Materials and methods: Autoethnographic patient-researcher methodology documented Type 1 narcolepsy patient experience across mainland China, Singapore, Hong Kong SAR (China), Germany, Spain and Sweden (2014-2025). The dual patient-researcher position provided unprecedented access to institutional mechanisms typically unavailable to external investigators. Data included detailed clinical encounters, diagnostic procedure timelines, pharmaceutical access attempts, institutional accommodation responses, comprehensive medical correspondence, and comparative policy reviews. Cross-cultural analysis systematically compared diagnostic accuracy, treatment availability, financial barriers, accommodation provision, and medical literacy using identical patient presentation. Findings were triangulated with epidemiological and policy literature to contextualize individual experience within documented system-level patterns.

Results: Dramatic disparities emerged across systems, revealing systematic rather than individual barriers.

Diagnostic access: Sweden (free orexin testing) > China (affordable PSG+MSLT, orexin testing available) > Hong Kong (expensive, genetic testing only) > Singapore (prohibitive costs, orexin testing unavailable in public healthcare).

Cross-border medical recognition: Sweden immediately accepted China's sleep study documentation without requiring additional testing. Germany, Spain, and Hong Kong explicitly rejected identical clinical evidence, forcing expensive retesting.

Treatment availability: Sweden (heavily subsidized Modafinil at minimal cost, free sodium oxybate through public healthcare) > Spain (subsidized but heavier patient contributions) >> China (prohibitive Modafinil costs ~\$3000 monthly, accessible locally-manufactured Pitolisant) > Hong Kong/Singapore (Modafinil criminalized and unregistered, available only through regulatory appeals).

Institutional medical literacy: Sweden maintained sophisticated national patient database of ~1000 individuals. China updated comprehensive open-access national clinical guidelines in 2022, officially recognizing narcolepsy as rare condition since 2023, promoting locally-manufactured Pitolisant as first-line treatment. Singapore demonstrated concerning knowledge gaps, minimized condition as "person falls asleep suddenly" in official health communications, with senior medical experts describing orexin deficiency as "evidence suggests" while explicitly denying established autoimmune pathophysiology.

Employment and accommodation: Sweden's private insurance systematically denied work capacity protection of T1N patients while social insurance resisted permanent disability recognition. Singapore demonstrated institutional employment stigma with public sector HR personnel commenting employees "will get fired if seen napping".

Systematic patterns revealed developed nations without rare disease infrastructure created greater barriers than developing nations with targeted resources. Treatment criminalization in Singapore contrasted with near-free provision in Sweden for identical medical necessity.

Conclusions: This study provides the first autoethnographic, cross-national comparative analysis of Type 1 narcolepsy diagnostic pathways. Findings demonstrate that healthcare responses correlate with diagnostic literacy rather than national economic development. Results underscore urgent need for harmonized international diagnostic protocols, equitable pharmaceutical access, and evidence-based accommodation and compensation policies. Patient-researcher methodologies offer invaluable insights complementing traditional clinical research for future guideline development.

Acknowledgments: The author acknowledges Narkolepsiföreningen (Swedish Narcolepsy Association) for community validation, Stockholm University for institutional support, and herself for maintaining consciousness while denied by systems.

Consistent Efficacy of Once-Nightly Sodium Oxybate on Disrupted Nighttime Sleep in People With Narcolepsy

Y. Dauvilliers¹, M.J. Thorpy², T. Roth³, C.A. Kushida⁴, A.M. Morse⁵, J. Harsh⁶, L.E. Ortiz⁷, J. Gudeman⁸

¹Sleep-Wake Disorders Center, Department of Neurology, Gui-de-Chauliac Hospital, Institute for Neurosciences of Montpellier INM, INSERM, University of Montpellier, Department of Neurology, Montpellier, France, ²Albert Einstein College of Medicine, New York, United States, ³Sleep Disorders and Research Center, Henry Ford Health System, Detroit, United States, ⁴Stanford University School of Medicine, Stanford, United States, ⁵Geisinger Commonwealth School of Medicine, Geisinger Medical Center, Janet Weis Children's Hospital, Danville, United States, ⁶Colorado Sleep Institute, Boulder, United States, ⁷Johns Hopkins Medical Institutions, Johns Hopkins All Children's Hospital, Petersburg, United States, ⁸Avadel Pharmaceuticals, Chesterfield, United States

Introduction: Once-nightly sodium oxybate (ON-SXB; LUMRYZ™) demonstrated efficacy in treating narcolepsy symptoms, including disrupted nighttime sleep (DNS), in the phase 3 REST-ON trial (NCT02720744). This post hoc analysis assessed ON-SXB efficacy on DNS across various participant subgroups.

Materials and methods: Participants aged ≥16 years with narcolepsy type 1 (NT1) or 2 (NT2) were randomized 1:1 to ON-SXB (week 1, 4.5 g; weeks 2-3, 6 g; weeks 4-8, 7.5 g; weeks 9-13, 9 g) or placebo. Least squares mean differences (LSMDs) in changes from baseline for ON-SXB vs placebo for number of sleep stage shifts and nocturnal arousals as measured by polysomnography, as well as patient-reported sleep quality and refreshing nature of sleep, were compared among demographic (age, sex, race, body mass index [BMI] category), narcolepsy type (NT1/NT2), and concomitant alerting agent use subgroups from the modified intent-to-treat population (mITT; participants with ≥1 efficacy measurement after receiving the 6-g dose).

Results: In the mITT population (ON-SXB, n=97; placebo, n=93), LSMDs for ON-SXB vs placebo demonstrated significant improvements from baseline ($P<0.001$) in number of sleep stage shifts at week 13 (9 g) across all participant subgroups, including age (<35, ≥35 years), sex (female, male), race (white, non-white), BMI (low [$<25 \text{ kg/m}^2$], high [$\geq 25 \text{ kg/m}^2$]), narcolepsy type (NT1, NT2), and alerting agent/no alerting agent use. LSMDs were significant in favor of ON-SXB 9 g vs placebo for change from baseline in number of nocturnal arousals ($P<0.05$) in all subgroups, except age ≥35 years. At week 13, ON-SXB was associated with significant improvement from baseline ($P<0.05$) in visual analogue

scale (VAS) sleep quality compared with placebo across all subgroups, except non-white. All subgroups exhibited significant improvements ($P \leq 0.01$) in VAS refreshing nature of sleep with ON-SXB 9 g vs placebo, except NT2. Comparable trends were observed with the 6-g dose at week 3 and the 7.5-g dose at week 8.

Conclusions: While the trial was not powered to test for subgroup differences, these post hoc analyses demonstrate the robust, consistent efficacy of ON-SXB in treating DNS, including reducing nocturnal arousals and increasing the refreshing nature of sleep, in patients with narcolepsy across various demographic and clinical characteristics.

Correlation Between Maintenance of Wakefulness Test and Epworth Sleepiness Scale Scores in REST-ON

T. Roth³, S. Ibrahim¹, A.M. Morse², J. Gudeman⁶, Y. Dauvilliers³

¹Sleep Disorders and Research Center, Henry Ford Health System, Detroit, United States, ²University Hospitals Cleveland Medical Center, Cleveland, United States, ³Geisinger Commonwealth School of Medicine, Geisinger Medical Center, Janet Weis Children's Hospital, Danville, United States, ⁴Avadel Pharmaceuticals, Chesterfield, United States, ⁵Sleep-Wake Disorders Center, Department of Neurology, Gui-de-Chauliac Hospital, Institute for Neurosciences of Montpellier INM, INSERM, University of Montpellier, Montpellier, France

Introduction: Low-to-moderate strength correlations between Maintenance of Wakefulness Test (MWT) and Epworth Sleepiness Scale (ESS) scores have been reported in clinical trials in narcolepsy. This post hoc analysis of REST-ON (NCT02720744), which demonstrated the efficacy of once-nightly sodium oxybate (ON-SXB; LUMRYZ™) for narcolepsy, assessed the correlation between mean sleep latency (MSL) on the MWT and ESS scores.

Materials and methods: REST-ON participants (age ≥ 16 years) with narcolepsy were randomized 1:1 to ON-SXB (week 1, 4.5 g; weeks 2-3, 6 g; weeks 4-8, 7.5 g; weeks 9-13, 9 g) or placebo. Pearson correlation coefficients assessed the relationship between MSL (min) on the MWT and ESS score by treatment arm in the modified intent-to-treat (mITT) population (≥ 1 efficacy measurement after receiving the 6-g dose) at baseline (pretreatment) and weeks 3 (6 g), 8 (7.5 g), and 13 (9 g).

Results: In the mITT population (ON-SXB, $n=97$; placebo, $n=93$), respective baseline MSL (SD) on the MWT and baseline mean (SD) ESS score was 5.0 (3.1) and 16.6 (3.8) for ON-SXB and 4.7 (2.6) and 17.5 (4.1) for placebo. At baseline, no correlation was observed between MSL on the MWT and ESS score for either arm (ON-SXB, $r=0.015$; placebo, $r=-0.023$). At weeks 3, 8, and 13, respective MSL (SD) was 13.1 (8.8), 14.5 (9.8), and 15.5 (9.8) minutes and respective ESS scores were 13.3 (5.9), 11.6 (6.1), and 10.4 (6.2) for ON-SXB; for placebo, MSL (SD) was 7.8 (5.9), 7.8 (6.3), and 9.4 (7.9) minutes, with ESS scores of 16.6 (4.6), 15.4 (5.3), and 14.9 (5.5). Moderate strength correlations between MSL on the MWT and ESS scores were observed in the ON-SXB arm ($r=-0.419$, -0.305 , -0.394 at weeks 3, 8, 13, respectively). Weak correlations were observed in the placebo group ($r=-0.193$, -0.271 , -0.181 at weeks 3, 8, 13, respectively).

Conclusions: After initiating ON-SXB treatment, the correlation between MWT and ESS scores strengthened, suggesting that improved wakefulness enhances awareness of sleepiness levels in people with narcolepsy.

Corticotropin-releasing hormone (CRH) in murine narcolepsy: What do genetic and immune models tell us?

J. Zhou^{1,2}, S. Melzi³, A.-L. Morel³, B. Georges³, T.E. Scammell⁴, G.J. Lammers^{1,2}, R. Fronczek^{1,2}, C. Peyron³

¹Leiden University Medical Center, Leiden, Netherlands, ²Stichting Epilepsie Instellingen Nederland (SEIN), Sleep-Wake Centre, Heemstede, Netherlands, ³Université Claude Bernard Lyon1, CNRS UMR5292, INSERM U1028, Sleep Team, Center for Research in Neuroscience of Lyon, Lyon, France, ⁴Department of Neurology, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, United States

Introduction: Narcolepsy type 1 is a chronic sleep disorder of putative autoimmune aetiology, primarily caused by the loss of orexin-producing neurons in the hypothalamus. An additional 88% reduction in corticotropin-releasing hormone-immunoreactive neurons of the paraventricular nucleus has been recently observed in post-mortem brains of individuals with narcolepsy type 1. It is however unknown whether this reduction is specific to the paraventricular nucleus or involves other brain regions expressing corticotropin-releasing hormone, such as the amygdala, which plays a central role in mood regulation, stress response, and cataplexy. This study examined whether orexin neuron loss and/or hypothalamic neuroinflammation would affect the expression of corticotropin-releasing hormone and other neuropeptides, including melanin-concentrating hormone and histidine decarboxylase as a proof of concept.

Materials and methods: We measured mRNA expression levels of CRH, histidine decarboxylase MCH, and orexin in the hypothalamus and CRH in the amygdala using quantitative PCR, in three NT1 mice models: (1) Orexin-KO mice which lack orexin peptides due to the disruption of the prepro-hypocretin gene; (2) Orexin-DTR mice which experience rapid ablation of orexin neurons after diphtheria toxin administration; and (3) Orexin-HA mice which have an autoimmune-mediated orexin neuron loss accompanied by hypothalamic neuroinflammation.

Results: CRH mRNA expression levels were unchanged in both the hypothalamus and amygdala across all three NT1 mice models compared to controls, regardless of the timeline or mechanism of orexin loss. CRH mRNA expression in the hypothalamus and amygdala did not correlate with levels of orexin mRNA expression. Similarly, HDC and MCH mRNA expression levels were unaffected in NT1 mice models.

Conclusions: Despite the loss of orexin neurons, CRH expression remained unaltered in the hypothalamus and the amygdala. These findings indicate that orexin deficiency alone does not directly influence CRH expression, and additional mechanisms may underlie the reduction of CRH neurons observed in NT1 patients. Further studies are needed to elucidate the mechanisms and functional implications underlying CRH neuron loss in NT1 patients and to determine whether similar changes occur in other brain regions.

Acknowledgments: The authors are grateful to Roland Liblau for providing the orexin-HA mice. ZJ received a fellowship from the China Scholarship Council (CSC) and an ESRS grant to conduct her research in Lyon.

Demographics and Comorbidities of Patients With Narcolepsy: A Propensity Score-Matched Cohort Study

M. Soltis¹, M.C. Lipford², A. Smither³, P. Kumar-M⁴, J. Gudeman⁵

¹Duke University, Durham, United States, ²Mayo Clinic, Rochester, United States, ³Inference, Cambridge, United States, ⁴Inference Labs, Bengaluru, India, ⁵Avadel Pharmaceuticals, Chesterfield, United States

Introduction: Narcolepsy is a rare, chronic sleep disorder associated with decreased quality of life. Narcolepsy has a complex phenotype associated with multiple comorbid conditions. This study used aggregate electronic health record (EHR) data to characterize the demographics and comorbidities of patients with narcolepsy.

Materials and methods: An EHR-based search identified first-time Duke Health patients between January 1, 2012, to March 31, 2024. Included patients had ≥ 1 narcolepsy-specific ICD-9 (347.*) and ICD-10 (G47.4*) codes and ≥ 1 disease-supportive statement in clinical notes, identified using a natural language processing algorithm. A control cohort was propensity-matched for birth year, age at first institutional encounter, sex, race, number of diagnosis code instances, and mortality; ethnicity was not available for matching. Common comorbidities were compared and ranked between cohorts by odds

ratio (OR). Statistical significance was determined using a chi-squared test; *P* values were corrected for multiple comparisons using Bonferroni correction to control for a 5% false discovery rate.

Results: Within the EHR database of 2,617,188 patients, 1659 patients with a narcolepsy diagnosis were identified (mean age at first presentation to Duke Health, 32.4 years; white, 69%; female, 69%); the propensity-matched control cohort included 1659 patients (mean age at first presentation to Duke Health, 32.3 years; white, 69%; female, 69%). Comorbidities that occurred statistically significantly more frequently (all *P*<0.0001) among the narcolepsy vs control cohort (OR [95% CI]) included sleep disorders: sleep-related movement disorders (26.26 [10.71, 64.40]), hypersomnia (16.56 [12.54, 21.87]), circadian rhythm sleep disorders (15.43 [6.73, 35.38]), obstructive sleep apnea (4.64 [3.85, 5.60]), restless leg syndrome (4.17 [2.93, 5.94]); pain disorders: trigeminal neuralgia (6.63 [2.80, 15.70]), fibromyalgia (5.30 [3.58, 7.85]), chronic pain syndrome (3.37 [2.46, 4.61]), peripheral neuropathy (2.94 [2.04, 4.23]), myalgia (2.69 [2.20, 3.29]), headache (1.69 [1.43, 2.00]); and psychiatric or mood disorders: post-traumatic stress disorder (3.08 [2.10, 4.52]), attention deficit hyperactivity disorder (2.90 [2.28, 3.68]), depression (2.66 [2.27, 3.11]), anxiety (1.84 [1.58, 2.14]). Chronic fatigue syndrome (8.17 [3.22, 20.75]), postural orthostatic tachycardia syndrome (7.24 [3.59, 14.61]), irritable bowel syndrome (3.13 [2.30, 4.25]), memory disorders and dementia (2.69 [1.99, 3.64]), spondylosis (2.11 [1.64, 2.71]), syncope (2.08 [1.64, 2.64]), asthma (1.80 [1.44, 2.25]), and gastroesophageal reflux disease (1.50 [1.28, 1.76]) were also higher among patients with narcolepsy vs the control cohort (all *P*<0.0001). Hypertension and cardiovascular disease were not among the top 23 comorbidities that occurred more frequently among the narcolepsy cohort vs the control cohort.

Conclusions: The findings from this agnostic analysis of EHR records support and extend those of prior studies that reported increased frequency of sleep, pain, and psychiatric or mood disorders in patients with narcolepsy compared with matched controls. Consistent with prior EHR research, sleep, psychiatric, and pain disorders were among the most frequently reported comorbidities of patients with narcolepsy; cardiovascular disease was not. Real-world data identifying the most frequent comorbidities increased in a narcolepsy cohort informs clinicians of the most relevant concomitant disease states to consider when evaluating potential therapies.

Development of a Novel, Oral Orexin Receptor 2 Agonist, ORX750 for Treatment of Patients with Narcolepsy (type 1 and 2) and Idiopathic Hypersomnia

G. Plazzi¹, Y. Dauvilliers², D. Plante³, E. Mignot⁴, T. Roth⁵, M. Sterkel⁶, E.B. Leary⁶, D. Hartman⁶, M.A. Accardi⁶, S. Saha⁶, S. Kanes⁶

¹University of Modena and Reggio Emilia and IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy, ²Gui de Chauliac Hospital, Institute for Neurosciences of Montpellier INM, INSERM, University of Montpellier, Montpellier, France, ³University of Wisconsin School of Medicine, Madison, United States, ⁴Stanford University, Palo Alto, United States, ⁵Henry Ford Health System, Detroit, United States, ⁶Centessa Pharmaceuticals, Boston, United States

Introduction: Narcolepsy types 1 (NT1), 2 (NT2), and idiopathic hypersomnia (IH) are rare, life-long, disabling central disorders of hypersomnolence characterized by excessive daytime sleepiness (EDS). None of the currently available treatments target the orexin system, which is a core element of wake-promoting circuitries and specifically, of NT1 pathology. ORX750 is a novel, investigational, highly potent, oral orexin receptor 2 (OX2R) agonist in development for the treatment of narcolepsy and idiopathic hypersomnia. Strong wake-promoting effects were observed in preclinical studies of ORX750, supporting clinical investigation. The development program is ongoing and includes a first-in-human phase 1 study to evaluate the safety and wake-promoting effects of single and multiple oral doses of ORX750, a phase 2a study (ORX750-0201 [CRYSTAL-1]) in NT1, NT2 and IH patients, and a long-term extension (LTE) study (ORX750-202) for participants who complete ORX750-0201.

Materials and methods: In the phase 1 study, safety, tolerability, and pharmacokinetics (PK) of ORX750 are evaluated at single-ascending doses (SAD) and multiple-ascending doses (MAD) in a randomized, placebo-controlled design in healthy participants. In parallel, wake-promoting effects are evaluated in placebo-controlled Proof of Concept (POC) cohorts with a two-way crossover design in acutely sleep-deprived participants utilizing the Maintenance of Wakefulness Test (MWT).

ORX750-0201 (CRYSTAL-1) is evaluating the safety, tolerability, efficacy, and PK of ORX750 in NT1,

NT2, and IH patients. Initial dosing is 1 mg (NT1) and 2 mg (NT2 and IH) with adaptive, sequential dose selection between cohorts. Efficacy endpoints include the MWT, Epworth Sleepiness Scale (ESS), and weekly cataplexy rate (WCR, NT1 only). Other exploratory assessments include measures of overall symptom improvement, sleep, cognition, attention, memory, and general health. Participants who complete ORX750-0201 can enroll in the LTE study (ORX750-202). In ORX750-202, the primary endpoint is safety, with efficacy assessments including MWT, ESS, and WCR (NT1 only), alongside other exploratory endpoints.

Results: In the phase 1 study, as of the data cut-off date of December 5, 2024, five SAD (total N=45 active, N=15 placebo), four POC (N=8, N=10, N=8), and three MAD cohorts (N=24 active, N=6 placebo) have completed the study. Observed least squares (LS) mean (95% confidence interval [CI]) sleep onset latencies (minutes) in the MWT were 17.6 (12.1, 23.2), 32.0 (22.2, 41.8), 33.6 (27.1, 40.1), and 37.9 (31.7, 44.0) at 1.0 mg, 2.5 mg, 3.5 mg, and 5.0 mg once daily (QD), respectively. Average least square (LS) mean (95% CI) difference from placebo for mean sleep latency was 8.1 (0.3, 15.9), $p=0.04$ for 1.0 mg, 15.2 (4.7, 25.8), $p=0.01$ for 2.5 mg, 20.2 (15.2, 25.2), $p<0.0001$ for 3.5 mg, and 22.6 (17.0, 28.2), $p<0.0001$ for 5.0 mg. Treatment emergent adverse events were transient and mild or moderate in severity.

Conclusions: ORX750 showed a favorable safety profile and clinically meaningful and statistically significant improvements on wakefulness in the phase 1 study in acutely sleep-deprived healthy volunteers. ORX750 was well tolerated, and normative wakefulness (>30 mins on the MWT) was achieved at the doses ≥ 2.5 mg. The phase 1 study, ORX750-0201 and ORX750-202 are open, and results will inform future clinical development.

Does body mass index differentiate the clinical and sleep characteristics of Chinese children and adults with narcolepsy type 1 differently?

M. Zhang¹, M.-m. Wang¹, X.-s. Dong¹, F. Han¹

¹Peking University People's hospital, Sleep medicine department, Beijing, China

Introduction: Narcolepsy is a rare sleep disorder caused by the deficiency of hypocretin neurons located in the hypothalamus. Children and adults with narcolepsy show different clinical picture especially for the obesity. The aim of the present study is to investigate whether body mass index (BMI) affect the clinical and sleep characteristics of Chinese children and adults with narcolepsy type 1 (NT1) differently.

Materials and methods: A total of 172 patients with NT1 were included from Peking University People's hospital. Patients with obesity, overweight and normal body weight were defined according to Chinese obesity and overweight criteria for children and adults. Clinical and sleep characteristics were compared between patients with obesity, overweight, and normal BMI in Chinese children and adults with narcolepsy, respectively.

Results: Age at disease onset, sleepiness onset, cataplexy onset and age at disease diagnosis were not significantly different among NT1 patients with obesity, overweight and normal BMI regardless of in children or adults with narcolepsy. Higher blood pressure was noted in children or adults with NT1 with obesity compared to patients with narcolepsy with normal BMI. Higher scores for abnormal eating behaviours, especially for uncontrolled eating behaviours were noted in children with obesity compared to children with normal BMI, whereas this abnormal eating behaviour was not observed in adults with narcolepsy with different BMI groups. A lower percentage of sleep paralysis was only noted in child NT1 patients with obesity compared to child NT1 patients with normal BMI but not in adult NT1 patients with different BMI groups as well. A higher percentage of stage N1 sleep and a higher apnoea hypopnea index (AHI) were noted in adult NT1 patients with obesity compared to adult patients with normal BMI, whereas these differences were not noted in child NT1 patients with different BMI groups. Shorter mean sleep latency on multiple sleep latency test (MSLT) was noted in children/adults with obesity or overweight versus children/adults with normal BMI.

Conclusions: Obesity is associated with lower hypocretin-1 levels and shorter mean sleep latency on MSLT regardless of in children or adults with NT1. Childhood obesity is associated with abnormal eating behaviours and lower percentage of sleep paralysis in NT1 patients. Adulthood obesity is associated with higher percentage of stage N1 sleep and higher AHI in NT1 patients. Obesity therefore affects the clinical and sleep characteristics differently in children and adults with NT1. Future

management of narcolepsy should be different in different age groups as shown by the different phenotype of obesity in children and adults with narcolepsy.

Acknowledgments: This study was supported by the National Natural Science Foundation of China (82400116, 82341243).

