/MSLT data were analyzed for 207 participants, age range 16-68 years, 65% were female ($n=134$).

The MSL mean values increased by F-TAP groups: low F-TAP ($n=92$) 8.35 ± 4.62 , medium F-TAP ($n=66$) 8.62 ± 5.09 , and high F-TAP ($n=49$) 9.76 ± 5.13 .

Similarly, the MSL mean values increased by O-TAP groups: low O-TAP ($n=55$) 8.21 ± 4.64 , medium O-TAP ($n=43$) 8.94 ± 5.03 , and high O-TAP ($n=109$) 8.99 ± 5.00 .

However, the one-way ANOVA analyses showed no significant difference in the mean of MSL between the 3 groups of F-TAP ($p = 0.26$) or O-TAP ($p = 0.616$), nor were significant differences found in post-hoc pairwise comparisons.

A correlation was observed between MSL and F3_TAP ($p=0.015$), but not with the other channels (F4_TAP $p=0.186$; O1_TAP $p=0.855$; O2_TAP $p=0.588$).

Conclusions: We observed some evidence that higher alpha power from the frontal lobe may be associated with increased sleep latency, though this finding requires more data and further examination of the impact of various medications and incorporating an arousal index threshold into the exclusion criteria.

Acknowledgments: To all the staff at the John Hunter Hospital adult sleep laboratory and the patients, thank you.

Chaos Theory Mathematically Characterizes EEG Brain Wave Patterns of Emotions

C.-B. Chen², Y. Wang², T. Imamura¹⁰, I. Tapia², V. Somers⁷, P. Zee⁹, D. Lim¹

¹University of Miami, Miami, United States, ²University of Pennsylvania, Philadelphia, United States,

³Mayo Clinic, Rochester, United States, ⁴Northwestern University, Chicago, United States, ⁵Miami VA, Medicine, Miami, United States

Introduction: What is “chaos theory”?

“Chaos” is when an observer perceives a dynamic system (e.g., weather or global economy) to be unpredictable and complex, noisy or disorderly. However, under the “chaos” are deterministic laws that give rise to structures and patterns.

A popular phrase within chaos theory is “the butterfly effect” where a tiny change in the atmosphere can lead to large-scale changes in weather e.g., hurricane.

The brain, a dynamic system, can be evaluated using 62-dimensions (or leads) of EEG data. On the surface, this can look “chaotic,” however, under the “chaos” are deterministic laws e.g., effect of sympathetic response during a nightmare on sleep/wake, daytime fatigue or hypertension. These deterministic laws give rise to specific brain structures and collectively, patterns.

Why we care about developing a methodology to identify emotions using 62-lead EEG data?

Emotions are a clear outcome that allows us to quickly develop methods to analyze high dimensional data captured by 62-dimensions of EEG data.

Once optimized, these methods can be adapted for clinical use, where big, high dimensional, dynamic data is collected. This includes the ICU, polysomnograms, 30-day Holter Monitors, wearables (over years/decades), and even histological slides.

Objective

To develop a novel methodology that uses chaos theory to mathematically describe (e.g., quantitative metrics) complex interactions and patterns of the brain using 62-lead EEG data. Then use AI to analyze the metrics to find patterns that correlate to 4 specific emotions (e.g., neutral, sad, fear, happy). Each step should be optimized to RETAIN all high dimensional data (nonlinear, unbiased) while balancing computing power (keeping it low).

Materials and methods: The proposed methodology was evaluated using the SJTU-SEED IV database. We first applied uniform manifold approximation and projection (UMAP) for manifold embedding of the

62-lead EEG signals into a lower-dimensional space. We then developed MHRA to characterize the complex recurrence dynamics of brain activity across multiple transition levels. Finally, we employed tree-based ensemble learning methods to classify four emotions (neutral, sad, fear, happy) based on the extracted MHRA features.

Results: Our approach achieved high performance, with an accuracy of 0.7885 and an AUC of 0.7552, outperforming existing methods on the same dataset. Additionally, our methodology provided the most consistent recognition performance across different emotions. Sensitivity analysis revealed specific MHRA metrics that were strongly associated with each emotion, offering valuable insights into the underlying neural dynamics.

Conclusions: 1. We developed a novel methodology, Multilevel Heterogeneous Recurrence Analysis (MHRA), which embeds the interactions underlying 62 dimensions of data to 4 dimensions, extract dynamic features of the pattern of interactions, derive thousands of quantitative metrics that describe the patterns and use ensemble learning to find patterns that classify 4 emotions.

2. Implication for the sleep field: MRHA outperforms Deep Learning alone in terms of Accuracy to identify 4 emotions. This will allow us to quantitate subtle, complex patterns within brain activity that can be applied to dynamic EEG polysomnogram data.

Clinical Application of a Polysomnography Report with an AI-Assisted Summary

K.-Y. Chen¹

¹Lo-Tung Poh-Ai Hospital, Pulmonary and Critical Care Medicine 2 internal Medicine, Luodong Township, Taiwan

Introduction: The interpretation of polysomnography (PSG) reports in clinical practice traditionally focuses on the Apnea-Hypopnea Index (AHI), often overlooking the complex interplay of underlying pathophysiological traits that define a patient's Obstructive Sleep Apnea (OSA). The Phenotyping Using Polysomnography (PUP) approach allows for the non-invasive estimation of these traits—including Loop Gain (LG), Arousal Threshold (AT), Anatomical Collapsibility (Pcrit), and Pharyngeal Compensation. However, manual calculation and interpretation of these traits are complex and not widely integrated into routine clinical workflows. We aimed to develop a novel tool to bridge this gap.

Materials and methods: We developed a web-based application utilizing a multimodal AI model (Google's Gemini) to automate the analysis of PSG reports during the study period of 2025/May/1 to 2025/Jun/26. The tool's workflow involves: (1) user upload of a standard PSG report image; (2) AI-powered extraction of key parameters (AHI, respiratory event counts, SaO₂, arousal index, sleep architecture); (3) execution of a rule-based algorithm, informed by recent literature, to score and rank the four primary PUP traits based on the extracted data; and (4) dynamic generation of a structured, downloadable PDF report that presents the data and a prioritized analysis of the likely pathophysiological drivers for the specific case. It is important to note that all figures and data transferred to the Large Language Model (LLM) for calculation are anonymous and free from any personal information to ensure patient privacy.

Results: The AI-assisted tool successfully automates the translation of a static PSG report image into a dynamic, interpretable summary. It generates an instantaneous analysis that prioritizes the patient's likely OSA endotypes. The final report provides clinicians with a clear, ranked list of the contributing physiological traits (e.g., "1. High Loop Gain," "2. Low Arousal Threshold"), along with data-driven justifications for the ranking. This output facilitates a more nuanced understanding of the individual patient's disease beyond a single AHI value.

Conclusions: This AI-assisted application demonstrates a practical and rapid method for integrating advanced PUP-based phenotyping into routine clinical practice. By automating the data extraction and analysis process, this tool has the potential to enhance clinical decision-making, facilitate the development of personalized treatment strategies for OSA, and ultimately improve patient outcomes by connecting complex sleep physiology research with day-to-day clinical care.

Comparative Study of Polysomnography and HSAT levels in Diagnosis of Sleep Apnea and Analysis of Subsequent Treatment Uptake in 300 Patients

P. Jayaram¹, P. Karkera^{1,2}, K.V Vyshna¹

¹SleepMed Solutions, Bengaluru, India, ²Ramaiah Institute of Technology, Department of Biotechnology, Bengaluru, India

Introduction: Obstructive Sleep Apnea (OSA) is a common but frequently underdiagnosed sleep disorder with significant health consequences, including increased risk of cardiovascular disease, metabolic dysfunction, and impaired quality of life. Early and accurate diagnosis, followed by prompt initiation of appropriate therapy, is essential for mitigating these risks and improving patient outcomes. Sleep studies-ranging from in-lab polysomnography (PSG) to home-based testing-are the cornerstone of OSA diagnosis. However, the pathway from diagnosis to treatment can be influenced by the type of diagnostic modality used, patient engagement, and the structure of follow-up care. This study aims to evaluate the distribution of sleep study types and analyse treatment initiation rates at SleepMed Solutions, a tertiary sleep centre in Bengaluru, India.

Materials and methods: • **Study Design:** Retrospective analysis

• **Setting:** SleepMed Solutions, Bengaluru, Karnataka, India

• **Study Period:** January 2024 – January 2025

• **Total Sleep Studies:** 301

• **Modalities:**

Level 1: In-lab polysomnography (n=61)

Level 2: Home polysomnography (n=132)

Level 3: Home Sleep Apnea Test (HSAT) (n=108)

• **Data Collected:** Number of studies by type, number of patients initiating treatment, number not taking treatment, number not meeting doctor post-diagnosis.

• **Analysis:** Calculation of treatment initiation rates by modality.

Results: In a study of 301 patients, the distribution of sleep study modalities was as follows: 61 patients underwent in-lab polysomnography (Level 1), 132 had home polysomnography (Level 2), and 108 completed home sleep apnea testing (HSAT, Level 3).

The rates of treatment initiation varied significantly by modality. In-lab polysomnography (Level 1) had the highest treatment uptake, with 70.49% of patients starting therapy after diagnosis; this equated to 43 patients out of 61. Home polysomnography (Level 2) showed a moderate initiation rate of 57.58%, with 76 patients taking treatment out of 132. In contrast, HSAT (Level 3) had the lowest uptake at 44.44%, with 48 patients out of 108 beginning treatment.

Overall, the treatment initiation rate across all modalities was 55.48%. Notably, 281 patients met with a doctor following their diagnosis, while 20 did not attend a post-diagnostic consultation.

These findings indicate that patients diagnosed through in-lab polysomnography are more likely to initiate treatment compared to those diagnosed via home-based modalities. This could be attributed to the comprehensive nature of in-lab studies, structured patient counselling, and immediate access to healthcare providers. Conversely, the lower uptake rates in home-based studies, particularly HSAT, may reflect milder disease severity, reduced patient engagement, or logistical challenges in follow-up. These disparities highlight the importance of providing robust post-diagnostic support and patient education, especially for those undergoing home-based testing.

Conclusions: In-lab polysomnography is associated with the highest rates of treatment initiation among patients diagnosed with OSA at SleepMed Solutions. Home-based diagnostic modalities, while increasing accessibility, are linked to lower treatment uptake. To enhance overall outcomes in OSA management, targeted interventions to improve patient engagement and follow-up after home-based diagnoses are warranted.

Acknowledgments: We thank the staff at SleepMed Solutions, Bengaluru and clinicians who referred patients to SleepMed for their diligent data collection and patient care. Special appreciation to the patients who participated in this study and contributed to advancing sleep medicine research.

COMPARISON AMONG GUIDELINES AND FRAMEWORKS FOR THE VALIDATION OF NEW SLEEP TECHNOLOGIES

G.N. Pires¹, E.S. Arnardóttir^{2,3}, A.S. Islind³, H. Korkalainen^{4,5}, T. Leppänen^{4,5,6}, T. Penzel⁷, W.T. McNicholas⁸

¹Universidade Federal de São Paulo, Departamento de Psicobiologia, São Paulo, Brazil, ²Reykjavík University, Sleep Institute, Reykjavík, Iceland, ³Reykjavík University, Department of Computer Science, Reykjavík, Iceland, ⁴University of Eastern Finland, Department of Technical Physics, Kuopio, Finland, ⁵Kuopio University Hospital, Diagnostic Imaging Center, Kuopio, Finland, ⁶University of Queensland, School of Electrical Engineering and Computer Science, Brisbane, Australia, ⁷Charité Universitätsmedizin, Germany, Brazil, ⁸St Vincent's Hospital Group, Department of Respiratory and Sleep Medicine, Dublin, Ireland

Introduction: Sleep medicine is witnessing a revolution in the development and implementation of new sleep technologies (NSTs), including both consumer sleep technologies and those directed to healthcare professionals. Despite the rising trust in NSTs, concerns have been raised regarding their diagnostic accuracy, therapeutic effectiveness, and overall reliability. Due to concerns about the low methodological quality of the validation studies, there is a need for structured guidelines and recommendations to standardize the development and validation processes of NSTs. The current work overviews the currently available guidelines for the development and validation of NSTs.

Materials and methods: NSTs were contextualized as those that fulfil the following criteria: 1. Are not currently considered as gold-standard procedures, 2. Are innovative technologies, or significant improvements in standard technologies, 3. Are intended to be used either by the consumer/patient or by healthcare professionals, and 4. Are mainly related to software or hardware developments. Based on a literature review, guidelines and methodological frameworks for the development and validation of NSTs were identified. Information was extracted regarding the coverage of these guidelines, their targeted sleep condition, targeted type of NST, involvement of stakeholders, and methodological approaches for issuing recommendations.

Results: Five guidelines related to the development of NSTs were found, published since 2020, which demonstrate that the field is still in development. Regarding targeted sleep conditions, two were devoted to sleep scoring, one to point-of-care obstructive sleep apnea (OSA) screening, and two to overall sleep monitoring. Altogether, all guidelines were related to diagnostic technologies, while none were devoted to the validation of therapeutic technologies (such as digital cognitive-behavioral therapy for insomnia (CBT-I), or treatment devices for OSA). Regarding the targeted type of NST, all were devoted to consumer sleep technologies, with two being specifically directed to wearable devices. None were directed to the standardization of medical-grade NSTs. Three of them involved the participation of important stakeholders in sleep research (Sleep Research Society, the Sleep Health Journal, and the World Sleep Society). Regarding the methodological approach, most of them are unclear or have not followed standard procedures for evidence synthesis or the establishment of consensus.

Conclusions: As NSTs have become widely accessible and are utilized by consumers and healthcare providers, the process of development and validation of these technologies should follow rigorous methodological standards. The guidelines analyzed provide actionable items to assist researchers and manufacturers, and represent valuable contributions towards the standardization of the development and validation of NSTs. However, significant challenges persist, including the absence of guidelines for therapeutic technologies (e.g. CBT-I apps and OSA treatment devices) and medical-grade devices, and the non-adherence to standard guidelines or consensus development techniques.

Comparison of cardiovascular disease mortality outcomes using oximetry event desaturation transient area-based methods

S. He¹, P. Cistulli², P. de Chazal¹

¹The University of Sydney, Charles Perkins Centre/ School of Biomedical Engineering, Camperdown, Australia, ²The University of Sydney, Charles Perkins Centre/ Royal North Shore Hospital, Sydney, Australia

Introduction: Desaturation area-based parameters derived from oximetry have recently emerged as novel predictors of cardiovascular disease (CVD) mortality in the context of obstructive sleep apnoea (OSA). Recent studies have proposed a novel desaturation area-based parameter, which may provide better prediction of CVD outcomes in community population and chronic heart failure-free population. Desaturation area-based parameters measure the desaturation event transient area under the oximetry trace during sleep but there are different variations in calculations. These different calculation methods can be categorised by their dependence on respiratory event scoring, the definition of sampling window, or their choice of baseline. Among parameters based on manually scored respiratory events, hypoxic burden (HB) and respiratory event desaturation transient area (REDTA) have been used for predicting CVD outcomes. HB is calculated by an event-specific baseline and a record-specific sampling window, while the sampling window and baseline of REDTA are fixed for all recordings and events.

Materials and methods: We evaluated the six possible combinations of baseline (event-specific, record-specific, or fixed) and sampling window (record-specific or fixed) to find an easy-to-calculate yet effective method area for predicting CVD mortality. The Sleep Heart Health Study data and corresponding CVD mortality outcomes were utilized. The predictive performance of each method was assessed by Cox proportional hazard regression analysis with adjustment for relevant covariates. To enable direct comparison of the areas, each area was normalised to a z-score. Normalization was performed by subtracting the mean value of each set of desaturation areas and dividing by its standard deviation accordingly. Based on normalised area values, the corresponding hazard ratios (HR) were calculated by the adjusted and unadjusted Cox proportional hazard regression models. The performance of each area-based method in predicting CVD mortality was compared based on the hazard ratios and the p-values.

Results: Results show that an area method using a record-specific baseline and a fixed sampling window and an area method using a record-specific baseline and sampling window performed the best.

Conclusions: We explored different calculation methods for desaturation area-based parameters and comprehensively compared their performance in predicting CVD mortality. The results show that a method using a fixed sampling window and a record-specific baseline to prevent noise interference and reduce computational complexity had the best performance.

Comparison of conventional and extended middle meatal antrostomy for the treatment of antrochoanal polyps with snore

Z. Lou¹, Z. Lou², Z. Chen²

¹Wenzhou medical university affiliated Yiwu Hospital, Yiwu, China, ²Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Department of Otolaryngology Head and Neck Surgery, Shanghai, China

Introduction: Objective: The objective was to compare the recurrence rate and complications between endoscopic middle meatal antrostomy (MMA) and extended MMA for the treatment of antrochoanal polyps with (ACPs) with snore.

Materials and methods: Methods and materials: 95 ACPs were prospectively enrolled to undergo MMA (n=48) or extended MMA (n=47). The recurrence rate and complications were compared between these groups.

Results: Results: All patients completed 24 months of follow-up. The recurrence of ACP was demonstrated by only endoscope at 6 and 12 months postoperatively but at 24 months postoperatively by endoscope and CT. Rates of recurrence of ACP differed between groups and significance at postoperative month 6 (7/48 patients in the MMA group and 0/47 patients in the extended MMA group, $P=0.02$), month 12 (16/48 vs. 2/47, $P<0.01$) and month 24 (21/48 vs. 3/47, $P<0.01$). No MMA closure was found in any group, 19.15% (9/47) patients complained of cheek numbness in the extended MMA group, however, no major complications were observed in both groups.

Conclusions: Conclusions: Extended MMA via antidromic extended medial wall of MS may effectively reduce the recurrence of ACP with lower complications.

Contactless objective sleep monitoring of inpatients at a psychiatric hospital

H.S.A. Heglum¹, D. Vethe², S. Lydersen¹, K. Langsrud², H. Kallestad^{1,2}

¹Norwegian University of Science and Technology, Trondheim, Norway, ²St. Olavs University Hospital, Trondheim, Norway

Introduction: Patient monitoring in acute psychiatric settings has remained largely unchanged for over a century, relying heavily on subjective staff observations. Low tolerance for on-body sensor equipment and high demands for sensitivity and privacy has made objective monitoring in this setting particularly challenging. There has been a critical gap in the use of objective tools to assess patients' physiological states and symptom trajectories. This study examines one way of performing objective characterization of sleep among acutely admitted psychiatric inpatients through the use of contactless, unobtrusive movement data measured with a radar sensor. The aim of this study was to explore radar technology as a tool for objective monitoring and characterization of sleep of psychiatric inpatients.

Materials and methods: All 40 bedrooms of an acute psychiatric hospital were equipped with contactless ceiling-mounted radar sensors able to record the movement of patients within the rooms and provide objective estimates of their sleep. In total, 1791 days of radar data were recorded from 327 unique hospital admissions (age 36.4 ± 13.9 (mean $\pm$ SD), 43% male, days admitted 6.4 ± 7.6). Primary diagnosis from hospital records were used to categorize patients in four groups: Severe depressive episode, psychosis, manic episode, and "other diagnoses".

An actigraphy-inspired model was applied to estimate the sleep/wake state of the patients from their radar-recorded body movement, and a heuristic sleep onset/offset search was performed to estimate their primary sleep period. Total sleep time (TST) was calculated as the patient's total duration of sleep within the primary sleep period for each day of the admission. A linear mixed model was used to evaluate TST over the course of admissions for the four diagnostic groups.

Results: At admission, the "other diagnosis" group (N=237, mean duration of admission 4.3 ± 4.8 days) had an estimated mean TST of 8.8 hours (95% confidence interval (CI) [8.5, 9.3]). Patients in a manic episode (N=17, mean duration of admission 17.2 ± 11.6 days), had 4.7 hours (95%CI [6.0, 3.3], $p < 0.001$) lower estimated mean TST at admission compared with the "other diagnosis" group, with an increase in TST per day of the admission of 12.7 minutes (CI [3.8, 21.7], $p < 0.001$). There were no significant differences for the depression or the psychosis subgroups compared with the "other diagnosis" group.

Conclusions: Clinically meaningful differences in sleep patterns can be detected in a feasible way using ceiling mounted radar sensors. We observe that both the amount of sleep at admission and the trajectory of sleep across an acute admission differs between distinct diagnostic groups.

Contactless Oxygen Desaturation Prediction and ODI Estimation from Nocturnal Breathing Sounds via Deep Learning

E. Cho¹, S. Kim¹, J. Hong¹, H. Kyung¹, S.Y. Kim¹, I.-Y. Yoon², J.H. Lee³, J.-W. Kim⁴, Y.-S. Chung⁵, D. Lee¹

¹Asleep Inc., Seoul, Korea, Republic of, ²Seoul National University College of Medicine, Seoul National University Bundang Hospital, Department of Psychiatry, Seongnam, Korea, Republic of, ³Dream Sleep Clinic, Seoul, Korea, Republic of, ⁴Seoul National University College of Medicine, Seoul National University Bundang Hospital, Department of Otorhinolaryngology-Head and Neck Surgery, Seongnam, Korea, Republic of, ⁵University of Ulsan, College of Medicine, Asan Medical Center, Department of Otorhinolaryngology-Head and Neck Surgery, Seoul, Korea, Republic of

Introduction:

Intermittent hypoxemia in obstructive sleep apnea (OSA), often termed "hypoxic burden," has emerged as a superior predictor of cardiovascular morbidity and mortality compared to the Apnea-Hypopnea Index (AHI). Although direct measurement of hypoxic burden requires high-resolution oximetry, the Oxygen Desaturation Index (ODI) - the average number of $\geq 4\%$ desaturation events per hour - serves as a well-validated proxy that correlates with cardiovascular outcomes. Conventional ODI assessment necessitates pulse oximetry during full polysomnography (PSG), limiting its scalability for home screening of at-risk populations. Given that apneas and hypopneas commonly lead to oxygen desaturation, and building on our previous work predicting OSA events using a sound-based AI model, we developed an AI model to directly detect desaturation events from nocturnal breathing sounds. This

approach aims to broaden access and enable contactless estimation of hypoxic burden via its surrogate, the ODI.

Materials and methods: We trained our binary classifier on 2,973 nights of synchronized PSG recordings - both hospital- and home-based - with audio captured via smartphone and PSG equipment. Ground-truth ODI values for the independent test cohort of 802 anonymized subjects (mean age 50.5 ± 15.4 years; BMI 25.5 ± 3.6 ; male:female = 530:272) were derived from oximetry during PSG. For each 30-second epoch, the model processes 80 consecutive Mel-spectrogram frames to decide whether a desaturation event occurred. By counting the number of epochs predicted as desaturation per hour, we obtain an estimated ODI for each night. Model performance was assessed at the epoch level using sensitivity, specificity, precision, recall, and F1 score; overall classification accuracy and macro-averaged F1; and agreement between estimated ODI and ground truth ODI was quantified via Pearson correlation and Bland-Altman analysis.

Results: On the test set, our model achieved a sensitivity of 0.79 and specificity of 0.95 for the desaturation detection, with a corresponding precision of 0.78 and an F1 score of 0.79 via each 30-second epoch by epoch evaluation. Overall classification accuracy reached 0.92, with a macro F1 of 0.87. Estimated ODI correlated strongly with ground-truth ODI (Pearson $r = 0.93$, $p < 0.001$). The mean true ODI was 17.71 events/hour, versus a mean estimated ODI of 17.92 events/hour. Bland-Altman analysis showed a mean difference of -0.21 events/hour (SD of differences: 6.91), with 95% limits of agreement from -13.75 to 13.32 events/hour. In binary classification, for ODI cutoff values of 5, 15, and 30 events/hr, the sensitivity was 0.92, 0.86, and 0.82, respectively, and the specificity was 0.89, 0.92, and 0.96, respectively.

Conclusions:

Our sound-based AI model achieves high accuracy in desaturation detection and reliable ODI estimation, matching oximetry-derived measures at the group level. By eliminating contact sensors, it enables scalable home screening for intermittent hypoxemia - a key factor in cardiovascular risk assessment. Integrating this approach with simultaneous AHI inference could deliver a comprehensive, non-contact sleep assessment platform. Future work will target individual-level precision improvements and prospective validation in community settings.

Deep Learning-based Detection of Atrial Fibrillation in Patients with Suspected Obstructive Sleep Apnea Undergoing Portable Sleep Monitoring

P.H. Gianjoppe dos Santos¹, P. Rodrigues Rocha¹, D. Munduruca Domingues¹, J.P. Walsh Crema¹, S. Quaglia de Campos Giampá², P. Rodrigues Genta², G. Lorenzi-Filho^{2,1}

¹Biologix Sistemas S.A., São Paulo, Brazil, ²Instituto do Coração, InCor, Hospital das Clínicas HCFMUSP, Universidade de São Paulo, Laboratório do Sono, LIM 63, Divisão de Pneumologia, São Paulo, Brazil

Introduction: Atrial fibrillation (AF) is the most common arrhythmia and is associated with increased cardiac risk. Its prevalence is notably higher among patients with obstructive sleep apnea (OSA). However, systematic AF screening during sleep monitoring remains uncommon. This study aimed to: 1) develop and validate a deep neural network (DNN) algorithm for automated AF detection using electrocardiogram (ECG)-derived RR intervals, and 2) evaluate its applicability to pulse-to-pulse (PP) intervals derived from photoplethysmography (PPG) in patients with suspected OSA undergoing portable sleep monitoring with the Biologix system.

Materials and methods: The study consisted of two phases. **Phase 1** involved developing a DNN model using four public long-duration ECG databases (MIT-BIH Atrial Fibrillation, MIT-BIH Normal Sinus Rhythm, Normal Sinus Rhythm RR Interval, and IRIDIA-AF), totaling 40.14 million annotated heartbeats from 249 subjects, including 10.56 million AF-labeled beats (26.31%). The model architecture comprised stacked bidirectional long short-term memory (biLSTM) layers, max pooling, and fully connected ReLU-activated layers. It classified windows of 60 consecutive RR intervals as AF or non-AF, requiring six cumulative minutes of AF-positive segments to classify a patient exam as positive, a threshold set to reduce false positives from transient irregularities. The dataset was split into training (90%) and hold-out test (10%) sets. Performance was evaluated over the training set via 10-fold cross-validation stratified by patient and validated on the independent test set. Beat-level performance was further

stratified by heart rate (HR): bradycardia (<60 bpm), normal (60–100 bpm), and tachycardia (>100 bpm). **Phase 2** involved testing the algorithm developed in Phase 1 in patients who underwent simultaneous type 1 polysomnography (PSG) and monitoring with Biologix oximeter (Oxistar™, Biologix Sistemas S.A., Brazil), which consists of a high-resolution oximeter with a built-in accelerometer, a smartphone app for recording snoring, and cloud-based analysis. AF detection using PPG signals from the Biologix oximeter was compared with single-lead ECG from PSG.

Results: Phase 1: Cross-validation showed strong beat-level performance, with an area under the curve (AUC) of 0.994 ± 0.003 , sensitivity of $96.6\% \pm 2.2\%$, specificity of $97.6\% \pm 1.0\%$, and accuracy of $97.4\% \pm 0.6\%$. Sensitivity across HR ranges was 94.5% (<60 bpm), 96.6% (60–100 bpm), and 96.7% (>100 bpm); corresponding specificities were 98.9%, 98.5%, and 89.9%, respectively. Patient-level analysis yielded an AUC of 0.957 ± 0.029 , sensitivity of $91.3\% \pm 5.8\%$, specificity of 100%, and accuracy of $94.1\% \pm 3.8\%$. On the hold-out test set, beat-level AUC was 0.994 with an accuracy of 99.4%, while patient-level AUC was 0.971, sensitivity 94.1%, and specificity 100%. **Phase 2:** PSG and Biologix assessments were conducted simultaneously in 220 patients with suspected OSA. All seven ECG-confirmed AF cases were correctly identified by PPG-based classification. Sensitivity, specificity, and accuracy for PPG detection were each 100%.

Conclusions: The proposed DNN algorithm reliably detects AF from PPG-derived PP intervals acquired by the Biologix system, enabling systematic AF screening during sleep assessments in patients with suspected OSA.