E2086, a Selective Orexin Receptor-2 Agonist, Study for Promoting Wakefulness in Patients With Narcolepsy Type-1

J. Cheng¹, N. Hall¹, S. Rawal¹, M. Moline¹

¹Eisai Inc., Nutley, United States

Introduction: There are approved symptomatic treatment options from several therapeutic classes to treat patients with narcolepsy type-1 (NT1). However, none addresses the root cause of NT1, orexin deficiency. E2086 is a novel orexin receptor-2 (OX2R) agonist. In vitro, E2086 activated OX2R with no strong off-target effects, indicating that E2086 is a highly selective agonist. E2086 is hypothesized to regulate the sleep/wake cycle by supporting wakefulness through the orexin neuronal pathway; its preclinical profile showed strong dose-dependent efficacy in promoting wakefulness and mitigating cataplexy. Here, results from the first clinical study of E2086 in patients with NT1 are reported.

Materials and methods: E2086-A001-101 was a multicenter, randomized, double-blind, double-dummy, single-dose, 5-period crossover study evaluating the efficacy, safety, and tolerability of three dose strengths of E2086 compared with placebo (PBO) and modafinil in adult subjects with NT1. Male and female adult participants with verified diagnoses of NT1 were randomized to receive study drug within an hour of waketime following an overnight polysomnogram. Forty-minute maintenance of wakefulness tests (MWTs) conducted based on standard criteria were commenced 2 hours after waketime and continued every 2 hours until ~9 hours postdose (4 total). The Karolinska sleepiness scale (KSS) was administered at the end of each MWT. Following a washout period of ≥3 days each, participants returned for the next 4 treatment conditions. Mean sleep latency (MSL) from the 4 MWTs was calculated. Using pairwise comparisons, each of the 3 doses of E2086 was compared with PBO and with modafinil. In addition, modafinil was compared with PBO to serve as assay sensitivity.

Results: Twenty-two subjects were randomized; 19 subjects were completers, defined as having received all 5 treatments and having efficacy data. In the safety analysis set of all randomized subjects who took study drug, 42.9% were female and 47.6% were White. The least squares mean (LSMean) sleep latency for E2086 was longer and statistically significant ($P=0.001$) compared with PBO and modafinil: MSL with modafinil was also significantly longer versus PBO, establishing assay sensitivity. LSmean KSS scores with E2086 were lower (improved) and statistically significant ($P=0.0001$) compared with PBO. LSmean KSS scores were also significantly higher than modafinil: E2086 was generally well-tolerated. Adverse events (AEs) demonstrated a dose-related trend with E2086. There were no discontinuations due to TEAEs, no serious AEs, and most TEAEs were mild to moderate in severity.

Conclusions: These data demonstrate that E2086 has the potential to improve daytime wakefulness in patients with NT1. The efficacy/safety profile supports continued investigation of E2086 in the narcolepsy patient population.

Effect of Narcolepsy and Idiopathic Hypersomnia on Relationships: A Social Media Analysis

M. Picone¹, J.M. Mundt², L.E. Ortiz³, A.M. Morse⁴, M. Horsnell⁵, F. Ascencion⁶, Z. Cline¹, C. DeFelice¹, J. Gudeman⁷

¹TREND Community, Philadelphia, United States, ²University of Utah, Salt Lake City, United States,

³Johns Hopkins Medical Institutions, Johns Hopkins All Children's Hospital, St. Petersburg, United States, ⁴Geisinger Commonwealth School of Medicine, Geisinger Medical Center, Janet Weis Children's Hospital, Danville, United States, ⁵Patient Author, Erin, United States, ⁶PWN4PWN, Tampa, United States, ⁷Avadel Pharmaceuticals, Chesterfield, United States

Introduction: Central disorders of hypersomnolence, such as narcolepsy and idiopathic hypersomnia (IH), contribute to quality-of-life challenges, including entering or maintaining relationships. A social

listening analysis was conducted to characterize the emotions and effects of narcolepsy and IH on romantic/social partners.

Materials and methods: This social listening analysis used natural language processing and other statistical techniques to analyze 447,347 posts and comments shared (August 2011 to September 2024) from 2 subreddits (r/Narcolepsy and r/idiopathichypersomnia) and the PWN4PWN Facebook group. The process used an Attributes of Daily Living (ADL) model to identify sleeping paragraphs and a span recognition model to filter paragraphs with spans labeled “relationship.”

Results: A total of 227,276 paragraphs that discussed sleeping were identified by the ADL model; of these, 8,871 (3.9%) also mentioned a partner. Across all conversations that mentioned both sleeping and a partner, the most common topics identified were sleep medication usage, narcolepsy journey, Xyrem/Xywav, falling asleep, medical diagnosis journey, and vivid dreaming. Of the most common sleep-related clinical topics identified, nighttime sleep disruptions were more likely to co-occur with the mention of a partner (OR [95% CI]; bad dreams, 2.8 [1.6-4.8]; night terrors, 2.2 [1.7-2.9]; rapid eye movement behavior disorder, 2.0 [1.3-3.0]; nightmares, 1.8 [1.5-2.1]; vivid dreams 1.4 [1.1-1.7]). The primary emotions expressed in paragraphs mentioning both sleep and a partner were fear (28.2%), anger (23.2%), and happiness (22.8%). In conversations that mentioned both sleep and a partner, the most associated sleep-related clinical topic and emotion (standardized pointwise mutual information squared [PMI²]) were sleep paralysis and fear (3.0). In paragraphs that discussed sleep and a partner, naps were associated with multiple emotions including frustration (2.6), love (2.5), anger (2.2), annoyance (1.7), and worry (1.6); sleepiness was associated with anger (1.9) and frustration (1.9); nightmares and night terrors were associated with fear (1.9 and 1.8, respectively).

Conclusions: These data suggest that nighttime sleep symptoms, including parasomnias, may be a source of concern within relationships of people with narcolepsy or IH. Sleepiness and bed sharing with a partner with narcolepsy or IH may cause relationship tension given the strong association with emotions with a negative connotation, such as anger and frustration.

Effect of Oral Orexin Receptor 2 Agonist Oveporexton (TAK-861) on the Severity of Symptoms in Individuals With Narcolepsy Type 1: Results From Two Phase 3 Studies

L. Barateau^{1,2,3}, I. Arnulf^{4,5,6}, Y. Dauvilliers^{1,2,3}, C. Liguori^{7,8}, F. Pizza^{9,10}, O. Sum-Ping¹¹, E. Stukalin¹², T. Olsson¹², P. von Rosenstiel¹²

Introduction: Narcolepsy type 1 (NT1) is a chronic, rare, neurologic disorder of hypersomnolence caused by loss of orexin producing neurons in the hypothalamus, and is characterized by excessive daytime sleepiness, sudden muscle weakness triggered by emotions (cataplexy), disrupted nighttime sleep, sleep paralysis, and hypnagogic/hypnopompic hallucinations. Orexin receptor agonists target orexin signaling and are promising treatments for NT1. Oveporexton (TAK-861) is an investigational orexin-receptor 2 (OX2R)-selective agonist that stimulates OX2R signaling and addresses the underlying orexin deficiency. Following positive results from the NCT05687903 phase 2b study, the efficacy and safety of oveporexton were further evaluated in two phase 3 trials in participants with NT1.

Materials and methods: A prespecified analysis of two randomized, double-blind, placebo-controlled, phase 3 studies (TAK-861-3001 and TAK-861-3002) was conducted to investigate the effect of oreoprexton on NT1 symptoms severity. Eligible participants were aged 16–70 years with an International Classification of Sleep Disorders, Third Edition (ICSD-3) or ICSD-3-Text Revision diagnosis of NT1 (supported by polysomnography and multiple sleep latency test results or orexin cerebrospinal fluid concentration ≤ 110 pg/mL), Epworth Sleepiness Scale (ESS) score ≥ 11 , and ≥ 4 partial/complete episodes of cataplexy/week in absence of treatment. Participants received twice daily oral oreoprexton 1 mg (TAK-861-3001 only) or 2 mg, or placebo, at least 3 hours apart for 12 weeks. Key secondary efficacy endpoints were the Narcolepsy Severity Scale for Clinical Trials (NSS-CT; a validated, self-administered 15-item scale assessing sleepiness, cataplexy, sleep paralysis, hallucinations, and disrupted nocturnal sleep, score range 0-57), and the Patient Global Impressions Scales of Severity (PGI-S) and Change (PGI-C).

Results: Overall, 273 participants were randomized (TAK-861-3001, n=168; TAK-861-3002, n=105) to oreoprexton 1mg/1mg (n=61), oreoprexton 2mg/2mg (n=136), or placebo (n=76). Mean age for the TAK-861-3001 and TAK-861-3002 studies was 31.4 years and 30.7 years, respectively; 98 (58.3%) and 50 (47.6%) participants were female. Mean NSS-CT total scores at baseline were 30.9 and 31.1, respectively. In TAK-861-3001, 65.5% of participants (PGI-S) rated NT1 symptoms as severe/very severe at baseline, and in TAK-861-3002, 65.7% of participants rated the symptoms as severe/very severe. Statistically significant improvements ($P < 0.001$) in NSS-CT total score from baseline to week 12 were achieved with all oreoprexton dose groups vs placebo. In TAK-861-3001, least square (LS) mean (95% CI) changes from baseline vs placebo were -14.37 (-17.81, -10.93) with oreoprexton 1mg/1mg and -16.88 (-20.24, -13.52) with oreoprexton 2mg/2mg (both $P < 0.001$). In TAK-861-3002, LS mean (95% CI) change from baseline vs placebo was -18.11 (-21.25, -14.96) with oreoprexton 2mg/2mg ($P < 0.001$). At week 12, in TAK-861-3001, 73.7%, 96.9%, and 22.2% of participants in oreoprexton 1mg/1mg, oreoprexton 2mg/2mg, and placebo dose groups, respectively, reported 'much improved' or 'very much improved' on the PGI-C. At week 12, in TAK-861-3002, 91.0%, and 14.7% of participants in the oreoprexton 2mg/2mg and placebo dose groups, respectively, reported much/very much improved on the PGI-C.

Conclusions: In these two phase 3 studies, oreoprexton showed significant improvements in frequency, severity, and impact of narcolepsy symptoms, as assessed with the NSS-CT and PGI-C versus placebo in participants with NT1 over 12 weeks.

Effect of the Oral Orexin Receptor 2 Agonist Oreoprexton (TAK-861) on Quality of Life in Individuals with NT1

S. Sivam¹, S. Hsiao², Y. Du², H. Romero², T. Olsson²

¹Woolcock Institute of Medical Research and Royal Prince Alfred Hospital, Sydney, Australia, ²Takeda Development Center Americas, Inc., Cambridge, United States

Introduction: Narcolepsy type 1 (NT1), a rare, chronic neurologic disorder that affects sleep-wake stability, is associated with detrimental effects on health-related quality of life (HRQoL). We evaluated the effect of oreoprexton (TAK-861), an orexin receptor 2 (OX2R)-selective agonist under investigation for the treatment of NT1, on measures of HRQoL (36-item Short-Form [SF-36] survey and EuroQoL 5-Dimensions 5-Levels [EQ-5D-5L] questionnaire), in two Phase 3 clinical trials.

Materials and methods: Results from two randomized, double-blind, placebo-controlled, Phase 3 studies (The First Light: TAK-861-3001 and The Radiant Light: TAK-861-3002) were evaluated to explore HRQoL with oreoprexton treatment in individuals with confirmed NT1. Eligible participants were aged 16–70 years with an International Classification of Sleep Disorders, Third Edition (ICSD-3) or ICSD-3-Text Revision diagnosis of NT1 (supported by polysomnography, multiple sleep latency test results or orexin cerebrospinal fluid concentration ≤ 110 pg/mL), Epworth Sleepiness Scale (ESS) score ≥ 11 , and ≥ 4 partial/complete episodes of cataplexy/week. Participants received twice daily oral oreoprexton 1 mg (The First Light only) or 2 mg, or placebo, at least 3 hours apart for 12 weeks. SF-36 Mental and Physical Component Summary scores were secondary endpoints (0-100 scale) and EQ-5D-5L visual analog scale (VAS; 0-100 scale) was an exploratory endpoint. Higher scores represented better quality of life. Efficacy and safety results are reported separately.

Results: Overall, 273 participants were randomized to ovesporexton 1mg/1mg (n=61), ovesporexton 2mg/2mg (n=136), or placebo (n=76). Mean age was 31.4 years (The First Light) and 30.7 years (The Radiant Light); 98 (58.3%) and 50 (47.6%) participants, respectively, were female. Mean baseline SF-36 and EQ-5D-5L VAS scores were similar across all study arms (SF-36 Mental Component Summary score [MCS]: 38.3-41.0; SF-36 Physical Component Summary score [PCS]: 46.9-50.5; EQ-5D-5L VAS score: 58.9-66.4). After 12 weeks, SF-36 MCS scores ranged from 47.1 to 49.2 with ovesporexton vs 38.2 to 38.5 with placebo, SF-36 PCS scores ranged from 54.7 to 55.8 with ovesporexton vs 49.1 with placebo, and EQ-5D-5L VAS scores ranged from 77.7 to 80.6 with ovesporexton vs 59.4 to 66.0 with placebo. Least square (LS) mean changes from baseline in SF-36 component summary scores were statistically significant for both ovesporexton dose groups vs placebo at week 12 (MCS score: The First Light: 6.79 [1mg/1mg], 10.11 [2mg/2mg], The Radiant Light: 9.32 [2mg/2mg], all $P < 0.001$, and PCS score: The First Light: 5.54 [1mg/1mg], 6.26 [2mg/2mg], The Radiant Light: 5.01 [2mg/2mg], all $P < 0.001$). Similarly, LS mean changes from baseline in EQ-5D-5L VAS score vs placebo were also nominally statistically significant (The First Light: 16.28 [1mg/1mg] and 20.15 [2mg/2mg], The Radiant Light: 14.65 [2mg/2mg], all $P < 0.001$).

Conclusions: In these Phase 3 clinical trials, ovesporexton showed statistically significant and clinically meaningful improvements in HRQoL, assessed with the SF-36 and EQ-5D-5L VAS compared with placebo in participants with NT1 over 12 weeks.

Effects of Once-Nightly Sodium Oxybate on Apnea-Hypopnea Index: Post Hoc Analysis From the Phase 3 REST-ON Clinical Trial

R. Bogan^{1,2}, B.C. Corser³, T. Stern³, B. Abaluck⁷, J. Gudeman⁷

¹University of South Carolina School of Medicine, Columbia, United States, ²Medical University of South Carolina, Charleston, United States, ³Sleep Management Institute, Cincinnati, United States, ⁴Advanced Respiratory and Sleep Medicine, PLLC, Huntersville, United States, ⁵Avadel Pharmaceuticals, Chesterfield, United States

Introduction: Sodium oxybate (SXB) is a central nervous system depressant used to treat narcolepsy and has the potential to cause respiratory depression. Registrational trials of SXB have generally excluded patients with respiratory depression, including those with an apnea hypopnea index (AHI) > 15 . This post hoc analysis of REST-ON evaluates the effect of once-nightly SXB (ON-SXB) compared to placebo on AHI in individuals with narcolepsy with either no sleep apnea or mild sleep apnea.

Materials and methods: REST-ON (NCT02720744) was a phase 3, double-blind, placebo-controlled randomized clinical trial. Participants (age ≥ 16 years) with narcolepsy and AHI < 15 were randomized 1:1 to ON-SXB (week 1, 4.5 g; weeks 2–3, 6 g; weeks 4–8, 7.5 g; weeks 9–13, 9 g) or placebo. AHI was measured using polysomnography at baseline and weeks 3, 8, and 13, and analyzed post hoc. Adverse drug reactions (ADRs) were assessed at each visit.

Results: Respective mean (min, max) AHI values were similar for the ON-SXB (n=97) and placebo groups (n=93) at baseline (2.7 [0, 15] and 2.8 [0, 13]), week 3 (0.1 [0, 5] and 0.1 [0, 2]), and week 8 (0 [0, 0] and 0 [0, 0]). At week 13, mean (min, max) AHI values were 0 (0, 0) and 0.2 (0, 10) in the ON-SXB and placebo groups, respectively. Least squares mean (LSM) change from baseline in AHI with ON-SXB and placebo was -3.0 and -2.9 , respectively, at week 3 (LSM difference [LSMD; 95% CI], -0.11 [-0.46 to 0.24]; $P=0.522$); -3.0 and -2.9 , respectively, at week 8 (LSMD [95% CI], -0.11 [-0.46 to 0.23]; $P=0.518$); and -3.0 and -2.9 , respectively, at week 13 (LSMD [95% CI], -0.12 [-0.46 to 0.23]; $P=0.515$). In the safety population, 1 (0.9%) and 1 (1.0%) participant in the ON-SXB and placebo arms, respectively, experienced ADRs of sleep apnea, and 1 (0.9%) participant receiving ON-SXB reported snoring; all were mild or moderate in severity.

Conclusions: Treatment with ON-SXB was not associated with worsened AHI at any tested dose. ON-SXB was well-tolerated, as the reported respiratory-related ADRs were minimal, and mild or moderate in severity.

Erectile function in Male patients with Narcolepsy

L. Zhang¹, S. Wu², F. Han²

¹Peking University People's hospital, Beijing, China, ²Peking University People's hospital, Beijing, China

Introduction: Explore the nocturnal erectile function of male patients with narcolepsy, and whether there are any changes after taking medications for narcolepsy.

Materials and methods: Eighteen adult male patients with narcolepsy admitted to Peking University People's Hospital from September 2024 to April 2025 were selected. Among them, 9 patients took Methylphenidate 9mg and Venlafaxine 75mg per day, and the other 9 patients took Methylphenidate 9mg and Clomiphen 12.5mg per day. Polysomnography (PSG) and RigiScan tests were performed at night after admission, and the examination was re-conducted 3 days after medication. PSG data were staged strictly according to the standards of the American Academy of Sleep Medicine. RigiScan data were converted and exported using the Spyder software. Meanwhile, questionnaires such as the Pittsburgh Sleep Quality Index (PSQI), Epworth Sleepiness Scale (ESS), Athens Insomnia Scale (AIS), International Index of Erectile Function-5 (IIEF-5), Erectile Hardness Score (EHS) questionnaire, and the 19-item Morningness-Eveningness Questionnaire (MEQ-19) were used to collect and analyze scores related to insomnia, anxiety, depression, erectile dysfunction, etc. of the included patients.

Results: About **16.7% (3/18)** of the patients were diagnosed with erectile dysfunction after undergoing tests on two nights. **83% (15/18)** of the patients had an IIEF-5 questionnaire score of less than 21, indicating erectile dysfunction. **88% (16/18)** of the patients had an EHS of less than or equal to 3 and considered that their erections were not firm enough. After the linear regression test, it was found that patients with higher scores in AIS ($p=0.004$), ESS ($p=0.025$) and EHS ($p<0.001$) have lower scores in IIEF-5 and shorter erectile duration after taking medication ($p=0.026$). Meanwhile, patients with higher AIS scores ($p=0.044$) also have higher EHS scores. The results of the paired samples t-test suggest that after taking the medicine, the patients' REM sleep time ($p < 0.001$), proportion ($p = 0.002$), and erection time ($p = 0.001$) all decrease significantly, and the REM sleep latency ($p < 0.001$) significantly prolongs.

Conclusions: There is a close connection between the psychological state of the patients and their erectile function, most male patients subjectively believe that they have erectile dysfunction, a small number of patients objectively have erectile dysfunction. Commonly used medications such as Methylphenidate, Clomiphen and Methylphenidate can significantly inhibit their REM sleep while affecting the erection of patients.

Acknowledgments: Thanks for every participants in this study, thanks for the support of Peking University People's Hospital, and thanks for the support of National Natural Science Foundations of China(32441101, 82341243 to HF), Natural Science Foundations of Beijing(2023YFE0118500 to HF)

Estimating the Clinical and Economic Effects of High- and Low-Sodium Oxybate Agents among the US Population with Narcolepsy: Microsimulation Cost Analysis

L. Pinto¹, N. Adair², J. Ortendahl², M. Sussman², S. Shah¹, S. Beaty¹, S.C. Markt¹, C. Drachenberg¹, B. Hutchinson³

¹Jazz Pharmaceuticals, Palo Alto, United States, ²Stratevi, LLC, Boston, United States, ³Chesapeake Cardiac Care, Bowie, United States

Introduction: Excess sodium intake is associated with increased risk of cardiovascular (CV), cardiometabolic (CM), and cardiorenal (CR) disorders. People with narcolepsy have a higher prevalence and risk of development/progression of certain CV/CM/CR conditions/events than people without narcolepsy. High-sodium oxybate agents, indicated to treat narcolepsy, contain 1640mg of sodium per nightly 9g dosage, while low-sodium oxybate agents contain 131mg per nightly 9g dosage. This study evaluated potential clinical and economic benefits associated with taking low-sodium versus high-sodium oxybate agents.

Materials and methods: A microsimulation model was developed to estimate the 10-year clinical and economic impacts of sodium intake in US adults with narcolepsy. Using US Census Bureau population data and published US prevalence estimates, the simulated cohort included 101,135 adults with narcolepsy. Two treatment scenarios were modelled (assuming continuous treatment over the 10-year horizon or until the patient reached 100 years of age): 1) taking a high-sodium oxybate agent (1640mg of sodium added to daily dietary sodium intake [based on age- and sex-stratified NHANES data]) and 2)

taking a low-sodium oxybate agent (131mg of sodium added to daily dietary sodium intake). Patients entered the model with or without a chronic condition (atrial fibrillation, chronic kidney disease [CKD], diabetes, heart failure, hypertension, non-alcoholic fatty liver disease), based on literature-identified, narcolepsy-specific prevalence estimates. Every 3-month cycle, individuals were at risk of developing new-onset chronic conditions or acute events (oedema, haemorrhagic stroke, ischaemic stroke, myocardial infarction) and were modelled with risk (hazard/odds ratios) adjusted based on treatment scenarios. Each cycle, patients could die from an acute event or overall mortality, aligned with risk estimates from published literature. The effect of sodium on each outcome was sourced from network meta-analyses or individual studies. US-based cost data from administrative claims and the Healthcare Cost and Utilization Project were applied per condition/event per cycle. Model outputs included clinical event counts and total and event-specific direct costs (2025 USD) over 10 years for each treatment scenario.

Results: Over the 10-year horizon, total direct healthcare costs among people with narcolepsy treated with a high-sodium oxybate agent were \$16.48B versus \$15.32B for individuals treated with a low-sodium oxybate agent, representing \$1.16B in cost savings. Reduced chronic condition costs with low-sodium agents accounted for most of these savings (\$1.15B). The largest cost reductions were observed in CKD (\$527.1M), diabetes (\$153.0M), and hypertension (\$82.5M). Savings among people with narcolepsy treated with a low-sodium agent were observed for all modelled health outcomes and driven primarily by avoidance of 4979 cases of hypertension, 2924 cases of diabetes, and 2490 cases of atrial fibrillation. Among acute events, 504 ischaemic strokes, 130 myocardial infarctions, and 92 haemorrhagic strokes were avoided with a low-sodium agent, as were 107 event-specific deaths.

Conclusions: This microsimulation suggests that treatment with a low-sodium versus high-sodium oxybate agent was associated with a notable reduction in negative health outcomes among US adults with narcolepsy, translating to \$1.16B in healthcare cost savings over 10 years. These findings underscore the importance of treatment strategies that minimise excess sodium exposure to mitigate elevated CV/CM/CR risks in this population.

Evaluating Progressive Learning Using Meta-Analytic and Claims Data: A Case Study in Narcolepsy

J. Brooks¹, E. Bixler¹, L. Berger¹, A.M. Morse²

¹Haymarket Medical Education, Paramus, United States, ²Janet Weis Children's Hospital, Geisinger Health System, Child Neurology and Pediatric Sleep Medicine, Danville, United States

Introduction: Between 2022 and 2024, Haymarket Medical Education (HME) launched 7 narcolepsy-focused online educational activities for sleep clinicians to address ongoing gaps in knowledge and practice. Using meta-analytic methodology, we compared single- and multiple-activity learners to evaluate the impact of repetition and reinforcement and environmental factors on knowledge, competence, and real-world behavior, using pre- and post-test, and claims data.

Materials and methods: Pre-/post-test responses from learners for 7 online narcolepsy educational activities conducted 2022-2024 were tagged by topic to ensure comparison of similar topics across questions. Pre- to post-activity changes were evaluated across years to show general trends or by year to highlight year-over-year differences. Within the group of sleep clinicians, we compared two cohorts: those who participated in 1 activity versus those who participated in >1 (repeat learners). The goal was to identify differences between the groups and assess whether repeated learning led to greater improvements in knowledge, competence, and practice.

We also evaluated whether the education resulted in performance (clinical) change, using real-world claims data from the PurpleLab database, matching learners using NPI numbers. Differences in use of diagnostic codes for narcolepsy and changes in recommended treatment selection prior to and after exposure to the education were measured.

Results: We included 1,773 sleep medicine learners from 7 activities; 331 (18.67%) were repeat learners.

Learners showed significant knowledge and competence gains across all topics, with the largest improvement in Use of Guidance (19%), Treatment Efficacy and Safety (14%) and Treatment Strategy (14%). Baseline scores dipped in 2023 (19–24%) compared to 2022 (28–40%), but recovered in 2024. We postulate this occurred due to novel guidelines and new trial data and approvals that occurred prior to 2023.

Repeat learners showed significant and greater improvements from pre- to post-test than single activity learners. Repeat learners had the largest gains in Use of Guidance (21%), Treatment Efficacy and Safety (15%) and Treatment Strategy (15%). Single activity learners showed significant but smaller gains in: Use of Guidance (18%), Treatment Efficacy and Safety (13%), and Treatment Strategy (14%). Year-over-year, positive trends were observed, except in Treatment Efficacy and Safety, where both groups saw baseline knowledge declines, possibly attributed to the number and complexity of questions, and uncertainty caused by emerging data and therapies during this period.

Using real-world claims data, we found that repeat learners versus single activity learners showed: differences in diagnosis of narcolepsy (increase by 67% vs. 40%); and prescription of recommended treatments (17% increase vs 17% decrease)

Conclusions: We demonstrated that serial learning strengthened clinical decision-making, boosted long-term knowledge retention, and optimized clinical behavior in sleep clinicians through repetition and reinforcement, whereas single exposure appears to result in suboptimal practice. Serial learning approaches are crucial for adapting to evolving environments and ensuring sustained, impactful learning. A limitation of this study is the failure to account for bias introduced through learner exposure to education beyond our activities.

Acknowledgments: Educational grant support for the activities was provided by Avadel Pharmaceuticals, Harmony Biosciences, and Jazz Pharmaceuticals.

Excessive adrenergic stimulation triggers narcolepsy and Food Protein Induced Enterocolitis (FPIES) along with increased Respiratory Effort during sleep (RE), tissue hypoxia, and oxidative stress through transformed foods and emerging allergens. Which allele should be explored in narcolepsy cases negative for HLA DQB1*06:02?

K. Kefala¹, P. Guerin²

¹Cabinet d'allergologie de l'enfant et de l'adolescent, Pediatric Allergology, PARIS, France, ²Clinique du Souffle, Les Clarines, Pulmonology department, Riom Es Montagnes, France

Introduction: Cataplexies have been linked to the presence of the HLA-DQB1*06:02 allele, which predisposes individuals to progressive destruction (autoimmune type) of orexin neurons. However, the type 2 narcolepsy group is characterized by the absence of SOREMP, and negative HLA-DQB1*06:02. In narcoleptic children, diagnosis is delayed by a minimum of one year. A delay in diagnosis could be a pivotal cause of the disease as it provides time for the ongoing reaction to destroy hypocretin neurons. For children younger than 6 years, current recommendations focus on providing adequate sleep time, taking naps during the day, treating comorbidities and accompanying medical disorders such as OSA, and sleep fragmentation. Food protein-induced enterocolitis (FPIES) is a severe non-IgE-mediated allergy of unknown origin, with an estimated incidence gradually increasing to 0.45%.

Materials and methods: We describe a 3-year-old child with FPIES positive for HLA-DQB1*03:02 and HLA-DRB1*04 suffering from cataplexies triggered by alimentary and drug excipients and a 14 year-old suffering narcolepsy positive for HLA DQB1*06:02.

Results: Case 1: A polyallergic child is nourished with amino-acid-formula since the age of 4,5 months.

3-year-old: Treatment with lactose and galactose-containing lactulose containing **polysorbate 80, maltodextrin, and sorbitol** induced severe hypnagogic hallucinations, nightmares, hyperactivity, aggressive behavior, excessive daytime sleepiness, persistent itching, crying, skin reactions and facial cataplexies which ceased after laxation cessation. **4-year-old:** a multivitamin sirop containing **maltodextrin** and **amidon** induced hypnagogic hallucinations, nocturnal terrors, nightmares, facial cataplexies, and neck hyperextension that reoccurred on food reintroduction, despite normal iron levels. She experienced FPIES, skin hyperextensibility, alopecia, dopamine dysregulation, increased pilosity, and 3-methylhistidine levels. CPAP helped better tolerate food reintroduction and occasionally adopted neck hyperextension. CPAP cessation led to an acute increase in the hydroxybutyrate and TNF- α levels. **HLA was positive for DQ8 (HLA-DQB1*03:02) and HLA-DRB1*04, negative for HLA-DQB1*06:02. The mother confirmed that, during cataplexies, the child consumed some gluten and gluten-free products. The early diagnosis and adequate treatment initiated for the 3-year-old child ceased narcolepsy signs and FPIES with no recurrence. Case 2:** A 14-year-old child underwent allergy consultation because of severe repercussion signs (Epworth scale 22/30), hypnagogic hallucinations, and chronic rhinitis. He had secondary nocturnal enuresis since the age of 11. PSG two months earlier revealed mild OSA, mainly in the dorsal position, and restless legs syndrome. The patient fell asleep

during the consultation and had the jaw dropping involuntarily. We performed PG at home, which revealed moderate OSA, aggravated in the non-dorsal position, severe sleep fragmentation, and increased RE during sleep. The child had low coefficient iron saturation, folate, Vit-D values, and increased noradrenaline and Eosinophilic Cationic Protein (ECP). We explored HLA which was positive for **HLA DQB1*06:02**. Both children experienced persistently increased respiratory effort during sleep despite a low apnea-hypopnea index (AHI).

Conclusions: Constant adrenergic stimulation through increased RE during sleep can trigger the onset of FPIES and narcolepsy in children with HLA predisposition. The industrialized mode of nutrition could detrimentally alter the gut microbiota through allergens such as polysorbate 80 and maltodextrin, and facilitate the lack of nutrients, vitamins, and antioxidants essential for protecting neurons and restraining the onset of FPIES and narcolepsy.

Acknowledgments: Special acknowledgments to patients and their parents

First-Line Treatments for Children with Narcolepsy Type 1: Retrospective Comparison of Pitolisant and Modafinil

M. Fayard¹, P. Boute¹, M. Comajuan¹, A. Guyon¹, J.-S. Lin², S. Plancoulaine², P. Franco¹

¹University Lyon 1, Pediatric Sleep Unit, Mother and children Hospital, HCL & INSERM U1068, CRNL, Lyon, France, ²University Lyon 1, INSERM U1068, CRNL, Lyon, France

Introduction: Narcolepsy Type 1 (NT1) is a rare, chronic neurological sleep disorder characterized by excessive daytime sleepiness (EDS) and REM sleep-related phenomena, including cataplexy, sleep paralysis, and hallucinations. Over 50% of NT1 cases manifest before the age of 20, highlighting the critical need for safe and effective pediatric therapies. Although Modafinil has been widely used to manage EDS in children, its use lacked formal pediatric approval. More recently, Pitolisant, a histamine H3 receptor inverse agonist, has been approved for NT1 in children, following randomized controlled trials demonstrating its efficacy in reducing EDS and cataplexy. This study aimed to retrospectively compare the efficacy and tolerability of Modafinil and Pitolisant as first-line pharmacological treatments in children with NT1.

Materials and methods: We included all children diagnosed with NT1 between 2009 and 2025 at the National Reference Center for Narcolepsy in Lyon, France. Patients systematically completed validated questionnaires assessing EDS (Adapted Epworth Sleepiness Scale for children, AESS) and depressive symptoms (Children's Depression Inventory, CDI). Anthropometric parameters, polysomnographic (PSG) data, multiple sleep latency test (MSLT) results, and adverse events were collected. Comparative analyses between groups treated with Modafinil or Pitolisant as first-line therapy were conducted using Wilcoxon rank-sum tests, Fisher's exact tests, and multivariable mixed models for ranked variables.

Results: A total of 90 patients (52 boys) were included, with 56 treated with Modafinil and 34 with Pitolisant. Compared to the Pitolisant group, patients treated with Modafinil were younger at disease onset (median 8 vs. 11 years; $p = 0.03$) and diagnosis (median 10 vs. 14 years; $p < 0.001$), with a shorter diagnostic delay (median 1 vs. 2 years; $p = 0.005$). The Modafinil group also exhibited shorter sleep latency on MSLT ($p < 0.001$), lower sleep efficiency on PSG ($p < 0.001$), greater N3 sleep proportion ($p = 0.001$), fewer arousals ($p = 0.01$), and fewer depressive symptoms ($p = 0.005$). No significant differences were observed in baseline AESS scores, cataplexy prevalence (91% vs. 88%), or BMI Z-scores.

After 1 to 5 months of treatment, AESS scores decreased by a median of 5 points with Modafinil and 4 points with Pitolisant (non-significant). The median dosage for Modafinil was 200 mg (range 100–400 mg) and for Pitolisant, 27 mg (range 9–36 mg). Adverse events were reported in 48% of Modafinil-treated patients and 61% of Pitolisant-treated patients, though Pitolisant-related side effects were mostly transient (headaches, insomnia). Treatment discontinuation was significantly higher with Modafinil (81% vs. 31%; $p < 0.001$). Only the Pitolisant group demonstrated a significant reduction in cataplexy frequency (88% to 61.7%; $p < 0.05$). No significant BMI Z-score changes were observed. Adjusted models revealed higher baseline depressive scores and more arousals in the Pitolisant group, with lower treatment discontinuation rates.

Conclusions: This retrospective, real-world study supports Pitolisant as a first-line treatment for NT1 in children, showing comparable efficacy in reducing EDS, additional benefits in reducing cataplexy, and significantly lower discontinuation rates than Modafinil. Prospective, long-term studies are needed to further guide pediatric NT1 management.

Gender differences in Chinese with narcolepsy type 1: comparison of clinical manifestations and sleep characteristics

M. Zhang¹, X.-s. Dong¹, F. Han¹

¹Peking University People's hospital, Sleep medicine department, Beijing, China

Introduction: Narcolepsy type 1 (NT1) is a chronic sleep disorder due to a hypocretin/orexin deficiency induced by immunological process. Given the male predominance and earlier age at disease onset of narcolepsy in China versus other ethnic groups, whether the gender contributes to different phenotypes of narcolepsy in Chinese remains to be determined. Accordingly, the present study aims to address the effects of gender on clinical and sleep characteristics in a large population of Chinese children and adults with NT1, respectively.

Materials and methods: A total of 1415 patients with NT1 were included from Peking University People's hospital and other sleep centers in China. Clinical and sleep characteristics were compared between girls and boys with narcolepsy according to age at both disease onset and diagnosis < 18 years, women and men with narcolepsy according to age at both disease onset and diagnosis ≥ 18 years, as well as patients with narcolepsy according to age at disease onset < 18 years but with age at disease diagnosis ≥ 18 years, respectively.

Results: Age at disease onset, sleepiness onset, and cataplexy onset were not significantly different between girls/women and boys/men with narcolepsy. Girls/women with narcolepsy have longer diagnostic delay than men with narcolepsy. Boys/men with narcolepsy showed a higher body mass index (BMI) than girls/women with narcolepsy. Girls with narcolepsy present a higher percentage of hypnagogic/hypnopompic hallucinations and a higher spontaneous arousal index than boys. Men with narcolepsy had a higher percentage of stage N1 sleep, a lower percentage of stage N3 sleep and a higher apnoea hypopnea index (AHI) on nocturnal sleep as well as a shorter mean sleep latency and more sleep onset rapid eye movement periods (SOREMPs) on multiple sleep latency test (MSLT) than women. HLA-DQB1*06:02 positivity is higher in boys with narcolepsy than in girls with narcolepsy and is tended to be higher in men with narcolepsy than in women with narcolepsy. Hypocretin-1 levels were tended to be lower in boys or men with narcolepsy versus girls or women with narcolepsy. No differences in terms of diagnostic delay, stage N1 sleep, stage N3 sleep, MSLT characteristics, hypocretin-1 levels and HLA-DQB1 06:02 genotype positivity were noted between different gender groups in patients with narcolepsy according to age at disease diagnosis during adulthood but with symptoms onset during childhood.

Conclusions: Men with narcolepsy present more severe clinical picture than women with narcolepsy, probably to some extent promoting sooner diagnosis of men with narcolepsy. However, girls with narcolepsy present a more severe clinical picture than boys with narcolepsy, suggesting gender affects differently children and adults with narcolepsy. Patients with narcolepsy have disease diagnosis during adulthood but with symptoms onset during childhood constitute a specific phenotype of narcolepsy different from those children or adults with narcolepsy. Prospective longitudinal study is warranted to investigate the disease progress between different sex to better understand the underlying pathology and to ensure a proper management of narcolepsy.

Hormonal Contraceptive and Pitolisant CYP3A4 Induction

C. Caussé¹, P. Robert², J.-C. Schwartz³

¹Bioprojet, Medical Affairs, Paris, France, ²Bioprojet, Pharmacology, Saint Grégoire, France, ³Bioprojet, Pharmacology, Paris, France

Introduction: Some narcolepsy treatments (e.g. modafinil) are contraindicated in narcoleptic patients taking oral contraceptives as they reduce their plasma levels by inducing CYP3A4. Pitolisant is a wake-promoting and anticataplectic agent approved in Europe, USA, Canada, Israel, China, Taiwan for the treatment of narcolepsy. We assessed its CYP3A4-inducing potential *in vitro* and *in vivo* to possibly

offer a therapeutic alternative for patients with narcolepsy wishing to continue their hormonal contraceptive treatment.

Materials and methods: In cultured human hepatocytes, pitolisant inducing potential was evaluated on CYP3A4 mRNA and enzyme catalytic activity. *In vivo* induction was evaluated in volunteers receiving pitolisant oad at 36 mg for 7 to 28 days with two approaches. In the traditional one the metabolism of midazolam was evaluated. In the second and more recent one (Goodenough, 2011) formation of a characteristic cholesterol metabolite (4- β -hydroxycholesterol, 4 β HC) was measured using a novel LC/MS method requiring only 50 μ L serum samples.

Results: Pitolisant demonstrated only minor changes in CYP3A4 mRNA levels whereas CYP 3A4 catalytic activity was not induced in hepatocytes across six subjects. In 18 volunteers receiving 36 mg pitolisant oad for 8 days, minor midazolam exposure modifications were evidenced without change in metabolite formation via CYP3A4. In another group of 48 volunteers receiving 18 to 45 mg oad for up to 28 days, 4 β HC level were not modified. This new test was validated in 18 other volunteers receiving for 8 days 600 mg/day of rifampicin, a prototypic CYP 3A4-inducer, in which 4 β HC levels were increased ($P < 0.00001$).

Conclusions: Pitolisant at therapeutic dose is devoid of any inducer activity on CYP3A4 and, therefore, represents a valuable alternative for treating Excessive Daytime Sleepiness and cataplexy in female patients with narcolepsy taking hormonal contraceptive drugs

Hypnagogic/Hypnopompic Hallucination Types Among Participants With Narcolepsy Type 1 From the Phase 3 REST-ON Trial

M.J. Thorpy², J.M. Mundt¹, S. Ibrahim², C.A. Kushida⁴, M. Lavender³, J. Gudeman⁵, T. Roth⁴

¹Albert Einstein College of Medicine, New York, United States, ²University of Utah, Salt Lake City, United States, ³University Hospitals Cleveland Medical Center, Cleveland, United States, ⁴Stanford University School of Medicine, Stanford, United States, ⁵Comprehensive Sleep Medicine Associates, Houston, United States, ⁶Avadel Pharmaceuticals, Chesterfield, United States, ⁷Sleep Disorders and Research Center, Henry Ford Health System, Detroit, United States

Introduction: Limited information is available to quantify hypnagogic/hypnopompic hallucination (HH) events people with narcolepsy (PWN) may experience. This post hoc analysis from the phase 3 REST-ON trial evaluated individual HH types.

Materials and methods: REST-ON (NCT02720744) participants (age ≥ 16 years) with narcolepsy were randomized 1:1 to once-nightly sodium oxybate (ON-SXB) (week 1, 4.5 g; weeks 2-3, 6 g; weeks 4-8, 7.5 g; weeks 9-13, 9 g) or placebo. HH events were assessed in participants with narcolepsy type 1. Modified intent-to-treat (mITT) population (≥ 1 efficacy measurement after 6-g dose) data were analyzed. Nocturnal HH types were evaluated via 6 yes/no questions and recorded in daily diaries. Daytime HHs were not assessed.

Results: In the mITT population with HH at baseline ($n = 112$ [ON-SXB, $n = 55$; placebo $n = 57$]), baseline mean [SD] number of HH events/day was 0.60 [0.35] and 0.66 [0.35] in the ON-SXB and placebo groups, respectively. Respective mean change from baseline (95% CI) in HH events/day to weeks 3, 8, and 13 was -0.16 (-0.21, -0.11), -0.28 (-0.37, -0.19), and -0.29 (-0.40, -0.18) with ON-SXB (all $P < 0.001$) and -0.14 (-0.20, -0.08), -0.18 (-0.26, -0.10), and -0.24 (-0.33, -0.14) with placebo (all $P < 0.001$). Participants chose from the following HH types: 1) feeling that shadows or objects are moving/distorting (total number of events with ON-SXB and placebo: 1693 and 2133), 2) feeling another presence in the room (1362 and 1839), 3) feeling that you are about to be attacked (655 and 1232), 4) feeling that you are flying through the air (543 and 1351), 5) feeling that you will soon fall into a hole (448 and 914), and 6) feeling caught in a fire (123 and 152). Of 12,455 HH events, 7762 (62%) were hypnagogic, and 4683 (38%) were hypnopompic.

Conclusions: There were low baseline HH rates in REST-ON, and a strong placebo effect was observed. However, these data provide insight into the HH types participants experienced. Relevant to clinician-patient discussions, approximately half the number of events where participants felt like they were about to be attacked, flying through the air, and falling in a hole were reported with ON-SXB vs placebo.

Hypothalamic Functional Connectivity, Depressive Symptoms, and Post-Treatment SOREMPs in Narcolepsy Type 1: Links to Sleep Latency and Mediation Mechanisms

F. Xiao¹, M. Wang¹, H. Zhang¹, X. Dong¹, F. Han¹

¹Peking University People's Hospital, Division of Sleep Medicine, Beijing, China

Introduction: Narcolepsy type 1 (NT1) is characterized by sleep-onset rapid eye movement periods (SOREMPs), reflecting dysregulated rapid eye movement (REM) sleep control. Treatment response variability in SOREMP persistence remains poorly understood, particularly regarding hypothalamic functional connectivity (FC) and depressive symptoms. This study investigated clinical, polysomnographic, and neuroimaging differences between NT1 patients with low (0-1) versus high (≥ 2) post-treatment SOREMPs, and explored whether hypothalamic FC mediates the relationship between depressive symptoms and SOREMPs outcomes.

Materials and methods: One hundred ten NT1 patients were categorized into low (n=62) and high (n=48) post-treatment SOREMPs groups. Demographic, clinical variables (symptoms and questionnaires), and polysomnography (PSG)/multiple sleep latency test (MSLT) parameters were compared. Resting-state fMRI assessed hypothalamic FC with whole-brain regions. LASSO regression modeled associations between FC, sleep latency, and clinical variables, while mediation analysis tested hypothalamic pathways as mediators of depression-SOREMP relationships.

Results: High post-treatment SOREMPs patients exhibited shorter pre/post-treatment REM sleep latency, lower post-treatment wakefulness index, and higher depressive symptom prevalence compared to low SOREMPs patients. Hypothalamic FC differed significantly between groups: low SOREMPs patients showed enhanced connectivity in right medial hypothalamus-right thalamus/left precuneus, left medial hypothalamus-left inferior parietal lobule (IPL), and right lateral hypothalamus-left IPL pathways, but reduced connectivity in left lateral hypothalamus-right insula/left anterior cingulate cortex pathways ($p < 0.05$, GRF-corrected). LASSO regression identified left medial hypothalamus-left IPL FC as a significant predictor of post-treatment MSLT mean sleep latency ($\beta = 0.272$, $p = 0.001$), alongside age and pre-treatment sleep latency. Mediation analysis revealed complete mediation by two hypothalamic pathways: depressive symptoms predicted reduced right lateral hypothalamus-left IPL FC (indirect effect: 0.15-1.05), associated with fewer SOREMPs, and increased left lateral hypothalamus-right insula FC (indirect effect: 40 0.08-1.14), associated with more SOREMPs.

Conclusions: Hypothalamic-parietal/insular FC abnormalities link depressive symptoms to post-treatment SOREMP variability in NT1, with specific pathways mediating opposing effects on REM sleep regulation. These findings highlight hypothalamic connectivity as a critical neural substrate for treatment response, integrating sleep-wake and emotional processing networks. Targeting these pathways may improve personalized management for NT1 patients with comorbid depression and treatment-resistant SOREMPs.

Identification of patients with narcolepsy type 1 through automatic scoring of multiple sleep latency tests

R. Angerbauer¹, M. Bonacina¹, A. Stefani¹, A. Ibrahim¹, K. Egger¹, E. Brandauer¹, A. Heidebreder², B. Högl¹, M. Cesari¹

¹Medical University of Innsbruck, Department of Neurology, Innsbruck, Austria, ²Kepler University Hospital, Johannes Kepler University Linz, Department of Neurology, Linz, Austria

Introduction: Narcolepsy type 1 (NT1), narcolepsy type 2 (NT2) and idiopathic hypersomnia (IH) are central disorders of hypersomnolence (CDH) sharing excessive daytime sleepiness (EDS) as main clinical feature. In clinical routine, multiple sleep latency test (MSLT) is performed for diagnostic purposes, but the current diagnostic criteria do not indicate MSLT-specific criteria for the identification of patients with NT1. In fact, NT1 shares the same diagnostic criterion on sleep onset rapid eye movement (REM) periods with NT2 and the same diagnostic criterion on mean sleep latency with NT2 and IH. Previous

studies indicated that other MSLT features (namely mean REM latency and mean REM duration) might be sensitive and specific for identification of patients with NT1. The first aim of this study is to confirm these findings in an independent cohort. Second, in light of recent advancements of artificial intelligence (AI) for sleep scoring, we aimed to evaluate the reliability of two AI-based sleep scoring algorithms in MSLT naps. Finally, we assessed whether the automatically derived mean REM latency and mean REM duration could reliably discriminate patients with NT1.

Materials and methods: We included 35 patients with NT1, 22 with NT2, 17 with IH and 45 participants who had subjective ESD (i.e., Epworth Sleepiness Scale score >10), but who did not have any CDH diagnosis. All participants underwent an MSLT following a full-night polysomnography according to international criteria. Sleep experts scored sleep stages in each of the five naps of the MSLT. We employed the previously validated U-Sleep and YASA AI-algorithms for scoring sleep stages in each MSLT nap. Agreement between manual and automatic scorings was calculated with Cohen's kappa. By using each scoring, we derived the mean REM latency and mean REM duration for each participant. Area under the receiver operating characteristic curves (AUC) was used to evaluate how these features discriminated patients with NT1 from all remaining participants.