DeepSpecFusion: Early Fusion Transformer for sleep staging using PSG

H. Yang¹, Y.-H. Park², K. Park², M. Lee², E.-I. Park¹, U-G. Ji¹, J.-M. Lee^{1,3}

¹Hanyang University, Department of Artificial Intelligence, Seoul, Korea, Republic of, ²Hyundai Mobis Co., Ltd, Seoul, Korea, Republic of, ³Hanyang University, Department of Biomedical Engineering, Seoul, Korea, Republic of

Introduction: Sleep stage classification is a crucial component in assessing sleep quality and associated pathologies. Manual sleep staging is an inefficient process requiring significant time and labor investment. Recent studies have employed late fusion architectures to extract information from multiple PSG channels including EEG, EOG, and EMG. However, cognitive psychology and neuroscience research demonstrates that multimodal fusion can occur early in the perceptual stack, enabling deeper integration of modalities. In this study, we propose DeepSpecFusion, an early fusion transformer-based model for automatic sleep staging using polysomnographic records.

Materials and methods: The DeepSpecFusion model employs a multi-channel fusion encoder based on transformer architecture that tokenizes along the time axis. We utilized continuous wavelet transform (CWT) instead of short-time Fourier transform (STFT) to generate spectrograms for improved sleep stage classification. The core mechanism involves random initialized fusion tokens updated through factorized channel interactions using cross-attention mechanisms. Pre-training was conducted using masked autoencoder (MAE) methodology, masking and restoring 50% of tokens to learn complex inter-channel interactions. Two public datasets were used: SleepEDF-78 (78 subjects, Fpz-Cz EEG/Pz-Oz EEG/ROC-LOC EOG) and SHHS (300 subjects, C3/C4 EEG/EOG_L/EOG_R/Chin EMG). Performance was evaluated using accuracy, macro F1-score, and sensitivity metrics.

Results: The proposed DeepSpecFusion model demonstrated superior performance compared to MultichannelSleepNet baseline across both datasets. On SleepEDF-78, we achieved accuracy of 82.69%, F1-score of 80.93%, and sensitivity of 82.93% versus baseline performance of 81.67%, 73.54%, and 73.75%, respectively. On SHHS dataset, our model achieved accuracy of 87.03%, F1-score of 80.83%, and sensitivity of 86.21% compared to baseline performance of 86.94%, 80.07%, and 81.63%, respectively. The model showed particularly improved performance in N1 stage classification across all sleep stages.

Conclusions: We demonstrated that early fusion transformer architecture successfully integrates multi-channel PSG features, yielding improved classification performance across all sleep stages, especially N1, relative to late fusion approaches. However, N1/N2 classification remains challenging for both baseline and proposed models, requiring further investigation to resolve class confusion. Our results

represent the potential of early fusion paradigms for enhanced sleep stage classification using polysomnographic signals.

Delivering Sleep Hygiene Interventions through Smartwatch-based Serious Sleep Games

N.H. Hoang¹, J. Villeneuve², H. Morrison³, A. Tu², T. Karunaratna¹, D. Hwang⁴, S. Chen⁴, K. Khotchasing¹, Z. Liang¹, E. Melcer²

¹Kyoto University of Advanced Science (KUAS), Faculty of Engineering, Kyoto, Japan, ²Carleton University, School of Computer Science, Ottawa, Canada, ³Ohio State University, Department of Computer Engineering, Columbus, United States, ⁴University of California, Santa Cruz, Santa Cruz, United States

Introduction: Sleep hygiene is a foundational element of cognitive behavioral therapy for insomnia (CBT-I). There is established evidence that sleep hygiene can positively impact sleep quality, with effects that often sustain beyond the intervention period. However, existing sleep hygiene programs largely rely on instruction and user self-discipline, which poses engagement challenges, especially among younger populations. The objective of this study is to explore alternative medium for delivering interventions so that it becomes easier for young users to follow through.

Materials and methods: We adopted an interdisciplinary approach integrating the sleep hygiene components of the CBT-I protocol, serious game design principles, and co-design methodology. This approach ensures that the intervention remains clinically aligned while enhancing user engagement through gamified experiences. Smartwatches were selected as the delivery platform, given their low blue-light emission and minimal sleep disruption compared to smartphones or large computer displays.

Results: The study progressed in two phases. Phase-I involved three empathy workshops with 51 university students aged 18 to 35. These workshops identified key factors contributing to sleep disturbances, including excessive screen time, stress, anxiety, irregular sleep schedules, poor eating habits, and uncomfortable sleep environments. These findings align with previous research. However, an interesting insight was that participants did not always view late-night disruptions as negative. For some, staying up late was a choice for creativity or productivity, not just procrastination. This challenges the conventional view that sleep disruptions should always be avoided, emphasizing the value of the co-design approach. The workshops generated design ideas to address these sleep disturbances and improve existing technologies. Proposed solutions included automated sleep environment optimization, screen time regulation, relaxation techniques, AI-driven sleep induction, and smoother transitions from sleep to wakefulness. These ideas emphasized actionable interventions targeting behavioral and psychological changes. Based on these insights, the research team developed three sleep game prototypes. In phase-II, a design workshop collected feedback on the three prototypes: Hero's Sleep Journey, Sleep Tamagochi, and Sleepland. We found that Hero's Sleep Journey was the most popular game, but Sleep Tamagochi was considered the most effective for improving sleep health. We also found that the preferred timing for interacting with each sleep game features varies depending on users' availability, their situated context, and the perceived functions of the feature.

Conclusions: Our findings suggest that smartwatch serious games can serve as a promising medium to foster sleep hygiene in young populations. Future designs should create games that resonate with users' personal lives, health goals, and situational contexts. A variety of game genres and features should be offered to cater to diverse needs. Moreover, allowing users to customize their experience and set technology boundaries will help foster a sense of control and autonomy in improving sleep hygiene.

Acknowledgments: This study was supported by JSPS KAKENHI (21K17670) and Kyoto University of Advanced Science (KUAS) Overseas Collaboration Grant. The author would also like to thank the workshop participants.

Detection of Arousal Epochs During Sleep Using a Sound-Based AI Model

S. Kim¹, E. Cho¹, D. Lee¹, J. Lee¹, T. Hong¹, N. Kim¹, D. Yoon¹, I.-Y. Yoon², M. Lee³, H. Choi⁴, K.-Y. Jung⁵

¹Asleep Inc., Seoul, Korea, Republic of, ²Seoul National University College of Medicine, Seoul National University Bundang Hospital, Department of Psychiatry, Seongnam, Korea, Republic of,

³Soonchunhyang University Seoul Hospital, Department of Psychiatry, Seoul, Korea, Republic of, ⁴Veterans Health Service Medical Center, Department of Psychiatry, Seoul, Korea, Republic of, ⁵Seoul National University College of Medicine, Seoul National University Hospital, Department of Neurology, Seoul, Korea, Republic of

Introduction: This study investigates the feasibility of detecting arousals using a sound-based AI model for sleep analysis. Arousals - brief awakenings during sleep marked by abrupt EEG shifts lasting at least 3 seconds - are clinically important indicators of sleep quality and are commonly used in diagnosing sleep disorders. However, their detection currently relies on polysomnography (PSG), which is costly, time-consuming, and impractical for long-term home-based monitoring. Previously, we demonstrated that our sound-based AI model accurately predicts sleep stages and sleep apnea events. Given that arousals are accompanied by characteristic changes in breathing - such as transient increases in ventilation and reduced inspiratory duration due to sympathetic activation - we hypothesized that nocturnal breathing sounds could also be used to infer arousal events.

Materials and methods: We developed a single-task classifier for arousal detection. The model processes 80 consecutive Mel spectrograms, each representing a 30-second epoch, to extract breathing-related acoustic features, and performs a three-class classification (sleep, wake, arousal). The training dataset included 2,973 nights comprising hospital PSG recordings (with PSG equipment audio or smartphone audio) and home PSG recordings (with smartphone audio). An independent test set of 802 nights was used for evaluation (mean age: 50.5 ± 15.4 years; BMI: 25.5 ± 3.6 ; AHI: 21.2 ± 20.6 ; male:female = 530:272). Model performance was evaluated on an epoch-by-epoch basis using sensitivity, specificity, F1 score, and area under the precision-recall curve (AUPRC) and receiver operating characteristic curve (AUROC). In addition, nightly arousal epoch counts predicted by the model were compared with PSG-derived reference counts.

Results: For detecting arousal-containing epochs, the model achieved a sensitivity of 0.65, specificity of 0.91, and an F1 score of 0.63. The AUPRC and AUROC for arousal detection were 0.64 and 0.88, respectively. For wake and sleep epochs, the model showed sensitivity, specificity, and F1 scores of 0.75 / 0.96 / 0.80 and 0.89 / 0.78 / 0.88, respectively. Overall three-stage classification resulted in an accuracy of 82.52% and a macro F1 score of 0.77. Predicted nightly arousal epoch counts correlated strongly with PSG-derived counts ($r = 0.92$), with mean predicted and actual values of 160.5 and 150.8, respectively.

Conclusions: Accurate estimation of arousal significantly enhances the capabilities of sound-based AI models for comprehensive sleep monitoring, particularly as a cost-effective, contactless home-based solution. The approach provides valuable insights into sleep quality by enriching diagnostic detail. Future developments will focus on improving the temporal resolution to capture brief arousal events effectively, enhancing the precision of arousal index predictions essential for detailed sleep assessments.

Development of a battery-free, wirelessly-controlled system for optogenetic stimulation of hypoglossal nucleus in mouse models of obstructive sleep apnea

G. Zoccoli¹, E. Augello², G. Battistini², C. Berteotti¹, D. Coraci¹, V. Lo Martire¹, M. Lops¹, E. Miglioranza¹, G. Paolini², A. Silvani¹, E. Volino¹, A. Costanzo², S. Bastianini¹

¹Alma Mater Studiorum - University of Bologna, Department of Biomedical and Neuromotor Sciences, Bologna, Italy, ²Alma Mater Studiorum - University of Bologna, Department of Electrical, Electronic, and Information Engineering "Guglielmo Marconi", Bologna, Italy

Introduction: Obstructive sleep apnea (OSA) is characterized by upper airway obstruction, usually caused by muscle hypotonia during sleep, especially REM sleep. Obstruction can be prevented by inducing contraction of these muscles during REM sleep. An innovative approach, testable on OSA murine models, is the activation of hypoglossal innervated muscles by optogenetic stimulation of their motoneurons. However, optogenetic currently available devices may impact on mouse sleep behaviour and are hardly compatible with use inside a whole-body plethysmograph, necessary for continuous monitoring of respiration. The aim of this study was to design a wireless power transfer (WPT) system based on a subcutaneous device to be used on mouse models of OSA.

Materials and methods: This system is based on an inductive coupling operating at a frequency of 13.56 MHz. It features a multi-coil array transmitter (TX) integrated into the semi-cylindrical wall of an

experimental chamber (height and radius = 50 mm). The TX array consists of 5 series-connected coils, 4 of which are made up of 2 rectangular turns and are located on the lateral wall; the fifth, a circular coil with a radius of 35 mm, is positioned at the bottom of the chamber. The receiver (RX), implantable subcutaneously in the mouse, consists of two identical rectangular coils, each composed of 5 turns, with dimensions of 14 x 15 mm². The shape, size and arrangement of the TX and RX coils have been optimized to obtain an omnidirectional and uniform distribution of the magnetic field inside the chamber, and to maximize the collected power independently of the movements or orientation of the mouse. This results in reliable operation of the selected optogenetic LED (wavelength = 470 nm).

Results: The system was first simulated and optimized using circuit simulation software to meet the power consumption requirements of the selected LED. Next, the fabricated prototype was tested with the RX device moving in six different positions with a transmitted power of approximately 740 mW. The worst-case scenario corresponds to the RX device at the edge of the TX system, far from the side coils and significantly misaligned compared to the one on the floor. In this case, the measured available rectified power is 14.7 mW.

Conclusions: Our system consistently meets the power demand and can maintain uninterrupted operation of the LEDs for effective optogenetic neurostimulation, even under the most challenging mouse positioning and orientation conditions. From a translational perspective, it may lead to the development of innovative therapeutic approaches for OSA.

Development of a Machine Learning Model to Estimate Psychomotor Vigilance Response Speed from Eyelid Opening Degree

T. Noguchi¹, H. Ando², T. Abe³

¹Ph.D. Program in Humanics, University of Tsukuba, Tsukuba, Japan, ²Advanced Institute for Materials Research, Tohoku University, Sendai, Japan, ³International Institute for Integrative Sleep Medicine (WPI-IIIS), Tsukuba Institute for Advanced Research (TIAR), University of Tsukuba, Tsukuba, Japan

Introduction: Responsiveness to stimuli declines under conditions such as sleepiness, leading to errors and reduced performance in tasks like driving. We previously developed a machine learning model to estimate response speed in the Psychomotor Vigilance Test (PVT)–quantified as reciprocal reaction time (RRT)–using eyelid opening degree measured by non-contact eye-tracking cameras under daily sleep conditions (Noguchi et al., 2024, ASSM). The present study aimed to improve the model's estimation accuracy by expanding the training dataset. Additionally, we evaluated whether the updated model could estimate PVT RRT under sleep deprivation. Since the PVT does not require eye movements, we also investigated whether estimated PVT RRT would similarly decrease during a visual search task (VST), which involves eye movements, under sleep-deprived conditions.

Materials and methods: We previously constructed a dataset comprising eyelid opening measurements from 98 healthy participants during a 40-minute PVT under daily sleep conditions, collected via eye-tracking camera (Taniguchi & Noguchi et al., 2023). To enhance estimation accuracy, we conducted hyperparameter tuning for a Gradient Boosting Decision Tree (GBDT) model across 100 randomized runs, selecting the most frequently occurring optimal hyperparameters to build the final model. For validation, 18 healthy participants (16 males; mean age 23.7 ± 6.4 years) completed a 10-minute PVT and an 8-minute VST before and after a night of either 8-hour normal sleep or total sleep deprivation. Eyelid opening degrees, collected during both tasks, were used to estimate PVT RRT.

Results: When the model trained on daily sleep condition data was applied to both normal sleep and sleep-deprived conditions, the intraclass correlation coefficient (ICC) between observed and estimated PVT RRT was 0.52, indicating moderate agreement. In the PVT, both observed and estimated PVT RRT significantly decreased after sleep deprivation compared to normal sleep ($p < 0.001$ for both). Similarly, in the VST, both observed VST RRT and estimated PVT RRT significantly decreased after sleep deprivation ($p < 0.001$ for both).

Conclusions: The model achieved moderate estimation accuracy, as indicated by the ICC. Notably, estimated PVT RRT significantly declined under sleep deprivation during both the PVT and VST, supporting the model's applicability under sleep-deprived conditions and in tasks involving eye

movements. Incorporating sleep deprivation data into the training set may further improve model performance in future studies.

DREEMER: Toolbox to manage and process Waveband data locally

K. Wong¹, J. Ong¹, M. Chee¹

¹National University of Singapore, Medicine, Singapore, Singapore

Introduction: The Beacon Biosignals Waveband allows for easy home-based EEG-derived sleep monitoring. Although the Waveband does not use the typical electrode montage, the Waveband staging algorithm has been shown to have an accuracy of 95.02% (Ong et. al., 2024). Raw sleep and staging data are available for download from Beacon servers. However, the file formats and naming conventions can be difficult to work with. Artifact detection methods as well as power spectral analyses are also not readily available. As such, we developed a toolbox to address these issues.

Materials and methods: Our team had previously conducted 2 studies using the Waveband. Currently, there are 5 different files to download for each recording: 1) complete raw data (h5 format), 2) PDF report based off the Waveband onboard processing, 3) lightly processed set of data (edf file), 4) sleep staging (text file), 5) a sleep report (csv file) generated from the Beacon servers. The file names of item 1 and 2 are the record ID, while files 3, 4, and 5 are named using the account ID and recording time stamp. Sorting these files is a time-consuming and error-prone process, therefore we developed a toolbox to automate this. We show an example extraction process from a recently completed multi-night (up to 12 nights) study with 60 participants with a total of 2502 files. In addition, detailed sleep staging overview can also be accessed through a plotting function which allows users to quickly highlight abnormalities in the data. Finally, artifact detection and power spectral analyses were also performed using Buckelmueller's (2005) method.

Results: We developed a toolbox in MATLAB to organize and process DHB recordings after they have been manually downloaded from the Beacon Biosignal servers. At the current development stage, the toolbox is able to:

1. Automatically read files and create a summary csv pulling data from individual report. Users can manually add study identifiers and the toolbox will update the file structure and consolidate files under individual participant folders and subfolders for each recording.
2. Plot staging data and save it, to allow for quick visual look at the data.
3. Convert raw h5 data into edf format.
3. Calculate and plot artifact-free power spectra of the recordings using EEGLAB.

Conclusions: Automation of data processing pipelines packaged into a toolbox can help users effectively manage, visualize and analyze large streams of Waveband data.

Effect of CPAP on cardiac function: Echocardiographic analysis using Speckle Tracking

B. Lamia¹, R. Ougouti², S. Gelinotte³

¹University of Normandie, Le Havre Hospital Groupe, le Havre, UR 3830 GRHVN, Pulmonary and Sleep, Le Havre, France, ²Le Havre Hospital Groupe, Le Havre, Le Havre, France, ³University of Normandie, Rouen, France

Introduction: Obstructive sleep apnea syndrome (OSAS) is associated with an increased risk of cardiovascular morbidity and mortality. The objective of our study was to analyze using echocardiography and speckle tracking imaging right and left ventricular functions of OSA patients at baseline and cardiac changes with CPAP treatment.

Materials and methods: We prospectively included 36 OSAS patients (diagnosed by polygraphy or polysomnography). Patient underwent transthoracic echocardiography (TTE) with conventional 2D analysis, pulsed, continuous, and tissue Doppler analysis, and a strain study using the Speckle Tracking

technique. Systolic and diastolic functions were analysed. Echocardiographic measurements were performed at baseline and repeated at one month and six months of CPAP treatment.

Results: We included mainly men (69%), aged 56 ± 12 years, and obese (73%) with a mean BMI of 35.1 ± 7.4 kg/m², all presented severe OSAS (RDI > 30/h). Echocardiographic parameters were as follow: we found significant improvement of right heart function with improvement in global and regional contractility: TAPSE (mm) increased from 22 ± 3 to 23 ± 3 ; $p < 0.05$, speckle tracking of right ventricle improved from 173.9 ± 89 to 119 ± 55.9 ms, $p < 0.05$. Left ventricular ejection fraction (61 ± 8 vs 63 ± 6 %) and LV diastolic function remains (1.2 ± 0.4 vs 1.2 ± 0.5) stable over 6 months of CPAP treatment.

Conclusions: We found significant improvement in RV global and regional contraction after one month of CPAP for OSAS. This beneficial effect of CPAP on right heart contraction was persistent at 6 months.

Estimating Daytime Productivity from Sleep-Time Biosignals with a Reduced Feature Set

C. Wang¹, R. Nitto¹, Y. Ban¹, M. Nakai², J. Shimizu², T. Ashikaga², S. Warisawa¹

¹The University of Tokyo, Tokyo, Japan, ²Daikin Industries, Ltd, Osaka, Japan

Introduction: Inadequate or poor-quality sleep erodes next-day alertness, psychomotor speed, and working-memory accuracy, all of which translate directly into lost productivity and safety risks. Conventional metrics such as total sleep time or stage proportions capture only fragments of sleep physiology and require cumbersome polysomnography. We therefore investigated whether a compact overnight biosignal array could directly forecast three concrete daytime outcomes—subjective sleepiness, psychomotor vigilance, and working-memory performance—and, if so, how few sensors were sufficient.

Materials and methods: After two adaptation nights, twenty healthy men (28.4 ± 4.9 y) spent four experimental nights in the laboratory (lights-off 22:00, lights-on 06:00); 59 recordings remained after artefact rejection and signal-quality screening. Signals were sampled at 1 kHz via a Biosignalsplux hub: 3-lead ECG, respiratory-inductance belt, palmar electrodermal activity (EDA) and bilateral external-oblique EMG. Twenty-five features—heart-rate-variability indices (pNN20, RMSSD, LF/HF, etc.), respiration rate/amplitude, EDA burst counts/amplitudes and EMG RMS—were z-scored participant-wise and fed to a three-layer Transformer encoder (d_model = 64, eight heads, cosine-decay Adam, early stopping at 100 epochs). At 06:00, 07:00 and 09:00 participants completed (i) the Stanford Sleepiness Scale (SSS) for self-rated alertness, (ii) a 5-min psychomotor vigilance task (PVT-B) for median reaction time, and (iii) a 3-back task for percent-correct working-memory accuracy. Four-fold cross-validation quantified performance. Shapley values ranked feature importance and guided two ablation routes: (i) dropping low-value sensors and (ii) dropping only low-value features.

Results: The full model explained $R^2 = 0.68$ – 0.77 of variance in median PVT reaction time and up to 0.76 in 3-back accuracy across the three test times; SSS sleepiness classification peaked at $F1 = 0.81$ at 07:00 (06:00 = 0.70 , 09:00 = 0.71). Approximate 95 % confidence intervals confirmed robustness (reaction-time R^2 0.64 – 0.80). HRV indices reflecting parasympathetic tone (pNN20, RMSSD) and sympatho-vagal balance (LF/HF), together with EDA burst counts, dominated psychomotor-speed prediction, whereas respiratory-stability metrics (mean RR, RR SD) emerged alongside HRV for working-memory accuracy. Removing the respiration belt and EMG electrodes—retaining only ECG and EDA—reduced reaction-time R^2 by < 0.20 while preserving ≥ 85 % of baseline performance, demonstrating a practical two-sensor solution.

Conclusions: An overnight recording of only heart-rate and skin-conductance signals can accurately forecast next-morning alertness (SSS score), psychomotor speed (median PVT reaction time), and working-memory accuracy (3-back percent correct) without explicit sleep-stage scoring. Transformer models capture long-range physiological patterns, and Shapley-guided pruning reveals that a two-channel wearable is enough for reliable early-shift screening of cognitive readiness. These findings support applications in shift-work fatigue management, driver vigilance checks, and remote-operator scheduling. Limitations include an all-male sample, controlled laboratory conditions, and a restricted cognitive battery. Future work will expand validation to larger, gender-balanced cohorts, real-world environments, and broader cognitive tasks, paving the way for longitudinal occupational deployment.

Evaluation of a Contactless Sleep Monitoring Device for Sleep Stage Detection against Home Polysomnography in a Healthy Population

M.-A. Stefanos^{1,2,3}, G. De Laboulaye³, D. Campo³, M. De Gourcuff³, P. Escourrou^{4,3}, B. Matrot¹, A.S. Islind², P.A. Geoffroy^{1,5,6}

¹Université Paris Cité, Paris, France, ²Reykjavik University, Reykjavik, Iceland, ³Withings, Issy-les-Moulineaux, France, ⁴Centre Interdisciplinaire du Sommeil, Paris, France, ⁵Département de psychiatrie et d'addictologie, AP-HP, GHU Paris Nord, Paris, France, ⁶Centre ChronoS, GHU Paris - Psychiatry & Neurosciences, Paris, France

Introduction: Sleep is essential for overall health and well-being, but assessing sleep architecture and quality is often costly and time-consuming, relying primarily on polysomnography (PSG). Wearable and nearable devices offer potential alternatives, but they regularly lack rigorous validation, especially in real-world settings.

Materials and methods: This study evaluates the accuracy and reliability of Withings Sleep Analyzer (WSA), a contactless sleep monitoring device, compared to PSG in a home setting using a large and diverse cohort of healthy individuals. A total of 117 participants (69 women; 39.9 ± 11.4 years, mean $\pm$ std) underwent home-based polysomnography (PSG) and simultaneous WSA recording. Data analysis focused on evaluating sleep-wake distinction and sleep stage identification using standard classification metrics.

Results:

WSA demonstrates high sensitivity (93%) for sleep detection and moderate sensitivity (73%) for wakefulness, achieving an overall accuracy of 87% for sleep-wake distinction. The device showed consistent performance across various demographic subgroups, including different age, BMI, mattress and sleep arrangements (with or without bed partner) categories. Challenges were noted in accurately classifying specific sleep stages, particularly in distinguishing between light and deep sleep, with a mean accuracy of 63% and a Cohen's Kappa of 0.49. The WSA tended to overestimate total sleep time (+20 min) and light sleep (+1h21 min) while underestimating REM (-15 min) and deep sleep (-46 min) durations. Disagreements between expert reviewers, particularly between light and deep sleep stages, mirrored in part the WSA's misclassifications. Participants reported significantly altered perceived sleep quality during the night with the PSG, suggesting potential discomfort during sleep.

Conclusions: WSA offers a promising approach to sleep monitoring in natural home environments. Being contactless and placed under the mattress, the WSA's allows for long-term monitoring of sleep measures. It shows competitive performance in sleep-wake and sleep stage identification compared to other consumer devices. Progress in wearable and nearable devices is necessary to enhance their accuracy to better support the monitoring of populations with strongly impaired sleep, although limited by an imperfect gold standard. This work also emphasizes the importance of using large, diverse, and challenging datasets, as well as the need for a standardized methodology for accurate sleep stage classification.

Feasibility and Application of a Novel Home-Based EEG Eye Mask for Personalized Sleep Pattern Modeling in an Elite Athlete: A Case Study

P.-H. Huang¹, L.-W. Wang¹, Y.-J. Lai², T.-H. Huang², C.-Y. Lin^{3,4}, S.-F. Liang¹

¹National Cheng Kung University, Department of Computer Science and Information Engineering, Tainan, Taiwan, ²National Cheng Kung University, Institute of Physical Education, Health and Leisure studies, College of Management, Tainan, Taiwan, ³Sleep Medicine Center, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan, ⁴Department of Otolaryngology, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan

Introduction: For athletes, appropriate training periodization is critical for performance optimization, yet leveraging objective sleep metrics to support periodization remains a challenge. The clinical gold standard, Polysomnography (PSG), is unfeasible for routine use due to its prohibitive cost and extensive waiting periods. Athletes often rely on subjective questionnaires and consumer-grade wearables, which

lack the electroencephalogram (EEG) signals required to analyze sleep architecture. Therefore, a portable home-based sleep monitoring device that provides valid and objective sleep metrics is highly desirable to bridge the gap between practical usability and reliable physiological measurement.

Materials and methods: This case study examined the relationship between daytime training stress and nighttime sleep patterns in a 27-year-old elite male triathlete across 38 consecutive days. Data acquisition involved two parallel streams: sleep data were recorded using a novel, self-applied EEG eye mask developed at National Cheng Kung University, while training data were quantified objectively via Training Stress Score (TSS) by the Garmin watch and subjectively via a four-tier intensity scale. To control for confounders, Obstructive Sleep Apnea (OSA) was screened using an ApneaLink Air device. Following data collection, raw EEG data exceeding four hours in duration were manually scored by sleep technicians to obtain precise and objective sleep metrics, including total sleep time (TST), sleep efficiency (SE), sleep onset latency (SOL), wake after sleep onset (WASO), arousal index, wake-sleep transitions, and stage transitions. These metrics, foundational for personalized sleep modeling, were also evaluated in relation to clinical normative thresholds. The primary objective was to validate a feasible home-based sleep monitoring methodology and establish a practical framework for personalized sleep pattern modeling in athletic populations.

Results: In evaluating the feasibility of home-based sleep monitoring, 27 of 38 nights (71%) resulted in successful data acquisition. Recordings of less than 4 hours ($n=7$) were excluded, along with 11 nights due to participant non-adherence ($n=8$) and poor signal quality ($n=3$). Sleep metrics across 20 nights showed the following distributions: $TST=354.9\pm54.9$ min, $SE=90.2\pm6.1\%$, $SOL=15.9\pm14.4$ min, $WASO=16.6\pm14.2$ min, arousal index= 14.2 ± 10.2 events/hour, wake-sleep transitions= 24.8 ± 9.7 counts, and stage transitions= 90.8 ± 33.2 counts. These values mostly fell in established clinical normative ranges. Analysis of threshold exceedances showed that SE fell below 85% in 1 of 20 nights (5%), SOL exceeded 30 minutes in 2 nights (10%), WASO exceeded 30 minutes in 3 nights (15%), and arousal index exceeding 14 events/hour in 6 nights (30%).

Conclusions: This study demonstrated the feasibility of the novel EEG eye mask as a portable sleep monitoring solution for an elite athlete, achieving a 71% data acquisition success rate. In addition, the personalized modeling approach revealed athlete-specific sleep patterns, underscoring the discrepancy between clinical norms and practical monitoring needs of athletic populations. Crucially, the integration of sleep-based modeling with training load data establishes a foundation for a data-driven framework, providing athletes and coaches with reliable metrics to optimize training periodization.