Results: U-Sleep had a significantly higher agreement with manual scoring compared to YASA (0.750 [inter-quartile range, IQR: 0.646-0.813] vs 0.660 [IQR: 0.557-0.747], p-value <0.001, signed ranksum test). Mean REM sleep latency could differentiate patients with NT1 with AUC values of 0.906 [95% confidence interval, CI: 0.823-0.953], 0.887 [95% CI: 0.796-0.940], 0.696 [95% CI: 0.582-0.784] for manual, U-Sleep and YASA scoring, respectively. Mean REM duration discriminated patients with NT1 with AUC values of 0.918 [95% CI: 0.850-0.963], 0.924 [95% CI: 0.844-0.966], 0.863 [95% CI: 0.788-0.924] for manual, U-Sleep, YASA scorings, respectively.

Conclusions: Mean REM latency and mean REM duration across the MSLT naps are reliable markers for discrimination of patients with NT1. U-Sleep had higher agreement with manual scoring compared to YASA. The results indicate that U-Sleep can be reliably used for MSLT scoring and for derivation of these promising NT1 diagnostic features.

Immunity to influenza B and cross-reactivity to Pandemrix/pH1N1 in narcolepsy

G. Luo¹, J. Zhang¹, E. Mignot¹

¹Stanford University, Palo Alto, United States

Introduction: Narcolepsy type 1 (NT1) is caused by 85-95% hypocretin (HCRT) neuron loss due to a combination of genetic and environmental risk factors and associated with DQA1*01:02/DQB1*06:02 (DQ0602, 98%) and T cell receptor (TCR) gene AJ24/AJ28/BV4-2. Pandemic influenza A H1N1 (pH1N1) and Pandemrix vaccination in 2009-2010 induced NT1 onset. Antigen specific T cell immune response in NT1 supports adaptive (auto)immunity against HCRT and Pandemrix/pH1N1. Despite this progress, the mechanism behind HCRT neuron loss and how the flu triggers a response against HCRT are unclear.

Materials and methods: Anti-hemagglutination (HA) antibody was first measured using HA inhibition assay. Binding affinity of B/Victoria candidate peptides to DQ0602 was next tested using a competition binding assay. Antigen-DQ0602 restricted/reactive T cells were further isolated using tetramer DQ0602 and single-cell RNA sequenced with 10X. Lastly, TCR clones were transfected into Jurkat 76 for TCR activation by a certain peptide presented by DQ0602.

Results: Two independent studies of our laboratory and a Chinese group have shown a higher HAI titer against B/Brisbane/60/2008 in NT1. I compared B/Brisbane/60/2008 with Pandemrix/pH1N1 and H3N2, and found a list of candidate peptides that most likely trigger immune response. Using the competition binding to DQ0602 at a relatively low concentration, four weak binders were further investigated using tetramer DQ0602 staining pooled PBMCs from multiple NT1 patients and healthy controls. I found a large population of reactive CD4+ T cells to a B/Victoria PB1 epitope that is homologous to Pandemrix/pH1N1 PB1 segment, and there is only one amino acid difference in their binding cores. Further, single cell RNA sequencing showed that over 85% of these cells are from NT1 patients and they are effector memory T cells. More than 35 clones were expanded at least 20 times, including several clones over 500 to 1,000 times. In addition, we built a TCR repertoire a) restricted by HCRT and Pandemrix/pH1N1 at baseline peripheral blood mononuclear cells (PBMCs) (n>430) and b)

from single-cell RNA sequencing cerebrospinal fluid(CSF) samples (n>2,000), and found the identical activated TCR clones in both baseline and cultured PBMCs.

Conclusions: Our research showed influenza B plays a role in NT1 pathogenesis and potential cross-reactivity to PB1 between B/Victoria and Pandemrix/pH1N1.

Impact of Stigma Associated with Narcolepsy Type 1: Insights from a Global Qualitative Study

A.M. Morse¹, A. Schokman², L. Jesteadt³, A. Martin⁴, H. Shaddock⁵, D. Pantalone⁶, K. Johnson⁶, K. Moore⁶

¹Geisinger Medical Center, Danville, PA, United States, ²The University of Sydney, Camperdown, Australia, ³Sleep Consortium, Inc., West Palm Beach, FL, United States, ⁴European Narcolepsy Alliance for Patients, Bruxelles, Belgium, ⁵Takeda Development Center Americas, Inc., Cambridge, MA, United States, ⁶VOZ Advisors, New York, NY, United States

Introduction: Qualitative research on the impact of stigma on individuals with narcolepsy type 1 (NT1) is lacking. The 'Stigma in Narcolepsy Interview Project' performed semi-structured interviews with individuals diagnosed with NT1 to understand their lived experiences with the disorder. The resulting key themes and insights are provided.

Materials and methods: The study period was November 2024 to February 2025. Individuals with NT1 were screened from seven countries (China, France, Germany, Italy, Japan, UK, and US) to recruit five participants per country. Recruitment was based on pre-determined quotas on age, sex, time since diagnosis, education, and employment to ensure geographic and demographic diversity. Participants were ≥18 years old with a physician-confirmed NT1 diagnosis and were comfortable discussing their experiences. Interviews were double-blinded, conducted by personnel familiar with market research and trained on the discussion guide, approximately 60 minutes long, and were conducted in participants' native languages before being translated for analysis. Interviews underwent thematic analysis via manual coding. Four identified themes were iteratively reviewed, and any discrepancies were reconciled through consensus-driven judgement.

Results: Five participants with NT1 from each country completed the study (N=35). Mean ages across the countries varied between 29–41 years old, 17 (48.6%) participants were female, and 25 (71.4%) reported being diagnosed within the last 10 years. By design, the proportion of participants with college degrees (40-80%) and full-time employment (20-100%) varied. At the start of the interview, 30 (85.7%) participants reported experiencing stigma due to NT1.

During screening, participants associated family and friends (69%), experiences at school (51%) or work (54%), and inaccurate media portrayals (31%) as main drivers of stigma. The three most reported strategies interviewees used to cope with stigma were internalization, humor, and proactive communication. Regarding societal perceptions, 63% of participants reported there was 'no understanding' of NT1 in their culture. Further, 80% reported that they were viewed as 'lazy'; other reported perceptions included being described as 'having a psychiatric condition' (40%), a 'substance abuser' (31%), or 'rude/bored' (20%).

Emerging as the first theme from interviews, stigma associated with NT1 significantly impacted participants' quality of life from an early age. Additional themes included participants feeling stigmatized by non-specialist healthcare providers. Many participants shared feelings of not being believed or trusted and worried about being misdiagnosed when discussing their symptoms, causing them to withhold details, thereby delaying diagnosis. Many interviewees hypothesized that there was a lack of NT1 education in non-specialist settings leading to inadequate treatment and care post-diagnosis. Interviewees acknowledged that stimulants and antidepressants were most stigmatized, but nearly all reported that it would not impact their willingness to try these or other treatments.

Conclusions: These findings highlight the significant impact of stigma on individuals with NT1 in this study. Fear of being misdiagnosed with a mental health condition, or judged for their symptoms, can lead some to withhold information from healthcare providers, resulting in delayed or misdiagnosis. Understanding these challenges is essential to create a more supportive environment for those living with NT1.

Impact of Switching From High- to Low-Sodium Oxybate on Ambulatory Blood Pressure in People With Narcolepsy

Y. Dauvilliers¹, V.K. Somers², R.J. Kovacs³, J.K. Alexander⁴, C. Baranak⁴, D.A. Nichols⁵, J. Dai⁵, M. Whalen⁵, A. Ajayi⁶, B. Hutchinson⁷, W.B. White⁸

¹University of Montpellier, Montpellier, France, ²Mayo Clinic, Rochester, United States, ³Cardiology Division, Indiana University School of Medicine, Indianapolis, United States, ⁴Jazz Pharmaceuticals, Inc., Philadelphia, United States, ⁵Jazz Pharmaceuticals, Inc., Palo Alto, United States, ⁶Children's Lung, Asthma and Sleep Specialists, Winter Park, United States, ⁷Chesapeake Cardiac Care, Bowie, United States, ⁸Calhoun Cardiology Center, University of Connecticut School of Medicine, Farmington, United States

Introduction: People with narcolepsy have an increased incidence of hypertension and cardiovascular disease (CVD) risk. Excess sodium intake is strongly associated with hypertension and CVD.

Materials and methods: XYLO, an open-label, single-arm study (NCT05869773), evaluated people with narcolepsy aged 18–70 years with screening systolic blood pressure (SBP) 130–155 mmHg taking twice-nightly high-sodium oxybate (SXB; Xyrem®) 6–9 g for ≥6 weeks, switching to low-sodium oxybate (LXB; Xywav®) at the same dosage/regimen for ≈6 weeks. The primary endpoint was change in mean 24-hour ambulatory SBP from baseline to end-of-treatment (EOT). Secondary endpoints were changes in mean daytime ambulatory, office (seated resting), and nighttime ambulatory SBP.

Exploratory endpoints included changes in mean 24-hour ambulatory, daytime ambulatory, office, and nighttime ambulatory diastolic blood pressure (DBP). An interim analysis using prespecified stopping criteria (75% completers) was performed. One-sided multiplicity-adjusted P-values ("*" denotes statistical significance) for SBP least squares mean (95% CI) changes adjusted for baseline values, and two-sided nominal P-values for corresponding DBP changes, are reported.

Results: Forty-three participants with narcolepsy (mean age, 45 years; 65% female; 33% on stable antihypertensives) were evaluated. At baseline, mean (SD) office SBP and DBP were 138.0 (5.7) and 85.2 (6.6) mmHg, respectively. Mean (SD) total SXB and LXB dosages were 8.0 (1.1) and 8.1 (1.1) g/night, respectively, representing 1457 (206) and 118 (16) mg sodium (difference of ≈1339 mg of sodium). The mean (SD) 24-hour urinary sodium was 4695.9 (2831.8) mg/day at baseline and 2934.9 (1401.3) mg/day at EOT. The mean (SD) 24-hour ambulatory SBPs at baseline and EOT were 132.3 (11.6) and 128.2 (12.0) mmHg, respectively; the change from baseline was –4.1 (–6.9, –1.4; $P=0.0019^*$) mmHg, meeting prespecified study stopping criteria. Changes in daytime and nighttime ambulatory SBP were –5.1 (–7.8, –2.4; $P=0.0003^*$) and –2.0 (–5.3, 1.4; $P=0.1265$) mmHg, respectively. The change in office SBP was –9.2 (–11.9, –6.5; $P<0.0001^*$). The change in 24-hour ambulatory DBP was –2.3 (–4.1, –0.5; $P=0.0118$). Changes in daytime and nighttime ambulatory DBP were –2.8 (–4.8, –0.9; $P=0.0045$) and –1.1 (–3.6, 1.5; $P=0.3993$); the change in office DBP was –3.8 (–6.0, –1.6; $P=0.0014$). Treatment-emergent adverse events (all mild/moderate) occurred in 33% of participants.

Conclusions: Switching from SXB to LXB reduced daily treatment-related sodium intake in participants with narcolepsy and was associated with clinically meaningful BP reductions, consistent with evidence on dietary sodium effects.

Impaired Vigilant Attention in Pediatric Narcolepsy Type 1

E. Montesano¹, B. Zhang¹, G. Wang¹, J. Worhach¹, K. Maski¹

¹Boston Children's Hospital, Dept of Neurology, Boston, United States

Introduction: Cognitive symptoms, such as decreased attention, are common in pediatric Narcolepsy Type 1 (NT1). However, objective data assessing attention dysfunction in this population are limited, particularly regarding its relationship with sleepiness or disrupted nighttime sleep. The psychomotor vigilance task (PVT) has been used to measure attention dysfunction in adults with central disorders of hypersomnolence but is not widely used in pediatric NT1. This study compared PVT metrics between pediatric NT1 patients and healthy controls. We hypothesized that attention dysfunction would be

worse in NT1 and associated with increased self-reported momentary sleepiness and disrupted nighttime sleep.

Materials and methods: 26 pediatric NT1 participants (mean age 15.9) and 16 healthy controls (mean age 16.3) completed 3-minute PVT testing in the evening before polysomnography (PSG) and again the following morning. Before each PVT, participants rated their sleepiness. Wake/N1 indices were extracted from PSG data as a measure of disrupted nighttime sleep. PVT metrics were compared between NT1 patients and controls using linear mixed models to evaluate the effects of age, gender, time of PVT, and group-time interactions. Outcomes included lapses (RT 355 ms), mean reaction time (RT), mean 1/RT, and slowest 10% 1/RT.

Results: NT1 participants showed reduced vigilant attention across PVT metrics compared to controls as measured by lapses ($p < .001$), mean RT ($p = .016$), mean 1/RT ($p = .003$), and slowest 10% 1/RT ($p = .021$). Contrary to our hypothesis, PVT performance was unrelated to momentary self-reported sleepiness. PVT performance was significantly correlated with more parent-reported concerns about attention, suggesting inattentiveness as measured by PVT may correspond with clinically significant attention dysfunction. Finally, poor PVT performance was correlated with disrupted nighttime sleep and percentage of time in stage NREM1 sleep, indicating that sleep quality may play a role in vigilant attention dysfunction in the pediatric NT1 population.

Conclusions: This study demonstrates that pediatric NT1 patients exhibit significant attention dysfunction as measured by PVT. Notably, momentary self-reported sleepiness did not predict PVT outcomes, suggesting that objective attention impairment in NT1 may not directly correspond to subjective sleepiness. PVT performance did correlate with measures of nocturnal sleep, which warrants further exploration. The 3-minute PVT is useful and feasible for assessing attention in pediatric NT1.

Improvement in Patient-reported Cognitive Functioning in Patients with Narcolepsy Type 1 Treated with the Orexin 2 Receptor Agonist Alixorexton (ALKS 2680)

G. Plazzi¹, Y. Dauvilliers², R.R. Grunstein³, E. Mignot⁴, G.J. Lammers⁵, D.T. Plante⁶, E. Buntinx⁷, R. del Río Villegas⁸, H. Chen⁹, C. Hopkinson⁹, B. Rege⁹, M. Yountz⁹, M. Doane⁹

¹IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy, ²University of Montpellier, INSERM Institute for Neurosciences of Montpellier, Montpellier, France, ³Woolcock Institute of Medical Research, Macquarie University, Sydney, Australia, ⁴Stanford University School of Medicine, Stanford Center for Narcolepsy and Hypersomnia, Stanford, United States, ⁵Leiden University Medical Center and Stichting Epilepsie Instellingen Nederland Sleep-Wake Centre, Leiden, Netherlands, ⁶University of Wisconsin-Madison, School of Medicine and Public Health, Madison, United States, ⁷ANIMA Research, Alken, Belgium, ⁸Universidad CEU San Pablo, CEU Universities, Vithas Madrid Hospitals, Madrid, Spain, ⁹Alkermes, Inc, Waltham, United States

Introduction: Narcolepsy type 1 (NT1) is typically characterized by excessive daytime sleepiness (EDS) and cataplexy. Patients also often complain of “brain fog,” impaired attention, and persistent fatigue—symptoms that are often not adequately addressed by available therapies or reflected in outcome measures. Cognitive complaints in narcolepsy only partly correlates with EDS severity and may persist even when EDS is pharmacologically controlled. Further, cognitive difficulties may be driven by underlying orexin pathway dysfunction. Alixorexton (ALKS 2680), a highly potent, oral, selective orexin 2 receptor agonist, may enhance cognition distinctly from sleepiness by activating receptors expressed throughout cognitive circuitry. In the Vibrance-1 study, once-daily alixorexton demonstrated clinically meaningful and statistically significant improvements from baseline in wakefulness compared to placebo in patients with NT1. The study also included patient-reported outcomes instruments to assess perceived problems with concentration, memory, expressing thoughts, word finding, thinking, and problem solving.

Materials and methods: Vibrance-1 was a global, placebo-controlled, dose-ranging phase 2 study with a 6-week randomized, double-blind, parallel group treatment period followed by an open-label extension. After 2 weeks of washout from narcolepsy medications, adult patients with NT1 were randomized to receive placebo or alixorexton once daily at doses of 4, 6, or 8 mg. The study included the British Columbia Cognitive Complaints Inventory (BC-CCI) as an exploratory endpoint. The BC-CCI is a 6-item instrument to capture patients' perception of cognitive difficulties within the past week. Total scores range from 0 to 18, with higher scores reflecting a greater degree of cognitive impairment.

Categories of cognitive complaints are: 0 to 4 (none or minimal), 5 to 8 (mild), 9 to 14 (moderate), and 15 to 18 (severe). The study also included the Patient Global Impression of Severity (PGI-S) for Cognition to measure patient's perception of the severity of their cognitive dysfunction.

Results: Ninety-two patients were randomized. At baseline, most patients reported mild or moderate cognitive symptoms, with mean (SD) total scores on the BC-CCI of 10.5 (4.83) in the placebo group and 8.3 (4.32), 7.8 (4.63), and 8.4 (3.01) in the alixorexton 4, 6, and 8 mg groups, respectively. Mean BC-CCI scores improved from baseline in all alixorexton dose groups at the first post-dose timepoint (Week 2) and were sustained through Week 6 (nominal p values at Week 6 all <0.0001 versus placebo). At Week 6, patients who received alixorexton were more likely to report less severe cognitive difficulties, as measured by PGI-S Cognition, than those who received placebo (nominal p<0.01 for all groups). Improvements on these cognitive scales mirrored improvements observed on study endpoints evaluating core symptoms of narcolepsy, as reflected by sleep latency on the Maintenance of Wakefulness Test, daytime sleepiness on the Epworth Sleepiness Scale, and the Narcolepsy Severity Scale.

Conclusions: In this phase 2 study, 6 weeks of treatment with once-daily alixorexton improved patient-reported cognitive functioning compared to placebo across all doses in patients with NT1.

Improvement in the Severity of Narcolepsy Symptoms and Fatigue in Patients with Narcolepsy Type 1 Treated with the Orexin 2 Receptor Agonist Alixorexton (ALKS 2680)

Y. Dauvilliers¹, R.R. Grunstein², E. Mignot³, G.J. Lammers⁴, D.T. Plante⁵, E. Buntinx⁶, R. del Rio Villegas⁷, H. Chen⁸, C. Hopkinson⁸, B. Rege⁸, M. Yountz⁸, M. Doane⁸, G. Plazzi⁹

²Woolcock Institute of Medical Research, Macquarie University, Sydney, Australia, ³Stanford University School of Medicine, Stanford Center for Narcolepsy and Hypersomnia, Stanford, United States, ⁴Leiden University Medical Center and Stichting Epilepsie Instellingen Nederland Sleep-Wake Centre, Leiden, Netherlands, ⁵University of Wisconsin-Madison, School of Medicine and Public Health, Madison, United States, ⁶ANIMA Research, Alken, Belgium, ⁷Universidad CEU San Pablo, CEU Universities, Vithas Madrid Hospitals, Madrid, Spain, ⁸Alkermes, Inc, Waltham, United States, ⁹IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy

Introduction: Excessive daytime sleepiness (EDS) and cataplexy are hallmarks of Narcolepsy type 1 (NT1); however, many patients also experience sleep paralysis, hypnagogic/hypnopompic hallucinations, and disrupted nighttime sleep. These symptoms, together with others such as fatigue and cognitive complaints, result in significant morbidity and impaired quality of life, and may be insufficiently addressed by current therapies. Orexin engages multiple neurologic pathways distributed throughout the brain, including those associated with wakefulness, fatigue, mood, and cognition. In Vibrance-1, once-daily alixorexton (ALKS 2680), a highly potent, oral, selective orexin 2 receptor agonist, produced clinically meaningful and statistically significant improvements in mean sleep latency and EDS compared to placebo in patients with NT1. Vibrance-1 also included, as exploratory endpoints, instruments to assess the severity of narcolepsy symptoms and fatigue.

Materials and methods: Vibrance-1 was a global, placebo-controlled, dose-ranging phase 2 study with a 6-week randomized, double-blind, parallel group treatment period followed by an open-label extension. After 2 weeks of washout from narcolepsy medications, adult patients with NT1 were randomized to placebo or alixorexton once daily at doses of 4, 6, or 8 mg. The Narcolepsy Severity Scale (NSS) assessed perceived severity, frequency, and consequences of the key symptoms of narcolepsy. The Clinical Global Impression of Severity (CGI-S) measured the severity of the disease from the clinician's perspective. The PROMIS-Fatigue Short-form 6a assessed patients' perceived fatigue within the past week calculated as a standardized T-score, with lower values representing less fatigue. The Patient Global Impression of Severity (PGI-S) for Fatigue measured patient-perceived severity of fatigue.

Results: Ninety-two patients were randomized. Baseline NSS scores reflected severe symptoms with mean (SD) values of 32.7 (7.36) in the placebo group and 32.5 (9.10), 29.0 (8.37), and 30.9 (9.46) in the alixorexton 4, 6, and 8 mg groups, respectively. At Week 6, mean NSS scores improved from baseline in all alixorexton dose groups (nominal p values all <0.001 versus placebo). Clinicians rated patients who received alixorexton as more likely to have less severe symptoms, as measured by CGI-S, compared to

placebo (nominal $p < 0.05$ for all groups). On PROMIS-Fatigue, most patients reported above-average fatigue at baseline, with mean (SD) T-scores of 66.17 (8.82) in the placebo group and 64.53 (7.64), 61.40 (7.97), and 63.60 (10.62) in the alixorexton 4, 6, and 8 mg groups, respectively. Mean PROMIS-Fatigue scores improved from baseline in all alixorexton dose groups at Week 6 (nominal p values all < 0.01 versus placebo). At Week 6, patients who received alixorexton were more likely to report less severe fatigue, as measured by PGI-S Fatigue, than those who received placebo (nominal $p < 0.01$ for all groups).

Conclusions: In all dose groups, 6 weeks of once-daily alixorexton led to improvement from baseline in the severity of disease symptoms and in patient-reported fatigue compared to placebo in this phase 2 study of patients with NT1.

Improvement of Individual Excessive Daytime Sleepiness Symptoms With Once-Nightly Sodium Oxybate for Narcolepsy

H. Merius¹, M.J. Thorpy², E. Wermter³, C.A. Kushida⁴, B. Abaluck⁷, J. Gudeman⁷

¹Stony Brook Medicine, Smithtown, United States, ²Albert Einstein College of Medicine, New York, United States, ³Restorative Sleep Medicine, Charlottesville, United States, ⁴Stanford University School of Medicine, Stanford, United States, ⁵Avadel Pharmaceuticals, Chesterfield, United States

Introduction: The Epworth Sleepiness Scale (ESS) is a commonly used 8-item patient-reported outcome measure for excessive daytime sleepiness. While aggregate data are typically presented, individual domains vary in clinical significance. This post hoc analysis from the phase 3 REST-ON trial (NCT02720744) evaluated the efficacy of once-nightly sodium oxybate (ON-SXB; LUMRYZ™) on individual ESS domains.

Materials and methods: Participants aged ≥ 16 years with narcolepsy were randomized 1:1 to ON-SXB (week 1, 4.5 g; weeks 2–3, 6 g; weeks 4–8, 7.5 g; weeks 9–13, 9 g) or placebo. ESS data from the modified intent-to-treat population (mITT; ≥ 1 efficacy measurement after receiving the 6-g dose) at weeks 3, 8, and 13 were analyzed.

Results: In the mITT population (ON-SXB, $n=97$; placebo, $n=93$), ON-SXB was associated with significant sleepiness improvements vs placebo for sitting and reading, watching TV, lying down to rest in the afternoon, and sitting quietly after lunch; all doses $P < 0.01$. ON-SXB was associated with significant sleepiness improvement vs placebo as a passenger in a car for an hour without a break (least squares mean difference [LSMD; 95% CI] in change from baseline: 6 g, -0.39 [-0.61 to -0.17]; 7.5 g, -0.59 [-0.85 to -0.32]; 9 g, -0.67 [-0.95 to -0.38]; all doses $P < 0.001$). Significant sleepiness improvements were observed with 7.5-g and 9-g ON-SXB when sitting inactive in public (LSMD vs placebo [95% CI]: 7.5 g, -0.34 [-0.61 to -0.07], $P=0.014$; 9 g, -0.44 [-0.71 to -0.18], $P=0.001$) and sitting and talking to someone (7.5 g, -0.29 [-0.47 to -0.11], $P=0.002$; 9 g, -0.24 [-0.44 to -0.04], $P=0.018$). Significant sleepiness improvement as a driver stopped in traffic was observed with 9-g ON-SXB (LSMD vs placebo [95% CI], -0.35 [-0.63 to -0.07]; $P=0.015$).

Conclusions: At all ON-SXB doses, participants had significant improvements vs placebo in sleepiness while completing routine activities. The greatest improvements in these activities were observed with the 9-g ON-SXB dose, including the domain for sleepiness as a driver stopped in traffic, a key safety concern. ON-SXB may be helpful in addressing safety challenges for people with narcolepsy.

Increased FoxA1⁺ Treg Cells Proportion of Peripheral Blood in Patients with Narcolepsy Type 1

Q. Sun¹, Q. Tang¹, Z. Wang¹

¹the First Hospital of Jilin University, Department of Neurology, Chang Chun, China

Introduction:

Narcolepsy type 1 (NT1) is a rare sleep disorder characterized by excessive daytime sleepiness (EDS), cataplexy, hypnagogic hallucinations, and sleep paralysis. The pathological hallmark of NT1 is the selective loss of hypocretin (Hcrt) neurons in the lateral hypothalamus, leading to decreased cerebrospinal fluid (CSF) hypocretin-1 (Hcrt-1) concentrations. The global prevalence of NT1 ranges from approximately 0.02% to 0.18%. Patients often experience disrupted nocturnal sleep, comorbid obstructive sleep apnea hypopnea syndrome, and REM sleep behavior disorder, which significantly impair daily functioning and increase the risk of injury due to cataplexy. The etiology of NT1 is multifactorial, involving genetic susceptibility, immune dysregulation, and environmental triggers. Notably, the incidence of NT1 rose following the 2009 H1N1 influenza pandemic and vaccination campaigns, highlighting the role of immune mechanisms. Regulatory T (Treg) cell dysfunction has been implicated in autoimmune diseases, contributing to chronic inflammation and tissue damage. FoxA1, a transcriptional activator, regulates Treg cell differentiation and function and has been linked to central nervous system autoimmune diseases. Given these findings, this study aimed to investigate the proportion of FoxA1⁺ Treg cells in peripheral blood mononuclear cells (PBMCs) of NT1 patients and explore associations with clinical features, providing insight into potential immunopathogenic mechanisms and therapeutic targets.

Materials and methods: Twenty-one patients with NT1 and 21 healthy controls were recruited to this study. All subjects were monitored via polysomnography and multiple sleep latency test (MSLT). The Epworth sleepiness scale (ESS) was used to assess the severity of excessive daytime sleepiness. Patients with NT1 were examined human leukocyte antigen (HLA) gene and cerebrospinal fluid hypocretin-1 (Hcrt-1) concentration. Peripheral blood samples of all subjects were collected, and Ficoll method was used to separate PBMC. Flow cytometry was used to analyze the percentage of FoxA1⁺ Treg cells.

Results: The CD4⁺ T cells proportion in peripheral blood of patients with NT1 group was higher than that in control group ($52.32\% \pm 6.79\%$ vs $45.07\% \pm 7.06\%$, $P < 0.05$). The CD25⁺ FoxA1⁺ Treg cells proportion in the CD4⁺ T cell population of patients with NT1 was higher than that in the control group ($5.20\% \pm 2.23\%$ vs $2.07\% \pm 0.88\%$, $P < 0.001$). There was no significant correlation between the percentage of CD25⁺ FoxA1⁺ Treg cells and the cerebrospinal fluid Hcrt-1 concentration, age, MSLT sleep latency or disease duration ($P > 0.05$).

Conclusions: The CD4⁺ T cells proportion in peripheral blood of patients with NT1 increased. In the CD4⁺ T cell population, the CD25⁺ FoxA1⁺ Treg cells proportion increased in patients with NT1.

Introduction: Dual orexin receptor agonists with effectiveness after systemic administration may be of interest for the treatment of narcolepsy and other pathological conditions.

Materials and methods: We designed a novel dual orexin receptor agonist (OX-D, international patent application WO 2024/003128 A1) and performed its initial pre-clinical evaluation in vitro on murine neuroblastoma Neuro-2a cells and human HEK-293T cells and in vivo on orexin knock-out mice, a model of narcolepsy type 1.

Results: In vitro, OX-D was able to cross the plasma membrane of Neuro-2a murine neuroblastoma cells, suggesting its ability to cross the blood-brain barrier. OX-D was effective in eliciting intracellular calcium responses in murine neuroblastoma cells transfected with either human orexin receptor 1 or 2, but not in non-transfected cells, and its estimated EC₅₀ in HEK-293T cells transfected with orexin receptors was 68 nM and 11 nM on orexin receptor 1 and 2, respectively. Intracerebroventricular infusion of OX-D (160 µM, 5 µL/h, for 6 h from lights on) in freely-behaving orexin knock-out mice (N = 8 females, C57Bl6/J background, 12:12 h light-dark cycle, 24-h EEG and EMG recordings) elicited a dramatic increase in wakefulness and a corresponding decrease in non-REM sleep throughout the light period and a dramatic decrease in REM sleep persisting also in the dark period compared with vehicle

infusion. Subcutaneous bolus injection of OX-D (160 nmol in 1 mL at lights on) in freely-behaving orexin knock-out mice (N = 12 females, C57Bl6/J background, 12:12 h light-dark cycle, 24-h EEG and EMG recordings) mildly but significantly decreased REM sleep during the light and dark periods and significantly decreased cataplexy-like state during the dark period compared with vehicle injection. This decrease in cataplexy like state occurred in 10 out of 12 mice and was confirmed to implicate a decrease in bona-fide cataplexy in a subset of 4 mice with simultaneous video recordings.

Conclusions: These results suggest that OX-D is a dual orexin receptor agonist with anti-cataplectic activity after subcutaneous administration in orexin knock-out mice.

iSPHYNCS: An Update on the Internationalization and New Approaches of the Swiss Primary Hypersomnolence and Narcolepsy Cohort Study

Introduction: The international Swiss Primary Hypersomnolence and Narcolepsy Cohort Study (iSPHYNCS) aims to provide new data to improve diagnostics and the management of primary central disorders of hypersomnolence (CDH). The three main specific aims of iSPHYNCS are 1) discovery of new biomarkers, 2) assessment of treatment adherence, and 3) patient-related outcomes, to set the ground for personalized patient treatment.

Materials and methods: The study plans to prospectively include 500 CDH patients and 60 healthy controls (HC) by the end of 2026. Recruitment is ongoing at 10 tertiary sleep centers in Switzerland, Germany, and the Netherlands. Italy and Norway plan to start recruitment shortly. The multi-modal study approach includes questionnaires, clinical assessments, video-polysomnography, the Multiple Sleep Latency Test (MSLT), vigilance tests, actigraphy, long-term activity monitoring with Fitbit, immunological studies, quantitative hypocretin measurements, proteomics, gut microbiomics, and genetics/epigenetics. AI-powered analyses, including unsupervised clustering, are used for data-driven patient phenotyping.

Results: 303 participants, including 13 children, have been recruited. The study population comprises 75 individuals with narcolepsy type I (NT1), 185 individuals of the "narcoleptic borderland" (NBL), such as narcolepsy type 2, idiopathic hypersomnia and insufficient sleep syndrome, as well as 43 HC. Initial analyses reveal notable differences among NT1, NBL, and HC groups across various domains, including questionnaire responses, neuropsychiatric profiles, gut microbiome, polysomnographic, Fitbit and vigilance data. We demonstrate that novel approaches like long-term activity monitoring with wearable devices has the potential to give new insights into sleep-wake behavior, disease progression and therapy success. First results on unsupervised patient clustering based on questionnaires, objective sleepiness measures and vigilance data indicate that symptom severity may be more affected by psychiatric co-morbidities than by the primary sleep disorders.

Conclusions: Following an initial three-year phase in Switzerland, the internationalization of iSPHYNCS was successfully launched in 2023. Preliminary results suggest novel and promising clinical, biological, and digital markers of CDH. Proteomics and genetics/epigenetics analyses are currently being explored.

Acknowledgments: The authors declare no conflict of interest. The study is supported by the Swiss National Science Foundation (SNF 320030_185362; SNF 32003B_215721).

Long-term assessment of social jetlag by Fitbit smartwatch in patients with central disorder of hypersomnolence

¹Clinic Barmelweid, Center for Sleep Medicine, Sleep Research and Epileptology, Barmelweid, Switzerland, ²University of Bern, Bern, Switzerland, ³Kantonsspital St. Gallen, St. Gallen, Switzerland, ⁴Neurocenter of Southern Switzerland, Lugano, Switzerland, ⁵Clinic for Sleep Medicine, Bad Zurzach, Bad Zurzach, Switzerland, ⁶Centre for Sleep Medicine Basel, Basel, Switzerland, ⁷University Witten/Herdecke, Witten, Germany, ⁸University of Oslo, Oslo, Norway, ⁹Leiden University Medical Centre, Leiden, Netherlands

Introduction: Patients with central disorders of hypersomnolence (CDH) suffer from excessive daytime sleepiness (EDS) and often have irregular or abnormal sleep-wake patterns. Social jetlag (SJL) reflects the mismatch between an individual's circadian rhythm and social schedule. SJL in CDH has rarely been studied, partly because standard questionnaires are not validated for this population. We aimed to characterize SJL in CDH using objective sleep-wake data from Fitbit smartwatch. We hypothesized that patients with CDH would show larger SJL compared to healthy controls (HC).

Materials and methods: We analyzed daily sleep-wake data measured by Fitbit smartwatches from 37 HC, 50 patients with narcolepsy type 1 (NT1), and 116 narcolepsy borderland (NBL) patients enrolled in the International Swiss Primary Hypersomnolence and Narcolepsy Cohort Study (iSPHYNCS) between September 2020 and April 2025. Weekly SJL was calculated as the difference between average mid-sleep points on weekends and weekdays. Monthly SJL was the mean of weekly SJL per month. A linear mixed model (LMM) predicted monthly SJL by diagnosis (HC as reference), adjusting for age, BMI, gender, season, daylight saving time (DST: summer vs. winter), and monthly mean nocturnal sleep duration.

Results: NBL patients (estimated difference: 19.0 min, $p = 0.0015$) and NT1 (estimated difference: 12.3 min, $p = 0.074$) had significantly larger or a trend towards larger SJL compared to HC in the LMM, controlling for confounders. No difference was found between NT1 and NBL ($p = 0.23$). These findings were replicated under DST summer-time conditions (NBL-HC: 21.4 min, $p = 0.0039$; NT1-HC: 14.2 min, $p = 0.097$; NBL-NT1: 7.18 min, $p = 0.25$); however, in winter-time only NBL had larger SJL than HC (NBL-HC: 16.0 min, $p = 0.047$), not NT1 ($p = 0.27$). HC showed significantly larger SJL in winter-time vs. summer-time (9.67 min, $p = 0.045$), whereas no such seasonal difference was found in patients (NT1: $p = 0.22$; NBL: $p = 0.15$). SJL was unrelated to BMI or gender, but was negatively associated with nocturnal sleep duration ($p = 0.021$). Post hoc pairwise Wilcoxon tests indicated that NT1 and NBL patients had greater variance in nocturnal sleep duration during weekends (NT1: $p = 0.041$; NBL: $p = 0.038$) but not during weekdays, compared to HC.

Conclusions: Wearable technologies enable the longitudinal assessment of SJL in patients with CDH during daily life. Patients with CDH exhibit larger SJL than healthy controls, particularly during summer-time. DST may influence SJL differently in CDH and healthy individuals. The persistent SJL difference between NBL and HC across DST conditions may be a potential marker of NBL. In contrast, increased SJL in HC but not in CDH during winter-time suggests a failure of compensatory mechanisms in CDH in response to circadian disruption or greater sleep need in winter. This limited ability to compensate for sleep debt may lead to varied coping strategies on days off, explaining the greater variability in nocturnal sleep duration on weekends among CDH patients.

Long-Term Safety and Tolerability of Once-Nightly Sodium Oxybate: A Post Hoc Analysis From RESTORE

S. Ibrahim¹, J. Harsh², B.C. Corser³, J.D. Hudson⁴, A. Santamaria⁵, P.K. Schweitzer⁶, B. Abaluck⁷, J. Gudeman⁷

¹University Hospitals Cleveland Medical Center, Cleveland, United States, ²Colorado Sleep Institute, Boulder, United States, ³Sleep Management Institute, Cincinnati, United States, ⁴FutureSearch Trials of Neurology, Austin, United States, ⁵Northwest Houston Neurology & Comprehensive Sleep Medicine Center, Houston, United States, ⁶Sleep Medicine & Research Center, St. Luke's Hospital, Chesterfield, United States, ⁷Avadel Pharmaceuticals, Chesterfield, United States

Introduction: Once-nightly sodium oxybate (ON-SXB; LUMRYZ™) is an extended-release formulation of sodium oxybate that eliminates the second, middle-of-the-night dose required by immediate-release twice-nightly oxybate (TN-OXB) formulations. RESTORE (NCT04451668) was an open-label/switch study evaluating the long-term safety/tolerability of ON-SXB in people with narcolepsy.

Materials and methods: Participants ≥16 years of age with narcolepsy who had completed the phase 3 REST-ON trial, were on stable-dose TN-OXB (switch participants), or were oxybate-naïve were eligible for RESTORE. Switch participants' initial ON-SXB doses were equivalent/closest to their prior total nightly TN-OXB dose. After participants titrated their ON-SXB dose (±1.5 g/week; maximum, 9 g/night) with no tolerability issues for ≥3 months, participants entered the stable dosing period. Treatment-emergent adverse events (TEAEs) were recorded quarterly for switch participants in the safety population (all participants who received ≥1 dose of ON-SXB).

Results: A total of 130 switch participants were included in the safety population and received ON-SXB for a median (range) duration of 502.5 (8-1169) days during the >3-year study. Of these participants, 115 continued into the stable dosing period and were included in this analysis. Of the 115 who entered the stable dosing period, 73.9% (85/115) reported ≥1 TEAE. TEAEs reported by ≥3% of participants included COVID-19 (18.3%), nasopharyngitis (11.3%), nausea (10.4%), sinusitis (8.7%), fall (8.7%), headache (7.0%), enuresis (7.0%), cough (6.1%), upper respiratory tract infection (5.2%), urinary tract infection (5.2%), somnolence (4.3%), tremor (4.3%), vomiting (3.5%), dyspnea (3.5%), rash (3.5%), decreased appetite (3.5%), hypertension (3.5%), concussion (3.5%), and contusion (3.5%). Eight (7%) participants reported ≥1 serious TEAE (events, n=10); of these, 2 serious TEAEs were deemed related to ON-SXB (gastroesophageal reflux disease and cataplexy). Five participants (4.3%) experienced ≥1 TEAE that led to ON-SXB discontinuation (upper abdominal pain, fatigue, fall, dizziness, paresthesia, irritability, nightmare, and hypertension; n=1 [0.9%] each).

Conclusions: Reported AEs were consistent with the known AEs of oxybates. Only 4% of participants discontinued owing to a TEAE during the stable dosing period, underscoring the largely transient nature of AEs and the long-term tolerability of ON-SXB.

Medical Education Significantly Improves Knowledge of the Role of Orexin in Narcolepsy Type 1 and the Neurocognitive Impact

SC. Rohani-Montez¹, K. Carpenter¹, F. David¹, M. Zenti², P.J. Jennum³, D. Plante⁴, G. Plazzi⁵, L. Barateau⁶, E. Mignot⁷

¹Medscape Education Global, London, United Kingdom, ²Italian Association of Narcolepsy (AIN [Associazione Italiana Narcolettici]), Verona, Italy, ³Rigshospitalet, University of Copenhagen, Copenhagen, Denmark, ⁴University of Wisconsin School of Medicine and Public Health, Madison, WI, United States, ⁵IRCCS Istituto delle Scienze Neurologiche di Bologna, University of Modena and Reggio Emilia, Modena, Italy, ⁶Gui-de-Chauliac Hospital, CHU Montpellier, National Reference Centre for Orphan Diseases, University of Montpellier, INSERM, Montpellier, France, ⁷Stanford University, Palo Alto, California, United States

Introduction: Understanding the role of orexin in patients with and without sleep disorders provides the basis for confidence in future decision-making regarding therapies that target the orexin system. However, most clinicians are unfamiliar with the role of orexin in sleep disorders. In addition, patients with narcolepsy commonly experience impairments in cognition that are underrecognized in practice.

We sought to improve physician knowledge of the role of orexin in narcolepsy type 1 (NT1) and the impact on neurocognitive symptoms in a series of two CME activities published in June and October 2024 (available at <https://www.medscape.org/viewarticle/1001223> and <https://www.medscape.org/viewarticle/1001723>).

Materials and methods: Physicians participated in one or both video-based, online, segmented CME activities with synchronized slides. The effects of the education were assessed using a repeated pairs, pre-assessment/post-assessment study design. Differences from pre- to post-assessment were evaluated using the McNemar's test. $P \leq .05$ is the significance level.

Results: 2,368 physicians completed both pre- and post-assessment questions for one or both activities, including 546 neurologists, 1,685 psychiatrists, and 137 pulmonologists. Significant improvements were seen across pre/post assessment questions in

1. Identifying the role of orexin in maintaining wakefulness, controlling muscle tone during REM sleep and motivation/reward (Correct response at pre-assessment vs post-assessment for neurologists 58% vs 71%, $P < .001$; for psychiatrists 54% vs 68%, $P < .001$; for pulmonologists 43% vs 54%, $P < .05$)
2. Recognizing that a CSF orexin-1 level below 110 pg/mL is the most specific way to differentiate NT1 from NT2 (Correct response at pre-assessment vs post-assessment for neurologists 18% vs 34%, $P < .001$; for psychiatrists 11% vs 25%, $P < .001$; for pulmonologists 11% vs 40%, $P < .001$)
3. Identifying memory and executive function as the cognitive domains most affected in NT1 apart from attention (Correct response at pre-assessment vs post-assessment for neurologists 75% vs 84%, $P < .001$; for psychiatrists 69% vs 81%, $P < .001$; for pulmonologists 77% vs 84%, $P = \text{NS}$)
4. Recognizing the inclusion of cognitive symptoms and mood as newer endpoints in narcolepsy clinical trials (Correct response at pre-assessment vs post-assessment for neurologists 56% vs 64%, $P < .01$; for psychiatrists 52% vs 61%, $P < .001$; for pulmonologists 57% vs 61%, $P = \text{NS}$)

Conclusions: This study demonstrates the success of online, accredited, multi-faculty, video-based education in improving knowledge amongst physicians in recognizing the role of orexin and the cognitive disturbances in NT1.

This knowledge is important for understanding the rationale behind the emerging orexin receptor agonists in development for NT1 and will prepare physicians to contemplate and eventually take action in implementing these therapies once available, to enable a better quality of life for patients with NT1.

Metabolic comorbidities in narcolepsy: a systematic review and meta-analysis

X. Zhang¹, J. Ren¹, Q. Zong¹, M. Zha¹, X. Zhou¹, J. Zhou^{1,2}

¹Sichuan University, Department of Neurology, West China Hospital, Chengdu, China, ²Sichuan University, Sleep Medicine Center, West China Hospital, Chengdu, China

Introduction: Narcolepsy is a chronic sleep-wake disorder, but patients also suffer from an increased risk of developing endocrine or metabolic dysfunctions. However, current evidence remains less consistent regarding the prevalence of specific metabolic disorders, especially across the narcolepsy subtypes. To address the disparities and clarify the morbidity risk of metabolic comorbidities in narcolepsy, we performed a systematic review and meta-analysis to delineate the prevalence rates and risk of metabolic disorders in this population and stratified subgroups.

Materials and methods: This meta-analysis assessed the prevalence of metabolic comorbidities in narcolepsy, categorized as Metabolic syndrome (MetS) and associated disorders (i.e., obesity, diabetes, hypertension, and dyslipidemia) and other metabolic disorders (i.e., overweight, prediabetes, pubertal praecox, non-dipping blood pressure, thyroid disease, and cardiovascular disorder). We searched PubMed, Web of Science, EBSCO, and Cochrane Library up to April 8, 2025. Pooled prevalence rates and odds ratios (ORs) between strata and the control group were calculated using the random-effects model. Sensitive analyses examined narcolepsy subtype (i.e., narcolepsy subtype 1, NT1 and narcolepsy subtype 2, NT2), age (i.e., children and adults), sex, stimulants and utilization of anticataleptic agents,

and the presence of orexin deficiency or human leukocyte antigen (HLA)-DQB1*06:02 genotype. For conditions with insufficient data, we performed the systematic review.

Results: A total of 54 studies with 9,827 males and 18,298 females were included. **For the MetS and associated disorders**, obesity emerged as the predominant disorder (29%), while the prevalence of diabetes, hypertension, and dyslipidemia was below 20%. MetS was present in 30%, affecting more than half of the adult patients with NT1. ORs indicated NT1 patients using the stimulants and antiepileptic agents suffered more from hypertension than the drug-naïve ones. Sensitivity analyses showed relatively higher prevalence of obesity (28% vs. 18%) and dyslipidemia (24% vs. 14%) in NT1, and of obesity in children (37% vs. 22%). Males exhibited a predominance in diabetes, hypertension, and dyslipidemia. In patients with confirmed orexin deficiency or the HLA-DQB1*06:02 genotype, the results were similar to NT1, except for a notably high prevalence of dyslipidemia (48%) in the orexin deficiency cluster. **For the other metabolic disorders**, in NT1 patients, Prediabetes and non-dipping blood pressure affected 33% and 53%, respectively. Pubertal praecox involved 18%. Moreover, the pooled prevalence of overweight increased with age. After all, data on cardiac diseases and NT2 patients were limited. The meta-results generated from studies designed with comparison groups showed an elevated risk of metabolic disorders in narcolepsy than the general population and patients with other hypersomnia or diseases, but the findings were less significant compared to the BMI-matched population.

Conclusions: Our study revealed a wide spectrum of prevalent metabolic disturbances in narcolepsy, especially MetS and related disorders. Notably, non-dipping blood pressure and prediabetes are common in NT1, warranting extra attention to their long-term cerebrovascular and cardiovascular risks. Additionally, the trend of increasing overweight but decreasing obesity with age suggests the early disease phase is critical for metabolic deterioration. Given the inconclusive literature and insufficient research on this topic, future studies need to better characterize these disturbances, particularly risk factors and mechanisms underlying orexin dysfunction.

Multimodal Detection of Narcolepsy Type 1 Using Genetic and Nocturnal Polysomnography Data

M. Olsen¹, A.N. Zahid^{2,3}, K. Galinsky¹, R. Retnam¹, L. Lin⁴, H. Yan⁴, B. Tracey¹, D.L. Buhl¹, D. Volfson¹, E. Mignot⁴

¹Takeda Development Center Americas, Inc., Cambridge, United States, ²Stanford-Takeda Post-doctoral program, Stanford University, Palo Alto, United States, ³Department of Applied Mathematics and Computer Science, Technical University of Denmark, Kongens Lyngby, Denmark, ⁴Stanford Center for Sleep Sciences and Medicine, Stanford University, Palo Alto, United States

Introduction: Efficient screening methods with high specificity which can be applied to large sample sizes are needed to improve significantly underdiagnosed people with narcolepsy type 1 (NT1). To address this unmet need, we combined polygenic risk scores (PRS), HLA typing, and nocturnal polysomnography (PSG) data. These methods are developed and validated using a dataset significantly larger than those used in previous studies, ensuring their reliability and generalizability.