Hemodynamic spectral signatures across vigilance states: a whole-night EEG/fNIRS investigation

S. Bakian Dogaheh¹, E. Delaire¹, G. D. Pinilla-Monsalve², A. Jegou³, C. Abdallah⁴, E. Mozhentiy⁵, M. Reyt², H. Benali⁶, J. Carrier⁷, B. Frauscher⁸, J.-M. Lina⁹, L. Peter-Derex¹⁰, T.T. Dang-Vu¹¹, C. Grova¹
¹Concordia University, Physics Department, Montreal, Canada, ²Centre de recherches de l'Institut universitaire de gériatrie de Montréal (CRIUGM), CIUSSS du Centre-Sud-de-l'île-de-Montréal, Montreal, Canada, ³University of Pittsburgh, Pennsylvania, United States, ⁴McGill University, Biomedical Engineering Department, Montreal, Canada, ⁵Concordia University, School of Health, Montreal, Canada, ⁶Concordia University, Department of Electrical and Computer Engineering, Montreal, Canada, ⁷Université de Montréal, Department of Psychology, Montreal, Canada, ⁸Duke University, Departments of Neurology & Biomedical Engineering, Durham, Canada, ⁹Ecole de Technologie Supérieure, Département de Génie Electrique, Montreal, Canada, ¹⁰University Hospital of Lyon, Centre de Médecine du Sommeil, Lyon, France, ¹¹Concordia University, Department of Health, Kinesiology and Applied Physiology, Montreal, Canada

Introduction: Sleep is not only characterized by Electroencephalography (EEG) signatures, but also by specificities in brain hemodynamic activity, measurable with functional Magnetic Resonance Imaging (fMRI) or functional Near-Infrared Spectroscopy (fNIRS). EEG/fMRI studies revealed distinct oscillations in regional blood-oxygen-level-dependent signal during N2 and N3 sleep, correlated with sleep spindles and slow waves. An enhancement in vasomotor (~0.1Hz) and respiratory (~0.2Hz) oscillations has also been reported during non-rapid-eye-movement (NREM) sleep which was linked to increased EEG slow oscillations. However, REM findings remain absent, highlighting the necessity of

whole-night investigations. Despite these insights, EEG/fMRI sleep studies are limited in duration due to immobility constraints and the acoustic noise impedes reliable investigation of REM phasic/tonic microstructure. Alternatively, fNIRS emerged as a promising approach for prolonged sleep monitoring, allowing measurement of hemodynamic fluctuations by estimating cortical oxygenated and deoxygenated hemoglobin concentration changes. We propose whole-night EEG/fNIRS, using an optimized locally dense montage to maximize fNIRS sensitivity to targeted bilateral frontoparietal regions, allowing to investigate sleep-state-specific and region-specific patterns of oxyhemoglobin oscillations in healthy subjects.

Materials and methods: Whole-night simultaneous EEG-fNIRS were recorded from 13 healthy young adults together with auxiliary signals (respiratory belt, pulse oximetry and mean arterial pressure (MAP)), monitoring systemic physiology. EEG sleep staging, including REM phasic/tonic states, followed the American Academy of Sleep Medicine manual. Our personalized fNIRS optimal montage, targeting bilateral frontoparietal regions (2 light-sources and 4 detectors per region) were computed for each participant using individual anatomical information to optimize fNIRS optodes placement (Delaire et al 2025). Standard fNIRS pre-processing included: filtering (0.002-0.5Hz), short distance channel regression, oxy/deoxyhemoglobin estimation. We then applied Morse analytical wavelet time-frequency analysis and disentangled oscillatory from aperiodic (1/f) components of hemodynamic signals. Oxyhemoglobin power spectra were estimated for each stable sleep state—including REM phasic/tonic, using the time-frequency maps. To assess whether relative changes of hemodynamic power during each sleep state (vs wakefulness) were significant, time-frequency results were normalized frequency-bin-by-frequency-bin to wake segments, before applying a t-test on the logarithm of such ratio. Similar time-frequency analysis was applied to auxiliary signals.

Results: Our results, based on 13 subjects (6 females, 18-35 years, mean sleep efficiency:90.3%), show sleep-state-specific signatures of hemodynamic oscillations in frontal and parietal regions. In frontal region, compared to wakefulness, N3 showed increase oxyhemoglobin power in respiratory band (~0.2Hz) and reduced power around 0.004-0.013Hz. N2 exhibited increased oscillatory power in respiratory band ~0.2Hz. REM sleep was characterized by overall increases in frequencies <0.15 Hz and respiratory-band oscillations. Both REM tonic and phasic states exhibited increased power in (<0.15 Hz) and respiratory band, with tonic REM showing a larger peak around 0.2Hz. Complementary analysis of auxiliary signals revealed dominant oscillatory component in pulse oximetry at ~0.2Hz and cardiac band (~1Hz), MAP at vasomotor ~0.1Hz and respiration belt at ~0.2Hz, suggesting that sleep-stage-specific hemodynamic oscillations were not solely driven by systemic physiology.

Conclusions: Whole-night personalized EEG/fNIRS appears as a new promising modality to study sleep physiology, suggesting that sleep-stage-specific hemodynamic signatures could be used to further characterize NREM and REM sleep in healthy and pathological conditions.

Impact of lifestyles and daily experiences on nocturnal heart rate variability and heart rate among 100,000 adults

S. Milton¹, A. Cotton-Clay², S. Baron², L. Fava², V. Easwar², A. Kinsolving², P. Kahn², J. Zitser³, C. Kushida⁴, Y. Leng¹

¹University of California, San Francisco, San Francisco, United States, ²Fullpower Technologies, Inc., Santa Cruz, United States, ³Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, ⁴Stanford University, Stanford, United States

Introduction: Both heart rate (HR) and heart rate variability (HRV) can be used to assess autonomic function. Lifestyle choices, such as alcohol use and smoking, may impact autonomic activity at night. However, it is unclear how nocturnal HRV and HR are impacted by these and other daily behaviors. Cutting-edge sleep technologies provide an opportunity to address this gap; in the current study, we do so using a large, real-world sample comprising adult users of an under-mattress sleep monitor.

Materials and methods: We assessed nocturnal HR and HRV using Sleeptracker-AI Monitors (Fullpower Technologies Inc., California, USA), which use under-mattress piezo-electric sensors. HRV measures included SDNN (overall HRV) and RMSSD (an index of parasympathetic activity). Each day, subjects self-reported alcohol use, smoking, eating habits, stress, caffeine use, sleep quality, and exercise. Data was collected from 9/1/2023-9/30/2024. We used mixed effects models with participant as a random effect to obtain estimated marginal mean (EMM) HR, SDNN, and RMSSD for

each response category of the self-report questions. We performed pairwise comparisons to assess the differences in EMMs across categories. Additionally, we examined the effects of age and gender adjustment and performed a completely within-subjects analysis in which we excluded participants who answered questions only one way, minimizing the effects of between-subject variability.

Results: Data availability differed by self-report question and HR/HRV metric, so analyses differed in sample size. Across all participants (47.3% female), the mean (standard deviation) age was 48.9 (13.2) years. The largest analysis (HR by exercise) included 100,990 participants (1,765,500 nights) and the smallest analysis (RMSSD by smoking) included 1,145 participants (12,519 nights). The mean analysis size was 35,120 participants (571,650 nights). All pairwise comparisons, except leisurely vs. no exercise for HR ($p: 0.09$), were significant ($p < 0.001$). On nights after which participants reported alcohol use (vs. non-use), participants had decreased SDNN (EMM: 37.3 vs. 40.6 ms) and RMSSD (EMM: 28.6 vs. 31.9 ms), and increased HR (EMM: 66.5 vs. 62.7 bpm). Similarly, self-reported smoking (vs. non-smoking) was associated with lower HRV (EMM, SDNN: 38.1 vs. 41.4 ms; RMSSD: 32.1 vs. 34.7 ms) and higher HR (EMM: 67.4 vs. 64.4 bpm) during the night. Additionally, SDNN and RMSSD were lower, while HR was higher, on nights after which participants reported caffeine non-use vs. use, having a stressful vs. normal vs. stress-free day, exercising at high intensity vs. leisurely vs. not exercising, eating a meal vs. a snack vs. not eating within two hours of bedtime, and sleeping not well vs. normally vs. well. For all metrics, alcohol use and smoking showed the largest effect sizes. Results were similar after age/gender adjustment and in the completely-within subjects analysis.

Conclusions: Decreased nocturnal HRV and increased nocturnal HR were linked to drinking alcohol, smoking, eating before bedtime, stress, caffeine non-use, self-reported poor sleep, and exercise. Nocturnal autonomic function may be particularly impacted by lifestyle choices such as drinking alcohol and smoking. Noninvasive sleep technologies will be invaluable in further uncovering the relationship between daily behaviors and nighttime autonomic function.

Implementation of the AI-Powered Belun Ring to Streamline Sleep Disorder Assessment in Primary Care: A Real-World Community Study

C.-W. Tsai¹, C. Cheung¹, L. Leung¹, Y.C. Chan², K.W. Tam², S.Y. Tse², K.K.K. Chan², J.I.W. Ho², C.C.H. Lau², K.K.W. Li², J.E. Tse², T.K. Wong², K.T. Yeung², H.Y. Choi², K.L. Chung²

¹Belun Technology Company Limited, Hong Kong, Hong Kong, SAR of China, ²The Chinese University of Hong Kong Medical Centre, Shatin, New Territories, Hong Kong, SAR of China

Introduction: The global increase in sleep disorders—driven by an aging population and rising obesity presents a significant public health challenge. Despite their high prevalence and association with cardiovascular, metabolic, and mental health conditions, many sleep disorders remain undiagnosed, contributing to increased healthcare utilization and socioeconomic burden. The delay in diagnosis and treatment is largely due to the long waiting time for diagnostic test (PSG) in public healthcare system as well as costly tests in private health care setting. Wearable sleep technologies offer a scalable and cost-effective alternative to traditional testing; however, their adoption in primary care remains limited. This study evaluated the use of the AI-powered Belun Ring (BR), a medical-grade wearable, to characterize sleep phenotypes and compare outcomes between individuals referred by primary care physicians (PCPs) and specialists in a real-world clinical setting.

Materials and methods: This retrospective study included 347 adults referred for sleep assessment at The Chinese University of Hong Kong (CUHK) Medical Clinics between June 2020 and June 2025. Participants completed at least three nights of home sleep monitoring using the BR, with ≥ 60 minutes of total sleep time per night required for data inclusion. The device generated objective sleep metrics, including the apnea-hypopnea index (bAHI4%, AASM 1B rule) and sleep efficiency (bSE). Based on these measures, participants were categorized into four sleep phenotypes: normal (bAHI4% <15 & bSE ≥ 80), obstructive sleep apnea (OSA: bAHI4% ≥ 15 & bSE ≥ 80), insomnia (bAHI4% <15 & bSE <80), and COMISA (bAHI4% ≥ 15 & bSE <80). A multinomial logistic regression model was used to assess the association between referral type (PCP vs. specialist) and sleep phenotype, adjusting for age, sex, and BMI.

Results: Of the 347 referred patients, 287 (83%) met data quality criteria. Among these, 53% screened positive for a sleep disorder phenotype: 30% met criteria for OSA, 16% for insomnia, and 6% for COMISA. PCP referrals accounted for 85% of the cohort. There were no statistically significant

differences in sleep phenotype distribution between PCP and specialist referrals (COMISA: Odds Ratio=2.34, 95% CI=0.67–8.14; insomnia: 1.40, 0.54–3.64; OSA: 0.86, 0.35–2.08). Age was significantly associated with increased odds of all three sleep disorder phenotypes (COMISA: 1.13; insomnia: 1.10; OSA: 1.05). Higher BMI was associated with increased odds of COMISA (1.31, 1.14–1.52) and OSA (1.26, 1.15–1.39), but not insomnia. Female sex was associated with lower odds of OSA (0.31, 0.14–0.67).

Conclusions: This study is among the first to demonstrate the feasibility and public health value of integrating AI-driven wearable technology into primary care for sleep disorder risk assessment. The comparable phenotype distributions between PCP and specialist referrals support the use of the BR as a frontline tool for identifying individuals at risk and triaging them for further evaluation. Integrating medical-grade wearables into primary care workflows could play a critical role in addressing the substantial burden of undiagnosed sleep disorders, reduce demand on specialist services, and enabling earlier care for at-risk individuals in community settings.

Improving Inter-Scorer Reliability in Polysomnography Interpretation: A Multi-Year, Case-Driven, Cloud-Based Training Program

Y.-T. Sun¹, K.-Y. Chen², L.-W. Wang², W.-K. Lin³, C.-Y. Lin^{3,4}, S.-F. Liang²

¹Institute of Medical Informatics, National Cheng Kung University, Tainan, Taiwan, ²Department of Computer Science and Information Engineering, National Cheng Kung University, Tainan, Taiwan, ³Sleep Medicine Center, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan, ⁴Department of Otolaryngology, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan

Introduction: Accurate interpretation of polysomnography (PSG) is essential for diagnosing sleep disorders, yet inter-scorer variability persists due to differences in patient presentations, scorer backgrounds, and application of American Academy of Sleep Medicine (AASM) standards. To address this, we developed a cloud-based platform, and, since 2021, have conducted annual workshops that utilize PSG and Multiple Sleep Latency Test (MSLT) case reviews, platform tools, and standards discussions to systematically improve inter-scorer consistency.

Materials and methods: This ongoing training program (2021–2025), conducted in collaboration with the Taiwan Society of Sleep Medicine, hosts annual sleep workshops on the cloud-based platform. The platform provides full-length PSG and MSLT recordings, supports online annotation of sleep stages and events, features an autosave function, and allows location-independent access. The workflow comprises a participant pre-test, an expert review of common errors, and interactive lectures covering AASM standards, and interpretation strategies. Participants then complete a post-test on the same data set; upon submission, the platform generates individualized reports summarizing overall agreement, and stage-specific concordance.

From 2021 to 2024, the workshop participants were primarily sleep technicians and physicians (n=70 in 2021; n=34 in 2022; n=13 in 2023; n=23 in 2024). To address diverse clinical challenges, each workshop centered on a specific case. The 2021 workshop focused on a 50-year-old male patient with a moderate apnea-hypopnea index (17.7). The 2022 session targeted an 80-year-old male with a severe sleep disorder and significant leg movements. The 2023 workshop addressed sleep fragmentation in an 85-year-old female patient. The 2024 case involved a 59-year-old male with severe nocturnal apnea (AHI=57.4) and daytime sleepiness, and the platform also incorporated a novel automated slow-wave (0.5–2 Hz) detection system (recall=0.979; precision=0.963). The upcoming 2025 workshop will focus on narcolepsy, featuring a 46-year-old male and adding new functions for REM sleep without atonia (RWA) annotation, integrated PSG/MSLT visualization, and MSLT light markers.

Results: The workshops have consistently improved scoring agreement over the years. In 2021, the median sleep stage agreement increased from 74.6% to 82.3% (P < .001 for N1, N2, N3, and overall), and the proportion of scorers achieving ≥ 80% agreement increased from 20.0% to 58.6%. For 2022 significant limb movement cases, sleep stage agreement improved from 71.6% to 80.8%, and periodic limb movements (PLMS) event agreement from 83.2% to 87.5%. In the 2023 study of complex elderly cases, stage agreement rose from 79.1% to 84.0% (P < .05 for N2 and overall). In 2024, with slow-wave detection to assist in scoring a case of severe sleep-disordered breathing, stage agreement improved from 65.7% to 72.7% (P = .00012), and respiratory event agreement increased from 72.8% to 89.4% (P = .00014).

Conclusions: This case-driven, cloud-based training paradigm effectively improves inter-scorer reliability for the interpretation of PSG and MSLT across diverse clinical scenarios by combining tailored instruction with advanced signal-detection tools. The transition to a global, online workshop in 2025 is expected to extend these benefits internationally, thereby promoting standardized sleep scoring practices.

Improving Sleep and Well-being Through VR Mindfulness: Evidence from a 5-Session Program

E. Kim¹

¹Ajou University, Psychology, Suwon, Korea, Democratic People's Republic of

Introduction: Virtual Reality (VR)-based mindfulness interventions have demonstrated promising effects on emotional well-being, including stress reduction and improved emotional regulation. However, few empirical studies have specifically examined the impact of VR mindfulness programs on sleep quality, a key indicator of psychological and physiological health. This study aimed to investigate the effects of a structured VR mindfulness program on sleep quality, perceived stress, and negative affect.

Materials and methods:

control group (n = 35). The experimental group participated in five 45-minute VR mindfulness sessions using *TRIPP* over two weeks. Each session consisted of a 10-minute check-in and emotional awareness activity, a 10-minute guided mindfulness meditation using *TRIPP*, a 10-minute mindfulness session with 360-degree natural landscape immersion, and a brief wrap-up and reflection. The control group received no intervention during the study period. Sleep quality was measured using two methods: the Pittsburgh Sleep Quality Index (PSQI) for self-reported sleep quality and smartwatch-based actigraphy using Galaxy Watch, which recorded sleep duration, onset latency, wake time, and sleep efficiency. Participants wore the Galaxy Watch overnight at three time points—pre-intervention, post-intervention, and follow-up (two weeks post-intervention). Perceived stress and negative affect were assessed using validated self-report questionnaires administered at the same time points.

Results: Repeated-measures ANOVA revealed significant interaction effects between time and group for all three outcome variables. Compared to the control group, the experimental group showed significant improvement in sleep quality, as indicated by lower PSQI scores and increased sleep efficiency recorded by the Galaxy Watch. Additionally, participants in the experimental group reported reduced perceived stress and decreased negative affect. These positive effects were evident immediately after the intervention and were maintained at the follow-up assessment.

Conclusions: This study demonstrates that a short-term, VR-based mindfulness program can effectively improve sleep quality and reduce psychological distress. The combination of self-report measures and objective data collected through the Galaxy Watch supports the reliability of these findings. VR meditation may offer a useful and engaging tool for promoting mental health and enhancing sleep in daily life.

Improving Sleep Stage Classification from Consumer Wearables Using a Two-Level Machine Learning Framework with Selective Correction

Z. Liang¹

¹Kyoto University of Advanced Science (KUAS), Faculty of Engineering, Kyoto, Japan

Introduction: Measuring sleep across extended periods is critical for capturing day-to-day variability in sleep dynamics. While polysomnography (PSG) remains the gold standard, its high cost and intrusiveness limit feasibility for longitudinal, real-world monitoring. Consumer-grade wearable activity trackers such as Fitbit are increasingly adopted in research due to their affordability, scalability, and ease of use. However, these devices are known to have limited accuracy in detecting sleep stages. This study proposes and validates a novel two-level machine learning framework that selectively corrects

Fitbit-derived sleep stage labels using only processed, readily available data. The aim is to improve sleep staging accuracy in free-living environments.

Materials and methods: A three-night, in-home sleep monitoring study was conducted with 23 healthy adults (mean age = 24.8 ± 4.4 years). Sleep was recorded using Fitbit Charge 2 and a medical-grade portable EEG (Sleep Scope). To minimize the first-night effect, data from the second night were primarily used. Fitbit-provided sleep stages, heart rate, and aggregated metrics (e.g., total sleep time, sleep efficiency) were synchronized with medical-grade labels. We constructed 21 features from Fitbit and questionnaire data, divided into static (e.g., age, PSQI, sleep summaries) and dynamic (e.g., epoch-wise heart rate changes, adjacent sleep stages) feature groups.

Each 30-second epoch received two labels: a binary label indicating Fitbit classification correctness (level-I), and a multi-class label representing the true sleep stage (level-II). Level-I classifiers (SVM, RF, NB) identified misclassified epochs, while level-II reclassified them using XGBoost. To address class imbalance, random up- and down-sampling techniques were applied at level-II. Models were evaluated using nested leave-one-subject-out cross-validation (LOSO-CV) and assessed via both microscopic (e.g., accuracy, kappa, MMCC) and macroscopic (e.g., normalized absolute bias [MAB]) performance metrics.

Results: The two-level models consistently outperformed Fitbit and one-level baselines. SVM + XGBoost with up sampling (SVM + XGBu) achieved the best per-epoch classification accuracy (0.731 ± 0.119), while RF + XGB with down sampling (RF + XGBd) showed the best agreement in total sleep stage durations (lowest MAB = 0.010, <1% of baseline error). SVM + XGBd achieved a balance between the two. Light sleep classification reached up to 89.6% accuracy, although accuracy for deep sleep remained lower. Compared to Fitbit, the models reduced misclassification between adjacent sleep stages, notably for REM and wakefulness. Performance was influenced by class imbalance and dataset shift, with resampling improving accuracy but also increasing sensitivity to inter-individual variability. Down sampling led to better generalizability, while up sampling improved detection of underrepresented stages at the cost of distribution shift.

Conclusions: This study demonstrates that accurate sleep stage classification is achievable using only processed outputs from consumer wearables, without relying on raw data or specialized equipment. The proposed two-level correction framework improves both per-epoch accuracy and stage-level duration estimates. These findings support the use of enhanced machine learning techniques to extend the utility of wearables in sleep research and digital sleep medicine.

In-lab experience with an AASM-certified AI for sleep staging using polysomnography data

E. Hofmann¹, E. Riese¹, G. Küchler¹, E.M. Essaki Arumugam¹

¹Schlafzentrum Am Sonnenstuhl, Randersacker, Germany

Introduction: In sleep laboratories, polysomnographic recordings are routinely evaluated manually, especially when it comes to sleep stage classification.

Often several scorers are employed in sleep laboratories, and discrepancies between them are common due to the subjective nature of visual scoring, even when standardized guidelines are followed. Sleep staging remains one of the most time-consuming tasks, accounting for approximately 50 to 80% of the total evaluation time. With the AASM-certified DOMINO-AI (SOMNOmedics AG, Germany), a scoring tool is now available that promises time-efficient sleep staging. This study compares AI-based staging with two human scorers (S1 and S2) in our sleep lab, assessing agreement, interrater variability, and efficiency.

Materials and methods: In a total of 26 patients (16 male; mean age 51.8 ± 15 years; 10 mild, 5 moderate, 5 severe obstructive sleep apnea (OSA); 15 periodic limb movement disorder (PLMD); 9 subjects presented comorbidity) standard polysomnography (SOMNO HD, SOMNOmedics AG, Germany) during diagnostic nights (four patients with mandibular advancement device, MAD) were performed. Recordings were scored independently according to current AASM guidelines by two qualified scorers (S1, S2) as well as by DOMINO-AI (Fig. 1). The results of S1 (default scorer) were compared with DOMINO-AI and S2. Agreement between AI and human scorers and the interrater variability between the two scorers was analyzed epoch-to-epoch (in total 21358 epochs, epochs with artefact excluded) using confusion matrices, Cohen's Kappa, F1 score.

Results: The interrater reliability between the manual scorer S1 and the AI-conducted analysis on average across all patients was $82.7 \pm 6.3\%$, between the two manual scorers the agreement was

80.8±6.2% (Fig.2). In the epoch-to-epoch evaluation of artefact-free epochs Cohen's kappa was 0.75 and F1 score 0.815 (Table 1). The comparison of S1 and S2 showed a Cohen's kappa of 0.71 and a F1 score of 0.787. The regression of the evaluated epochs (E) for S1 vs. AI and S1 vs. S2, respectively, was as follows (Table 2): Wake phases (W): $R^2 = 0.925$ and $R^2 = 0.963$; N1/N2: $R^2 = 0.789$ and $R^2 = 0.737$; N3: $R^2 = 0.813$ and $R^2 = 0.737$; REM sleep (REM): $R^2 = 0.812$ and $R^2 = 0.745$.

Conclusions: The AI-based analysis showed an agreement of 80%, which was slightly higher than the agreement observed between the two in-lab scorers (S1 vs. S2: 79%). The inter-rater reliability between AI and S1 was substantial (Cohen's kappa = 0.75, F1 score = 0.815), indicating a strong level of agreement in sleep staging– slightly higher than the agreement between the two manual scorers (Cohen's kappa = 0.71, F1 score = 0.787). The level of agreement, Cohen's Kappa, and F1 score are in the same range as reported in the literature^{1,2,3}. These results are particularly notable given the challenging nature of the dataset, which included fragmented sleep patterns due to conditions such as OSA and PLMD. Given its sufficient accuracy, better than our in-lab rater variability and significant time savings, the AI-based pre-analysis proves to be a valuable tool for routine use in our sleep laboratory.

Management of adult laryngeal hemangioma with snore using low-temperature plasma radiofrequency coblation

Z. Lou², Z. Lou¹, Z. Chen²

¹Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Department of Otolaryngology Head and Neck Surgery, Shanghai, China, ²Wenzhou medical university affiliated Yiwu Hospital, Yiwu, China

Introduction: Objective: This study investigated the therapeutic effects of low-temperature plasma radiofrequency (LPRF) coblation on adult laryngeal hemangiomas (ALHs) with snore using suspension laryngoscopy.

Materials and methods: Material and Methods: The clinical data of 23 patients with ALH with snore treated by LPRF coblation were analyzed retrospectively. All patients underwent edge coagulation before ablation resection. Postoperative voice and swallowing were assessed.

Results: Results: The 23 ALHs were diagnosed clinically as 6 cavernous hemangiomas and 17 capillary fibroangiomas. All 23 cases achieved success after a single LPRF coblation, and there was no postoperative bleeding, dyspnea, dysphagia, dysphonia, or other complications. None required postoperative tracheotomy. The patients were followed for 1 year without recurrence. Before surgical intervention, only 2 (8.7%) of the 23 patients had mild (n = 1) or moderate (n = 1) dysphagia. Postoperative dysphagia was assessed at the 1- and 3-month follow-ups. At 1 month, 5 (21.7%) of 23 patients had mild dysphagia, including 3 (13.0%) reporting new mild dysphagia. However, at 3 months postoperatively, none of patients had any dysphagia. The mean Voice Handicap Index was 11.2 ± 3.7 preoperatively, 7.1 ± 2.8 at 1 month postoperatively, and 4.8 ± 3.1 at 3 months postoperatively; the mean maximum phonation time was 10.8 ± 3.7 s preoperatively and 12.6 ± 1.8 and 14.1 ± 3.9 s at 1 and 3 months postoperatively, respectively.

Conclusions: Conclusions: LPRF coblation is an effective minimally invasive method for treating ALHs with snore with better voice and swallowing recovery. Edge coagulation before ablation resection may reduce intraoperative bleeding.

Manual Versus Automated Polysomnography Scoring: Inter-rater Accuracy in a Single-Center Thai Cohort

N. Saiborisut^{1,2}, A. Pugongchai^{1,2}, C. Tepwimonpetkun^{2,3}, K. Ladthavorlaphatt^{1,2}

¹Thammasat University Hospital, Medical Diagnostics Unit, Khlong Luang District, Thailand,

²Thammasat University Hospital, Sleep Centre of Thammasat, Khlong Luang District, Thailand,

³Thammasat University, Pulmonary and critical care medicine, Department of internal medicine, Faculty of Medicine, Khlong Luang District, Thailand

Introduction: The demand for trained sleep study personnel is rising, but the relative accuracy of advanced sleep technicians (ASTs), sleep disorder specialists (SDSs), and commercial autoscoring

software (AUTO) has not been quantified in Thailand. We evaluated inter-rater agreement, scorer bias, and clinical comparability among these three methods.

Materials and methods: A retrospective analysis was performed on 250 consecutive diagnostic polysomnography (PSG) studies recorded between September 2022 and February 2023 (102 women, 148 men; mean age 48.5 ± 17.5 y; BMI 29.1 ± 6.6 kg/m²). Each record was independently scored by a randomly assigned certified AST (n = 10), a blinded SDS and AUTO (default settings). Sleep stages, respiratory events and derived indices were extracted. Categorical agreement was assessed with Cohen's κ ; continuous agreement with intraclass-correlation coefficients (ICC, two-way random, absolute agreement). Bias and limits of agreement were evaluated using Bland–Altman analysis. Apnoea–hypopnoea index (AHI), arousal index (ARI) and sleep efficiency (SE) were compared across raters with repeated-measures ANOVA and Tukey post-hoc tests ($\alpha = 0.05$).

Results: AST–SDS staging agreement was almost perfect ($\kappa = 0.832$ – 0.980). In contrast, AST–AUTO agreement ranged from slight for NREM1 ($\kappa = 0.081$) to moderate for wake ($\kappa = 0.599$), producing stage-specific differences between AST–SDS and AST–AUTO for every stage except NREM2 (overall $p < 0.0001$; NREM2 $p = 0.099$). For respiratory events, AST–SDS reliability was substantial to perfect (ICC = 0.684 for central apnoea; 0.945–0.998 otherwise), whereas AST–AUTO reliability spanned poor (central apnoea, ICC = 0.023) to strong (mixed apnoea, ICC = 0.869). The same pattern emerged for derived indices: AST–SDS ICCs were excellent for AHI (0.982), ARI (0.982) and periodic limb movements (PLMs, 0.965); AST–AUTO ICCs were moderate for AHI (0.564) and ARI (0.496) and poor for PLMs (0.149). Bland–Altman plots showed significant bias across all variables ($p \leq 0.0487$). Repeated-measures ANOVA revealed significant rater effects for AHI ($p = 0.042$) and ARI ($p = 0.028$); SE differed for seven of ten ASTs ($p < 0.006$). Post-hoc tests confirmed AST differed from AUTO for AHI ($p = 0.013$) and ARI ($p = 0.030$) but not from SDS.

Conclusions: Manual scoring conducted by ASTs and SDSs, following the AASM 2020 guidelines, shows a strong level of agreement and minimal bias. In contrast, the commercial AUTO algorithm demonstrates lower reliability and clinically significant discrepancies, particularly regarding NREM1 sleep, central apnoea, and periodic limb movement detection. Therefore, expert review remains crucial until the performance of these algorithms is improved. This data serves as a foundation for national training standards and identifies specific areas for improvement, including NREM1, PLMs, and CA discrimination, to guide the development of future AI-enhanced autoscoring tools.

Acknowledgments: The authors sincerely thanked Thammasat University Hospital for funding and appreciated all participants who contributed to our research.

Monitoring the motor fingerprint of the nocturnal sleep period and its cardiovascular correlates with a wearable multi-sensor array

M. Sicbaldi¹, P. Di Florio¹, L. Palmerini¹, R. Ferri², L. Chiari¹, A. Silvani¹

¹University of Bologna, Bologna, Italy, ²IRCCS Oasi, Troina, Italy

Introduction: Wearable technology allows for unobtrusive monitoring of cardiovascular and motor function. We explored the feasibility of characterizing the motor fingerprint of the nocturnal sleep period and its cardiovascular correlates using an array of wearable sensors.

Materials and methods: Twelve healthy adult volunteers (6 females) from the LOOKING-GLASS MIAR study were monitored at home throughout their self-reported sleep period with simultaneous use of Axivity AX6 accelerometers at five body segments (both wrists, both ankles, and the lower back), a Polar H10 ECG chest strap, and a Polar Verity Sense photoplethysmography arm band. The two Polar sensors were connected via Bluetooth to a smartphone with a custom-built app (VEGA). Movements were detected with a threshold-crossing algorithm based on the envelopes of the accelerometer signal magnitude vector over time. The algorithm was validated against visual scoring based on raw acceleration recordings. Movements were categorized as segmental, regional, or global if occurring in 1, 2–4, or 5 body segments, respectively. Changes in cardiovascular control associated with movements were assessed based on heart rate (HR) and pulse wave amplitude (PWA) changes compared to the pre-movement baseline. The nocturnal sleep period was defined based on sleep diary. Sleep and wakefulness during the nocturnal sleep period were scored based on non-dominant wrist acceleration with a validated algorithm implemented in the GGIR open-source software.

Results: Segmental and lower-body regional movements were significantly greater fractions of total movements during nocturnal sleep than during nocturnal wakefulness, whereas the opposite occurred

for global movements. Segmental and regional movements were associated with mono- or bi-phasic changes in HR and PWA, with early increases in HR and decreases in PWA variably followed by later opposite changes. Global movements were associated with larger, monophasic increases in HR and decreases in PWA. The changes in HR and PWA started 2-4 s earlier than the onset of movement.

Conclusions: Our study indicates the feasibility of recording movement-related HR and PWA patterns during nocturnal sleep and wakefulness with a combination of wearable sensors. The motor fingerprint of nocturnal sleep and wakefulness and the sleep movement-related HR and PWA patterns have the potential to be developed into biomarkers of sleep and cardiovascular disorders.

Multi-Night At-Home Evaluation of Oura Ring Against Dreem Headband in Free-Living Older Adults

H. Aghayan Golkashani¹, K. Foong Wong¹, S. Qin¹, J.L. Ong¹, M. Chee Wei Liang¹

¹National University of Singapore, Singapore, Singapore

Introduction: Although sleep-tracking wearables are widely used, few validation studies have assessed their accuracy and night-to-night stability in older adults under free-living conditions. This study evaluated the Oura Ring against the Dreem headband across multiple nights, focusing on both measurement bias and intra-individual variability.

Materials and methods: Forty-five older adults [mean age $\pm$ SD: 74.4 $\pm$ 2.4 years; 23 females] concurrently wore the Oura Ring and Dreem headband at home. The Dreem headband served as a research-grade EEG reference to evaluate the performance of the Oura Ring in free-living older adults. We analysed 215 nights of paired data to compare nightly estimates of total sleep time (TST), sleep efficiency (SE), wake after sleep onset (WASO), sleep onset latency (SOL), and time spent in each sleep stage. Bias (Oura – Dreem) and the standard deviation (SD) of nightly bias were calculated for each subject to evaluate measurement stability. We also report epoch-by-epoch agreement metrics including accuracy, sensitivity, specificity, Cohen's kappa and prevalence-adjusted bias-adjusted kappa (PABAK).

Results: On average, Oura underestimated TST by 17.5 $\pm$ 42.3 minutes, SE by 3.5 $\pm$ 8.4%, and REM by 23.2 $\pm$ 36.9 minutes, and overestimated SOL by 11.5 $\pm$ 27.3 minutes, WASO by 6.0 $\pm$ 38.9 minutes, and light sleep by 7.8 $\pm$ 46.5 minutes. Deep sleep was slightly underestimated (-2.1 $\pm$ 32.2 minutes). Mixed models showed no significant effect of night on bias across any variable, supporting stability over time. The night-to-night variability (SD) of these biases was significantly lower in participants with higher SE; indicating greater measurement stability in more efficient sleepers. Accuracy, sensitivity, and specificity for sleep-wake classification were 85.6% ($\pm$ 6.7%), 88.4% ($\pm$ 7.5%), and 75.7% ($\pm$ 15.4%), respectively, with a Cohen's kappa of 0.58 ($\pm$ 15%) and PABAK of 0.71 ($\pm$ 13%).

Conclusions: In this multi-night validation study under free-living conditions in older adults, Oura Ring demonstrated reasonably accurate and stable multi-night sleep estimates when compared to the Dreem headband, with systematic but consistent biases across nights. Notably, higher sleep efficiency was associated with reduced night-to-night variability in Oura's measurement bias, suggesting a link between sleep fragmentation and device reliability. These findings support the use of Oura for longitudinal sleep monitoring under naturalistic conditions in older adults, with appropriate consideration of its limitations in subjects with lower sleep efficiency.

Non-Contact Supine Position Estimation Using a Sound-Based AI Model

H. Choi¹, S. Kim², E. Cho², D. Lee², S. Heo², H. Kyung², J. Hong², I.-Y. Yoon³, K.-Y. Jung⁴, J.-W. Kim⁵

¹Veterans Health Service Medical Center, Department of Psychiatry, Seoul, Korea, Republic of, ²Asleep Inc., Seoul, Korea, Republic of, ³Seoul National University College of Medicine, Seoul National University Bundang Hospital, Department of Psychiatry, Seongnam, Korea, Republic of, ⁴Seoul National University College of Medicine, Seoul National University Hospital, Department of Neurology, Seoul,

Korea, Republic of, ⁵Seoul National University College of Medicine, Seoul National University Bundang Hospital, Department of Otorhinolaryngology-Head and Neck Surgery, Seongnam, Korea, Republic of

Introduction: In this study, we introduced sleep position prediction - specifically supine position detection - as an auxiliary task within a sound-based AI model for sleep analysis. Supine-predominant obstructive sleep apnea (OSA) is frequently observed, with supine sleep consistently associated with greater OSA severity in adults. However, the proportion of time spent in the supine position is often overrepresented during hospital-based polysomnography (PSG), potentially due to physical constraints imposed by the monitoring apparatus. These discrepancies between sleep positions recorded during PSG and those typically assumed at home may lead to inaccuracies in the apnea-hypopnea index (AHI) and its clinical interpretation. Home-based sleep position monitoring, conducted under natural conditions, could offer valuable complementary information to contextualize PSG findings - especially when enabled by contactless tools such as sound-based AI models.

Materials and methods:

The latest sound-based AI model processes 80 consecutive Mel spectrograms, each representing a 30-second epoch, and employs a feature extractor to capture breathing pattern characteristics, followed by classifiers to predict sleep stages, OSA events, and snoring. Maintaining this two-stage structure, we extended the model by adding a position classifier trained to distinguish supine epochs from non-supine epochs using PSG-derived labels. The training dataset included 2,973 nights comprising hospital PSG recordings (with PSG equipment audio or smartphone audio) and home PSG recordings (with smartphone audio). A separate evaluation set of 802 nights was used (mean age: 50.5 ± 15.4 years; male:female = 530:272; mean BMI: 25.5 ± 3.6 ; mean AHI: 21.2 ± 20.6). Supine position predictions were evaluated on an epoch-by-epoch basis, and predicted supine ratios (percentage of total sleep time spent in the supine position) were compared with PSG-derived references.

Results: For the supine class, the model achieved a sensitivity of 0.85, specificity of 0.72, and an F1 score of 0.85 across the entire evaluation dataset. The overall epoch-by-epoch accuracy for supine versus non-supine classification across the evaluation dataset was 81.44%, with a macro F1 score of 0.79. When evaluated on smartphone-recorded audio only (237 nights), supine-specific sensitivity, specificity, and F1 score were 0.80, 0.71, and 0.80, respectively. The overall accuracy and macro F1 score in this subset were 76.84% and 0.75. The mean supine ratio based on PSG labels was 66.19% (SD 21.32), while the model-predicted supine ratio was 66.17% (SD 25.02). Predicted supine ratios showed moderate correlation with PSG-derived values ($r = 0.67$), with a mean error of 0.02% (SD 19.03).

Conclusions: This study demonstrates the potential of a sound-based AI model as a contactless tool that aids interpretation of AHI measurements affected by sleep position. While the model showed moderate agreement at the group level, its accuracy in estimating individual supine ratios from single-night data remains limited. Further refinement in detecting position-specific acoustic features from Mel spectrograms may enhance prediction performance. Nonetheless, integrating non-contact sleep position monitoring with sleep staging and OSA detection strengthens the role of sound-based AI as a practical and scalable complement to conventional sleep diagnostics.

Optimizing PPG Sequence Length for Deep Learning-based Sleep Stage Classification

H. Lee¹, M. Kim¹, H.-G. Kim¹, K.-Y. Kim¹

¹Electronics and Telecommunications Research Institute (ETRI), Daegu-Gyeongbuk Research Division, Daegu, Korea, Republic of

Introduction: Photoplethysmography (PPG) is a non-invasive and cost-effective measurement for sleep monitoring, particularly suitable for wearable applications. Although electroencephalography (EEG) remains the gold standard for sleep staging, PPG-based approaches have gained attention for their potential in unobtrusive home monitoring. Deep learning-based sleep stage classification using PPG has shown promising results; however, the effect of input sequence length—especially considering temporal dependencies between sleep stages—remains underexplored. This study investigates how varying PPG sequence lengths affect the performance of a deep learning model in classifying sleep stages, aiming to identify an optimal trade-off between model accuracy and sequence length.

Materials and methods: We utilized the publicly available Multi-Ethnic Study of Atherosclerosis(MESA) dataset, which provides comprehensive overnight physiological recordings, including PPG signals. PPG data from 321 subjects were segmented into non-overlapping 30-second epochs and preprocessed using standard filtering and normalization procedures. Each epoch was originally annotated with one of five sleep stages—Wake, N1, N2, N3, and REM—according to the American Academy of Sleep Medicine(AASM) guidelines. For this study, the stages were relabeled into four categories by merging N1 and N2 into Light Sleep(LS), and designating N3 as Deep Sleep(DS). The dataset was then split into training, validation, and test sets in a 7:1:2 ratio through subject-level stratified partitioning, ensuring generalization to unseen subjects.

Sequences were constructed from consecutive 30-second PPG epochs, with durations ranging from 30 seconds to 10 hours(i.e., N=1 to 1200). A sequence-to-sequence classification framework was implemented by adapting TinySleepNet, originally developed for EEG-based sleep staging. Considering the distinct characteristics of PPG, we modified the architecture by replacing the LSTM layer with bidirectional GRU units to capture bidirectional temporal dependencies while maintaining computational efficiency.

Results: The length of PPG sequences significantly influenced the sleep stage classification performance. Short sequences(N=1–30, corresponding to ≤ 15 minutes) showed low classification accuracy, particularly for LS and REM stages, suggesting insufficient temporal context for reliable stage discrimination. As sequence length increased, classification performance progressively improved. The optimal balanced performance across all stages was observed at N=300(2.5 hours), achieving a DS accuracy of 54.6%, thereby highlighting improved detection of this minority class. Notably, extending the sequence length beyond N=600(5 hours) led to continued improvement in Wake and LS stage accuracy, but increased misclassification of DS, indicating that class imbalance and overfitting to dominant sleep stages may have negatively impacted overall stage discrimination.

Conclusions: This study demonstrates that PPG sequence length has a substantial influence on deep learning-based sleep stage classification. Sequences of 1.5–2.5 hours(N=180–300) achieved the most balanced performance, maintaining consistent classification accuracy across both majority and minority stages. In contrast, sequences longer than 5 hours led to higher misclassification for minority stages, likely due to class imbalance and overfitting to dominant classes. These results highlight that selecting optimal sequence length is important to maximize the performance of PPG-based sleep staging models, particularly in real-world monitoring environments.

Participation in at-home obstructive sleep apnoea monitoring: Findings from six months of daily mobile-based check-ins

J. Fitton¹, B. Lechat¹, A. C Reynolds¹, J. Manners¹, S. Mukherjee¹, S. Proctor^{1,2}, K. A Loffler¹, B. Toson¹, A. Vakulin¹, D. J Eckert¹

¹Flinders University, Flinders Health and Medical Research Institute: Sleep Health, Adelaide, Australia,

²Southern Adelaide Local Health Network, Department of Respiratory, Sleep and Ventilation, Bedford Park, Australia

Introduction: Multi-night monitoring of obstructive sleep apnoea (OSA) severity is important to understand individual disease characteristics. To fully capture OSA's impact on daily life, it is equally important to assess daytime functioning; however, traditional measures of sleep-related daytime impairment are difficult to employ longitudinally. Therefore, we investigated the feasibility of a smartphone-based 'check-in' for long-term daily monitoring of self-reported daytime functioning in an OSA sample.

Materials and methods: Participants were recruited from public and private outpatient sleep clinics in Adelaide, South Australia, after referral for suspected OSA. Over a 6-month period, participants responded daily to a brief (<1 minute) daytime functioning questionnaire using Hoap, a consumer-available 'check-in' smartphone application. Questionnaire items, derived from the validated Acute Recovery Stress Scale, relate to six domains: sleep, fatigue, motivation, mental capacity, physical capability, and emotional balance. The Withings Sleep Analyser, a validated and FDA-approved under-mattress sleep sensor, was used to derive the nightly apnoea-hypopnoea index (AHI; events/hr). The

feasibility of this naturalistic monitoring approach was assessed through descriptive statistics and non-linear mixed effect modelling (Generalised Additive Models) of (a) initial self-report uptake (≥ 8 self-reports within first fortnight), (b) time-dependent change in adequate self-report rate (≥ 4 reports per week), and (c) the probability of a self-report occurring on any given day, as a function of various sleep-related and demographic predictors.

Results: On average, participants ($n=68$; 54% female) were obese [mean $\pm$ SD] (BMI: 32 ± 8 kg/m²), middle-aged (53 ± 15 years), had moderately severe OSA (AHI: 16.6 ± 18.4 events/hr), and made a self-report 3.7 (± 2.4) times per week. The proportion of the sample who achieved an adequate self-report rate declined over time but remained above 70% for one month post recruitment. The probability of adequate initial uptake was highest for those aged ~ 40 years and declined with increasing age (e.g., 40-50% less probable for those aged ~ 70 years), $p = 0.012$. Adequate initial uptake was more probable for females (probability: 87%) than males (probability: 58%), $p = 0.011$. Baseline sleep variables, including OSA severity, did not predict adequate initial uptake (all $p > 0.05$). Time-dependent variation in adequate self-report rate differed by all baseline demographic and sleep-related predictors (smooth-by-factor interactions: $p < 0.001$), though effect sizes were minimal. Within-individuals, the probability of a self-report on a given day was 10% greater following a night of high OSA severity (75th percentile; AHI = 23.5) than a night of low OSA severity (25th percentile; AHI = 2.8); smooth terms $p < 0.0001$.

Conclusions: These novel data support the feasibility of app-based check-ins within a clinical OSA cohort, with self-reports every second day appearing achievable for many. Although future research is needed to identify factors that enhance initial uptake and sustained use, our findings have important implications for both sleep clinicians and researchers monitoring daytime functioning over extended periods. They also serve as a foundation for future decision-making about daily prompts and app utility for longitudinal studies in clinical sleep health contexts. Appropriate use of daily check-ins may also help to advance knowledge of temporal relationships between OSA severity and daytime functioning.

Introduction: This study evaluates the efficacy of a sound-based AI model for predicting the apnea-hypopnea index (AHI) in pediatric populations as a potential non-contact adjunct to traditional polysomnography (PSG). Diagnosis of obstructive sleep apnea (OSA) in children with sleep-disordered breathing (SDB) typically requires overnight, hospital-based level I PSG. However, PSG is often challenging in pediatric populations due to the discomfort and burden of physical contact from electrode and sensor placement. Given these barriers, a sound-based contactless approach could enable more accessible and child-friendly OSA monitoring at home.

Materials and methods:

The performance of a sound-based AI model for AHI prediction was evaluated using synchronized audio recordings from PSG equipment and corresponding PSG data collected over 195 nights from 191 pediatric patients who slept alone in a hospital setting. Participants had a mean age of 15.04 years (SD: 3.26; range: 2.7-18.9), a mean body mass index (BMI) of 22.66 (SD: 5.50), and a mean AHI of 7.65 (SD: 17.39). Based on PSG-derived AHI values, the dataset was categorized as follows: 91 nights with no OSA (AHI < 1), 59 nights with mild OSA ($1 \leq \text{AHI} < 5$), 13 nights with moderate OSA ($5 \leq \text{AHI} < 10$), and 32 nights with severe OSA (AHI ≥ 10). The AI model detects apnea and hypopnea events in 6-second sub-epoch intervals and estimates AHI based on the counts of predicted events and predicted sleep stages. The model was previously trained and validated in adults, achieving high accuracies (92%, 93%, 94%), sensitivities (0.94, 0.94, 0.93) and specificities (0.88, 0.91, 0.95) at AHI thresholds of 5, 15, and 30.

Results: In the pediatric dataset, epoch-by-epoch four-stage sleep staging accuracy was 72.66%, with a macro F1 score of 0.71. Three-class classification of respiratory events (normal, apnea, and hypopnea) in 6-second sub-epochs yielded an accuracy of 96.64% and a macro F1 score of 0.71. AHI estimation based on these predictions showed high correlation with PSG-derived AHI ($r = 0.94$) and a mean error of 0.17 events/hour (SD 5.80). At clinically relevant pediatric AHI thresholds (≥ 1 , ≥ 5 , and ≥ 10), the model achieved accuracies of 77%, 89%, and 94%; sensitivities of 0.66, 0.75, and 0.84; specificities of 0.91, 0.94, and 0.96; ROC AUC values of 0.84, 0.91, and 0.95, respectively. For four-category OSA severity classification, the model yielded 68.20% accuracy and a macro F1 score of 0.56. While sensitivity at lower AHI thresholds was reduced compared to adult data, model performance at the AHI ≥ 15 threshold remained comparable, with sensitivity of 0.92 and specificity of 0.97.

Conclusions:

This study demonstrates the potential of a sound-based AI model as a viable, non-contact approach for pediatric AHI monitoring. Limitations include the relatively low audio quality of PSG recordings and the small number of nights recorded from children under 10 years of age (only 17 nights). Nonetheless, the results support the feasibility of sound-based AI models for accurate and comfortable in-home pediatric OSA monitoring.

Pilot Study Objectively Identifies Veterans with PTSD and Nightmares from Polysomnograms Using a Chaos Theory Approach

D. Lim⁵, E. Kim⁵, Y. Wang⁵, C.-B. Chen¹

¹Miami VA, Medicine, Miami, United States, ²University of Miami, Miami, United States

Introduction: Our Veterans suffer from a high prevalence of post-traumatic stress disorder (PTSD) that they experience uncontrollably during wake and sleep. PTSD is diagnosed using subjective history and questionnaires. PTSD is complex and heterogeneous; no single treatment is effective. Data supports an increase in sympathetic activity in some PTSD patients with nightmares; this may be a pathophysiological mechanism that increases their risk of cardiovascular disease. Prazosin crosses the blood brain barrier and blocks the response of norepinephrine and epinephrine in the brain. Challenge: A large VA study did not demonstrate efficacy of prazosin to decrease nightmares.

Hypothesis: Objective quantification of physiological sleep pattern using raw signals from the sleep study when Veterans are unconscious will identify which PTSD subtype will benefit from prazosin.

Objective: Use a chaos theory approach to identify PTSD during sleep using raw signals from the polysomnogram (PSG).

Materials and methods: Data: PSGs from Veterans at the Philadelphia VA.

Raw Signals: EEG leads and ECG lead was used to plot a trajectory for each Veteran.

HRA-based Dynamic Index: 5-minute intervals of sleep for a total of 120 minutes for each subject was used to calculate 112 metrics for each Veteran.

UMAP was used to visualize similarities and differences of their dynamic properties between subjects.

Results: Panel A Representative of a normal sleep pattern: a Veteran [subject 226] that does not have PTSD and does not have Obstructive Sleep Apnea (OSA).

Panel B Representative of a PTSD sleep pattern: a Veteran [subject 225] that does have PTSD but does not have OSA.

Panel C Representative of an OSA sleep pattern: a Veteran [subject 199] that does not have PTSD but does have OSA.

Panel D Table of characteristics of subjects including the Apnea-Hypopnea Index (AHI), PCL5 score (Questionnaire for diagnosing PTSD), PTSD diagnosis (taken from CPRS problem list), history of nightmares, traumatic brain injury (TBI) and hypertension (HTN). We calculated the Weighted Hypoxemia Index (WHI) and used the arousal index from the PSG to represent degree of sleep fragmentation (SF).

Panel E Box plot that demonstrates the HRA-based index for each of the subjects.

Panel F UMAP of all subjects to visualize the similarities and differences.

Panel G UMAP comparing Normal vs PTSD.

Panel H UMAP comparing Normal vs OSA.

Conclusions: 1. The sleep pattern is significantly different between a Veteran without PTSD (Panel A) and a Veteran with PTSD (Panel B) and a Veteran with OSA (Panel C).
2. The heterogeneity within Veterans with PTSD (Panel G) and OSA (Panel H) could be explained by age & medications.
3. Implication for the sleep field: This pilot study suggests that physiological raw signals from the PSG may identify a PTSD subtype that could benefit from prazosin.

Prospective real-world validation of a smartwatch-based OSA detection algorithm: A comparative study with polysomnography

D. Kim¹, J.Y. Han², D.Y. Song¹, K.R. Kim¹, Y.G. Jung¹

¹Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Otorhinolaryngology-Head and Neck Surgery, Seoul, Korea, Republic of, ²Samsung Electronics, Mobile eXperience, Seoul, Korea, Republic of

Introduction: Obstructive sleep apnea (OSA) is a significant health concern that requires accurate diagnosis and monitoring. While polysomnography (PSG) remains the gold standard for diagnosis, recent advancements in wearable technology offer potential alternatives for screening. In February 2024, the Galaxy Watch algorithm received de-Novo FDA approval for detecting signs of moderate to severe obstructive sleep apnea in adults aged 22 and older. This study aims to evaluate the accuracy of this device in estimating the Apnea-Hypopnea Index (AHI).

Materials and methods: We prospectively recruited adults aged 22 and older with suspected obstructive sleep apnea (OSA) from August 2023 to June 2024. All participants underwent simultaneous level 1 polysomnography while wearing the Galaxy Watch 6. We assessed the correlation between the estimated AHI (eAHI) from the Galaxy Watch algorithm and the AHI from polysomnography using Pearson's correlation analysis. Additionally, we performed a ROC curve analysis to determine the optimal eAHI cut-off value for diagnosing moderate to severe sleep apnea (AHI $\geq$ 15) and evaluated its accuracy.

Results: Data from 58 subjects were included in the analysis. The Pearson correlation coefficient between eAHI and AHI was 0.848 ($p < 0.001$), indicating a strong positive correlation. ROC curve analysis revealed that an eAHI cut-off value of 12.5 could differentiate moderate to severe sleep apnea (AHI $\geq$ 15) with 95% accuracy (sensitivity 90%, specificity 100%).

Conclusions: The AHI estimated by the Galaxy Watch algorithm shows a high correlation with the AHI from polysomnography and can accurately identify moderate to severe sleep apnea. These findings suggest that the Galaxy Watch is potentially valuable as a sleep apnea screening tool.

Protocol for creating a multimodal, free-living sleep and physical activity validation dataset for the human activity recognition and epidemiological communities

T. Plekhanova¹, B. Maylor¹, L. Brocklebank¹, R. Sharman¹, S. Kyle¹, A. Doherty¹

¹University of Oxford, Oxford, United Kingdom

Introduction: Wearable sensors offer a convenient and cost-effective alternative to polysomnography for large-scale sleep assessment. They are also less disruptive, therefore more likely to capture usual behaviour. However, they have limited ability to detect sleep, primarily because most validation studies have been conducted in small, homogenous samples under laboratory conditions. These studies often rely on a single modality (e.g., accelerometer only) collected over one night, without considering the full 24-hour activity cycle. Our aim is to collect a multimodal validation dataset capturing all 24-hour physical behaviours (i.e., sleep, sedentary behaviour, and physical activity) and to annotate wearable sensor data with gold-standard, ground-truth labelled data, for application to large-scale accelerometer datasets with linked health records.

Materials and methods: We will recruit 150 young adults aged 18-30 years from the general population. Data collection will take place over 4 nights and 3 days. During this period, participants will be asked to continuously wear five devices: a research-grade ActiGraph LEAP device on the dominant wrist, a consumer-grade Fitbit device on the non-dominant wrist, an Axivity AX6 device on the dominant thigh and ankle, and a chest-mounted wearable ECG patch (Bittium Faros 180). Participants

will also be asked to place a consumer-grade sleep sensor under their mattress (Withings). Ground-truth measures will be obtained from a standard at-home polysomnography (PSG) assessment on the first night for sleep, a wearable video camera for waking behaviours, and the ECG patch for heart rate. Additionally, we will collect information about participants' sleep quality (PSQI), insomnia symptoms (ISI), and mental health (GAD-7 and PHQ-9) to characterise the prevalence of sleep disturbances and depressive symptoms within our sample.

Results: Data collection is ongoing. This study will enable comparison of sleep estimates from wearables worn on different parts of the body and the under-mattress sleep sensor with the gold-standard PSG as reference. Additionally, it will allow for the validation of physical activity classifications using ground-truth video camera annotations and heart rate and heart rate variability from wrist-worn photoplethysmography (PPG) sensors against a ground-truth chest-worn ECG patch. Furthermore, combining different signals from PPG and accelerometry may improve the detection of physical behaviours. The final annotated dataset will be made publicly available upon completion.

Conclusions: This study will generate one of the largest multimodal validation datasets to date for 24-hour behavioural monitoring in free-living conditions. It will allow researchers to improve existing and develop new methods of sleep and physical activity measurement, ultimately improving our understanding of how these behaviours relate to health outcomes in large-scale wearable datasets such as the UK Biobank.