Materials and methods: People with diagnosed narcolepsy were studied across 7 different global locations, involving multiple collaborators. We developed a custom U-Sleep model for variable-resolution sleep staging using electroencephalography, electrooculography, and electromyography data from 19,381 PSG recordings from the National Sleep Research Resource and the Stanford Sleep Clinic. Sleep staging was performed across epochs from 0.25 to 3600 seconds, leveraging novel multiscale transition matrix (MTM) features to capture NT1-specific transitions and overlapping sleep stages. Next, a Gaussian processes classifier was trained on features from 21,846 PSGs across 14 cohorts (NT1: n=327; controls: n=21,519) and tested on 634 separate PSGs (NT1: n=317; controls: n=317). An ensemble model combined multiple time resolutions, weighted by prediction accuracy. Classifier performance was evaluated using 5-fold cross-validation. We developed a multi-information model integrating new PRS scores with HLA DQB1*06:02 typing, where HLA- and PRS+ conditions map to control and NT1 prediction, respectively, with PSG used when neither applies.

Results: Adding PRS to HLA increased the specificity from 81.9% to 100.0%, with a sensitivity of 42.6%, enabling potential screening of NT1 using genetics alone. PSG alone yielded 90.9% sensitivity at 99.5% specificity, surpassing State-of-the-Art (SOTA). When combining PSG with HLA, our approach increased to 91.2% sensitivity at the same high specificity. Adding PRS further rescued HLA+ cases missed based off PSG, and increased sensitivity to 95.0% while maintaining 99.5% specificity. MTM

features meaningfully boosted classification performance (approximately 1% gain) compared to SOTA features, which themselves significantly outperformed standard clinical PSG measures. Ensemble models showed that combining multiple resolutions improved performance, notably specificity. Additionally, post-hoc analyses showed that genetic information noticeably improved model robustness.

Conclusions: These findings suggest that the proposed multimodal model is a robust framework for NT1 classification, providing more specific and sensitive screening methods.

Narcolepsy as a potential risk factor for Schizophrenia

R. Eghtedarian¹, A.M. Tervi², S.E. Jones², M. Partinen³, E. Viippola², H.M. Ollila²

¹University of Helsinki/Institute for Molecular Medicine Finland (FIMM), HiLIFE, Helsinki, Finland,

²University of Helsinki, Institute for Molecular Medicine Finland (FIMM), HiLIFE, Helsinki, Finland,

³Helsinki Sleep Clinic, Terveystalo Healthcare, Helsinki, Finland

Introduction: Narcolepsy is a severe sleep disorder with characteristics of fatigue, fragmented sleep, cataplexy and hypnagogic hallucinations. Earlier clinical studies have reported the onset of schizophrenia after narcolepsy but the causality behind narcolepsy and schizophrenia is unknown. Our goal was to understand the causality between narcolepsy and schizophrenia.

Materials and methods: To estimate the comorbidity between narcolepsy and schizophrenia, we employed data from the FinRegistry that contains data for the total population of Finland in total 7.2 million individuals (N = 1664 individuals with narcolepsy and 55,372 with schizophrenia). We then used Mendelian randomization and previously published genome-wide association data to test the causality between narcolepsy and schizophrenia.

Results: We observed a robust causal association from narcolepsy to schizophrenia using the HLA-independent lead variants ($P\text{-value} = 6.0 \times 10^{-4}$), which was accentuated when including the HLA locus ($P\text{-value} = 4.48 \times 10^{-7}$). Furthermore, we observed a modest bidirectional causality from schizophrenia to narcolepsy ($P\text{-value} = 0.015$). There was no evidence of pleiotropy.

Conclusions: Our findings indicate a causal relationship where narcolepsy may increase the risk for schizophrenia, and a bidirectional causality from schizophrenia to narcolepsy. Additionally, our results clarify the psychiatric burden in narcolepsy.

Acknowledgments: This work was supported by The Alfred Kordelin foundation (RE), NIH R01HG012810, R01CA283469 and R01AI170850 (HMO). We want to acknowledge the participants and investigators of the FinnGen study.

Narcolepsy is associated with an increased risk of HLA-related autoimmune diseases: Evidence from a nationwide healthcare system data in South Korea

S.-C. Hong¹

¹Seung-Chul Hong, Suwon, Korea, Republic of

Introduction: To determine the incidence rate of narcolepsy in South Korea and closely examine the relationship between narcolepsy, which is believed to be an autoimmune response, and other systemic autoimmune diseases.

Materials and methods: We examined data from the South Korean nationwide health insurance claims database from 2010 to 2019. Our study included patients with narcolepsy as well as age- and sex-matched controls without narcolepsy. We estimated the incidence of narcolepsy and the odds ratio of narcolepsy and associated autoimmune comorbidities in South Korea.

Results: We identified 8710 patients with narcolepsy (59.8% men and 40.2% women). The incidence of narcolepsy was 0.05%. Patients with narcolepsy were at a significantly high risk of ankylosing spondylitis, rheumatoid arthritis, and Sjögren's syndrome, which diseases are known to be related to human leukocyte antigen (HLA) genes.

Conclusions: Narcolepsy is closely related to systemic autoimmune diseases, particularly those related to HLA genes.

Narcolepsy Revolution: Interpretable machine learning for automated sleep stage classification in narcolepsy and hypersomnia

A. Rajaram¹, H.O. Orkouby^{1,2}, G. Padmanabhan^{1,2}, E. Senior^{3,4}, A. Birdseye^{5,4}, L. Pérez-Carbonell^{5,4}, T. Rossor^{3,4}, [P. Gringras](#)^{3,4,6}, U. Bartsch^{1,2}

¹University of Surrey, Surrey Sleep Research Centre, Guildford, United Kingdom, ²University of Surrey, Surrey Institute for People-Centred Artificial Intelligence, Guildford, United Kingdom, ³Evelina London Children's Hospital, London, United Kingdom, ⁴Guys' and St Thomas' NHS Foundation Trust, London, United Kingdom, ⁵St Thomas' Hospital, Sleep Disorders Centre, London, United Kingdom, ⁶King's College London, Sleep Medicine, London, United Kingdom

Introduction: Narcolepsy is a rare neurological disorder with the occurrence of rapid eye movement sleep after sleep onset as a typical symptom. Current diagnostic protocols rely on manual assessments of sleep neurophysiology, including overnight polysomnography followed by the Multiple Sleep Latency Test (MSLT) by clinically trained personnel. These procedures are resource-intensive and operationally demanding, contributing to prolonged diagnostic delays in many healthcare systems due to limited clinical capacity. Machine learning offers significant promise for improving the diagnosis of narcolepsy and other sleep disorders by enabling automated, data-driven analysis of sleep neurophysiology.

Materials and methods: We used an open-source, annotated polysomnography dataset (MNC, [sleepdata.org](#)) and implemented a data analysis and sleep stage classification pipeline aimed at supporting diagnostic decision-making in clinical practice. We extracted features from a single frontal EEG trace, which included time-domain features, frequency-domain features, cross-frequency coupling metrics, and features derived from empirical mode decomposition. We then trained machine learning models including XGBoost and Random Forest (RF) to predict sleep stages in healthy control, narcolepsy, and hypersomnia datasets.

Results: The RF classifier demonstrated the best performance for sleep stage classification, achieving up to 82% accuracy, 82% specificity, and 92% sensitivity when trained on combined feature sets. Features with the highest importance for sleep stage classification included permutation entropy, the mean frequency of the EMD derived intrinsic-mode-function 1, and low frequency power of the autocorrelation. A subsequent Vision-informed Transformer (ViT base, patch 32) trained on the images of hypnograms achieved 100% accuracy on 6 test samples comparing narcolepsy to healthy controls.

Conclusions: By leveraging features extracted from a single lead sleep EEG, machine learning can identify diagnostically relevant features with high accuracy and consistency. This approach can be directly translated to the use of wearable devices that employ dry-electrode EEG recordings during sleep, and has the potential to streamline diagnostic workflows, reduce clinician workload, and shorten time to diagnosis, particularly in resource-constrained settings.

Narcolepsy's Sustained Attention Deficits: Unveiled by Dysfunctional Brain Dynamics

X. Han¹, J. Xu², L. Zhang², F. Chen¹

¹Bio-X Laboratory, School of Physics, Zhejiang University, Hangzhou, China, ²Department of Neurology, Sir Run Run Shaw Hospital, School of medicine, Zhejiang University, Hangzhou, China

Introduction: Narcolepsy Type 1 (NT1) has significant sustained attention deficits, which is a rare chronic neurological disorder caused by orexin neuron loss or dysfunction. sustained attention is a fundamental component of human cognition, these deficits directly impact NT1 patients' daily functioning and work capacity, leading to them as a potential diagnostic criterion. Yet the underlying neural mechanisms remain unclear. Here, we hypothesized that both **low arousal levels** and **attentional misallocation** contribute to these deficits.

Materials and methods: In total, 40 NT1 patients were recruited from the Department of Neurology of Sir Run Run Shaw Hospital, School of Medicine, Zhejiang University, China. Another 41 healthy controls matched for age, sex were recruited from the school or community by advertisement. We employed resting-state EEG microstate analysis combined with behavioral measures to investigate the neural correlates of attention impairments in NT1 (n = 40) and Controls (n = 41). Sustained attention

deficits were assessed using the Sustained Attention to Response Task (SART). Participants' resting-state EEG was recorded using a 64-electrode cap, followed by microstate analysis to investigate abnormal brain network dynamics in NT1. Source localization analysis was employed to identify the neural generators of the observed microstates. Correlation analyses were conducted to test our two potential hypotheses regarding low arousal and attentional misallocation.

Results: Behavioral results showed significantly sustained attention deficits in NT1 patients, with higher omission errors (33.33 ± 33.70 vs. 7.95 ± 12.27 , $P < 0.001$), slower reaction times (373.13 ± 71.88 vs. 321.36 ± 45.97 ms, $P < 0.001$), and larger response time variability (115.06 ± 60.86 vs. 66.89 ± 18.12 ms, $P < 0.001$). Distinct patterns of microstate were altered in NT1 patients, including reduced properties in microstate C and D and increased characteristics in microstate A and F. Crucially, we found that a lower occurrence of microstate C ($r = -0.47$, $P = 0.003$), microstate D ($r = -0.57$, $P < 0.001$), and a longer duration of microstate F ($r = 0.60$, $P < 0.001$) indicated lower attentional performance in NT1 patients. Source localization results supported our hypotheses: microstate D sources overlapped with the attention control network; microstate C showed major activity in the default mode and limbic networks; and microstate F sources corresponded to the anterior default mode network.

Conclusions: Our study provides evidence that sustained attention deficits in narcolepsy type 1 are linked to dysfunctional brain dynamics. The distinct patterns of microstate alterations, combined with specific brain-behavior correlations, support our dual-process hypothesis of attention impairments in NT1. Clinically, the identification of specific microstate patterns associated with sustained attention deficits could serve as potential biomarkers for diagnosis and treatment monitoring.

Nocturnal Fragmentation and Dream Enactment behaviors in Narcolepsy: Diagnostic Biomarkers Associated with Hypocretin-1 Deficiency

H. Zhang¹, Y. Zhang¹, Y. Yang¹, S. Zhan¹

¹Xuanwu Hospital, Capital Medical University, neurology, Beijing, China

Introduction: Narcolepsy, a rare chronic neurological disorder, is characterized by excessive daytime sleepiness (EDS) and disrupted nocturnal sleep patterns, substantially compromising patients' quality of life. While EDS and cataplexy are hallmark features, nocturnal manifestations remain undercharacterized. This study investigates distinctive sleep phenotypes in narcolepsy, particularly nocturnal frequent awakenings (at least ≥ 5 times) and REM sleep-related dream enactment behaviors (RBD-like symptoms), aiming to establish clinically relevant biomarkers for early diagnosis and mechanistic exploration.

Materials and methods: In this retrospective cross-sectional study, we analyzed 126 patients with EDS from Xuanwu Hospital from 2023 to 2025, stratified into three groups: type 1 narcolepsy (NT1, $n=78$), type 2 narcolepsy (NT2, $n=21$), and clinical controls (CC, $n=27$; suspected central hypersomnia with normal cerebrospinal fluid hypocretin-1 [hcrt-1] levels and negative multiple sleep latency test [MSLT] results). Data collection included standardized questionnaires assessing 35 sleep symptoms and polysomnography (PSG) metrics. Comparative analyses employed χ^2 tests, ANOVA, and ROC curve modeling to identify narcolepsy-specific signatures.

Results: Narcolepsy patients exhibited near-universal EDS (97.4%), with high rates of cataplexy (NT1: 85.7%), hypnagogic hallucinations (38.4%), and sleep paralysis (42.3%). Notably, nocturnal disturbances significantly distinguished narcolepsy from controls: frequent awakenings (89.7% vs. 59.2%; $\chi^2=9.437$, $P=0.002$) and dream enactment behaviors (50.0% vs. 25.9%; $\chi^2=4.022$, $P=0.045$). PSG revealed narcolepsy-specific pathophysiology, including elevated periodic limb movement indices (13.5 ± 28.1 vs. 4.8 ± 19.9 /h; $P=0.002$) and arousal indices (24.6 ± 11.4 vs. 17.7 ± 9.0 /night; $P=0.014$). In NT1, arousal indices inversely correlated with CSF hcrt-1 levels ($r=-0.257$, $P=0.016$). ROC analysis identified three discriminators: cataplexy (AUC=0.798, sensitivity 88.9%, specificity 70.7%), frequent awakenings (AUC=0.633, sensitivity 85.9%, specificity 40.7%), and dream enactment (AUC=0.608, sensitivity 47.5%, specificity 74.1%).

Conclusions: Nocturnal fragmentation (frequent awakenings) and REM-related motor dysregulation (dream enactment) emerge as clinically significant features of narcolepsy, serving as accessible diagnostic red flags. These phenotypes facilitate early differentiation from other sleep disorders, potentially minimizing diagnostic delays. The inverse relationship between hcrt-1 deficiency and nocturnal hyperarousal in NT1 suggests hypocretinergic modulation of sleep stability, providing novel

mechanistic insights. These findings underscore the importance of comprehensive nocturnal evaluation in narcolepsy workups and lay groundwork for targeted biomarker development.

Acknowledgments: This research was supported by a grant from the National Natural Science Foundation of China (Grant No.82371489). I would like to express my sincere gratitude to my advisor, Professor shuqin Zhan, for her invaluable guidance and support throughout this research.

Once-Nightly Sodium Oxybate Improves Narcolepsy Symptoms in People With Narcolepsy: Interim Results From the Real-World REFRESH Study

S. Meskill¹, G. Meskill¹, A. Roy², A. Santamaria³, R. Porpiglio⁴, O. Mamedov⁵, S. Ibrahim⁶, O. Bailey⁷, R. Bogan⁸, L.B. Herpel⁹, M. Davis¹⁰, J.D. McConnell¹¹, G.S. Richards¹², B. Abaluck¹², J. Gudeman¹²

¹Tricoastal Narcolepsy and Sleep Disorder Center, Sugar Land, United States, ²Ohio Sleep Medicine Institute, Dublin, United States, ³Northwest Houston Neurology & Comprehensive Sleep Medicine Center, Houston, United States, ⁴Ghaly Sleep Management Services, LLC, Syracuse, United States, ⁵Comprehensive Sleep Center, East Lansing, United States, ⁶University Hospitals Cleveland Medical Center, Cleveland, United States, ⁷Biorhythms, El Paso, United States, ⁸University of South Carolina School of Medicine, Columbia, United States, ⁹Bogan Sleep Consultants, Columbia, United States, ¹⁰Patient First MD, Middletown, United States, ¹¹Florida Sleep Specialists, Bradenton, United States, ¹²Avadel Pharmaceuticals, Chesterfield, United States

Introduction: Once-nightly sodium oxybate (ON-SXB; LUMRYZ™) is approved to treat excessive daytime sleepiness (EDS) or cataplexy in patients 7 years of age and older with narcolepsy. Interim results from REFRESH (NCT06792708), a multicenter, observational, real-world study assessing clinical effectiveness, patient satisfaction, and safety of ON-SXB for treatment of narcolepsy, are reported.

Materials and methods: REFRESH enrolled adults aged ≥18 years with narcolepsy type 1 (NT1) or 2 (NT2) who switched from current twice-nightly oxybates (TN-OXB; switch participants), previously used TN-OXB, or were oxybate-naïve. Prior/current treatment with ON-SXB was exclusionary. ON-SXB dosing followed product labeling (eg, titration in 1.5-g increments weekly or more gradual, based on efficacy and tolerability, up to 9 g). Participants completed the Epworth Sleepiness Scale (ESS) weekly (weeks 1-6) and then every other week (weeks 8-16). The Narcolepsy Severity Scale (NSS) and Sheehan Disability Scale (SDS) were completed over 4 monthly clinic visits. Patient Global Impression of Change (PGI-C) and Clinical Global Impression of Change (CGI-C) surveys were completed at the end-of-study visit. Safety data are reported as adverse drug reactions (ADRs; ie, adverse events related to study drug).

Results: As of April 4, 2025, 86 participants were screened and 67 initiated ON-SXB treatment (NT1, n=24 [35.8%]; NT2, n=43 [64.2%]; mean [SD] age, 38.0 [13.4] years); month 4 data were available for 20 participants. Twenty-five (37.3%) participants were currently taking TN-OXB, 9 (13.4%) had prior TN-OXB experience, and 33 (49.3%) were oxybate-naïve. Respective mean (SD) ESS scores for switch and non-switch participants were 10.4 (5.4) and 14.5 (4.5) at baseline and 7.1 (4.6) and 8.8 (4.4) at week 16; mean (SD) change from baseline (CFB) was -3.2 (3.4) and -5.6 (5.7). Respective mean (SD) NSS total scores for switch and non-switch participants were 16.0 (8.1) and 23.4 (9.5) at baseline and 11.4 (11.1) and 14.1 (8.6) at month 4; mean (SD) CFB was -5.0 (5.3) and -7.3 (5.6). Respective mean (SD) SDS scores for work/school, social life, and family life/home domains for all participants were 5.3 (2.9), 5.8 (2.7), and 5.9 (2.8) at baseline and 3.1 (2.5), 3.5 (2.8), and 3.7 (2.9) at month 4 (mean [SD] CFB: -1.9 [2.0], -0.8 [2.1], and -1.8 [2.6]). On the PGI-C (n=26) and CGI-C (n=24), 76.9% and 79.2% of participants, respectively, were “much” or “very much” improved. ADRs were reported by 22/67 (32.8%) participants; common ADRs (≥10% of participants) were nausea (28.4%), vomiting (14.9%), dizziness (11.9%), and headache (10.4%). Most (86.1%) events were mild or moderate; severe events included nausea (n=4), vomiting (n=3), dizziness (n=2), and enuresis (n=1). ON-SXB treatment was discontinued by 3/67 (4.5%) participants owing to tolerance concerns.

Conclusions: After switching from current TN-OXB use to ON-SXB, participants experienced clinically meaningful improvements in ESS scores to within the normal range; narcolepsy disease severity on the NSS improved from moderate at baseline to mild by end of study. Similar results were observed for participants who had prior TN-OXB use or were oxybate-naïve. ON-SXB was well tolerated; ADRs were consistent with known oxybate safety profiles.

Optogenetic activation of the histaminergic system in the amygdala of narcoleptic mice reduces the occurrence of cataplexy

R. Maciel¹, M. Villalba¹, M. Grenot¹, A.-L. Morel¹, J.-C. Schwartz², O. Finance², X. Ligneau², C. Peyron¹

¹Université Claude-Bernard Lyon1, CNRS UMR5292, INSERM U1028, SLEEP team, Bron, France,

²Bioprojet Biotech, Saint-Grégoire, France

Introduction: Cataplexy, the pathognomonic symptom of narcolepsy type 1 (NT1), is characterized by a loss of muscle tone during wakefulness and triggered by a strong positive emotion. A large body of evidence have demonstrated that activation of GABAergic neurons of the amygdala, a structure of the limbic system that processes emotions, plays a key role in triggering cataplexy mouse models of NT1 (Sardar et al, 2023). Of interest, Pitolisant®, used as one treatment option for NT1, greatly reduces cataplexy (Szakacs et al., 2017; Davis et al, 2021), but mechanisms involved are poorly understood. Through its antagonism/inverse agonism on H3R autoreceptors, Pitolisant® enhances the release of histamine (HIS) into the extracellular space (Ligneau et al., 2007). We thus hypothesized that Pitolisant® might suppress cataplexy by acting on the limbic system, particularly the amygdala. To test this hypothesis, we first tested whether Pitolisant® suppressed cataplexy in NT1 mice; second, we encovered which portion of the amygdala was activated during cataplexy by using the neuronal marker of activation c-fos, and finally, we optogenetically stimulated HIS axonal fibers locally in the amygdala and investigated the effect on cataplexy in a newly developed mouse model of narcolepsy, the Historex mice (a cross breeding of orexin-deficient mice with mice expressing the enzyme CRE-recombinase exclusively in HIS neurons).

Materials and methods: (1) Pitolisant® was dose-dependently administered i.p. in orexin-deficient mice (orex-KO) mice;

(2) Four orex-KO and 4 wild-type mice were given chocolate at 7pm and sacrificed 6hrs later. Brains were collected and processed with c-Fos immunohistochemistry. Number of c-fos neurons were counted in all subdivision of the amygdala. (3) Historex mice were stereotactic bilaterally injected with AAV-EF1-DIO-ChR2-EYFP (n=7) or AAV-EF1-DIO-EYFP control (n=4) viruses. All mice were implanted for polysomnography (EEG/EMG). HIS axonal fibers were optoactivated locally in the amygdala (10Hz, 5mW/mm², for 6h from light-off, n=11). Experiments were performed in triplicates.

Results: Pitolisant successfully suppressed cataplexy in orex-KO mice. We also found and increased c-Fos activated neurons throughout the rostrocaudal extent of the amygdala in orex-KO mice compared to wild-type mice. We found that 24-30% penetrance of the cre-transgene in HIS neurons only. Nevertheless, chronic photoactivation of histaminergic fibers overlying the amygdala induced a significant 20% and 27% reduction in the total amount and number of episodes of cataplexy, respectively. Optogenetic photoactivation induced no change in Historex control group, which does not express the ChR2 photoreceptor. Finally, chronic photoactivation of histaminergic fibers had no effect on the total amount or fragmentation of vigilance states.

Conclusions: Our findings indicate that optoactivation of HIS in the amygdala reduces the amount and number of cataplexy without altering vigilance states. Interestingly, recent data show that optoactivation of HIS axons in the amygdala of healthy mice significantly suppresses glutamatergic transmission in the central amygdala via H3 receptors (Zhang et al, 2024). Altogether, these data suggest that Pitolisant® may suppress cataplexy by dampening the amygdala response to positive emotions. We provide here the first mechanistic insights into the potential mode of action of Pitolisant® in cataplexy.