Real-Time Ventilation and Air Purification Improve Sleep Quality in Healthy Adults

S. Heo¹, D. Lee¹, J. Hong¹, J. Oh¹, S. Park¹, D. Yang¹, S. Moon¹, H. Bak², S. Kim², Y.-S. Chung³, K.-Y. Jung⁴

¹Asleep Inc., Seoul, Korea, Republic of, ²KyungDong Navien, Seoul, Korea, Republic of, ³University of Ulsan, College of Medicine, Asan Medical Center, Department of Otorhinolaryngology-Head and Neck Surgery, Seoul, Korea, Republic of, ⁴Seoul National University College of Medicine, Seoul National University Hospital, Department of Neurology, Seoul, Korea, Republic of

Introduction: Poor indoor air quality, particularly elevated levels of carbon dioxide (CO₂), particulate matter (PM₁₀), and fine particulate matter (PM_{2.5}), has increasingly been recognized as a disruptor of healthy sleep. In this study, we hypothesized that improving indoor air quality through a ventilation purification system capable of simultaneously reducing CO₂, PM₁₀, and PM_{2.5} levels could enhance sleep quality. To test this hypothesis, we evaluated objective sleep parameters under two operating modes of the system: a basic ventilation mode and an enhanced mode featuring real-time sensor-based automated control, to assess whether these interventions could meaningfully improve sleep architecture.

Materials and methods: In this prospective crossover study, 22 healthy adults underwent overnight polysomnography (PSG) under three distinct conditions: (1) no air quality intervention, (2) basic ventilation mode (Ventilation Mode 1), and (3) enhanced ventilation with real-time CO₂-driven automated control (Ventilation Mode 2). Mode 1 maintained levels at 1000 ppm, while Mode 2 increased ventilation airflow to sustain CO₂ concentrations at 700 ppm. The primary endpoint was sleep architecture measured by PSG.

Results: Air quality differed significantly across conditions. During the no-intervention nights, average CO₂ levels reached 2476 ppm, with PM₁₀ and PM_{2.5} concentrations at 13.7 and 9.2 µg/m³, respectively. Ventilation Mode 1 reduced CO₂ to 1035 ppm and nearly eliminated airborne particulates (PM₁₀: 0.97 µg/m³; PM_{2.5}: 0.30 µg/m³). Ventilation Mode 2 achieved even lower CO₂ concentrations (720 ppm), while maintaining particulate levels at similarly low ranges.

Ventilation Mode 1 resulted in significant improvements: sleep efficiency increased from 86.4% to 90.7% ($p = 0.045$), REM sleep time increased from 65.7 to 92.7 minutes ($p = 0.037$), and WASO decreased from 52.7 to 34.4 minutes ($p = 0.039$). Ventilation Mode 2 demonstrated broader and more pronounced benefits across multiple parameters: total sleep time increased from 374.0 to 402.9 minutes ($p = 0.002$), and sleep efficiency improved from 86.4% to 91.0% ($p = 0.007$). Additional gains were observed in REM sleep, which increased from 65.7 to 92.6 minutes ($p < 0.001$), and in WASO, which decreased from 52.7 to 28.9 minutes ($p = 0.005$). Although there was no statistically significant difference between Ventilation Mode 1 and Mode 2, the magnitude of improvement was greater with Mode 2.

Conclusions: Both ventilation strategies led to measurable improvements in sleep architecture when compared to no intervention, suggesting that even moderate control of indoor CO₂ can positively influence sleep quality. However, the advanced system used in Ventilation Mode 2, which offered tighter CO₂ control and continuous air quality optimization, produced greater improvements across a broader range of sleep outcomes. These findings underscore the clinical value of intelligent environmental regulation as a non-pharmacologic approach to enhancing sleep health.

Reliability of YASA for automated longitudinal sleep scoring in stroke and Parkinson's Disease

A. Movchan¹, P. Pchelina², L. Nastasi¹, E. Tsatsaki^{3,4}, V. Kasties^{5,4}, R. Huber^{5,4,6}, N.-H. Moser^{3,4}, A. Maric^{3,4}, C. Easthope Awai¹

¹Lake Lucerne Institute, Data Analytics & Rehabilitation Technology (DART), Vitznau, Switzerland, ²cereneo - center for Neurology & Rehabilitation, Vitznau, Switzerland, ³University Hospital of Zurich, Neurology, Zurich, Switzerland, ⁴University of Zurich, Zurich, Switzerland, ⁵University Children's Hospital Zurich, Child Development Centre, Zurich, Switzerland, ⁶University of Zurich, Department of Child and Adolescent Psychiatry, Zurich, Switzerland

Introduction: Sleep disturbances are common in both stroke and Parkinson's disease (PD). Characterizing and developing treatment strategies requires scalable, reliable sleep staging. Preferably, this should be accurate and feasible for longitudinal use in clinical and research contexts. Currently, sleep assessments often rely on single-night recordings, potentially missing transient features or subtle changes in sleep architecture.

Manual EEG scoring, while the gold standard, is time-consuming and subject to high intra- and inter-rater variability. Several automated algorithms have been developed and validated on large PSG datasets, including clinical populations such as PD. These include Z3Score (Patanaiik et al., 2018; ~90% accuracy in healthy adults, ~72% in Parkinson's), Stanford-stage (Stephansen et al., 2018; ~87%), SeqSleepNet (Phan et al., 2019; ~87%), and U-Sleep (Perslev et al., 2021; F1 ~0.79 in healthy adults, ~0.76 in sleep apnea). However, these methods are trained on full PSG data from controlled environments, and their performance on EEG from wearable devices in at-home settings remains unclear.

To address this, we evaluated the reliability of the open-source YASA (Vallat & Walker, 2021) algorithm using wearable EEG data from patients with stroke and PD. Establishing its accuracy is key to enabling large-scale sleep monitoring, including future assessments of night-to-night variability.

Materials and methods: This longitudinal study includes patients with stroke (S, n = 12) and Parkinson's disease (PD, n = 8), with ongoing recruitment. Each participant undergoes 15 nights of sleep monitoring using the Tosoo AXO wearable EEG device, which includes four dry electrodes placed on the forehead, bilateral temples, and the mastoid region. As of now, the dataset comprises over 300 nights of EEG recordings.

To validate YASA accuracy, a random subset of 20 nights (10 S, 10 PD) was manually scored by two trained scorers with experience in clinical EEG analysis using ScoringHero, producing a gold-standard reference. Automated scoring was then performed using YASA on the same data. Agreement between manual and automated annotations was assessed using Cohen's kappa and F1 scores for each sleep stage.

Results: Sleep stage distributions (epochs) were as follows:

S: Wake – 4123, N1 – 323, N2 – 2878, N3 – 2439, REM – 1524

P: Wake – 4556, N1 – 155, N2 – 3266, N3 – 1341, REM – 445

F1 scores were highest for Wake, N2, and N3: Wake – 0.889 (S), 0.927 (P); N2 – 0.682 (S), 0.791 (P); N3 – 0.753 (S), 0.727 (P). N1 performed poorly (0.248 in S, 0.173 in P), consistent with its rarity and fragmentation. REM agreement was moderate in stroke (0.611) but lower in PD (0.28), likely due to reduced and disrupted REM in PD patients. Mean Cohen's kappa was 0.639 (S) and 0.691 (P), indicating moderate overall agreement.

Conclusions: Limited performance for N1 and REM may be due their underrepresentation in these specific populations. Overall, YASA generalises remarkably well to neurological populations, demonstrating only minor penalties in accuracy of Wake, N2, N3 and facilitating large-scale use in clinical contexts.

Acknowledgments: The authors thank the participants, the StimuLOOP consortium, and our funders: The medical research center "The LOOP Zurich", Vontobel Foundation, and P&K Foundation.

Self-operable Wearable Transcranial Photobiomodulation on the Sleep Symptoms of People Living with Major Depressive Disorder: A Secondary Analysis of a Randomised, Sham-controlled Clinical Trial

W.-J. Li¹, P. Cassano^{2,3}, T.-W. Guu^{4,5}

¹Asia University, Department of Nursing, Taichung, Taiwan, ²Harvard Medical School, Boston, United States, ³Massachusetts General Hospital, MGH Division of Neuropsychiatry, Boston, United States, ⁴China Medical University Beigang Hospital, Division of Psychiatry, Department of Internal Medicine, Yunlin, Taiwan, ⁵King's College London, Centre for Healthy Brain Ageing, Institute of Psychiatry, Psychology, and Neuroscience, London, United Kingdom

Introduction: Major depressive disorder (MDD) is closely linked to sleep disturbances, and there is a two-way relationship between them. Near-infrared transcranial photobiomodulation (tPBM) is a safe neuromodulation technique with potential antidepressant and hypnotic effects. Our recently published study (Guu et al., 2025) has found an intriguingly sub-optimal mood-elevating effect, along with a significant sleep-enhancing effect using a patient-operable wearable tPBM device. In the present study, we conducted a secondary analysis to further explore the potential mechanisms contributing to this effect.

Materials and methods: Forty-eight outpatients with major depressive disorder (MDD) were randomized 1:1 to the wearable transcranial photobiomodulation (tPBM) or sham group. Participants used the intervention daily for at least 20 minutes, up to 8 weeks. The Pittsburgh Sleep Quality Index (PSQI) was used to assess sleep symptoms from baseline to week 12. Data were analyzed using the Mann-Whitney U test and the Wilcoxon signed-rank test.

Results: Poor sleep (PSQI global score > 5) was common in both the tPBM group (mean = 10.58, SD = 3.05) and the control group (mean = 11.64, SD = 2.98) at baseline. A significant difference in the PSQI global score between the two groups was observed at week 8 ($z = -2.90$, $p = 0.004$), with the tPBM group showing a greater improvement. In the tPBM group, the PSQI global score significantly decreased at both week 8 ($z = -2.92$, $p = 0.004$) and week 12 ($z = -3.19$, $p = 0.001$), compared to baseline (week 0). Among all the sub-components, sleep latency significantly decreased at week 8 compared to baseline in the tPBM group ($z = -2.44$, $p = 0.02$), but not the control group ($z = -1.59$, $p = 0.11$). In contrast, sleep disturbances scores significantly increased from baseline at both week 8 and week 12 in both the tPBM and sham groups (tPBM week 8: $z = -3.12$, $p = 0.002$, week 12: $z = -2.97$, $p = 0.003$; sham week 8: $z = -3.36$, $p = 0.001$, week 12: $z = -2.31$, $p = 0.021$). Further analysis showed that participants with better sleep latency in the tPBM group (PSQI sleep latency score < 2) had a greater reduction in BDI scores from week 0 to week 8 ($M = 12.31$, $SD = 11.41$) compared to those with poorer sleep latency (score ≥ 2 ; $M = 7.64$, $SD = 12.07$), although the difference was not statistically significant ($z = -1.19$, $p = 0.25$).

Conclusions: Self-administered wearable tPBM might improve sleep symptoms in people living with MDD mainly through reducing the sleep latency. The discomfort of wearing the device at bedtime might contribute to the increased sleep disturbance score, which was offset by the sleep induction effect of tPBM, and therefore resulted in the overall sleep improvement only in the tPBM group. Based on this study, the sleep latency reduction effect of wearable tPBM might be further pursued in larger study to characterize its impact on the mood symptoms.

Acknowledgments: The authors thank all the participants who joined this clinical trial for their valuable time, trust, and commitment. We also extend our appreciation to the research staff and collaborators who contributed to data collection, monitoring, and logistical support throughout the study.

Self-supervised learning of breathing-related patterns improves sleep staging from wrist accelerometry

N.R. Lorenzen¹, A. Brink-Kjaer¹, P.J. Jennum², E. Mignot³

¹Technical University of Denmark, Digital Health, Kgs. Lyngby, Denmark, ²Danish Centre for Sleep Medicine, Copenhagen University Hospital- Rigshospitalet, Glostrup, Denmark, ³Stanford, Department of Psychiatry and Behavioral Sciences, Stanford, United States

Introduction: Accurately measuring sleep architecture is critical for understanding how sleep influences mental, neurological, and physical health. Wrist-worn accelerometers offer a convenient, low-cost option for monitoring sleep at home, but most existing methods can only distinguish between sleep and wake. Detailed staging including identifying REM and deep sleep remains a challenge due to limited physiological information in the signal and small labeled datasets. However, small fluctuations during still periods may reflect breathing patterns, which could help resolve sleep stages. Here, we apply self-supervised learning to overcome the issue of limited dataset sizes and propose a task focused on extracting breathing information.

Materials and methods: We applied a self-supervised learning strategy recently proposed by the authors to leverage the large unlabeled UK Biobank dataset, containing ~700,000 days of wrist-worn accelerometer data from 109,000 subjects. A transformer masked autoencoder was pretrained using UK Biobank data by reconstructing the masked signal using the Log-Scale Mean Magnitude (LMM) loss and an adaptation termed Band-Amplification (BA) loss, in which the model reconstructs a signal with the 0.1–0.6 Hz band amplified 1,000-fold for input patches without movement. For downstream evaluation, we used data from 247 subjects with wrist accelerometry and sleep stage labels from concurrent polysomnography, grouping N1 and N2 stages into 'light sleep'. Outputs from the frozen encoders of the pretrained models were used to train linear classifiers. For comparison, we also trained the full model from scratch. All downstream evaluations were done in a 5-fold cross-validation setting with 80-20 train-validation split.

Results: The best overall performance came from the model pretrained with the respiration-enhancing loss, which achieved a macro F1 score of 0.415 ± 0.018 . The standard pretrained model followed with 0.406 ± 0.012 , while the model trained from scratch performed worst at 0.370 ± 0.010 . For the BA loss model, the stage-specific F1-scores were: 0.407 ± 0.02 for deep sleep, 0.34 ± 0.014 for light sleep, 0.294 ± 0.028 for REM sleep, and 0.619 ± 0.03 for wake.

Conclusions: We demonstrated that self-supervised pretraining is a viable strategy for improving deep learning-based sleep staging from wrist-worn accelerometry. Furthermore, this work showed that applying field knowledge to tailor the pretraining by focusing on the 0.1-0.6 Hz band, where we expect to find a breathing signal intermittently, can further improve performance, especially for REM sleep.

Silicon Nanowire Field-Effect Transistor Biosensors for the Detection of Melatonin as Sleep Disorder Biomarker

T. Ou¹, Q. Wei¹, Y. Liu², F. Han², C. Li³, F. Wei¹

¹GRINM (Guangdong) Institute for Advanced Materials and Technology, State Key Laboratory of Advanced Materials for Intelligent Sensing, Foshan, China, ²Peking University People's Hospital, Division of Sleep Medicine, Beijing, China, ³University of Science and Technology Beijing, Institute for Advanced Materials and Technology, Beijing, China

Introduction: With the increasing of the incidence of circadian rhythm sleep disorder (CRSD), developing continuous monitoring methods for CRSD becomes an important trend for assessing individual sleep quality and guiding treatment. Among that, melatonin is one of key biomarkers of CRSD, which concentration in physiological samples effectively reflects the status of an individual's circadian rhythm disorder at different times. However, current melatonin detection technology is still insufficient to meet the practical application requirements for immediate clinical diagnosis. In this study, we developed a simple and efficient method for melatonin detection using an aptamer-modified silicon nanowire field-effect transistor (SiNW FET) biosensor. This biosensor enables real-time, highly sensitive, and rapid detection of melatonin over a wide concentration range (15 fg/ml to 1.5 ng/ml), with a lower limit of detection reaching the fg/ml level. It is demonstrated that the melatonin detected by the SiNW FET biosensor shows good agreement with those detected by mass spectrometry, which is commonly used in clinical applications for melatonin detection. It is expected that modifying SiNW FET biosensors with aptamer monolayers can provide a promising method for examining melatonin in future CRSD treatments.

Materials and methods: Materials: the following chemicals were used: melatonin aptamer ; 3-aminopropyltriethoxysilane (APTES), anhydrous ethanol, acetone, 1-(3-dimethylaminopropyl)-3-ethylcarbodiimide (EDC, $\geq 98\%$), N-hydroxysuccinimide (NHS), bovine serum albumin (BSA, $\geq 98\%$) and phosphate buffer solution (PBS). All other chemicals used in this study were of reagent grade, and

deionized water was utilized for all experiments.

Methods: In our melatonin detection study, we utilized a Keysight B1500A semiconductor analyzer to apply a precise voltage to SiNWs-FET and accurately measure their current responses. To evaluate the performance of the SiNWs-FET, we initially established a baseline control using a 1×PBS.

Subsequently, a series of PBS solutions containing varying concentrations of melatonin were prepared and delivered precisely to the SiNWs surfaces via microfluidic technology for comprehensive performance testing.

Results: we prepared melatonin solutions with concentrations ranging from 15 fg/mL to 1.5 ng/mL. The SiNWs-FET biosensor possesses high specificity for detecting melatonin biomarkers. The binding of the aptamer to the target molecule near the silicon nanowire surface induces conformational changes, which enhance the carrier concentration in the channel and consequently produce a significant electrical signal.

Compared with conventional mass spectrometry methods used in clinical settings for detecting melatonin, using an aptamer-modified SiNWs-FET biosensor offers a significantly shorter detection time. Despite the promising results, further validation with a large number of actual saliva samples is necessary to ensure the stability and consistency of the detection outcomes before commercialization can be pursued.

Conclusions: we achieved highly sensitive detection of melatonin in solutions using SiNWs-FET biosensors surface-modified with aptamers. The detection limits ranged from 15 fg/mL to 1.5 ng/mL, and the current response exhibited a strong linear correlation with the logarithm of the melatonin concentration. It was confirmed that silicon nanowire SiNWs-FET modified with melatonin-specific aptamers demonstrated a specific response to melatonin. This approach facilitated highly sensitive and continuous monitoring of saliva collected at different times from patients with circadian rhythm sleep disorders.

Sleep Phenomics and Annotator: A Website Tool for Individual-Level Sleep Phenotype Quantification for Clinicians and Researchers

M.G. Arun^{1,2}, S. Rao¹, MB. Westover¹, R.J. Thomas¹, H. Sun¹

¹Beth Israel Deaconess Medical Center, Boston, United States, ²University of Illinois Urbana-Champaign, Champaign, United States

Introduction: Polysomnography (PSG) signals contain rich phenotypic information, which is crucial for assessing sleep disorders and the pathology of various organ systems. Clinicians often generate hypotheses directly inspired by clinical practice and directly beneficial to patients, but they lack the ability to quantify and test them due to a lack of computational training in clinical education. This gap is widened by the rapid advancements in artificial intelligence (AI), when sleep medicine begins to incorporate AI-derived metrics. However, accessing AI metrics is again challenging for clinicians. For example, many clinicians implicitly consider the burden imposed by apneas. In this case, quantifying hypoxic burden would significantly enhance the precision of individual-level decision-making. Therefore, we urgently need an accessible tool to fill the gap and promote technical integration in sleep medicine.

Materials and methods: We introduce Sleep Phenomics and Annotator (SPA), a clinician-friendly web platform designed for the easy quantification of PSG-derived sleep phenotypes, as well as the viewing of PSG signals and spectrograms. After logging in, users can upload signal files in the European Data Format (EDF), which can be exported by many mainstream clinical PSG software. Then, the user is taken to a screen where they can map channels from their uploaded EDF file to a standardized list of channel names. SPA automatically calculates various sleep metrics and allows users to download the results as a tabular file. In the backend, we used several packages, such as: (1) Flask as a web framework; (2) MNE for neurophysiological data processing; (3) NumPy and SciPy for signal processing. In the frontend, the technologies include: (1) Plotly.js for an interactive EEG waveform visualization; (2) jQuery for a dynamic user interface. Users are responsible for ensuring data privacy, such as de-identifying the exported EDF, a function commonly provided in clinical PSG software. The backend will automatically delete all uploaded files once the analysis is complete.

Results: SPA displays the PSG plot along with three spectrograms for the frontal, central, and occipital regions of the brain, respectively, if available. SPA computes various sleep metrics in addition to the standard parameters in sleep report, including EEG band powers, sleep depth, sleep spindles, slow

oscillations (SOs), spindle-SO coupling, brain age, arousal burden, sleep atonia index, heart rate and variability, respiration rate, apnea/hypopnea self-similarity (loop gain), and oxygen saturation metrics (average SpO₂, hypoxic burden). Metrics are stratified by sleep stages as appropriate. The platform features a modular design, enabling the easy integration of new metrics in the future. We provide detailed explanations and normative ranges for each metric to support individual-level decision-making. SPA is being deployed in Beth Israel Deaconess Medical Center internally and will be publicly available after the internal phase.

Conclusions: SPA provides an intuitive and accessible interface tailored for clinicians and researchers, eliminating the need for coding and bridging the gap between clinical sleep medicine and quantitative sleep research. SPA supports individual-level sleep data analyses, which may potentially lead to a paradigm shift in sleep medicine.

Sleep physiology characteristics in patients with Obstructive Sleep Apnea from Vietnam

B.T. Nguyen¹, K. Bui-Diem^{1,2}, T. Dang Huynh Anh^{1,2}

¹University of Medicine and Pharmacy at Ho Chi Minh City, Ho Chi Minh, Vietnam, ²University Medical Center, Ho Chi Minh, Vietnam

Introduction: Obstructive sleep apnea (OSA) profoundly disrupts sleep architecture, respiratory patterns, and cardiovascular function. While OSA polysomnographic characteristics are well-documented in Western populations, comprehensive data from Southeast Asian populations remain limited. This study characterizes sleep physiological parameters across OSA severity levels in Vietnamese patients, providing essential normative data for this underrepresented population.

Materials and methods: We conducted a cross-sectional analysis of 374 patients diagnosed with OSA (AHI ≥ 5 events/hour) who underwent overnight polysomnography at a tertiary hospital in Ho Chi Minh City, Vietnam. Patients were stratified into mild ($5 \leq \text{AHI} < 15$), moderate ($15 \leq \text{AHI} < 30$), and severe ($\text{AHI} \geq 30$) OSA groups. Comprehensive polysomnographic parameters were analyzed, including sleep architecture (N1, N2, N3, and REM stages), sleep quality indices (total sleep time, sleep efficiency, REM latency, and wake after sleep onset), respiratory event distribution, and heart rate variations across sleep stages. Statistical comparisons were performed using ANOVA with significance set at $p < 0.05$.

Results: The cohort comprised 374 patients (mean age 50.74 ± 14.81 years, 79.68% male) with severe OSA predominating (52.94%), followed by moderate (25.67%) and mild OSA (21.39%). Mean AHI was 37.20 ± 23.80 events/hour.

Sleep architecture showed marked disruption: reduced total sleep time (5.55 ± 1.33 hours), poor sleep efficiency (69.99%), prolonged REM latency (2.24 ± 1.64 hours), and elevated wake after sleep onset (1.67 ± 1.04 hours). Sleep stage distribution revealed pathological changes: increased N1 (21.66% vs normal 5-10%), predominant N2 (63.69%), severely reduced N3 (3.14% vs normal 15-25%), and decreased REM sleep (11.18% vs normal 20-25%).

Respiratory events demonstrated distinct sleep stage preferences: 65.36% occurred during N1-N2, 12.46% during REM, and only 1.42% during N3 sleep. This distribution varied significantly according to OSA severity ($p < 0.001$). Interestingly, mild OSA showed higher NREM-AHI than REM-AHI (16.13 ± 15.59 vs. 8.13 ± 3.42 events/hour), while severe OSA affected both stages equally (NREM-AHI: 49.03 ± 23.90 , REM-AHI: 55.59 ± 18.17 events/hour).

Cardiovascular parameters were correlated with OSA severity. Mean heart rate increased progressively: 66.57 ± 9.71 (mild), 67.95 ± 10.11 (moderate), and 71.89 ± 13.23 beats/min (severe) ($p < 0.001$). Similar patterns were observed during N1-N2 and REM sleep ($p < 0.01$), whereas the N3 heart rate remained stable across severity groups ($p = 0.743$), suggesting preserved autonomic regulation during deep sleep.

Notably, traditional sleep continuity parameters (total sleep time, REM latency, sleep efficiency, and wake after sleep onset) showed no significant differences across severity groups (all $p > 0.05$), indicating that sleep fragmentation is a universal OSA feature, regardless of severity.

Conclusions: This study provides a comprehensive sleep physiology characterization in Vietnamese OSA patients, revealing profound sleep architecture disruption with increased light sleep, reduced restorative sleep, and differential respiratory event impact across sleep stages. The finding that mild OSA preferentially affects NREM sleep, whereas severe OSA equally affects all sleep stages, offers important pathophysiological insights. Preserved N3 cardiovascular stability despite respiratory disturbances highlights the protective nature of slow-wave sleep. Progressive cardiovascular activation

with increasing OSA severity underscores the systemic effects of this disorder. These normative data establish important baseline characteristics for OSA management and research in Southeast Asian populations, where genetic, anthropometric, and environmental factors may influence disease expression differently from Western cohorts.

SleepRes auto-adjusting positive airway pressure, with and without KPAP™, is equivalent to Philips-Respironics's for the treatment of obstructive sleep apnea

L. Messineo¹, D. White¹, B. Hete², R. Berry³, W. Noah²

¹Harvard Medical School, Boston, United States, ²Sleep Centers of Middle Tennessee, Murfreesboro, United States, ³University of Florida, Gainesville, United States

Introduction: Auto-adjusting positive airway pressure (APAP) is the most commonly prescribed PAP modality for obstructive sleep apnea (OSA) treatment in the US. Kairos PAP™ (KPAP™) is a SleepRes proprietary feature that allows pressure to be decreased for better comfort during inspiration and much of expiration. Although KPAP™ showed equivalent efficacy to CPAP in a recent study, it has not been tested with APAP. Now, SleepRes has been developing their own APAP algorithm incorporating KPAP™. Therefore, in this study, we compared the efficacy of SleepRes APAP, with or without KPAP™, to that of a previously FDA-approved and widely-used APAP model (Philips-Respironics Omnilab) on OSA severity

Materials and methods: Thirty-five participants previously diagnosed with OSA (apnea-hypopnea index (AHI)>10 events/h) were randomized to receiving SleepRes or Philips-Respironics APAP in two separate, in-laboratory sleep studies, according to a randomized, crossover design. Additionally, a non-randomized third-night was conducted to test the efficacy of SleepRes APAP combined with KPAP™ vs. Philips-Respironics APAP. Sleep studies were all conducted within a six-week time frame. Both manufacturers' devices were set to their full pressure range (5-20 cmH₂O). Sleep studies were scored by a registered polysomnographic technician blinded to treatment allocation at a central scoring facility. The primary outcome of the study was the effect of the interventions on the AHI with 4% desaturations (AHI₄). Secondary outcomes were the AHI_{3a} (hypopneas scored with 3% desaturations or arousals), and the AHI in separate sleep stages. Study endpoints were assessed using linear mixed-models, adjusting for period, sequence, baseline AHI and percentage of sleep time spent supine.

Results: Of the randomized participants, thirty-three completed at least one treatment arm and were analyzed according to a modified-intention-to-treat approach. They were 54 ± 11 year old (mean ± SD), had a BMI of 34.2 ± 4.8 kg/m², and a baseline AHI of 34.7 ± 21.8 events/h. The majority of them was male (58%), white (55%; 33% black, 6% Asian) and non-hispanic (88%). Philips-Respironics APAP reduced AHI₄ and AHI_{3a} to 2.6 and 7.9 events/h, respectively. SleepRes APAP yielded an AHI₄ and AHI_{3a} similar to that of Philips-Respironics APAP's (mean difference [95%CI]: -0.2 [0.8, -0.4] events/h, P=0.451; -0.4 [-1.9, 1.4] events/h, P=0.669; respectively). Results were similar when KPAP™ was added (-0.1 [-1.2, 1.2] events/h, P=0.840; 1.1 [-1.9, 4.7] events/h, P=0.520; respectively, vs. Philips-Respironics). AHI₄ and AHI_{3a} were comparable with the primary outcome in non-rapid eye movement sleep (non-REM). This was also the case for AHI_{3a} in REM sleep. However, the REM AHI₄ was reduced slightly more only on SleepRes APAP vs. Philips-Respironics APAP (-1.5 [-2.7, 0] events/h, P=0.046). The same did not occur when comparing KPAP™ vs. Philips-Respironics APAP (i.e., AHI₄ was unchanged between interventions). A total of 29 participants completed all treatment arms of the study (N=1 dropped out for equipment intolerance, N=1 due to onset of central apnea, N=1 was lost to follow-up, N=3 for personal reasons).

Conclusions: SleepRes APAP and APAP plus KPAP are efficacious and comparable to Philips-Respironics APAP for the treatment of OSA despite a substantially lower pressure with KPAP™.

Sleep Stage Classification Using Cardiorespiratory Features from Smart Mattress Signals: A Case-Based Validation Study

H.-R. Lin^{1,2}, C.-H. Chuang¹, Y.-K. Lee¹

¹National Sun Yat-sen University, Institute of Medical Science and Technology, Kaohsiung, Taiwan, ²Kaohsiung Armed Forces General Hospital, Nursing Department, Kaohsiung, Taiwan, ³Kaohsiung

Armed Forces General Hospital, Medical Education and Research Center, Kaohsiung, Kaohsiung, Taiwan

Introduction: Non-contact physiological signal-based sleep staging has recently gained attention as a potential alternative to polysomnography (PSG). High-resolution smart mattress systems with a sampling rate of 200 Hz can detect subtle vibrations associated with cardiac and respiratory activity. This study investigates the feasibility of predicting sleep stages by separating heartbeat and respiration signals through two case-based analyses. To evaluate the capability of a high-frequency smart mattress system to separate cardiac and respiratory components from raw pressure signals, and to classify sleep stages based on cardiorespiratory features.

Materials and methods: Raw data were sampled at 200 Hz with the smart mattress system (Huijia Health Life Corporation) for approximately 25,000 seconds, totaling about 5 million data points. Each 30-second segment (epoch), containing 6,000 samples, underwent signal processing: a band-pass filter was used to detect respiratory peaks, while a band-pass filter extracted R-peaks for calculating heart rate (HR) and root mean square of successive differences (RMSSD). Features extracted per epoch included HR, RMSSD, respiratory rate, and respiratory variability. These features were input into a personalized classification function to estimate sleep stage labels (Wake, N1, N2, N3, REM) in accordance with AASM 30-second epoch standards.

Results: Both case studies demonstrated the feasibility of sleep stage classification using the extracted features. Case A exhibited physiological transitions consistent with expected patterns across Wake, non-REM (N1–N3), and REM stages. In Case B, 66.4% of total sleep time was identified as N2 stage, with detectable transitions in heart rate variability and respiratory dynamics across different stages. The proposed method yielded stable staging performance without requiring BCG or EEG signals.

Conclusions: This study demonstrates the potential of high-frequency smart mattress signals for non-invasive, epoch-based sleep stage classification. By using basic signal processing and classification methods to identify heart rate and breathing patterns, we can accurately determine sleep stages, which sets the stage for future large-scale, contactless sleep monitoring.

Acknowledgments: We sincerely thank the Kaohsiung Armed Forces General Hospital for providing clinical resources and institutional support. We also acknowledge Huijia Health Life Corporation for supplying the smart mattress system used in this study. Special thanks to Bo-Sheng Chen for his technical expertise in AI model development and implementation.

Sleep Stage Classification Using RGB-Fused Multimodal Images from Physiological Signals

H.-G. Kim¹, H. Lee¹, M. Kim¹, K.-Y. Kim¹

¹Electronics and Telecommunications Research Institute (ETRI), Daegu-Gyeongbuk Research Division, Daegu, Korea, Republic of

Introduction: This study proposes a novel approach for sleep stage classification by fusing three physiological signals, Heart Rate (HR), Photoplethysmogram (PPG), and Oxygen Saturation (SpO₂), into a single RGB image. Each signal is transformed into a 2D visual representation using methods suitable for its characteristics: Gramian Angular Field (GAF) for HR, Markov Transition Field (MTF) for PPG, and Recurrence Plot (RP) for SpO₂. These 2D representations are assigned to the red, green, and blue channels of a composite image. A convolutional neural network (CNN) is then employed to classify the fused image into one of sleep stages. Experimental results on the publicly available sleep dataset demonstrate the effectiveness of this multimodal visual fusion method.

Materials and methods: We utilized the MESA (Multi-Ethnic Study of Atherosclerosis) dataset with full-night signals recorded during polysomnography (PSG). Each subject's data is segmented into 30-second epochs, excluding segments with missing or zero values. Then the HR, PPG, and SpO₂ signals are transformed into a 2D representation tailored to its physiological properties using GAF, MTF, and RP, respectively. These modality-specific visualizations are mapped to RGB color channels, HR (red), PPG (green), and SpO₂ (blue), resulting in a single image. This fusion strategy not only preserves the temporal uniqueness of each signal but also encodes them into a coherent visual format suitable for deep CNNs. We employed a ResNet-based CNN and the model is trained with categorical cross-entropy loss and Adam optimizer using subject-wise splits (70% train, 15% validation, 15% test). To evaluate model performance under different class resolutions, we conducted experiments using three different label settings: 5-class (Wake, N1, N2, N3, REM), 4-class (Light Sleep merges N1 and N2), and

3-class (NREM merges N1~N3). This approach enables comprehensive assessment of model performance under various clinical and application-relevant scenarios.

Results: The performance of the proposed method is evaluated through experiments using multiple classification schemes. In the 5-class, the model achieved an overall accuracy of 38.3% and a Cohen's Kappa of 0.24, with reasonable performance in classifying Wake and REM stages but reduced precision for intermediate stages like N1 and N2. The 4-class scenario showed improved balance and yielded an accuracy of 44.0% (Kappa: 0.26). In the 3-class, the model reached the best performance with 63.0% accuracy (Kappa: 0.40). These results demonstrate that the proposed method is useful for sleep stage classification, even though the numerical score is modest compared to EEG-based systems, the distinct visualization strategy achieves this using only peripheral signals, which can be collected with a single wearable sensor, such as a fingertip pulse oximeter.

Conclusions: This study demonstrates the feasibility and effectiveness of RGB-fused multimodal signal visualization for sleep staging. The proposed pipeline provides a scalable solution for sleep analysis using minimally intrusive biosensors, and introduces a novel multimodal image fusion framework with strong potential for broader biosignal classification tasks.

Sleep Stage is Visible: Non-contact Sleep Staging using Infrared Video

K. Jang¹, Y.R. Choi¹, D. Park¹, H.-W. Shin^{2,3,4,5}, H.-S. Kim¹

¹Seoul National University, Graduate School of Data Science, Seoul, Korea, Republic of, ²Seoul National University College of Medicine, Obstructive Upper Airway Research (OUaR) Laboratory, Department of Pharmacology, Seoul, Korea, Republic of, ³Seoul National University College of Medicine, Department of Biomedical Sciences, Seoul, Korea, Republic of, ⁴Seoul National University Hospital, Department of Otorhinolaryngology-Head and Neck Surgery, Seoul, Korea, Republic of, ⁵OUaR Lab, Inc, Seoul, Korea, Republic of

Introduction: Sleep staging, the classification of sleep into Wake, N1, N2, N3, and REM stages, is essential for diagnosing sleep disorders and understanding sleep-related health outcomes. Polysomnography (PSG), the clinical gold standard, involves overnight monitoring with multiple wired sensors and manual scoring by experts. While accurate, it is costly, labor-intensive, and uncomfortable, often disrupting natural sleep patterns and making it impractical for everyday use. To overcome these limitations, we present a deep learning framework that directly classifies sleep stages from raw infrared video. This approach brings sleep monitoring closer to everyday settings by enabling fully non-contact, unobtrusive, and robust observation without requiring wearable devices or clinical supervision.

Materials and methods: We conducted experiments using a subset of the Korea Video Sleep Study (KVSS) dataset, consisting of 475 overnight infrared video recordings from a single hospital, including both healthy individuals and patients with sleep disorders. Each recording includes labels scored by experts and was captured at 640×480 resolution and 5 fps. To ensure subject independence, the data were split into 70 subjects for validation, 70 for testing, and the rest for training.

Our framework adopts a two-stage architecture designed to address the temporal characteristics of sleep video at multiple scales. Stage 1 utilizes a 3D convolutional neural network (MoViNet) to process short-term dynamics within each 30-second epoch, aiming to extract fine-grained motion features like breathing and subtle body movements. To further enhance sensitivity, we incorporate a pixel-wise temporal encoding module and apply an intra-subject discriminability loss during training. Stage 2 leverages a MAMBA-based sequence model to capture long-range temporal dependencies and model the global sleep architecture across the full night.

Results: Our model achieved 0.79 accuracy and 0.75 macro F1-score in the four-class setting, where N1 and N2 stages are merged into a single Light category, and 0.69 for both metrics in the five-class setting. We introduced three domain-specific techniques: pixel-wise temporal encoding, intra-subject discriminability loss, and long-range sequence modeling using Mamba. These components each contributed significant performance gains and worked together to address the challenges of video-based sleep staging. To interpret the model's behavior, we applied Video Eigen-CAM to activation maps in MoViNet. The resulting spatiotemporal saliency maps revealed that the model successfully captured rhythmic patterns in the chest region, as well as subtle body movements.

Conclusions: We propose the first deep learning framework that performs sleep staging directly from raw infrared video without relying on intermediate physiological signals. By incorporating strategies tailored to sleep video, the model achieves strong performance across diverse subjects including patients. The approach offers a fully non-contact alternative to traditional polysomnography, paving the way for scalable, at-home sleep monitoring using infrared video in everyday settings.

Acknowledgments: This research was supported partly by the Creative-Pioneering Researchers Program through Seoul National University, partly by the AI-Bio Research Grant through Seoul National University.

SLEEPYLAND: Trust begins with fair evaluation of automatic sleep staging models

A. Dei Rossi^{1,2}, M. Metaldi², M. Bechny^{2,3}, J. van der Meer⁴, M.H. Schmid⁴, C.L. Bassetti⁴, A. Tzovara^{3,4}, F.D. Faraci², L. Fiorillo^{2,5}

¹Università della Svizzera Italiana, Faculty of informatics, Lugano, Switzerland, ²Institute for Digital Technologies for Personalized Healthcare, University of Applied Sciences and Arts of Southern Switzerland, Department of Innovative Technologies, Lugano, Switzerland, ³University of Bern, Institute of Informatics, Bern, Switzerland, ⁴University of Bern, Sleep Wake Epilepsy Center | NeuroTec, Department of Neurology, Bern, Switzerland, ⁵Ente Ospedaliero Cantonale, Neurocenter of Southern Switzerland, Lugano, Switzerland

Introduction: Despite the recent surge in deep-learning algorithms for automatic sleep staging, fair comparisons remain unfeasible, as models are rarely evaluated on the same set of data, and pre-trained model weights rarely released publicly. We present SLEEPYLAND, the first fully open-source tool that fairly benchmark state-of-the-art algorithms on the same harmonized corpus of **in-domain ~27'500** sleep recordings, i.e., **~220'000 hours**, drawn from **17 different cohorts** hosted in the National Sleep Research Resource (NSRR) repository. To leverage the complementary strengths of individual models, we introduce **SOMNUS** (Soft-voting Over Multiple Networks for Unified Sleep-staging), an ensemble that aggregates probabilistic outputs across different models and channel configurations.

Materials and methods: U-Sleep [1], DeepResNet [2] and SleepTransformer [3] models have been re-implemented in a unified framework, and re-trained on NSRR recordings (single- and multi-channel EEG/EOG setup) with consistent preprocessing and sleep-segments sampling, as described in [4]. Pre-trained models weights openly released in [5]. The generalization of SOMNUS was quantified on additional **7 out-of-domain datasets**, i.e., **~84'000 hours** sleep recordings, mainly including the large Bern Sleep-Wake Registry (BSWR), with 8'410 recordings from patients and healthy subjects aged 0-91 years, and the Dreem Open Datasets (DOD-H, DOD-O), with 80 recordings, each scored by five independent physicians. Per-recording macro-F1 (MF1) and Cohen's κ were computed, and soft-consensus hypnoidensity similarity was assessed by average cosine similarity (ACS) [6]. Performance and clinical-marker estimation consistency among architectures were modelled with GAMLSS [7-8], conditioning MF1 and stage-specific errors on age, gender, apnoea-hypopnoea index (AHI) and periodic-limb-movement index (PLMI).

Results: On in-domain test sets, SOMNUS achieved a median MF1 of 78 % (range: 69–87%), exceeding the best single-model in 90% of cases/recordings ($p < 0.001$). On the large out-of-domain BSWR, SOMNUS reached a median MF1 of 72%, showing robustness, but only a modest +1% gain over top individual models. On multi-scored data, SOMNUS outperformed the best human scorer, i.e., MF1 85.2% vs 80.8% on DOD-H, and 80.2% vs 75.9% on DOD-O, better reproducing the scorer consensus than any individual expert ($\kappa = 0.89/0.85$ and $ACS = 0.95/0.94$ for healthy/OSA cohorts). The analyses revealed consistent patterns of demographic and clinical bias across all models, including SOMNUS. Performance (MF1) and clinical-marker estimation errors were systematically modulated by age, AHI, and PLMI, with variations exceeding ± 5 percentage points across the 5th–95th percentiles. While SOMNUS improved robustness overall, it did not reduce or compensate for bias.

Conclusions: SLEEPYLAND provides the largest, most transparent benchmark to date for sleep-staging research, releasing reproducible pre-trained models and an extensible evaluation framework. **The SOMNUS ensemble consistently outperforms individual deep-learning models across 24 datasets, even exceeding expert-level agreement on multi-scorer data**, demonstrating strong generalization and alignment with consensus scorers. SOMNUS does not mitigate demographic or clinical bias, with all models exhibiting systematic performance variation across age, AHI and PLMI. SLEEPYLAND sets a new standard for fair benchmarking and paves the way for clinically robust sleep automatic systems.

Snoring Sound Detection: An Explorative Study on Use of TensorFlow.js for Sleep Quality Monitoring

Z. Afir¹, N.A.Q.N. Haq², S.S. Alam³, R. Rakhmatiar¹, B. Munir⁴, S.A. Ernanda¹

¹Brawijaya University, Department of Neurology, Faculty of Medicine, Brawijaya University, Malang, Indonesia, Malang, Indonesia, ²Brawijaya University, Faculty of Medicine, Malang, Indonesia, ³Brawijaya University, Faculty Of Medicine, Malang, Indonesia, ⁴Brawijaya University, Department of Neurology, Faculty of Medicine, Malang, Indonesia

Introduction: This study presents the development and evaluation of a browser-based snoring detection application leveraging TensorFlow.js. The application was designed to perform real-time monitoring and analysis of snoring patterns as a non-invasive method for assessing sleep quality and conducting preliminary screening for potential sleep apnea.

Materials and methods: The model was trained on a dataset comprising 500 seconds of snoring audio (300 seconds from publicly available sources and 200 seconds of researcher-generated samples) and 500 seconds of background noise recordings. Testing was conducted over a cumulative duration of 200 seconds in various acoustic environments. All audio files were processed using Google's Teachable Machine platform, which segments input into 1-second intervals. No manual preprocessing or noise reduction techniques were applied. Model training was conducted using the Teachable Machine's built-in binary classification system powered by the TensorFlow framework, for 100 epochs using default hyperparameters. Model performance was evaluated based on sensitivity and specificity using a separate test split of the dataset.

Results: Performance evaluation revealed a high overall accuracy of 94.12%, supported by a sensitivity of 95.00%, specificity of 93.22%, precision of 93.44%, and an F1-score of 94.71%. These findings indicate the system's strong ability to reliably detect snoring events while minimizing false positives from ambient background noise. The model maintained consistent performance across varying acoustic environments without requiring manual preprocessing or noise filtering, underscoring the robustness of the browser-based approach. Additionally, the application was able to generate session-level statistics, such as snoring duration, frequency, and proportion, which enhance its utility for practical sleep quality monitoring.

Conclusions: The solution offers several advantages, including requiring no specialized hardware beyond a standard microphone, functioning entirely within a web browser without installation, ensuring privacy by processing all audio data locally, and providing detailed session statistics such as snoring duration, count, and percentage. This work demonstrates the potential of leveraging modern web technologies for accessible sleep monitoring solutions. It shows a high level of accuracy in distinguishing snoring sounds from ambient noise and provides relevant statistical information for sleep quality assessment. This approach opens new opportunities for creating user-friendly and widely accessible sleep monitoring technologies. Future research involving larger-scale studies with diverse user characteristics and environmental conditions is recommended to validate the system's external applicability and robustness in real-world settings. Furthermore, its web-based design enables potential integration with other health platforms or wearable devices for broader sleep monitoring applications.

Acknowledgments: This study was made possible through the collaborative efforts of the development team, insightful feedback from academic peers, and the utilization of open-source resources, complemented by AI-assisted grammatical correction, which collectively supported the training and evaluation of the snoring detection system.

Sound-Based AI Sleep Staging in Pediatric Patients

E. Cho¹, S. Kim¹, J. Hong¹, S.K. Park¹, S. Kim¹, H. Kyung¹, D. Lee¹, I.-Y. Yoon², Y.-S. Chung³, J.-W. Kim⁴
¹Asleep Inc., Seoul, Korea, Republic of, ²Seoul National University College of Medicine, Seoul National University Bundang Hospital, Department of Psychiatry, Seongnam, Korea, Republic of, ³University of Ulsan, College of Medicine, Asan Medical Center, Department of Otorhinolaryngology-Head and Neck Surgery, Seoul, Korea, Republic of, ⁴Seoul National University College of Medicine, Seoul National University Bundang Hospital, Department of Otorhinolaryngology-Head and Neck Surgery, Seongnam, Korea, Republic of

Introduction: This study evaluates the efficacy of a sound-based AI model for pediatric sleep staging as a non-contact adjunct to traditional polysomnography (PSG). Sleep disturbances are prevalent in children and can significantly affect development, behavior, and quality of life. PSG remains the gold standard for evaluating these conditions. However, PSG presents significant challenges in pediatric populations due to the physical contact required for electrode and sensor placement. Previous studies report that one-third of parents consider their child's sleep during PSG to be atypical compared to home sleep. Even home-based PSG systems face limitations, notably due to young children removing monitoring leads. These challenges highlight the need for contactless technologies as a practical alternative, particularly in pediatric home settings.

Materials and methods: We evaluated the performance of a sound-based AI sleep staging model using synchronized audio recordings from PSG equipment and corresponding PSG data from 195 nights, obtained from 191 pediatric patients sleeping alone in a hospital setting. Participants had a mean age of 15.04 years (SD: 3.26; range: 2.7–18.9), a mean body mass index (BMI) of 22.66 (SD: 5.50), and a mean apnea-hypopnea index (AHI) of 7.65 (SD: 17.39). The sound-based AI model used in this study was previously validated in adults with an accuracy of 80.01% and a macro F1 score of 0.76 for four-stage classification. Epoch-by-epoch accuracy was evaluated, and macro F1 scores calculated per night were analyzed for correlations with age.

Results: Across the pediatric dataset, epoch-by-epoch sleep staging accuracy was 72.66%, with a macro F1 score of 0.71, indicating a modest reduction from adult performance by approximately 7% in accuracy and 0.05 in macro F1. Stage-specific performance analyses showed consistent reductions compared to adults for Wake, Light, and REM stages, each decreasing by approximately 0.08 in F1 scores. In contrast, the F1 score for the Deep sleep stage increased by about 0.06, primarily due to a significant improvement in precision. When examining macro F1 scores of individual nights by age, a positive correlation coefficient of 0.33 was observed between age and model performance. Linear regression analysis indicated that performance improved proportionally with age, with a slope of 0.02 and an intercept of 0.36, resulting in near-adult macro F1 scores of approximately 0.74 by age 19.

Conclusions:

This study demonstrates the potential of a sound-based AI model as a non-contact adjunct to PSG for pediatric sleep staging, particularly beneficial for children sensitive to conventional PSG procedures. Limitations include the relatively poor audio quality of PSG recordings and the scarcity of data from younger children, with only 17 nights recorded from children under 10 years old. Nonetheless, these findings suggest that incorporating additional younger pediatric data into model training could further enhance performance, ultimately supporting the practical application of sound-based AI models for accurate and comfortable pediatric sleep monitoring.

Submental Ultrasonography versus Drug-Induced Sleep Endoscopy for Upper Airway Assessment in Obstructive Sleep Apnea Patients

W. Tungsatitchai¹, W. Banhiran¹, S. Rungmanee¹, M. Uataya¹, N. Kasemsuk¹

¹Faculty of Medicine, Siriraj Hospital, Mahidol University, Department of Otorhinolaryngology, Bangkok, Thailand

Introduction: To compare submental ultrasonography (SMUS) with drug-induced sleep endoscopy (DISE) for assessing upper airway configuration in obstructive sleep apnea (OSA).

Materials and methods: In this cross-sectional study, adult OSA patients scheduled for DISE underwent SMUS beforehand to assess airway collapse at four anatomical levels using the VOTE classification. Agreement between SMUS and DISE findings was analyzed with Cohen's weighted kappa coefficient. Additionally, accuracy of artificial intelligence (AI)-derived apnea-hypopnea index (AHI) from SMUS compared with polysomnography (PSG)-derived AHI was assessed.

Results: Thirty-five patients (mean age 44.5 ± 12.3 years, 74% male) completed the study. Agreement between SMUS and DISE was low across all sites, with kappa values from -0.116 to 0.028 (velum: -0.009 to -0.106 ; oropharynx: -0.012 ; tongue base: 0.028 ; epiglottis: -0.116 to -0.030). AI-predicted AHI had limited accuracy: correct predictions occurred in 28.6% of cases, with underestimation in 48.6% and overestimation in 22.9%. AI-predicted AHI demonstrated limited accuracy: correct predictions occurred in 28.6% of cases, while 48.6% were underestimated and 22.9% overestimated. Underestimation was most pronounced in severe OSA, with a mean difference of 27.4 events/h compared to correct predictions ($p < 0.001$). Overestimation showed a smaller, borderline significant difference (14.2 events/h; $p = 0.052$)

Conclusions: SMUS demonstrated limited agreement with DISE for upper airway collapse assessment and limited accuracy in AI-derived AHI prediction. While SMUS cannot replace DISE for detailed evaluation, its non-invasive nature suggests potential as a supplementary tool when DISE is unavailable. Larger studies with refined protocols and improved AI algorithms are warranted to validate its clinical applicability.

Success of the Newly Instigated Certification in Sleep Science Credential: An Initiative of the Australia New Zealand Sleep Science Association

K. Melehan¹, T. Churchward², N. Verginis³, B. Duce^{4,5}, R. Jayswal⁶, A. Campbell⁷, W. Reuhland²

¹University of Sydney, Faculty of Medicine and Health, Sydney, Australia, ²Institute for Breathing and Sleep, Austin Health, Melbourne, Australia, ³Monash Children's Hospital, Monash Health, Ward 4E Melbourne Children's Sleep Centre, Melbourne, Australia, ⁴Princess Alexandra Hospital, Department of Respiratory, Sleep & Mycobacterial Medicine, Brisbane, Australia, ⁵Queensland University of Technology, Faculty of Health, Brisbane, Australia, ⁶University of Western Australia, Perth, Australia, ⁷University of Otago, Department of Medicine, Wellington, New Zealand

Introduction: While international examinations of sleep physiologist knowledge exist, these do not always align with the specific context of sleep science in Australian and New Zealand. Thus, the Australian and New Zealand Sleep Science Association Certification Exam (ACE) providing the Certification in Sleep Science (CSS) credential was developed to cater for a more locally relevant credential and introduced in March 2024. The ACE represents a significant advancement in the recognition and standardisation of professional competency in sleep science across Australia and New Zealand. Aimed at recognising and supporting the professional development of sleep physiologists and scientists, the ACE builds on the former New Zealand Sleep Certification Examination (NZSCE), required for Clinical Physiologist registration in New Zealand.

Materials and methods: A multidisciplinary panel of subject-matter experts developed and govern the ACE. The assessment covers six core domains covering the comprehensive knowledge base expected of professionals working in sleep science. Questions underwent iterative development: drafted and reviewed by subject-matter experts. Individual exams are drawn at random from a large, vetted question bank: piloted by panel members and subjected to post-sitting review and difficulty analysis to inform ongoing calibration. The exam is delivered online under secure, proctored conditions, ensuring accessibility for candidates in metropolitan, regional, and remote locations while preserving integrity.

Results: Sixty candidates have participated across three exam sittings so far, yielding a 57 percent pass rate, demonstrating the exam's ability to discriminate competency levels. To date, 61 individuals hold the CSS credential, which includes those who have sat the exam, as well as 21 practitioners grandfathered via previous NZSCE success, and six members of the exam development committee.

Conclusions: The ACE exam represents a rigorous, adaptive assessment of sleep-science competency. Bi-annual exam sittings are planned to increase the cohort of CSS-credentialled professionals. Other goals include embedding the CSS into accreditation standards and achieving wider recognition by employers. Moreover, insights derived from exam performance data will inform ANZSSA's professional

education strategy, thereby enhancing the quality, consistency and impact of sleep-science practice across Australia and New Zealand.

Acknowledgments: With thanks to Australia New Zealand Sleep Science Association for this initiative.

Telemedicine/Telemonitoring in Sleep Laboratories - a Game Changer for Resource Efficiency Without Compromising Patient Care?

K. Mühlbacher¹, M. Krol¹, V. Liebler¹, E. Komar¹, J. Gano¹, E. Cauza¹

¹Herz Jesu Hospital Vinzenz Kliniken Wien, Department of Sleep Medicine, Vienna, Austria

Introduction:

Obstructive sleep-related breathing disorders have significant individual and socioeconomic implications due to their increasing prevalence in terms of impairing performance at work, road safety, quality of life, and their impact on the cardiovascular and metabolic system. Positive-airway pressure (PAP) therapy is widely considered to be the gold standard in treating severe sleep-related breathing disorders, but therapy success is only achieved through sufficient adherence. However, the increasing number of patients needing PAP treatment is straining the capacities of sleep labs in terms of available sleep lab positions for diagnosis and adjustment to PAP therapy, as well as the individual long-term care of PAP patients.

The aim of this study was to investigate the use and contribution of telemedicine/telemonitoring in relieving inpatient resources in sleep labs and to determine the practical benefits of telemonitoring in clinical practice.

Materials and methods: In a prospective observational study, 2394 continuous PAP (CPAP) patients were telemedically monitored over a period of 91 weeks in a sleep lab setting. 1814 patients, who had been using CPAP therapy for 3 months, have been included into this study. Of those, 1650 patients agreed to be telemedically monitored. After CPAP adjustment, therapy data is first assessed via telemonitoring after 2-4 weeks to determine if the therapy is proceeding effectively or if interventions were necessary. The study examined therapy dropout rate, time to first intervention, type of intervention, resource situation, willingness to participate, and age distribution compared to the group of patients who rejected telemonitoring in the same period.

Results: The use of telemedicine/telemonitoring led to a significant reduction in dropout rate in the "TM yes" group (5.21%) compared to the "TM no" group (10.3%). The average age was similar in both groups. The willingness to participate in telemonitoring was 91.95%. The period between CPAP adjustment and initial information regarding therapy efficiency was 37 days in the "TM yes" group compared to 204 days in the "TM no" group. The most successful intervention was online pressure adjustment, which significantly improved compliance after 3 months. An increase in CPAP settings by 57% and PSGs by 26%, as well as a reduction in on-site checks at the sleep lab by 30.7%, were noted.

Conclusions: The implementation of telemedicine/ telemonitoring in clinical practice is an effective measure to relieve capacities in the sleep lab, by reducing waiting times for diagnostic nights and enable time-sensitive adjustments of PAP treatments, which allow for early intervention in case of therapy problems, improve the quality of long-term care, and reduce dropout rates

Acknowledgments: I would like to thank the entire sleep laboratory team at Herz Jesu Hospital in Vienna for their valuable support and collaboration

The Effect of Different Auditory Stimulation Modalities on Sleep Slow Wave Activity and Cognitive Performance

C. Jones¹, G. Garcia Molina^{2,3}, B. Riedner⁴, M. Basner¹, S. Jones³, E. Strainis³, B. Peterson³, G. Tononi³

¹University of Pennsylvania Perelman School of Medicine, Department of Psychiatry, Philadelphia, United States, ²Sleep Number Labs, San Jose, United States, ³University of Wisconsin-Madison, Psychiatry, Madison, United States, ⁴University of Wisconsin-Madison, Department of Kinesiology, Madison, United States

Introduction: Insufficiently restorative sleep is a significant public health concern, impacting health and daytime function. Evidence suggests that the benefits of sleep, including sleep quality, are associated with sleep EEG slow waves. Enhancing slow-wave activity (SWA) during sleep with auditory tones is a

promising non-pharmacological approach to improving restorative sleep. This study explores the effect of auditory stimulation modalities on SWA enhancement and the impact on daytime cognitive performance.

Materials and methods: Twenty-seven healthy subjects (16F; M_{age} : 38.1 ± 5.7 years) with regular sleep schedules. Participants used a closed-loop stimulation device (SmartSleep) at home, which recorded EEG data over multiple nights.