Oveporexton (TAK-861) Improves Wakefulness in People with NT1: Assessment of At-home Napping and In-clinic Microsleeps

R. Torres¹, Y. Gong¹, B. Tracey¹, F. Onorati¹, A. Cai¹, T. Olsson¹, Y. Pyatkevich¹, P. Tierney¹, E. Mignot², D. Volfson¹

¹Takeda Development Center Americas, Inc., Cambridge, United States, ²Stanford Center for Sleep Sciences and Medicine, Stanford University, Palo Alto, United States

Introduction: Excessive daytime sleepiness (EDS) in narcolepsy profoundly impacts daily life. In clinical trials, EDS is commonly assessed using the Maintenance of Wakefulness Test (MWT), which measures

the ability to stay awake in soporific conditions. However, sleep onset latency (SOL), the primary endpoint in MWT studies, does not capture the quality of wakefulness prior to falling asleep, nor provide information on EDS in an uncontrolled real-world environment. Here, we explore two EDS measures that are complementary to MWT SOL. We use wrist-worn accelerometry to assess at-home napping and characterize EDS during MWT by measuring microsleeps (3-15 sec periods of sleep prior to sleep onset). In a phase 2 randomized, placebo-controlled trial (NCT05687903), naps and microsleeps are evaluated as biomarkers for EDS following treatment with oreporexton (TAK-861), an oral orexin receptor 2-selective agonist, in narcolepsy type 1 (NT1).

Materials and methods: Participants with NT1 were randomized to receive oreporexton (first dose at 8AM; 0.5mg twice 3 hours apart; 2mg twice 3 hours apart; 2mg then 5mg 3 hours later; or 7mg once daily) or placebo. Wrist-worn accelerometry data were collected continuously during baseline and treatment periods, and naps were estimated using a previously described algorithm. Derived nap endpoints included the proportion of nap-free days, total minutes of daytime sleep on days with ≥ 1 nap, and nap count. MWTs were in-clinic 40 minute wake trials (10AM/12PM/2PM/4PM) conducted at baseline and after 28 and 56 days of treatment. Microsleeps were scored manually following AASM standards, and annotated events were used to compute microsleep rate (number of microsleep divided by SOL) and time-to-first microsleep. Nap endpoints were analyzed with generalized linear mixed-effects models. Microsleep rate was analyzed via a zero-inflated negative binomial mixed-effects model, with SOL as an offset. Time-to-first microsleep was assessed using a mixed effects Cox proportional hazard model, which included treatment, visit, and time, and their interactions as fixed effects, and random intercept per subject.

Results: Data were collected for 112 participants with NT1 (placebo: n=22, 0.5mg/0.5mg: n=23, 2mg/2mg: n=21, 2mg/5mg: n=23, 7mg: n=23). All oreporexton-treated groups experienced increases in nap-free days over 4 weeks and slept less time per day (all $p < 0.001$) after placebo-correction and baseline adjustment, except the 0.5mg/0.5mg group for the latter endpoint. Microsleep rates decreased by Weeks 4 and 8 across oreporexton-treated groups versus baseline (from ~6 microsleeps per 10 minutes to < 2 per 10 minutes, all $p < 0.001$). Placebo-corrected change from baseline revealed reductions in microsleep rates across oreporexton-treated groups at Weeks 4 and 8 (all $p < 0.05$). Time-to-first microsleep increased at Weeks 4 and 8 across oreporexton-treated groups versus baseline (all $p < 0.001$). Hazard ratios for all treatment groups versus placebo at Weeks 4 and 8 were < 0.2 (all $p < 0.002$). No significant effects were observed in the placebo group.

Conclusions: Oreporexton reduced multiple aspects of EDS, including at-home napping and in-clinic microsleeps. These reductions observed in both an unconstrained, natural home environment and in controlled clinical settings demonstrate oreporexton's potential as an effective treatment for EDS in participants with NT1.

Oxybate Awareness, Usage, and Experience Among People With Narcolepsy: A MyNarcolepsyTeam Survey Analysis

M. Lavender¹, H. Merius¹, B. Schneider², D. Cronin², L.E. Ortiz³, A.M. Morse⁴, J. Gudeman⁶

¹Comprehensive Sleep Medicine Associates, Houston, United States, ²Stony Brook Medicine, Smithtown, United States, ³MyHealthTeam, San Francisco, United States, ⁴Johns Hopkins Medical Institutions, Johns Hopkins All Children's Hospital, St. Petersburg, United States, ⁵Geisinger Commonwealth School of Medicine, Geisinger Medical Center, Janet Weis Children's Hospital, Danville, United States, ⁶Avadel Pharmaceuticals, Chesterfield, United States

Introduction: Narcolepsy is characterized by excessive daytime sleepiness (EDS) and can occur with or without cataplexy. Oxybates are FDA-approved to treat EDS or cataplexy in people with narcolepsy. Immediate-release twice-nightly sodium oxybate (TN-SXB) and calcium, magnesium, potassium, and sodium oxybates (mixed-salt oxybates) are administered at bedtime and 2.5-4 hours later, whereas extended-release once-nightly SXB (ON-SXB; FT218) is administered once at bedtime. This study assessed oxybate awareness, usage, and experience among people with narcolepsy (PWN).

Materials and methods: The MyNarcolepsyTeam survey was an anonymous, voluntary survey conducted from April 10 to May 9, 2024. Eligible participants were age ≥ 21 years, United States residents, and reported a narcolepsy diagnosis. The 36-item survey assessed respondents' demographics, symptom management, and relationships with healthcare providers (HCPs).

Results: Of 88 respondents, 77% were female, 75% were ≥ 50 years of age, and 39% and 50% had narcolepsy type (NT) 1 and NT2, respectively. Respondent brand awareness of oxybates was high (70%), with highest awareness for TN-SXB (55%), followed by mixed-salt oxybates (43%) and ON-SXB (23%). Of 82 respondents seeing an HCP, only 39% had discussed oxybates with their HCP. Current oxybate use was reported by 13% of respondents (15% of NT1 respondents; 7% of NT2 respondents), 82% of whom experienced symptom improvement within 2 weeks of starting oxybate treatment. Benefits of oxybate use included getting a better night's sleep (64%) and waking up refreshed (64%). Of 77 respondents not currently taking oxybates, 36% reported they did not know enough about oxybates. Of respondents who had previously taken an oxybate, 28% discontinued within 1 month of initiating treatment. The most commonly reported reason for discontinuing oxybate treatment was side effects (40% [age ≥ 60 years, 47%; age < 60 years, 27%]).

Conclusions: These results demonstrate that while respondents were moderately aware of oxybates, over one-third reported lacking enough information to consider starting oxybate treatment. Despite TN-SXB approval by the FDA in 2002, only 1:8 respondents were currently receiving oxybates. As narcolepsy medication regimens can be daunting, clinicians have the opportunity to counsel PWN about oxybate treatment options, including the potential for early symptom improvement and proactive side effect management to reduce discontinuation.

Pan-Cancer Prognostic Modeling Using Narcolepsy-Associated Genes: A Transcriptomic Framework Bridging Sleep Regulation and Tumor Biology

J.-W. Chen¹, K.-F. Chang², C.-H. Yuan³, Y.-K. Lee¹

¹Kaohsiung Armed Forces General Hospital, Medical Education and Research Center, Kaohsiung, Taiwan, ²Kaohsiung Armed Forces General Hospital, Kaohsiung, Taiwan, ³Kaohsiung Armed Forces General Hospital, Department of Otolaryngology, Kaohsiung, Taiwan

Introduction: Narcolepsy is a chronic neurological sleep disorder involving dysregulation of REM sleep and immune function. Emerging evidence indicates that genes implicated in narcolepsy may also contribute to oncogenic processes such as epithelial mesenchymal transition (EMT), immune escape, and cell proliferation. However, the potential application of narcolepsy-associated genes as prognostic markers in cancer has not been systematically investigated.

Materials and methods: A curated set of narcolepsy-related genes was identified through literature and neuroimmunology databases. Using transcriptomic profiles from The Cancer Genome Atlas (TCGA), we applied LASSO Cox regression to construct a 12-gene prognostic signature. The derived narcolepsy risk score stratified patients into high- and low-risk groups, and its predictive performance for overall survival (OS), disease-specific survival (DSS), and progression-free interval (PFI) was assessed across 33 cancer types. Validation was performed using independent cohorts from CGGA and GEO.

Results: The narcolepsy-based prognostic model exhibited strong predictive value in multiple cancers, especially lower-grade glioma, clear cell renal carcinoma, and colorectal carcinoma. High-risk groups showed upregulation of EMT-related genes, mitotic activity, and extracellular matrix remodeling, along with reduced immune infiltration. Functional enrichment analysis confirmed that risk-associated genes were involved in immune evasion and tumor-promoting inflammation. Immunohistochemistry (IHC) on tumor tissues further supported the differential expression of selected signature genes.

Conclusions: We present a novel pan-cancer prognostic signature derived from narcolepsy-associated neuroimmune genes. This model reveals a potential mechanistic link between sleep regulation pathways and tumor progression, and offers a clinically relevant tool for risk stratification. The findings support further exploration of sleep-immune-tumor crosstalk as a novel axis in oncology.

Patient Experience of Oveporexton (TAK-861) for Narcolepsy Type 1 in a Phase 2 Clinical Trial

S. Crawford¹, Y. Savva¹, H. Romero¹, L. Stassek², O. Eseyin², G. Plazzi^{3,4}, R. del Rio Villegas^{5,6}, M. Naylor¹, T. Olsson¹

¹Takeda Development Center Americas, Inc., Cambridge, MA, United States, ²PPD Evidera Patient-Centered Research, Thermo Fisher Scientific, Waltham, MA, United States, ³IRCCS, Istituto delle Scienze Neurologiche, Bologna, Italy, ⁴Department of Biomedical, Metabolic, and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy, ⁵Neurophysiology and Sleep Disorders Unit, Vithas Hospitals, Madrid, Spain, ⁶Universidad CEU San Pablo, CEU Universities, Madrid, Spain

Introduction: Oveporexton (TAK-861) is a novel oral orexin receptor 2 agonist developed for the treatment of narcolepsy type 1 (NT1). The safety and efficacy of oveporexton was investigated in an 8-week randomized, double-blind, placebo-controlled, dose-ranging Phase 2 trial (NCT05687903) in patients with NT1. While clinical trials provide information on the efficacy and safety of new treatments, qualitative feedback from patients on their treatment experience, in addition to standard patient questionnaires, offers a more comprehensive understanding of a treatment's impact on patients' lives. This cross-sectional, qualitative analysis explored patient perceptions of treatment and overall experiences of participation in the NT1 Phase 2 oveporexton trial.

Materials and methods: Participants aged 18-70 years, with an Epworth Sleepiness Scale (ESS) total score >12, and ≥4 partial/complete episodes of cataplexy/week were randomized to twice daily oral oveporexton or placebo (0.5mg/0.5mg, 2mg/2mg, 2mg/5mg, 7mg/placebo, or placebo/placebo). Participants who completed the final Week 8 visit were given the option to complete an exit interview. Semi-structured interviews were conducted by a third party vendor within 3 weeks of the final visit. Interviewees provided separate informed consent prior to interviews. Questions focused on participants' experience of the trial and treatment impact on narcolepsy symptoms and daily life. Transcripts were analyzed using content analysis (ATLAS.ti) to identify recurring themes and concepts. Responses were summarized using descriptive statistics.

Results: Twenty-five participants (oveporexton n=21, placebo n=4; 52% female; mean age 30.4 [SD 11.2] years, mean 10.2 [8.7] years since diagnosis) completed an exit interview. Eleven (44%) reported the reason for joining the trial was to have better symptom control, and 9 (36%) wanted to try a new treatment. Twenty-three interviewees (92%) indicated they were dissatisfied with their previous treatment(s); 15 (65%) reported low effectiveness and 7 (30%) reported side effects as their rationale. Twenty-one indicated that the trial team satisfactorily managed their expectations regarding dosing, administration, side effects, and outcomes. Oveporexton-treated participants reported noticeable improvements in the symptoms they rated as being most important to improve: excessive daytime sleepiness (18/18 [100%]), cataplexy (19/19 [100%]), cognitive symptoms (9/9 [100%]), and disturbed nighttime sleep (7/9 [78%]), versus 1/3 (33%), 0/1 (0%), 1/4 (25%) and 0/3 (0%), respectively, of participants on placebo. Improvements in these same top symptoms were meaningful for 67-100% of oveporexton-treated participants versus only 1 (25%) participant on placebo. Most (83-100%) oveporexton-treated participants noted improvements in work impacts, social and leisure activities, independence/self-care, physical activities, daily activities, activities avoided due to cataplexy, family time, and mood/emotions versus no reported improvement in impacts with placebo. Eighteen of 19 (95%) of responding oveporexton-treated participants indicated they would recommend it to someone else with narcolepsy.

Conclusions: Participants with NT1 reported a favorable impact on their symptoms and quality of life with oveporexton treatment, with good overall treatment perception. Qualitative patient perception findings can serve to support efficacy and treatment satisfaction data of newer treatments for regulatory assessments and subsequently for treatment decision-making.

Phenotypic clusters of narcolepsy type 1: Insights from age of onset, weight gain, sleep patterns, and impulsivity

M. Wang¹, F. Han¹, F. Xiao¹, X. Dong¹, L. Wu¹, W. Wang¹

¹Peking University People's Hospital, Division of Sleep Medicine, Beijing, China

Introduction: This study aimed to discern the underlying relationships between clinical manifestations and neuroimaging phenotypes among patients with narcolepsy type 1 (NT1).

Materials and methods: Demographic characteristics, clinical manifestations, polysomnography parameters, and comorbidities were collected in 158 NT1 patients. Using R software, we applied k-means cluster analysis to create homogeneous NT1 patient clusters. Subsequently, we identified

clinical and neuroimaging features within each cluster and examined associations between neuroimaging and clinical phenotypes across different subgroups.

Results: Four clusters were found: patients with the youngest onset-age exhibit more severe objective sleepiness. However, it is easily ignored or not reported due to mild subjective sleepiness, which may be responsible for the long delay between disease onset and diagnosis in this group of patients. Patients with teenage onset and greater weight gain showed shorter sleep latency, more obvious disturbed nocturnal sleep (DNS), the highest proportion of hallucination and sleep paralysis, as well as the highest motor impulsivity score, but minimum volumes in the left para-hippocampal gyrus (PHG) and right precuneus. Patients with teenage onset and less weight gain showed the longest sleep latency and maximum volumes in the right frontal region and left posterior cingulate cortex (PCC). Adult-onset patients reported the highest Epworth Sleepiness Scale (ESS) scores, more obvious impulsivity behavior and more sleep apnea comorbidity. Volumes in left PHG and left PCC were associated with mean sleep latency, respectively.

Conclusions: Narcolepsy patients with teenage onset and greater weight gain exhibit severe sleepiness, severe DNS and high motor impulsivity. Results from this research will provide a new reference for the pathogenesis, diagnosis, and management of narcolepsy.

Precision medicine approach in Brazilian patients with primary hypersomnias using hypocretin and high-resolution HLA sequencing : insights from an admixture population

C. Martins Correa da Silva¹, V. Mendes², L.C. Porto², D. Secco², C.O. Brandão³, E. Mignot⁴, S. Alves Leon⁵

¹Rio de Janeiro State University, Neurology, Rio de Janeiro, Brazil, ²Rio de Janeiro State University, HLA-LAB, Rio de Janeiro, Brazil, ³Neurolife, Rio de Janeiro, Brazil, ⁴Stanford University, Palo Alto, United States, ⁵Federal Fluminense University, Post Graduation Program in Neurology and Neurosciences, Niterói, Brazil

Introduction: The major genetic risk factor for narcolepsy is HLA-DQB1*06:02, which is closely associated with low cerebrospinal fluid (CSF) hypocretin, a characteristic of narcolepsy type 1 (NT1), although it's also associated with narcolepsy type 2 (NT2) to a lesser degree. Genetic factors underlying idiopathic hypersomnia (IH) remain unclear. Brazil boasts a large and diverse population, with a genetic background often underrepresented in population studies with a low prevalence of HLA-DQB1*06:02 (around 60-70%) among NT1 patients compared to other countries (nearly 90-95% in Chinese, Korean, most of Europe, and North Americans). However, these low prevalence of HLA-DQB1*06:02 came from studies that were conducted without hypocretin measurement. Recent data shows that when CSF hypocretin levels are measured and documented to be low the association with NT1 of HLA-DQB1*06:02 rises to 98-100%.

Materials and methods: Patients suspected of having primary hypersomnias underwent a comprehensive investigation at the Hypersomnia Research Center in Pedro Ernesto University Hospital, which included polysomnography, multiple sleep latency tests, genetic testing, and CSF hypocretin measurement via radioimmunoassay at the Stanford Narcolepsy Centre in the USA. This study included 68 patients diagnosed with narcolepsy or IH according to ICSD-3 criteria from November 2021 to January de 2024: 24 NT1, 27 NT2, and 17 IH. Genetic data from 340 healthy individuals of the Brazilian Bone Marrow Donor Registry (REDOME) was used for comparison, considered the third largest biobank in the world. High-resolution HLA sequencing was performed using the Next Generation Sequencing (NGS) Holotype HLA kit from Omixon, Inc., Budapest, Hungary, and allele frequencies were compared between the case and control groups, matched by sex, ethnicity, and geographic location, using a 1:5 case-to-control ratio. The risk of susceptibility or protection was determined by comparing the diagnostic groups and their controls by calculating the odds ratio (OR), using the chi-square test or Fisher's exact test and corrected by the Bonferroni factor, using Epi Info©. A 95% confidence interval and p-value<0.05 were determined.

Results: All NT1 patients (100%) carried the HLA-DQB1*06:02 allele, significantly higher than controls (25%), patients with NT2 (18.52%), or IH (23.53%) (p < 0.001). The allele DRB1*15:03, linked to African

heritage, emerged as the second most prevalent allele among NT1, forming a haplotype DRB1*15:03~DQB1*06:02 with an odds ratio of 39.0 (95% CI: 9.6–157.8, $p < 0.001$) in comparison with controls; however NT1 subgroup didn't present black people as the majority. No risk allele was observed comparing NT2 and IH with their controls ($p > 0.05$). Risk alleles already described in the literature for narcolepsy were found among 67/68 patients of all types of hypersomnias (NT1, NT2, and IH).

Conclusions: HLA-DQB1*06:02 was the main risk factor for NT1, but not for NT2 and IH, with a high frequency (100%), similar to what is seen in other ethnicities. The second risk allele for NT1 was DRB1*15:03 instead of DRB1*15:01, which suggests a higher influence of African heritage in the population studied.

Acknowledgments: Thanks to the Brazilian Patients Association with Narcolepsy and Idiopathic Hypersomnia (ABRANH) for referring suspected people to diagnostic investigation at the reference center.

Prevalence and Incidence of Comorbidities in Individuals With Narcolepsy or Idiopathic Hypersomnia: A Systematic Literature Review

C. Drachenberg¹, S.C. Markt¹, A. Hodkinson², A. Jenkins², E. Hardy², J.K. Alexander¹, M. Whalen³, S. Beaty¹, V.K. Somers⁴

¹Jazz Pharmaceuticals, Palo Alto, United States, ²Petauri Evidence, York, United Kingdom, ³Jazz Pharmaceuticals, Philadelphia, United States, ⁴Mayo Clinic, Rochester, United States

Introduction: Narcolepsy and idiopathic hypersomnia (IH) are hypersomnolence disorders primarily characterised by excessive daytime sleepiness. Previous studies have observed an increased prevalence and risk of developing cardiovascular (CV) and cardiometabolic (CM) diseases among individuals with narcolepsy. However, prevalence and incidence estimates vary across studies due to differing populations, study designs, time periods, and outcome definitions. This systematic literature review (SLR) aimed to identify studies evaluating the prevalence and incidence of comorbidities in individuals with narcolepsy or IH.

Materials and methods: This gold-standard SLR was conducted following PRISMA guidelines to identify relevant studies. Electronic database searches, supplemented by review of conference proceedings and trial registries, were conducted through 10 December 2024 based on prespecified *Population, Intervention, Comparison, Outcomes, and Study Design* criteria. Screening and data extraction were conducted by two independent reviewers; discrepancies were resolved by a third reviewer. Quality assessment was conducted using relevant *Critical Appraisal Skills Programme* checklist domains.

Results: Of 3130 records screened, 127 publications were included in the SLR; most were cohort or cross-sectional studies ($n=106$; 83.5%) and were primarily among people with narcolepsy ($n=118$; 93.0%). For narcolepsy, data were available for narcolepsy overall ($n=45$), narcolepsy subtypes 1 and 2 (NT1; NT2; $n=34$), NT1 only ($n=36$), and NT2 only ($n=2$). Fifty-five (43.3%) narcolepsy publications also reported data for a relevant comparative population. Prevalence data were reported in almost all narcolepsy publications ($n=114$; 98.3%) for 310 different comorbidities as frequency measures (percentages) or measures of association (odds ratios [OR]). Prevalence estimates of CV/CM conditions were most commonly reported as frequencies, including hypertension ($n=26$), cardiovascular disease (CVD; $n=22$), diabetes ($n=29$), dyslipidaemia ($n=18$), obesity ($n=44$), and overweight ($n=14$). Within the 27 publications reporting association data, the prevalence of comorbidities was generally higher in people with narcolepsy; higher prevalence of hypertension (7/8 studies), CVD (7/8), diabetes (6/10), obesity (7/7), and dyslipidaemia (5/6) was reported in individuals with narcolepsy compared to those without. Five studies reported incidence of comorbidities as measures of frequency, and 8 reported incidence as a measure of association (eg, OR) using a comparison group. The data for IH were more limited. Prevalence of comorbidities in people with IH was reported in 23 publications for 90 different comorbidities. The most commonly reported CV/CM comorbidity frequency estimates were for hypertension ($n=4$ studies), diabetes ($n=4$), and CVD ($n=3$). Measures of association were reported in 8 publications; 7 studies compared individuals with and without IH and found a higher prevalence of hypertension ($n=3/3$), CVD ($n=4/4$), and stroke ($n=3/3$) in the IH cohort; 1 study found a lower prevalence of type 1 diabetes ($n=1/1$).

Conclusions: This SLR found a growing literature base evaluating the prevalence and incidence of CV/CM comorbidities in individuals with narcolepsy and IH, though evidence is more scarce for IH.

Most studies found higher prevalence of CV (eg, hypertension, CVD) and CM (eg, obesity) comorbidities among individuals with narcolepsy or IH versus those without, with varying prevalence estimates reported. Incidence data were limited in narcolepsy, and even more limited in IH. Meta-analyses will be conducted to empirically synthesize findings from this SLR.

Psychiatric and Sleep Disturbances in Narcolepsy Patients and Their Families: An Epidemiological Study

T.W. Kim¹, S.-C. Hong¹, Y.C. Kim¹

¹The Catholic University of Korea/ St. Vincent's Hospital, Dept. of Psychiatry, Suwon, Korea, Republic of

Introduction: Narcolepsy has a known genetic component, with first-degree relatives of patients having a 20-40 times increased risk of developing the disorder. This study aimed to investigate the prevalence of psychiatric problems and sleep disturbances in families of narcolepsy patients, considering the potential genetic influence and their psychiatric burden.

Materials and methods: We conducted a cross-sectional study by enrolling narcolepsy patients aged 12 and older (including children) who have been diagnosed with narcolepsy at St. Vincent's Hospital Sleep Clinic and other medical institutions and family members. As of now, 132 narcolepsy patients and 113 family members (1st degree) are involved. Participants completed validated questionnaires by internet based survey including the Pittsburgh Sleep Quality Index (PSQI), Beck Depression Inventory II (BDI-II), Epworth Sleepiness Scale (ESS), and Adult ADHD Self-Report Scale (ASRS) to assess sleep quality, depression, daytime sleepiness, quality of life, and ADHD symptoms, respectively.