Four conditions were tested: SHAM (no stimulation), ITI (continuous 1-second fixed inter-tone interval (ITI) stimulation), PHASE (stimulation timed to a slow wave up-state), and BLOCK (15 tones-ON/15 tones-OFF with 1-second inter-tone interval stimulation). Each condition lasted 10 nights over two weeks. The three stimulation conditions were presented in randomized order separated by two SHAM weeks.

Cognitive assessments were conducted using the Cognition battery, which consists of 10 assays of accuracy and speed on major cognitive domains, including executive functions, episodic memory, and complex cognitive processing.

EEG data were automatically scored into four stages (Wake, Light NREM, Deep NREM, REM) using a validated deep neural network. SWA was calculated for each NREM epoch as power in the 0.5–4 Hz band. SWA enhancement for each stimulation condition was defined as the average SWA increase relative to SHAM.

Cognitive performance data were corrected for practice and stimulus set effects and z-transformed to facilitate comparisons across cognitive domains. Sleep architecture, SWA, and cognitive performance were analyzed using linear mixed-effects models. We adjusted the statistical significance values for multiple comparisons using the Benjamini-Hochberg procedure.

Results: Sleep architecture revealed that ITI increased Wake-After-Sleep-Onset (+2.8 min ; $p=0.049$), and BLOCK increased time-in-bed (+7.5 min; $p=0.045$). SWA did not differ among conditions, but the number of responders ($\geq 5\%$ SWA enhancement) was higher in BLOCK (14/27) than PHASE (10/27) or ITI (11/27) conditions.

Higher SWA in BLOCK was associated with better vigilance ($r: 0.64$; $p < 1e-4$) on the Psychomotor Vigilance Task and reduced risk-taking ($r: -0.49$; $p=0.012$) on the Balloon Analog Risk Task.

Conclusions: These findings suggest that block stimulation during sleep improves alertness the next day and may enhance slow wave activity.

The Impact of a Sleep Stage-Based Personalized Environmental Control Algorithm ("HeySleep") on Sleep Quality

S. Heo¹, D. Lee¹, J. Hong¹, S. Kim¹, S. Kang¹, K.H. Ahn², S.W. Shin², I.-Y. Yoon³, J.-W. Kim⁴, K.-Y. Jung⁵
¹Asleep Inc., Seoul, Korea, Republic of, ²Hyundai Engineering & Construction R&D Division, Seoul, Korea, Republic of, ³Seoul National University College of Medicine, Seoul National University Bundang Hospital, Department of Psychiatry, Seongnam, Korea, Republic of, ⁴Seoul National University College of Medicine, Seoul National University Bundang Hospital, Department of Otorhinolaryngology-Head and Neck Surgery, Seongnam, Korea, Republic of, ⁵Seoul National University College of Medicine, Seoul National University Hospital, Department of Neurology, Seoul, Korea, Republic of

Introduction: Sleep quality plays a vital role in various aspects of physical and mental health, including immune function, cognition, and cardiovascular health. However, modern living environments often compromise sleep due to uncontrolled environmental factors such as light, temperature, ventilation, and noise. Previous studies have examined these factors individually in fixed, non-responsive settings. This study aims to evaluate the effectiveness of a real-time, closed-loop environmental control system ("HeySleep") that adjusts ambient conditions, including lighting, temperature, ventilation, and oxygen, according to polysomnography (PSG)-determined sleep stages, in order to improve both objective and subjective sleep quality.

Materials and methods: To minimize potential bias from the first night effect, 12 healthy participants were randomly assigned in a 1:1 ratio to one of two sequences: (1) control condition followed by HeySleep intervention, or (2) HeySleep intervention followed by control. Each participant completed two overnight PSG sessions in a controlled sleep clinic setting. Under the HeySleep condition, the system dynamically adjusted the ambient environment in real time based on detected sleep stages. At the onset of the sleep trial, room lighting was gradually dimmed over a 30-minute period to facilitate endogenous melatonin secretion and support circadian alignment. Once asleep, room temperature was

adjusted via the air conditioner - raised by 1°C during light sleep (N1-N2) and 2°C during deep sleep (N3) - to enhance thermal comfort. During REM sleep, temperature was held constant to accommodate the body's diminished thermoregulatory capacity. Air quality was managed through an automated ventilation system that maintained carbon dioxide (CO₂) levels below 700 ppm and actively filtered airborne particles. Additionally, an oxygen concentrator was deployed during sleep to ensure adequate oxygen delivery. Objective sleep parameters including sleep latency, total sleep time (TST), sleep efficiency (SE), and sleep architecture (light sleep, deep sleep, REM, and WASO) were assessed via PSG.

Results:

Compared to the control night, HeySleep led to significant improvements in several objective sleep parameters. SL decreased from 9.4 to 4.7 minutes ($p = 0.044$), TST increased from 347.5 to 446.1 minutes ($p = 0.012$), and SE improved from 82.1% to 91.8% ($p = 0.017$). WASO was reduced from 126.6 to 35.4 minutes ($p = 0.022$).

In terms of sleep architecture, deep sleep increased from 12.4% to 18.4% ($p = 0.027$), and REM sleep from 15.4% to 23.0% ($p = 0.007$). Wake time during the sleep period also decreased from 26.5% to 7.4% ($p = 0.020$). No significant changes were observed in light sleep, REM latency, respiratory disturbance index (RDI), or snoring metrics.

Conclusions: The implementation of HeySleep, a real-time, sleep-stage-responsive environmental control system, significantly enhanced key objective sleep parameters, including SL, TST, SE, and WASO. Notably, it also increased deep and REM sleep durations, two stages critical for physical and cognitive recovery while reducing wakefulness during the night. These findings suggest that personalized, closed-loop environmental control tailored to physiological sleep stages may offer a promising approach to improving sleep architecture and overall sleep quality in healthy adults.

Towards Digital Twins with Wearables: A Fully Data-driven Causal Analysis of Lifestyle Effects on Sleep Biomarkers

R. Švihrová^{1,2}, A.H. Petersen³, D. Marzorati², A. Dei Rossi^{4,2}, A. Tzovara^{1,5}, T. Gerosa⁶, F.D. Faraci²

¹University of Bern, Institute of Computer Science, Bern, Switzerland, ²University of Applied Sciences and Arts of Southern Switzerland, Institute of Digital Technologies for Personalized Healthcare, Lugano, Switzerland, ³University of Copenhagen, Section of Biostatistics, Copenhagen, Denmark, ⁴Università della Svizzera italiana, Faculty of Informatics, Lugano, Switzerland, ⁵Bern University Hospital and University of Bern, Inselspital, Department of Neurology, Bern, Switzerland, ⁶University of Applied Sciences and Arts of Southern Switzerland, Institute of Applied Sustainability to the Built Environment, Lugano, Switzerland

Introduction: Over the past decade, mobile and wearable devices have seamlessly integrated into daily life, offering researchers unprecedented opportunities to analyze lifestyle habits. Continuous unobtrusive monitoring with wearables, combined with user input and contextual information collected over time, enables the exploration of complex relationships in multi-source data. These new data streams offer valuable insights into how lifestyle factors, such as alcohol intake and stress, interact with sleep. While previous studies have established associations, causal relationships remain unclear. To identify modifiable risk factors and guide effective interventions for improving sleep quality, it is essential to uncover the underlying causal mechanisms. In this work, we apply data-driven causal inference methods to estimate the effects of lifestyle factors on sleep, laying the groundwork for personalized digital twin prototypes that support lifestyle simulations and intervention design.

Materials and methods: Data collected over 30 days by 294 participants with wearables were aggregated daily, combined with contextual information from questionnaires and weather data, resulting in an analytical sample of 277 individuals. The wearable-derived metrics included active time, average stress, heart rate, and sleep-related measures such as resting heart rate, proportions of sleep stages, sleep score, and other sleep-derived biomarkers. We used causal discovery algorithms to construct a Maximal Partially Directed Acyclic Graph (MPDAG), initialized with a temporally ordered PC algorithm and refined with the Structural Expectation-Maximization algorithm. Bootstrapping ensured stability, while background knowledge on temporal ordering and exogeneity was incorporated. Adjustment sets for each research question were derived through the Intervention with DAG Absent

(IDA), which identifies valid local adjustment sets for causal effect estimation. Causal effects were then estimated using linear mixed-effects models to account for inter-individual variability.

Results: Causal discovery on the data from 80% of the participants yielded a lifestyle structure consistent with literature. Estimated causal effects (95% CI) on the hold-out set of 56 participants showed that alcohol intake decreased REM sleep percentage by either -4.76 (-6.02 ; -3.49) or -4.17 (-5.45 ; -2.90), corresponding to the two valid IDA-derived adjustment sets compatible with the MPDAG. Daily stress reduced REM percentage by -0.22 (-0.25 ; -0.18), and total sleep time increased the sleep score by 4.85 (4.25 ; 5.45). Random intercepts indicated significant inter-individual variability, highlighting personal differences across participants.

Conclusions: In this work, we showed that causal discovery methods can be exploited with longitudinal lifestyle data, enabling the identification of meaningful mechanisms. Further analysis aiming to understand individual-level effects revealed differences between participants, underscoring the value of personalization. Learned causal effects represent a foundation for constructing digital twins - personalized, computational representations of individuals that evolve with data. By enabling counterfactual reasoning (e.g., "What if I slept more?"), these models can simulate the impact of lifestyle changes before interventions are implemented and help inform patients and healthcare professionals. This supports the development of adaptive systems for behavioral coaching and health optimization, with the possibility of incorporating also reinforcement learning enhanced personalization. Future work will focus on extending the presented methodology with longer observation periods to uncover personalised behavioral insights.

Towards in-cabin contactless sleep prediction

M. Guagnano¹, S. Groppo¹, V. Serchi², G. Beltrao², L. Pugliese³, M. Violante¹

¹Politecnico di Torino, Control and Computer Engineering, Torino, Italy, ²IEE Smart Sensing Solutions, Bissen, Luxembourg, ³Sleep Advice Technologies, Torino, Italy

Introduction: Drowsy driving is a major cause of fatal vehicle crashes, contributing to 10–30% of all road traffic incidents. Driver monitoring systems are designed to detect drowsiness and are categorized into four main approaches: vehicular-, behavioral-, physiological-, and hybrid-based. Physiological systems are the most accurate, already providing great results exploiting cardiac parameters extracted with contact-based solutions; however, these systems are intrusive and costly.

This work proposes a physiology-based, non-contact method for sleep prediction by analyzing Respiration Rate (RR), acquired on-the-fly using a short-range, 60 GHz, automotive, standalone radar in a driving-seat-mockup and driving-simulator environments. Sleep events were, for the first time in this context, robustly validated by a sleep expert medical doctor using the American Academy of Sleep Medicine (AASM) guidelines for the Maintenance of Wakefulness Tests (MWT) scoring, with a special focus on microsleep events. Therefore, a preliminary solution for sleep prediction in drivers, using RR acquired by radar, was successfully developed and validated.

Materials and methods: The radar detects chest and abdominal motion to estimate RR at 1 Hz. Data are processed offline to simulate real-time operation. A classification algorithm labels each second as ALARM or NOT-ALARM, predicting a potential sleep event.

Participants wore a Polysomnographic (PSG) setup. Data were collected during a modified-MWT conducted in two settings:

- Driving-seat-mockup: 13 subjects (mean age: 39 ± 10 , 5 female) sat in a cockpit simulator and followed repetitive driving instructions on a tablet for 40 minutes.
- Driving-simulator: 13 subjects (mean age: 40 ± 20 , 4 female) sat in a Maserati Ghibli dynamic cockpit simulator and completed a 45-minute low-stimulus driving session with dim lighting and minimal external input.

Participants were instructed to resist sleep. The PSG data have been scored by a sleep expert medical doctor following the guidelines of AASM. The scored sleep events (Microsleep, NREM1, NREM2, NREM3, REM, Awake) are the Ground Truth labels.

Ground truth was compared against algorithm predictions using a confusion matrix.

Results: Evaluation was based on the timing between the ALARM and the sleep event scored by the medical doctor:

- True Positive (TP): ALARM occurred before the first sleep event.
- False Negative (FN): ALARM occurred after (or concurrently) the sleep event or was not triggered at all.
- False Positive (FP): ALARM was triggered, but no sleep event occurred.
- True Negative (TN): Neither ALARM nor a sleep event occurred.

Therefore, the overall accuracy was evaluated as follows.

- Prediction of the 1st sleep event:

Driving-seat-mockup: 69% (TP=9, TN=0, FP=3, FN=1)

Driving-simulator: 85% (TP=1, TN=10, FP=1, FN=1)

- Prediction of all sleep events:

Driving-seat-mockup 94% (TP=79, TN=0, FP=4, FN=1)

Driving-simulator 80% (TP=2, TN=10, FP=1, FN=2)

Conclusions: This study is a preliminary step towards assessing the feasibility of using RR acquired by an automotive-grade radar in a highly challenging environment for sleep prediction in drivers. Despite the unbalanced and limited sample size of the datasets, the results are promising. More investigations are needed, on the one hand to extend the dataset, on the other to test the radar capabilities in natural driving sessions where motion artifacts can play a significant role in degrading signal quality.

Transdiagnostic comparison of sleep measures across chronic physical and mental health disorders using FitBit data in the All of Us dataset

X. Huang¹, C. Hsieh¹, Q. Nguyen¹, M.E. Rentería¹, P. Gharahkhani¹

¹QIMR Berghofer Medical Research Institute, Brisbane, Australia

Introduction: The association between sleep and chronic diseases is well established. However, most studies have examined individual disease groups separately, with few exploring sleep patterns transdiagnostically across multiple physical and mental health conditions. This study first compares sleep measures across groups of individuals with sleep disorders, mental health disorders, and cardiovascular disease, and subsequently evaluates the predictive ability of these measures for classifying disorders.

Materials and methods: Participants from the All of Us Research Program with more than 21 days of continuous sleep data collected prior to the prescription of sleep-affecting devices or medications were included. Sub-cohorts were identified using ICD-9 and ICD-10 codes mapped via the PheWAS package in R, comprising obstructive sleep apnea (OSA, N = 2,233), insomnia (N = 1,449), major depressive disorder (MDD, N = 2,370), anxiety (N = 3,128), bipolar disorder (N = 725), PTSD (N = 577), cardiovascular disease (CVD, N = 2,075), and controls (N = 3,954). Minute-level sleep-stage data (wake, light, deep, REM) were used to derive nightly sleep metrics including sleep efficiency, fragmentation, stage-transition dynamics, sleep onset latency, napping behaviour, and wake after sleep onset (WASO). These nightly metrics were summarised across each participant's longest continuous recording period by calculating statistical features such as the mean, coefficient of variation (CV), and entropy. Features were compared within sub-cohorts and against controls. An XGBoost binary classifier was fitted for each disorder versus controls using all sleep features, adjusting for age, sex, race, ethnicity, BMI, waist, and hip circumference. Model performance was assessed against a baseline model (without sleep features) and a model using sleep features only.

Results: Certain sleep measures showed marked differences between disorder cohorts and controls. For example, the CVD cohort had the highest WASO (SMD = 0.3), lowest sleep efficiency (SMD = -0.3), lowest percentage of deep and REM sleep (SMD = -0.5), and highest variability in the percentage of light, deep, and REM sleep stages (SMD = 0.6). While higher frequency and duration of morning naps were common across disorders, these measures were especially elevated in PTSD (SMD ≈ 0.5–0.6). The PTSD cohort also showed the highest variability in sleep onset times (SMD = 0.5), followed by MDD and bipolar disorder (SMD = 0.3), and anxiety, OSA, and insomnia (SMD = 0.2). XGBoost models achieved ROC AUC scores ranging from 0.69 (anxiety) to 0.78 (CVD) and 0.80 (OSA). Incorporating

sleep features improved classification metrics across all conditions, notably an improvement in ROC AUC score in classifying MDD (+0.07), PTSD (+0.06), bipolar (+0.06), and anxiety (+0.05), whereas the improvement in classifying CVD (+0.01), OSA (+0.03) and Insomnia (+0.03) are less pronounced. Models using only sleep features also demonstrated ROC scores >0.63 for all disease areas, confirming the predictive relevance of sleep patterns.

Conclusions: Our study highlights different patterns in sleep characteristics across diverse chronic health disorders. However, simple statistical summaries alone may lack sufficient granularity for accurate disease classification. Future extraction of higher-resolution sleep features could further distinguish these patterns, potentially enabling more accurate disease classification and prediction.

Transformer-Based Reconstruction of Thoracic Movement from Infrared Sleep Video for Non-contact Respiratory Monitoring

Y. Lee^{1,2}, H.K. Lee^{1,2}, Y. Na^{1,2}, S. Lim^{1,2}, J. Min^{1,2}, H.-W. Shin^{1,2,3,4}

¹Seoul National University College of Medicine, Obstructive Upper airway Research Laboratory, the Department of Pharmacology, Seoul, Korea, Republic of, ²Seoul National University College of Medicine, Department of Biomedical Sciences, Seoul, Korea, Republic of, ³Seoul National University Hospital, Department of Otorhinolaryngology-Head and Neck Surgery, Seoul, Korea, Republic of, ⁴OUaR LaB Inc, Seoul, Korea, Republic of

Introduction: Thoracic movement patterns during sleep provide valuable biomarkers for both sleep stage classification and the diagnosis and severity assessment of obstructive sleep apnea (OSA). While conventional in-laboratory polysomnography (PSG) with thoracic belts remains the gold standard, its dependence on skin-contact sensors and vulnerability to motion artifacts limit its utility for long-term, home-based monitoring. In this study, we propose a non-contact infrared camera-based approach that reconstructs thoracic movement signal from de-identified video data.

Materials and methods: We utilized the Korea Video Sleep Study (KVSS) dataset, which comprises 475 infrared sleep video recordings synchronized with PSG data, totaling over 3,000 hours of footage collected in clinical settings. Participants (n = 475; 26% female) had a mean age of 53.4 ± 14.5 years and a mean BMI of 26.5 ± 4.2 kg/m². OSA severity was classified as follows: Normal (9.3%), Mild (21.5%), Moderate (25.9%), Severe (43.3%). To ensure anonymity, patient faces in the videos were de-identified. Video resolution was 640×480 pixels at 5 Hz frame rate. Using 60-second windows, we extracted motion-based features. These features were fed into a modified transformer architecture to reconstruct the thoracic signal. We measured thoracic movement-derived respiratory rate (TRR), defined as the number of breathing cycles per minute from both the PSG-derived thoracic movement signal and reconstructed thoracic signal using a power spectral density peak method in the 0.1–0.5 Hz frequency band.

Results: Our model achieved a mean absolute error (MAE) of 0.87 TRR, a root mean squared error of 2.58 TRR, and a mean absolute percentage error of 8.39%. In the frequency domain, the Pearson correlation coefficient was 0.911, and the concordance correlation coefficient was 0.803. Notably, our MAE of 0.87 TRR (≈ 0.87 breaths/min) is well below the ± 3 breaths/min clinical acceptability threshold reported in prior wearable vital sign studies.

Conclusions: Our proposed methodology offers non-contact, de-identified thoracic movement monitoring, minimizing patient discomfort and facilitating continuous tracking in environments such as homes, hospitals, and sleep clinics. We believe that it has the potential to replace traditional belt-based measurements in OSA diagnosis and sleep stage classification.

Acknowledgments: This research was supported partly by the Creative-Pioneering Researchers Program through Seoul National University, partly by the AI-Bio Research Grant through Seoul National University.

Unobtrusive skin temperature estimation during sleep on a smart bed

G. Garcia Molina^{1,2}, T. Winger^{3,4}, N. Makaram¹, M.R. Rao¹, P. Chernega⁵, Y. Shcherbakov⁶, L. McGhee³, V. Chellamuthu¹, E. Veneros⁷, R. Mills³

¹Sleep Number Labs, San Jose, United States, ²University of Wisconsin-Madison, Psychiatry, Madison, United States, ³Sleep Number Corporation, Minneapolis, United States, ⁴University of Minnesota,

Department of Computer Science and Engineering, Minneapolis, United States, ⁵GlobalLogic Ukraine, Kyiv, Ukraine, ⁶GlobalLogic, Spain, Madrid, Spain, ⁷Nanami, Enumclaw, United States

Introduction: The transition from wakefulness to sleep is associated with a decrease (of about 1 °C) in core body temperature which is facilitated by an increase in cutaneous blood flow that helps dissipate internal heat into the microenvironment surrounding the sleeper's body. The rise in cutaneous blood flow causes the skin temperature at distal (hands and feet) and proximal (near the abdomen) sites to increase by about 1 °C and 0.5 °C respectively.

Understanding the association between the dynamics of skin temperature, sleep onset and maintenance may inform strategies to optimize the in-bed microenvironment to enhance sleep quality. Characterizing the dynamics of skin temperature variations across sleep phases on a large scale requires an unobtrusive, longitudinal method for estimating skin temperature, ideally under ecologically valid (real-world) conditions.

Materials and methods: Leveraging the data from a temperature sensor strip (TSS) with five individual temperature sensors (separated from each other by 14 cm) embedded near the surface of a smart bed's mattress, we have developed an algorithm to estimate the distal skin temperature with a minute-long temporal resolution.

The TSS is transversally oriented with respect to the sleeper's body, spans a 67-cm-wide region, and is located 61-cm from the top of the bed.

The data from 18 participants (9M/9F; 44.4 [SD: 6.9] years-old) who recorded TSS and ground-truth skin temperature data from sleep during 14 nights at home and 2 nights in a lab were used to develop a regression model that uses a two-stage architecture (gradient boosted tree followed by a random forest) to estimate the distal skin temperature.

Using the in-home data, a five-fold cross-validation procedure was applied to train and validate the model such that the data from a participant could only be either in the training or validation set but not in both. The algorithm verification was performed with the in-lab data.

Results: The regression model can estimate the distal skin temperature at a minute-level resolution, with accuracy characterized by a mean bias of -0.002 °C, mean limits of agreement [-0.79 to +0.79 °C] and mean coefficient of determination $R^2=0.87$.

Thus, 95% of absolute approximation errors are below 0.8 °C and almost 90% of the variability in skin temperature can be explained by the regression model.

The verification with the in-lab data showed agreement with the ground-truth distal skin temperature characterized by a coefficient of determination of 0.90.

Conclusions: The temperature sensing approach and regression model proposed in this study may enable accurate, unobtrusive, longitudinal and ecologically valid collection of distal skin temperature values during sleep. To the best of our knowledge, this is the first study reporting on the feasibility of unobtrusively estimating skin temperature while lying in bed. Additional research is needed to confirm these encouraging results in a larger cohort.

User-friendly and inter-operable software for automatic quantification of muscle activity during sleep

M. Cesari¹, R. Ferri², B. Högl¹, A. Stefani¹, A. Silvani³

¹Medical University of Innsbruck, Department of Neurology, Innsbruck, Austria, ²Oasi Research Institute-IRCCS, Troina, Italy, ³University of Bologna, Department of Biomedical and Neuromotor Sciences, Bologna, Italy

Introduction: Although several algorithms for the analysis of muscle activity during sleep have been developed and validated, the lack of user-friendly interfaces and inter-operability across different polysomnography (PSG) software limits their use. We aimed to develop "Sleep Open-source Muscle Activity Analysis System" (SOMAS), the first user-friendly and inter-operable software for automatic quantification of muscle activity during sleep.

Materials and methods: We developed SOMAS as a stand-alone executable based on freely available MATLAB (The Mathworks, Inc.) Runtime shared libraries. SOMAS operates on data files in inter-operable European Data Format+ (EDF+) on local computers without any data sharing online. SOMAS quantifies muscular activity during sleep with two previously validated algorithms: the atonia index (AI) and the distribution of normalized electromyogram (EMG) values (DNE). Both algorithms provide metrics of muscle activity during all sleep stages and wakefulness. In addition, SOMAS calculates leg

movement (LM) indices according to the 2016 World Association of Sleep Medicine (WASM) criteria. Through several user-friendly interfaces, the user is asked to specify the desired analyses, to define annotations defining the hypnogram, to specify the electromyographic signals, and to define any other relevant annotation (e.g. artifacts to be excluded from analysis, annotations of LM). To confirm the validity of SOMAS, we considered sleep recordings of eight patients with isolated rapid eye movement (REM) sleep behavior disorder (iRBD), five with restless legs syndrome (RLS), seven with sleep breathing disorders and five clinical controls. For all subjects and sleep stages, the AI and LM indices calculated by SOMAS in the chin, upper and lower extremities were compared to the ones derived by Hypnolab (a previously proposed software) by means of Spearman correlations. In addition, the AI and DNE in REM sleep calculated in the chin, upper and lower extremities obtained by SOMAS were used to discriminate patients with iRBD from the remaining subjects by means of area under the curve (AUC). Finally, the periodic leg movement index and periodicity index calculated by SOMAS were compared between patients with RLS and clinical controls, and the AUC was used to assess the ability to discriminate between the two groups.

Results: The AI derived by SOMAS and Hypnolab showed high agreement across all muscles and sleep stages (Spearman $r > 0.97$ in 24 out of 25 comparisons). Similarly, all LM indices had excellent agreements (Spearman $r > 0.99$ in all comparisons). The AI and DNE in REM sleep also showed excellent discrimination abilities in differentiating patients with iRBD from the remaining subjects (AUC in the range 0.890-1.000). Finally, patients with RLS had higher PLMS index than controls ($30.31/h \pm 39.1/h$ vs $4.21/h \pm 5.52/h$) as well as higher periodicity index in sleep (0.509 ± 0.328 vs 0.254 ± 0.251). These two indices discriminated patients with RLS from controls with AUC of 0.750 and 0.714, respectively.

Conclusions: The high correlations between SOMAS and Hypnolab as well as the expected discriminations of patients with iRBD and RLS support the validity of the algorithms' implementation. SOMAS will help researchers by providing automatic, standardized and reliable methods for quantification of muscular activity during sleep.

Using Machine Learning to Identify Patient-Ventilator Asynchrony during Non-Invasive Ventilation in Patients with Motor Neurone Disease

J. Yang¹, C. Wang², E. Caparo², A. Stell², M. Howard³, U. Aickelin², D. Berlowitz¹

¹The University of Melbourne, Department of Physiotherapy, Parkville, Australia, ²The University of Melbourne, School of Computing and Information Systems, Parkville, Australia, ³Institute for Breathing and Sleep, Austin Health, Heidelberg, Australia

Introduction: Motor Neurone Disease (MND) is a rare and fatal neurodegenerative disorder. It progressively destroys the motor neurones responsible for voluntary muscle contraction, with symptoms worsening until the ability to speak, swallow, move, and even breathe unassisted are lost. For people living with MND, this onset of respiratory failure is often the final and most devastating stage of their illness. Non-invasive ventilation (NIV) is the most effective intervention currently available, extending survival times threefold compared to the best available medication. Yet despite this, NIV remains underutilised and poorly adhered to, with challenges to both uptake and usage. A key contributor to poor adherence is patient-ventilator asynchrony (PVA). PVA is a mismatch between a person's breathing effort and the mechanical assistance provided by their ventilator. This mismatch undermines their treatment by reducing comfort, disrupting sleep, lowering adherence, accelerating decline, and eventually hastening their demise. Identifying PVA currently requires labour-intensive manual review of polysomnography (PSG) recordings by skilled clinicians, a process that is difficult to scale. Acquiring these PSG recordings also involves an overnight titration study in a sleep lab, which poses significant logistical hurdles for patients and their families and is impractical to repeat frequently, particularly in this patient population. This project aims to address this therapeutic gap by developing a machine learning (ML) model that automates the detection and classification of PVA events. This program of work ultimately aims to bring automated real-time ventilator re-synchronisation to the bedside.

Materials and methods: A curated dataset of 30 PSG recordings with >9,000 clinician-scored PVA events acquired during a prior randomised controlled trial was used to train and validate a machine-learning algorithm. Multivariate time-series models were used to detect and classify two common and

distinct forms of PVA from PSG data – namely, Ineffective Effort and Double Trigger. Validation was then performed against clinician annotation to assess accuracy.

Results: 85% of Ineffective Effort events were concordant between clinician and ML scoring, with the remainder comprising 10% that were clinician-scored only and 5% being ML-scored only. In contrast, 51% of Double Trigger events were concordant between clinician and ML scoring, with 7% that were clinician-scored only and 42% being ML-scored only. The model achieved an F1 score of 0.92 for Ineffective Effort and 0.68 for Double Trigger. The reduced specificity observed in Double Trigger is likely heavily influenced by the substantially lower number of Double Trigger events in comparison to Ineffective Effort within both the training and validation data sets.

Conclusions: This project delivers a translational step toward automated PVA identification and correction for people with MND. Future research will determine if reducing reliance on manual clinician analysis will allow timelier and more effective NIV optimisation. We hope to deliver meaningful survival and quality-of-life gains for a population with very limited therapeutic options, sooner and more reliably than any pharmacological advance currently on the horizon.

Acknowledgments: This project is a collaboration between the University of Melbourne, the Institute for Breathing and Sleep (IBAS), and Austin Health. We gratefully acknowledge funding support from FightMND and AEA Ignite.

Validation of an Under-Mattress Monitoring Device Against Polysomnography for Heart Rate (HR) and Heart Rate Variability (HRV) Accuracy Assessment

E. Adibi¹, A. Cotton-Clay², A. Wray², V. Easwar², A. Kinsolving², P. Kahn², C. Kushida³, A. Hekmat⁴

¹Prime West Consortium, Division of Internal Medicine, Redding, United States, ²Fullpower Technologies, Santa Cruz, United States, ³Stanford University, Division of Sleep Medicine, Stanford, United States, ⁴Stanford University, Division of Sleep Medicine, Palo Alto, United States

Introduction: Heart rate variability (HRV) is a widely used physiological marker for assessing autonomic nervous system function and overall sleep health. While electrocardiogram (ECG)-based HRV measurements obtained during polysomnography (PSG) are considered the gold standard, their complexity limits accessibility for routine or home-based monitoring. Advances in artificial intelligence have enabled the development of contactless, non-invasive sleep monitoring devices such as the Sleeptracker-AI, which utilizes multiple piezoelectric sensors placed under the mattress to detect heartbeats, respiration, and movement via ballistocardiography (BCG). This study aims to validate the accuracy of Sleeptracker-AI's heart rate and HRV metrics, specifically HR, Standard Deviation of Normal-to-Normal intervals (SDNN), and Root Mean Square of Successive Differences (RMSSD), by comparing them to simultaneous PSG-derived values.

Materials and methods: The study was performed on 102 adults (55% men and 45% women; mean age 40.6 ± 13.7 years; BMI 26.8 ± 5.8 kg/m²) who underwent a one-night unattended study and were simultaneously monitored using standard PSG and Sleeptracker-AI. HR and HRV metrics were compared between the two devices by analyzing both 5-minute windows and full-study averages. Data were evaluated across all ECG beats and matching beats (ECG beats within 500ms of a detected Sleeptracker-AI beat) during all sleep stages and periods of wakefulness while the participant was in bed. Agreement was assessed using Bland-Altman plots and Pearson correlation coefficients. Mean absolute error (MAE), root mean square error (RMSE), median absolute error, and robust RMSE were also calculated to quantify accuracy and variability for matching and non-matching beat conditions.

Results: The Sleeptracker-AI showed strong agreement with PSG across key cardiac metrics. RR interval analysis using matching beats demonstrated a small bias of -0.5 ms, with limits of agreement from -15.0 to $+14.9$ ms. HR analysis over the entire study duration showed excellent agreement with PSG, with high correlation coefficients ($r = 1.00$ for matching beats; $r = 0.99$ for all beats) and low median absolute errors (0.10 bpm for matching beats; 0.48 bpm for all beats). Analysis of the time-domain HRV components SDNN and RMSSD also demonstrated strong performance. SDNN showed strong correlations when based on matching ECG beats ($r = 0.98$) and declined when all beats were included ($r = 0.90$), further decreasing during wakefulness. Corresponding median absolute error increased from 2.34 ms (matching beats) to 16.18 ms (all beats), reflecting SDNN's high sensitivity to beat exclusion, particularly during motion. RMSSD showed a similar, but less pronounced pattern ($r = 0.96$ with matching beats; $r = 0.93$ with all beats), with values lowest during wake, and an increase in median absolute error (from 3.84 ms to 4.74 ms).

Conclusions: These findings indicate that the Sleeptracker-AI system provides reliable, long-term HR and HRV monitoring, particularly when beat detection coverage is high. Its non-invasive, contactless design makes it a practical tool for tracking cardiac autonomic dynamics and sleep health in real-world settings, supporting its utility for both research and clinical applications.

Validation of Automatic Sleep Stage Classification and Sleep Quality Assessment Using Smartwatch Technology

L. Fang¹, A. Wu¹, J. Zhang², S. Zheng¹, Y. Huang³, A. Zhang³, B. Zhang¹

¹Nanfang Hospital, Department of psychiatry, Sleep Medicine Center, Guangzhou, China, ²Shanxi Datong University School of Medicine, Datong, China, ³Huawei Device (Dongguan) Co., Ltd, Dongguan, China

Introduction: Polysomnography (PSG) is costly and impractical for evaluating widespread problems of insomnia and poor sleep quality. Despite consumer wearables are being alternatively used in sleep research, the validity of the devices and their resulting sleep measures remains a source for concern. To validate the automatic sleep stage classifier algorithm based on 3D-accelerometer (3D-ACC) and photoplethysmogram (PPG) signals derived from the Huawei® Watch against PSG. Additionally, we seek to establish a predictive model linking objective sleep parameters to subjective sleep parameters.

Materials and methods: The developed smartwatch technology was successfully applied to overnight recordings of 108 healthy subjects, with simultaneous one-night PSG measurements, and subjective sleep questionnaire were records manually by the subjects. We extracted objective sleep parameters, including total sleep time (TST), light sleep (% TST), slow wave sleep (% TST), and rapid eye movement sleep (REM, % TST) from smartwatch-based sleep staging, and subjective sleep quality index from subjective sleep questionnaire. The 9-fold cross-validation was used to evaluate the concordance between manual PSG scoring and smartwatch-based sleep staging. A nonlinear regression model was used to explore the relationship between objective and subjective sleep parameters, and we finally generate estimates of the overall sleep quality index.

Results: In this study, participants aged 18 years or older, of whom 53.70% were male. The mean[SD] of TST, light sleep time, slow wave sleep time and REM sleep time calculated by the smartwatch technology were 413.16[75.66] min, 269.74[60.92] min, 75.61[34.57] min and 67.81[32.41] min, respectively. Compared to the PSG, the accuracy of total sleep duration was 95.38%. The automatic sleep stage classification demonstrated moderate accuracy and kappa coefficient, which was 74.50% and 0.52, respectively. The objective sleep parameters explained an R-squared value of 31.2% for the subjective sleep quality index, with a mean absolute error of 3.1.

Conclusions: The smartwatch technology demonstrated moderate-to-high accuracy in automatic sleep stage classification when compared with PSG, supporting its potential as a practical tool for consumer-level sleep health assessment. Additionally, the moderate association between objective sleep parameters and subjective sleep quality suggests the feasibility of using wearable-derived data to infer subjective sleep quality, though further refinement of modeling approaches is warranted.

Visualizing Temporal Patterns in Sleep Tracker Accuracy: A Novel Approach to Validating Consumer Sleep Technologies

Z. Liang^{1,2}, M.A. Chapa-Martell³

¹Kyoto University of Advanced Science (KUAS), Faculty of Engineering, Kyoto, Japan, ²The University of Tokyo, Institute of Industrial Science (IIS), Tokyo, Japan, ³Silver Egg Technology, Osaka, Japan

Introduction: Consumer-grade sleep trackers such as Fitbit are widely used to monitor sleep in daily life, but concerns remain regarding their data accuracy—especially in detecting sleep stages. While prior validation studies often evaluate overall agreement with gold-standard methods, they typically treat device accuracy as a static property, overlooking the inherent temporal dynamics of human sleep. In particular, deep sleep tends to dominate early in the night, while REM sleep increases toward morning. This raises an important question: does the accuracy of sleep trackers vary across the night in relation to these temporal sleep patterns? This study proposes a novel, visually-driven validation approach to explore how sleep tracker accuracy fluctuates across sleep cycles. Instead of conventional methods

such as Bland–Altman plots or global accuracy scores, our method highlights time-dependent variation in sleep staging performance.

Materials and methods: We collected concurrent sleep data from 22 healthy adults (mean age 24.8 ± 4.4 years, 8 women) using both a Fitbit Charge 2 and a medical-grade single-channel EEG device during one night of at-home sleep. Epoch-level sleep staging from the EEG device was reviewed by an expert scorer. Fitbit data were extracted at 1-second resolution and aggregated into 30-second epochs, yielding a total of 18,759 epochs. To capture temporal trends, we segmented each participant's hypnogram into approximate sleep cycles (200 epochs per segment, based on average cycle length). Using R (ggplot2), we visualized epoch-by-epoch agreement across cycles to generate color-coded spectrums of classification accuracy for each stage.

Results: Visual analysis revealed clear temporal patterns in Fitbit-derived sleep staging. Accuracy for deep sleep was highest during the first two sleep cycles, while accuracy for REM sleep improved significantly in the latter half of the night. In contrast, accuracy for light sleep and wake stages remained relatively stable across cycles. These findings indicate that device performance is not uniform across the night and may align with physiological shifts in sleep architecture.

Conclusions: This is the first study to apply data visualization as a complementary validation method for sleep tracker accuracy across sleep cycles. Our approach uncovers temporal fluctuations in classification performance, providing new insights into how consumer devices behave across different sleep stages and times of night. Future algorithm development and validation efforts should incorporate temporal context (e.g., through segmented modeling) to improve the reliability of wearable sleep technologies.

Wearable-derived Sleep Digital Biomarkers and Well-being: Preliminary Insights from Longitudinal Observational Study

R. Švihrová^{1,2}, A. Dei Rossi^{3,2}, D. Marzorati², F.D. Faraci²

¹University of Bern, Institute of Computer Science, Bern, Switzerland, ²University of Applied Sciences and Arts of Southern Switzerland, Institute of Digital Technologies for Personalized Healthcare, Lugano, Switzerland, ³Università della Svizzera italiana, Faculty of Informatics, Lugano, Switzerland

Introduction: Wearables and mobile health applications are increasingly used across diverse populations, enabling the continuous collection of behavioral and physiological data. By combining wearable-derived metrics with daily and clinically validated questionnaires, we can gain deeper insights into daily lifestyle habits and their relationship with health outcomes. In this preliminary analysis, we investigate how wearable-derived sleep digital biomarkers relate to next-day user-reported mood and whether mood and lifestyle factors, in turn, influence sleep architecture.

Materials and methods: We collected data from 21 participants over at least one month using Labfront, integrating longitudinal wearable data, daily self-reports, monthly validated questionnaires, and demographics. Participants also completed the PSQI, SF-12, and Bernese Sleep Health Questionnaire at baseline and monthly. Wearable-derived lifestyle and sleep-related digital biomarkers were aggregated on a daily basis. Repeated-measurement correlation analyses and Bayesian mixed-effects models were used to assess associations between mood and sleep measures. For all model coefficients, the probability of direction (PoD) was calculated.

Results: The cohort consisted of 6 (29%) female participants, and the average (sd) age was 31 (8) and BMI was 24 (3). All participants had university-level education. Sleep difficulties were mainly attributed to external or acute respiratory factors, with only one participant reporting use of sleep medication. Correlation analyses showed that higher mood was associated with more frequent social interaction ($r=0.11$, $pval<0.001$), while working hours were negatively associated with higher mood ($r=-0.095$, $pval=0.003$). No correlation was found between mood and cognitive load. Two Bayesian mixed-effects models provided additional insights on the effects directions and their PoD. Firstly, we examined association between wearable-derived sleep digital biomarkers on the next day's mood. Better mood was positively associated with total sleep time (94.1%) and deep sleep percentage (84.4%), but negatively associated with REM% (82.4%) and the number of nocturnal awakenings (99.8%). This indicates that long sleep with more of a deep sleep percentage was linked to improved next-day mood,

whereas fragmentation and REM-heavy sleep were associated with worse mood. Secondly, we investigated how mood and lifestyle factors influenced REM%. Here, REM% decreased with higher mood (53.7%), alcohol consumption (100%) and average daily stress (100%), but increased with greater cognitive load (95.4%). However, the too low PoD for mood suggests that mood does not predict subsequent REM%. Significant random intercepts in both models suggest inter-individual variability.

Conclusions: This study demonstrates the feasibility of combining wearable-derived digital biomarkers with self-reported measures to monitor sleep and well-being. Our findings suggest that specific sleep characteristics, such as longer total sleep time and greater deep sleep percentage, may predict better next-day mood, while fragmented or REM-heavy sleep is linked to lower mood. In contrast, mood showed limited predictive value for subsequent REM percentage, indicating that the relationship between mood and sleep may be more unidirectional. These preliminary results highlight the potential of integrating wearable and self-report data for real-time mental health and sleep monitoring. Future studies with larger cohorts and longer follow-up periods are needed to validate these associations and explore causal mechanisms.

Acknowledgments: We thank Labfront for the honorary grant. The dataset will be made publicly available.

Wearable EEG Acquisition during IVF demonstrates High Feasibility and Acceptability

J. Goldschmied¹, D. Miranian², S. Senapati²

¹University of Pennsylvania, Psychiatry, Philadelphia, United States, ²University of Pennsylvania, Obstetrics and Gynecology, Philadelphia, United States

Introduction: Advances in portable EEG technology can greatly expand both clinical and research capabilities for multi-night recordings in the home environment. However, the usability and feasibility of this technology over extended periods is largely unknown. The Compumedics Somfit, an adhesive wireless EEG monitoring system, worn on the forehead, was evaluated for its acceptability in a pilot study involving women undergoing in vitro fertilization (IVF) for up to 16 days.

Materials and methods: Participants were recruited as part of an ongoing study examining the relationship between sleep slow-wave activity and assisted reproductive treatment outcomes. The present preliminary sample included 5 women, aged 25-35, who underwent IVF for fertility treatment. Each participant wore the Somfit for 2 nights (adaptation, baseline) before and 8-14 nights during ovarian stimulation in their own homes. Outcome metrics on acceptability were collected from a survey administered upon completion of the study in 3 areas: sleep disturbance (difficulty falling asleep, difficulty staying asleep), difficulty with the device technology (associated mobile application, starting the recording, completing the recording), and physical disturbance (tightness, irritation, itching, headache). Participants were asked to rate these 9 items on a 3-point Likert scale (1 = None of the time, 2 = Some of the time, 3 = All of the time).

Results: All five women enrolled, completed the study. The mean difficulty score was 1.4 (SD = 0.5) for sleep disturbance and 1.5 (SD = 0.5) for device technology, indicating general satisfaction with regard to ability to use and sleep with the device. The mean difficulty score for physical disturbance was slightly higher, at 1.6 (SD = 0.6), with skin irritation as the item with the highest difficulty score.

Conclusions: In this preliminary analysis, the Somfit device proved to be well-tolerated, with minimal disruption to daily life. Participant feedback emphasized the comfort and convenience of the device, with most reporting no interference with their typical routines. While the IVF population provides a critical and under-explored context for wearable EEG technology, the findings also suggest that this approach can be extended to other clinical and health research settings where multi-night in-lab study is ill-advised, including in those with chronic conditions, mental health disorders, and aging-related changes.

Acknowledgments: This study was supported by funding from the American Academy of Sleep Medicine [JG: 337-SR-24]

We thank Andrea Morley and Kamilah Degraphenreed who provided assistance during recruitment and data collection

Weighted Hypoxia Index, a Translational Quantitative Metric, Predicts All-Cause Mortality

D. Lim¹, C.-B. Chen², A. Paul³, Y. Wang², J. Kim⁴, S. Yook⁵, E. Kim¹, E. Kim¹, A. Das⁶, M. Wangpaichitr¹, V. Somers⁷, C.H. Lee⁸, P. Zee⁹, T. Imamura¹⁰, H. Kim⁵

¹Miami VA, Medicine, Miami, United States, ²University of Miami, Miami, United States, ³MD Anderson, Houston, United States, ⁴University of Nevada, Las Vegas, Las Vegas, United States, ⁵University of Southern California, Los Angeles, United States, ⁶Drexel University, Philadelphia, United States, ⁷Mayo Clinic, Rochester, United States, ⁸National University of Singapore, Singapore, Singapore, ⁹Northwestern University, Chicago, United States, ¹⁰University of Pennsylvania, Philadelphia, United States

Introduction: Oxygen saturation, measured by pulse oximetry, is widely utilized in clinical settings, however a method to quantify hypoxemia severity from basic science to clinical scenarios is lacking.

Materials and methods: We developed the Weighted Hypoxemia Index (WHI) to be adapted to different clinical settings by applying 5 steps to the S_pO_2 curve: (1) Identify desaturation/resaturation event by setting the upper threshold; (2) Exclude events as artifact by setting a lower threshold; (3) Calculate weighted area for each as X; (4) Calculate a normalization factor for each subject; (5) Calculate WHI as the summation of all weighted areas multiplied by . We assessed the WHI's predictive value for all-cause mortality and cardiovascular mortality using the Sleep Heart Health Study (enrollment 1995-1998, 11.1 years mean follow-up).

Results: We set varying upper thresholds at 92%, 90%, 88%, and 86%, a lower threshold of 50%, calculated area under the curve (AUC) and area above the curve (AAC), with and without a linear weighted factor (duration of each event), and used the same normalization factor of total sleep time <90% divided by total sleep time. After excluding subjects with missing data, we analyzed 4,509 participants (Alive: N=3,769; All-cause mortality: N=1,071; CVD mortality: N=330). Since WHI-AUC90 had the best results in predicting all-cause mortality, we then compared it to the Apnea-Hypopnea Index and Total Sleep Time <90%. WHI-AUC90 showed statistical significance across quintiles for all-cause mortality, but not cardiovascular mortality, in adjusted Cox regression models.

Conclusions: The WHI offers a versatile and clinically relevant method for quantifying hypoxemia severity, with potential applications to evaluate mechanisms and outcomes across various patient populations.

What are the optimal bedroom temperatures for sleep?

X. Fan^{1,2}, H. Zhang^{1,3}, J.C.-Y. Lo^{2,4,5}, T. Parkinson^{6,4}, S. Schiavon^{1,3,7,8}

¹Berkeley Education Alliance for Research in Singapore (BEARS), Singapore, Singapore, ²National University of Singapore, Yong Loo Lin School of Medicine, Centre for Sleep and Cognition, Singapore, Singapore, ³University of California, Berkeley, Center for the Built Environment, Berkeley, United States, ⁴Campus for Research Excellence and Technological Enterprise (CREATE), Singapore, Singapore, ⁵National University of Singapore, Yong Loo Lin School of Medicine, Human Potential Translational Research Programme, Singapore, Singapore, ⁶University of Sydney, School of Architecture, Design and Planning, IEQ Lab, Sydney, Australia, ⁷University of California, Berkeley, Department of Architecture, College of Environmental Design, Berkeley, United States, ⁸University of California, Berkeley, Department of Civil and Environmental Engineering, College of Engineering, Berkeley, United States

Introduction: Adequate high-quality sleep is essential for optimizing physical, mental, and cognitive health. The bedroom temperature affects sleep quantity and quality. However, the optimal temperatures for sleep are unknown. Existing building standards define acceptable indoor temperature ranges, but these mostly apply to general living spaces rather than bedrooms. It remains unclear whether these prescribed conditions are generalizable to sleep. The purpose of this study is to review the evidence of optimal temperatures for sleep under steady-state temperature conditions.

Materials and methods: We conducted a literature search on Web of Science using the keywords "bedroom" AND "temperature" AND "sleep." Only peer-reviewed journal articles in English of laboratory experimental studies on the effects of room temperature on sleep were included. We excluded observational or lab studies involving personal comfort devices or dynamic temperature changes, as their focus extended beyond steady-state room conditions. We also reviewed dominant international standards and guidelines related to indoor thermal environments, with a specific focus on recommendations for sleeping environments.

Results: Eleven peer-reviewed studies met the inclusion criteria. Of these, three were conducted in the cooling season, four in the heating season, one in both seasons, and two did not specify the season. One study reported no significant changes in both objectively monitored and subjectively reported sleep quality across a broad temperature range (10–32.2 °C). In the remaining ten studies that found significant impacts of room temperatures on both objectively measured and subjectively rated sleep quality, the optimal temperature for sleep appeared to depend on the need to have heating or cooling. In cooling, the highest sleep quality was observed at temperatures between 24–29 °C across experimental ranges of 21–37 °C. In heating, sleep quality was highest at temperatures between 16–23 °C across experimental ranges of 10–23 °C. Variations in optimal temperature between the reviewed studies are mainly attributed to differences in the insulation of bedding and clothing (0.8 to 4.66 clo). A review of international standards and guidelines found general recommendations for residential indoor temperatures but no specific guidance for bedrooms. For instance, the WHO Housing and Health Guidelines (2018) suggests an indoor temperature range of 18–24 °C. CIBSE Guide A (2021) recommends 23–25 °C in summer and 17–19 °C in winter, while EN 16798 (2019) suggests 25.5–28 °C for summer and 16–21 °C for winter. ASHRAE standard 55 (2017) does not specify temperature ranges for sleeping people.

Overall, recommended temperatures generally align with experimental optima, though WHO and CIBSE advise cooler-than-evidenced levels for the cooling season.

Conclusions: The optimal bedroom temperatures for sleep appear to be 24–29 °C in the cooling season and 16–23 °C in the heating season. While current standards on temperature requirements are broadly consistent with experimental findings, revisions may be needed to address sleep comfort amid energy goals and warming nights.

When deep learning models align: matching human consensus in sleep staging

A. Dei Rossi^{1,2}, M. Metaldi², M. Bechny^{3,2}, J. van der Meer⁴, M.H. Schmidt⁴, C.L. Bassetti⁴, A. Tzovara^{3,4}, F.D. Faraci², L. Fiorillo^{2,5}

¹Università Della Svizzera Italiana, Faculty of Informatics, Lugano, Switzerland, ²Institute for Digital Technologies for Personalized Healthcare, University of Applied Sciences and Arts of Southern Switzerland, Lugano, Switzerland, ³University of Bern, Institute of Informatics, Bern, Switzerland, ⁴University of Bern, Sleep Wake Epilepsy Center | NeuroTec, Department of Neurology, Bern, Switzerland, ⁵Ente Ospedaliero Cantonale, Neurocenter of Southern Switzerland, Lugano, Switzerland

Introduction: Deep learning has led to rapid progress in automatic sleep scoring, with increasingly accurate models rivaling expert-level performance. However, the evaluation of such models must account for the well-known variability among trained sleep technologists [1]. Given that medical consensus consistently yields higher accuracy than individual expert assessments [2], models should strive to align with consensus-based scoring rather than emulate any single scorer's decisions. In this work, leveraging multi-scored datasets [3], we investigate consensus-aligned behavior by ensembling state-of-the-art deep learning models pre-trained on over 27'000 polysomnographic recordings under a unified, large-scale benchmarking protocol [4].

Materials and methods: We leveraged the out-of-domain DREAM Open Datasets [3], comprising 80 full-night polysomnographic recordings - 25 from healthy individuals (DOD-H) and 55 from patients with obstructive sleep apnea (DOD-O) - each independently annotated by five experienced sleep technologists. To investigate consensus-aligned performance, we aggregated predictions, without any additional fine-tuning on DOD, from pre-trained U-Sleep [5], DeepResNet [6], and SleepTransformer [7] models into an average-based ensemble, SOMNUS. Predictions were evaluated against those of individual human experts, their aggregated consensus, and against an in-domain benchmark model trained directly on the consensus itself. Performance was assessed using macro F1 score (MF1), Cohen's *kappa*, and per-stage F1 scores. To capture agreement with probabilistic consensus, we compared model-generated and consensus-derived hypnogram profiles exploiting the averaged cosine similarity (ACS) metric [8], quantifying the similarity between predicted and reference sleep stage probability distributions over time. Finally, we examined whether ensemble-derived

uncertainty, quantified by Shannon entropy and pairwise disagreement among the constituent models of SOMNUS, could identify epochs characterized by disagreement in the human consensus.

Results: Across both healthy (DOD-H) and OSA cohorts (DOD-O), SOMNUS consistently outperformed all individual human experts and the in-domain benchmark model (MF1_{DOD-H}: +4.4% and +2.8%; MF1_{DOD-O}: +4.3% and +2.6%). Ensemble predictions aligned more closely with the consensus than with any single scorer, both in discrete labels ($\kappa_{\text{DOD-H}}$: 88.9, $\kappa_{\text{DOD-O}}$: 85.4) and hypnosity profiles (ACS_{DOD-H}: 0.947, ACS_{DOD-O}: 0.939). Individual models within the ensemble also exhibited this consensus-oriented behavior. Ensemble disagreement was shown to track human scoring ambiguity: ensemble entropy and pairwise model divergence predicted regions of scorer disagreement with ROC AUCs up to 0.828.

Conclusions: Our findings demonstrate that training on heterogeneous datasets and diverse scoring styles enables deep learning models to generalize robustly to new data without further adaptation, achieving consensus-level performance, consistently outperforming individual human scorers and reducing the impact of inter-scorer variability. Alignment with consensus can be further enhanced by aggregating predictions from complementary models spanning different architectures and input configurations, as realized in SOMNUS. In addition, ensemble-derived uncertainty provides a robust signal of scoring ambiguity, offering a principled route to automated uncertainty quantification that can aid in flagging ambiguous epochs for potential review. Together, these results advocate for the use of ensemble-based approaches, pre-trained on large, diverse datasets, as effective consensus approximators and uncertainty-aware tools for automated sleep staging.

Z4IP – Comprehensive Sleep and Activity Phenotyping Through Multifactor Mobile Data Integration

C.S. Soon¹, X.Y. Chua¹, K.H.M. Chong¹, M.W.L. Chee¹

¹National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore

Introduction: The ubiquity of smartphones offers unprecedented opportunities for scalable, real-time data collection over extended periods in naturalistic settings. We developed a proprietary mobile app (Z4IP; iOS and Android compatible) to collect multi-stream objective and subjective data for building a comprehensive profile of individual sleep, activity and wellbeing. Each of six functional modules, cognitive tests, questionnaires, audio diaries, time-use diaries, movement patterns and wearable integration, can be customized to satisfy different protocol requirements, and has been field-tested in studies involving community-dwelling, lab-based and hybrid monitoring. Here we assessed the feasibility of long-term monitoring via sleep and activity diaries across different age groups and study contexts: 1) freshmen monitored over their first semester in college (20 weeks); 2) junior doctors undergoing shifts during residential training (8 weeks); 3) older adults past statutory retirement age (10 days).

Materials and methods: Z4IP provides three modes of assessment: 1) ecological momentary assessments (EMA) within study-specific time windows (cognitive tests, questionnaires, audio diaries); 2) self-reports at participant's convenience (time-use diaries); and 3) continuous passive smartphone-derived metrics (movement patterns) and wearable-based behavioural phenotyping (Oura Ring). To foster sustained engagement, the platform incorporates a task completion and reward system, providing personalized feedback through participants' smartphones and enabling large-scale backend monitoring for researchers.

Compliance rates for the two components which demand the most active effort from participants – daily EMA incorporating a sleep diary, and time-use diary – were evaluated across the three aforementioned studies to assess the app's feasibility for long-term monitoring across different age groups.

Results: In Study 1 involving college freshmen (N=638; 51.7% female; mean age [SD]=20.4 [1.3]), the compliance rate of daily EMA questionnaires changed by -1.6% (linear fit) per week (80.1% in week 1 to 45.2% in week 20, end of study). Time-use diaries were completed for three separate fortnights: weeks 1–2, 84.0%; weeks 7–8, 66.2%; and weeks 15–16, 52.6%.

In Study 2, daily EMA compliance rates for medical interns (N=96; 59.4% female; mean age [SD]=24.7 [1.1]) changed by -3.8% (linear-fit) per week (77.1% in week 1 to 52.4% in week 8, end of participation). Time-use diary completion rate averaged 65.2% across the study.

The 10-day compliance rate in Study 3 involving older adults (N=411; 49.6% female; mean age [SD] = 74.2 [2.7]) was 92.3% for EMA questionnaires and 96.0% for time-use diaries.

Conclusions: The EMA sleep diaries effectively complemented wearable-derived objective sleep measures to provide comprehensive and sustainable sleep assessment, demonstrating Z4IP's robust utility for long-term monitoring. Although a gradual decline in compliance was observed over time – as is typical in longitudinal studies – engagement remained notably high. Over half of the freshmen completed EMA and time-use diaries through their examinations (week 16). Despite demanding internship shift schedules, most medical interns maintained daily reporting. High adherence among older adults further underscores the app's accessibility and user-friendliness. These results highlight Z4IP's potential as a scalable and adaptable tool for sustained digital phenotyping in real-world settings.