Results: Narcolepsy patients showed significantly poorer sleep quality (PSQI mean $\pm$ SD : 12.88 $\pm$ 2.82) compared to their family members (PSQI mean $\pm$ SD: 10.17 $\pm$ 3.05), both groups with higher PSQI scores compared to the general population norm, indicating poorer sleep quality. Patients exhibited higher excessive daytime sleepiness (ESS mean $\pm$ SD : 16.93 $\pm$ 4.26) compared to family members (ESS mean $\pm$ SD : 6.03 $\pm$ 5.13). Patients also demonstrated more severe depressive symptoms (BDI-II mean $\pm$ SD: 43.2 $\pm$ 14.84) than their families (BDI-II mean $\pm$ SD: 26.98 $\pm$ 9.16). Significantly, 54 participants (47.7%) in family group showed moderate depression, while 40 participants (35.3%) showed severe depression. Moreover, ADHD symptoms were more prevalent in patients (ASRS mean $\pm$ SD: 11.5 $\pm$ 5.87) compared to family members (ASRS mean $\pm$ SD: 4.27 $\pm$ 4.29).

Conclusions: This study reveals a substantial burden of psychiatric problems and sleep disturbances in both narcolepsy patients and their family members, with patients showing significantly more severe symptoms across all measures. The findings highlight the need for comprehensive care approaches that address not only the patients' needs but also the mental health and sleep quality of their family members. Further genetic studies are warranted to elucidate the specific mechanisms underlying these familial patterns and to develop targeted interventions for this population

Real-World Experience of Once-Nightly Sodium Oxybate Treatment in People With Narcolepsy: Interim Results From REFRESH

S. Meskill¹, G. Meskill¹, A. Roy², A. Santamaria³, R. Porpiglio⁴, O. Mamedov⁵, S. Ibrahim⁶, O. Bailey⁷, R. Bogan⁸, L.B. Herpel⁹, M. Davis¹⁰, J.D. McConnell¹¹, G.S. Richards¹², B. Abaluck¹², J. Gudeman¹²

¹Tricoastal Narcolepsy and Sleep Disorder Center, Sugar Land, United States, ²Ohio Sleep Medicine Institute, Dublin, United States, ³Northwest Houston Neurology & Comprehensive Sleep Medicine Center, Houston, United States, ⁴Ghaly Sleep Management Services, LLC, Syracuse, United States, ⁵Comprehensive Sleep Center, East Lansing, United States, ⁶University Hospitals Cleveland Medical Center, Cleveland, United States, ⁷Biorhythms, El Paso, United States, ⁸University of South Carolina School of Medicine, Columbia, United States, ⁹Bogan Sleep Consultants, Columbia, United States, ¹⁰Patient First MD, Middletown, United States, ¹¹Florida Sleep Specialists, Bradenton, United States, ¹²Avadel Pharmaceuticals, Chesterfield, United States

Introduction: Oxybate treatment improves quality of life (QOL) for people with narcolepsy; however, the middle-of-the-night dosing required by twice-nightly oxybate (TN-OXB) can be burdensome. Once-

nightly sodium oxybate (ON-SXB; LUMRYZ™) is approved to treat excessive daytime sleepiness (EDS) or cataplexy in patients 7 years of age and older with narcolepsy. Interim survey data from REFRESH (NCT06792708), a prospective, real-world study assessing clinical effectiveness, patient satisfaction, and safety of ON-SXB for narcolepsy treatment, are reported.

Materials and methods: REFRESH enrolled adults aged ≥18 years with narcolepsy type 1 or 2 who switched from current TN-OXB use (switch participants), had prior TN-OXB use, or were oxybate-naïve. Exclusion criteria included prior/current treatment with ON-SXB and any condition deemed exclusionary by the study clinician or contraindicated by product labeling. ON-SXB dosing followed product labeling (eg, titration in 1.5-g increments weekly or more gradual, based on efficacy and tolerability, up to 9 g). At baseline and end of study (EOS), all participants completed a 7-question survey about their QOL and narcolepsy symptoms (eg, fatigue). Switch participants completed a baseline survey about their experience with TN-OXB treatment (switch survey). All participants completed an EOS questionnaire about their experience with ON-SXB treatment.

Results: As of April 4, 2025, 67 participants initiated ON-SXB treatment; 25 (37.3%) were switch participants, 9 (13.4%) had prior TN-OXB use, and 33 (49.3%) were oxybate-naïve. Mean (SD) QOL on a scale of 0=“worst possible” to 10=“best possible” was 5.6 (1.42) at baseline (n=67) and 7.1 (1.41) at EOS (n=26). Mean (SD) fatigue on a scale of 0=“never fatigued” to 10=“extremely fatigued” was 7.3 (1.81) at baseline (n=67) and 4.6 (2.06) at EOS (n=26). All 25 switch participants completed the switch survey; 76% split 2 TN-OXB doses equally and 24% took a higher first dose. The second TN-OXB dose was moderately-to-extremely burdensome for 80% of switch participants; 80% missed the second dose during the 3 months prior to study entry, of whom 55% missed the second dose at least once a week. Missed doses resulted in worsening fatigue and sleepiness for 85% and 80% of participants, respectively. EOS questionnaires were completed by 26 participants (switch=11); participants reported their narcolepsy was “somewhat better” or “much better” with ON-SXB (switch=73%, overall=89%). With ON-SXB treatment, participants reported benefits: being better able to not fall asleep during the day (switch=55%; overall=69%), being better able to sleep through the night (switch=64%; overall=81%), getting more done at work/school (switch=46%; overall=58%), being better able to socialize (switch=46%; overall=62%), and experiencing less drowsy driving (switch=27%; overall=42%). In total, 91% of switch participants preferred ON-SXB, 9% had no oxybate preference, and no participant preferred TN-OXB; 73% reported better adherence to a once-nightly dosing schedule.

Conclusions: Participants in REFRESH experienced meaningful symptom improvement with ON-SXB, including improved QOL, reduced drowsy driving, and improved nocturnal sleep. Prior to study entry, switch participants found twice-nightly dosing of TN-OXB burdensome and often missed doses; >90% of switch participants preferred ON-SXB to TN-OXB.

Acknowledgments: This study was funded by Avadel Pharmaceuticals (Chesterfield, MO).

Real-World Risk of Sodium-Associated Negative Clinical Outcomes Among Individuals With Narcolepsy in the United States

S.C. Markt¹, C. Drachenberg¹, P.R. Taub², L.A. Surkin³, K. Easson⁴, J.K. Alexander¹, P. Gagnon-Sanschagrin⁴, M. Whalen⁵, R. Bellefleur⁴, S. Beaty¹, M. Levesque-Leroux⁴, A. Guérin⁴, R.J. Kovacs⁶
¹Jazz Pharmaceuticals, Palo Alto, United States, ²Division of Cardiovascular Medicine, University of California San Diego, San Diego, United States, ³CardioSleep Diagnostics, Greenville, United States, ⁴Analysis Group ULC, Montreal, Canada, ⁵Jazz Pharmaceuticals, Philadelphia, United States, ⁶Cardiology Division, Indiana University School of Medicine, Indianapolis, United States

Introduction: Narcolepsy is associated with an elevated prevalence of comorbid cardiovascular, cardiometabolic, and renal diseases, with risk potentially exacerbated by excess sodium intake. This study aimed to compare the risk of sodium-associated negative clinical outcomes (NCOs) between individuals with and without narcolepsy and to quantify the risk of NCOs among individuals with narcolepsy, comparing those with and without prior risk factors.

Materials and methods: Komodo Research Data (01/01/2016–31/01/2024) were used to identify US individuals diagnosed with narcolepsy (*index*: first observed narcolepsy diagnosis) and individuals without narcolepsy (*index*: randomly selected date within ≥48 months of continuous healthcare plan eligibility), using a 1:5 ratio of individuals with and without narcolepsy. All individuals were required to have ≥12 months of continuous enrolment in both the pre- and post-index periods. Entropy balancing was used to balance demographic characteristics (index year, age, sex, race/ethnicity, US region of

residence, and health plan type at index) between cohorts. The narcolepsy cohort was stratified into two subgroups: higher-risk (≥ 1 sodium-associated risk factor during the 12-month pre-index period) and lower-risk (no risk factors in the pre-index period). Based on pragmatic literature review and clinical expert discussion, sodium-associated NCOs were defined as cardiovascular (hypertension, stroke, transient ischaemic attack, heart failure, major adverse cardiovascular event [MACE; ie, heart failure, stroke, myocardial infarction, unstable angina, or coronary revascularisation procedures]), cardiometabolic (oedema), and renal (kidney failure, chronic kidney disease, proteinuria) conditions. Development of incident NCOs or progression of NCOs were identified during the post-index period. Risk was compared between the narcolepsy and non-narcolepsy cohorts and between the higher-risk and lower-risk narcolepsy subgroups using weighted and unweighted Cox proportional hazards models. **Results:** Among 29,317 and 146,585 individuals in the narcolepsy and non-narcolepsy cohorts, respectively, demographics were similar after balancing. Mean (standard deviation) age was 41.4 (17.0) and 41.5 (17.3) years, respectively, and 62.1% were female in both cohorts. The narcolepsy cohort had a higher risk (hazard ratio [HR; 95% confidence interval (CI)]) of any NCO (1.79 [1.75–1.83]), hypertension (1.72 [1.67–1.76]), MACE (1.90 [1.76–2.05]), oedema (2.12 [2.00–2.25]), and renal NCOs (1.77 [1.67–1.87]), compared with the non-narcolepsy cohort. Within the narcolepsy cohort, 58.8% ($n=17,227$) of individuals were identified as higher-risk. Risk of any NCO (HR [95% CI]) was elevated among higher-risk versus lower-risk individuals (2.06 [1.97–2.15]). Higher-risk individuals had an increased risk (HR [95% CI]) of hypertension (1.59 [1.52–1.67]), MACE (10.08 [7.87–12.92]), oedema (7.66 [6.51–9.02]), and renal NCOs (6.82 [5.86–7.95]) compared with lower-risk individuals. **Conclusions:** In this real-world study, individuals with narcolepsy had an elevated risk of development or progression of cardiovascular, cardiometabolic, and renal NCOs relative to those without narcolepsy. More than half of individuals with narcolepsy had prior sodium-associated risk factors; these individuals had an increased risk of NCOs relative to those without pre-existing comorbidities. These results emphasise the need to reduce sodium intake and mitigate the risk of NCOs among individuals with narcolepsy. Lowering sodium intake may help to reduce the clinical burden of short- and longer-term sodium-associated NCOs in individuals with narcolepsy. **Acknowledgments:** Funded by Jazz Pharmaceuticals.

Rising Pressure to Understand the Risks of Hypertension in Children with Narcolepsy Type 1

E. Montesano¹, M.E. Garcia², S. Lyon³, J. Worhach¹, G. Wang¹, B. Zhang¹, J. August⁴, K. Maski¹
¹Boston Children's Hospital, Dept of Neurology, Boston, United States, ²Ponce Health Science University, School of Medicine, Ponce, Puerto Rico, ³Boston Children's Hospital, Dept of Cardiology, Boston, United States, ⁴Boston Medical Center, Dept of Neurology, Boston, United States

Introduction: Most children/adolescents with Narcolepsy Type 1 (NT1) are treated with stimulants or modafinil, yet the cardiovascular effects of these medications have not been investigated in this population. We compared vital signs in youth with NT1 before and after exposure to stimulants/modafinil to test the hypotheses that these medications increase rates of elevated blood pressure (BP) and hypertension (HTN) and that body mass index (BMI) influences these outcomes. We also explored whether there was a relationship between baseline HTN risk and features of nocturnal sleep, including percentage of rapid eye movement (REM) sleep and wake/N1(NREM1) index, which is an objective measure of disrupted nighttime sleep (DNS).

Materials and methods: In this retrospective study, we collected electronic medical data including vital signs and polysomnography/multiple sleep latency test (PSG/MSLT) results from 39 youth with NT1 aged 7-18 at three points over 20-month period: baseline (drug-naïve/weaned), after initiating treatment, and after treatment optimization. We performed stepwise regression to determine predictors of baseline elevated BP/HTN. We used McNemar's test and generalized estimating equations to assess the effects of stimulant/modafinil exposure on vital signs.

Results: The prevalence of elevated BP/HTN at baseline was 51% in our cohort and increased 21% from baseline to the final visit ($p = .03$). Systolic BP increased significantly with stimulant/modafinil exposure ($p < 0.05$), while diastolic BP and heart rate (HR) showed non-significant increases. BMI was associated with increased systolic BP and HR across the three time points but not at baseline. We did not find any relationship between sleep features and risk of elevated BP/HTN at baseline.

Conclusions: Youth with NT1 are at risk for elevated BP/HTN, particularly after stimulant/modafinil treatment. We recommend revising clinical guidelines to address this risk and advocate for controlled

studies to better understand the cardiovascular risks and implications of these treatments in pediatric NT1.

Risk of Developing Tolerance During Treatment for Excessive Daytime Sleepiness in Patients with Narcolepsy

Y. Winter¹, D. Apel², E. Ellwardt³, S. Javidi⁴, G. Mayer⁵

¹Saarland University Medical Center, Department of Neurology, Homburg, Germany, ²Johannes Gutenberg-University, Department of Neurology, Mainz, Germany, ³Helios-HSK Wiesbaden, Department of Neurology, Wiesbaden, Germany, ⁴Hephata Klinik, Neurology, Schwalmstadt, Germany, ⁵Philipps-University, Neurology, Marburg, Germany

Introduction: Treating excessive daytime sleepiness (EDS) with psychostimulants can potentially lead to tolerance, resulting in a loss of efficacy and the need to continuously increase the medication dosage. However, data comparing the risk of tolerance between different psychostimulants and wake promoters are not currently available. We conducted a long-term observational study to compare the risk of tolerance among three first-line medications approved for treating excessive daytime sleepiness in patients with narcolepsy.

Materials and methods: The prospective observational study included drug-naïve patients with narcolepsy types I and II who received their first monotherapy with modafinil, pitolisant, or solriamfetol for EDS. The study had a long-term follow-up period of seven years. All cases of tolerance were documented, and the incidence of tolerance and changes in medication dosage were compared. The EDS was measured by Epworth Sleepiness Scale (ESS).

Results: Of the 351 study participants, 131 (37.3%) received modafinil, 112 (31.9%) received pitolisant, and 108 (30.8%) received solriamfetol. There were no significant differences in age, gender, or initial ESS scores between the treatment groups. During the study period, 35.9% of patients on modafinil, 14.8% on solriamfetol, and 2.7% on pitolisant developed tolerance ($p < 0.05$). The majority of patients on pitolisant or solriamfetol (94.8%) developed tolerance within the first two years of treatment. Among patients taking modafinil, two patterns of tolerance development were observed. 46.8% percent of tolerance cases occurred within the first two years of therapy, and 44.7% of cases were observed after five years. The following increases in the daily dose were observed among patients who developed tolerance: 184% for modafinil, 116% for solriamfetol, and 78% for pitolisant ($p < 0.05$). No cases of cross-tolerance were observed among patients who switched medications, including those who switched to modafinil, solriamfetol, pitolisant, sodium oxybate, or methylphenidate.

Conclusions: In this study, we found that modafinil was associated with the highest risk of tolerance development in patients treated for narcolepsy with cataplexy (EDS), whereas pitolisant was the most favorable in terms of the risk of tolerance. Additionally, two major patterns of modafinil tolerance development were observed: „early“ tolerance, which occurred within the first two years of treatment, and „late“ tolerance, which develops after five years of therapy. In contrast, solriamfetol and pitolisant mainly had cases of early tolerance. Late tolerance was not typical for these medications.

Risk of New-onset Cardiovascular and Cardiometabolic Conditions in Narcolepsy: An Analysis of the All of Us Research Program

S.C. Markt¹, A. Zhou², K. Irwin³, C. Drachenberg¹, S. Beaty¹, J.M. Stroh³, M. Zagari³, J.K. Alexander¹, M. Whalen⁴, J. Saber³, C.L. Wassel¹, B. Hutchinson⁵

¹Jazz Pharmaceuticals, Palo Alto, United States, ²Genesis Research Group, Hoboken, United States, ³Innopipany, Irvine, United States, ⁴Jazz Pharmaceuticals, Philadelphia, United States, ⁵Chesapeake Cardiac Care, Bowie, United States

Introduction: Narcolepsy is a central disorder of hypersomnolence characterised by excessive daytime sleepiness and disrupted nighttime sleep. The prevalence of cardiovascular and cardiometabolic conditions is higher among individuals with versus without narcolepsy; however, literature on potential differences in new onset of cardiovascular or cardiometabolic conditions between people with and without narcolepsy is limited. This study aimed to evaluate the incidence of hypertension, obesity,

hyperlipidaemia, and coronary arteriosclerosis (CA) among US participants in the *All of Us* Research Program, comparing those with versus without narcolepsy.

Materials and methods: A retrospective, observational cohort study was conducted using electronic health record (EHR) and survey data from *All of Us*, a nationwide initiative aimed at comprehensively characterizing the health of the diverse US population. Participants with narcolepsy were selected using Systematized Nomenclature of Medicine (SNOMED) codes (1/1/2009–31/1/2022). Non-narcolepsy participants were matched 3:1 to those with narcolepsy at index (earliest narcolepsy diagnosis) date on age, sex, earliest EHR, time in EHR, and social determinants of health survey completion. Hypertension, hyperlipidaemia, obesity, and CA were defined using SNOMED codes, in addition to antihypertensive medication use for hypertension. For the total follow-up period, as well as 1-, 3-, and 5-year periods after index, crude incidence rates (IRs) per 100 person-years (PY) were calculated; adjusted hazard ratios (HRs) were estimated using Cox proportional hazards models.

Results: This study included 694 participants with narcolepsy (mean [standard deviation; SD] age: 48.0 [16.8] years; 71.5% female; mean [SD] follow-up: 5.2 [3.5] years) and 2072 without narcolepsy (mean [SD] age: 49.2 [16.4] years; 69.9% female; mean [SD] follow-up: 5.2 [3.5] years). Over the total follow-up, participants with versus without narcolepsy had higher IRs (95% confidence interval [CI]) per 100 PY of hypertension (6.74 [5.91, 7.57] vs 4.00 [3.16, 4.85]), hyperlipidaemia (5.93 [5.08, 6.77] vs 3.57 [2.72, 4.42]), obesity (5.02 [4.19, 5.85] vs 2.53 [1.69, 3.37]), and CA (1.92 [1.07, 2.77] vs 1.07 [0.21, 1.93]). Among participants with narcolepsy, the highest rate of hypertension was in the 1-year follow-up period (16.82 [14.86, 18.78]), followed by the 3-year (10.18 [9.05, 11.31]) and 5-year (7.05 [6.17, 7.92]) follow-up periods. Similar trends were observed for obesity, hyperlipidaemia, and CA. In adjusted models, participants with versus without narcolepsy had significantly higher risk of developing hypertension (HR [95% CI]: 2.02 [1.53, 2.67]), hyperlipidaemia (1.96 [1.52, 2.54]), obesity (2.42 [1.93, 3.05]), and CA (1.75 [1.27, 2.42]) over total follow-up. Those with versus without narcolepsy had a greater risk of developing hypertension at 1-year follow-up (3.84 [2.37, 6.22]); HR (95% CI) was 2.67 (1.89, 3.77) and 2.25 (1.66, 3.06) at the 3- and 5-year follow-up periods, respectively. Similar trends were observed for obesity, hyperlipidaemia, and CA.

Conclusions: Participants with narcolepsy had a higher risk of developing hypertension, hyperlipidaemia, obesity, and CA versus those without narcolepsy. Cardiovascular and cardiometabolic risk should be considered when managing narcolepsy.

Acknowledgments: Funded by Jazz Pharmaceuticals. We gratefully acknowledge *All of Us* participants for their contributions and thank the National Institutes of Health's *All of Us* Research Program for making available the participant data examined in this study.

Safety and Tolerability of Once-Nightly Sodium Oxybate: A Post Hoc Analysis From the Long-Term RESTORE Study

B.C. Corser¹, J. Harsh², J.D. Hudson³, S. Ibrahim⁴, A. Santamaria⁵, P.K. Schweitzer⁶, D. Burroughs⁷, B. Abaluck⁷, J. Gudeman⁷

¹Sleep Management Institute, Cincinnati, United States, ²Colorado Sleep Institute, Boulder, United States, ³FutureSearch Trials of Neurology, Austin, United States, ⁴University Hospitals Cleveland Medical Center, Cleveland, United States, ⁵Northwest Houston Neurology & Comprehensive Sleep Medicine Center, Houston, United States, ⁶Sleep Medicine & Research Center, St. Luke's Hospital, Chesterfield, United States, ⁷Avadel Pharmaceuticals, Chesterfield, United States

Introduction: In the phase 3 REST-ON clinical trial, extended-release, once-nightly sodium oxybate (ON-SXB) demonstrated a safety profile consistent with the known oxybate safety profile, with adverse drug reactions (ADRs) primarily related to tolerability. The long-term safety and tolerability of ON-SXB were investigated in the open-label/switch study RESTORE (NCT04451668).

Materials and methods: Participants in RESTORE were ≥16 years of age with narcolepsy type 1 or 2 who had completed the REST-ON trial (without starting another oxybate), were on immediate-release twice-nightly SXB (TN-SXB) for ≥1 month, or were oxybate naive. For participants who completed REST-ON but had not initiated TN-SXB or who were oxybate naive, ON-SXB was initiated at 4.5 g/night and increased weekly by 1.5 g/night as needed up to 9 g/night during a 1- to 2-month titration period. Participants then received ON-SXB until they could be transitioned to commercial therapy. This analysis included data from participants who completed REST-ON (without starting another oxybate) or who were oxybate naive and received ≥1 dose of ON-SXB (safety population). Safety data are reported

as treatment-emergent adverse events (TEAEs; ie, any AE that occurs during treatment) and ADRs (ie, TEAEs considered drug-related).

Results: Of the 50 participants (mean age, 33 years; female, 60%; white, 80%; mean [range] ON-SXB treatment, 408.1 [8–1098] days) who were from REST-ON (n=15) or were oxybate naïve (n=35), 76% (38/50) reported ≥ 1 TEAE; most were mild (n=18; 36%) or moderate (n=18; 36%) in severity. TEAEs occurring in $\geq 10\%$ of participants included nausea (26%), COVID-19 (12%), somnolence (12%), dizziness (10%), vomiting (10%), sinusitis (10%), and tremor (10%). One (2%) participant reported ≥ 1 serious AE considered related to ON-SXB treatment (anxiety, delusional thoughts) that led to ON-SXB discontinuation. ADRs were reported by 56% (28/50) of participants. ADRs occurring in $\geq 10\%$ of participants included nausea (24%), somnolence (12%), and dizziness (10%). Seven (14%) participants experienced ≥ 1 ADR that led to ON-SXB discontinuation; only nausea led to discontinuation in >1 participant (n=2).

Conclusions: These data from RESTORE demonstrate that REST-ON and oxybate-naïve participants tolerated ON-SXB well, as TEAEs were primarily mild/moderate in severity. ADRs were aligned with the known safety profile of TN-SXB.

Samelisant, a potent and selective histamine H3 receptor inverse agonist: safety, tolerability and pharmacokinetics following single and multiple ascending doses in healthy subjects

V. Benade¹, V.R.C. Palacharla¹, V.K. Goyal¹, S.K. Pandey¹, I. Kalaikadhiban¹, R. Nirogi¹

¹Suven Life Sciences Ltd., Hyderabad, India

Introduction: Samelisant is a potent and selective histamine H3 receptor inverse agonist currently under development for the treatment of excessive daytime sleepiness and cataplexy in patients with narcolepsy. By antagonizing the H3 receptor, Samelisant increases the release of key wake-promoting neurotransmitters, histamine, dopamine, and norepinephrine, in the cortex of rats.

Electroencephalogram (EEG) studies conducted in various rodent models have demonstrated Samelisant's ability to promote wakefulness. These preclinical findings strongly support the therapeutic potential of Samelisant for the management of sleep-related disorders such as narcolepsy.

Materials and methods: In a Phase-1 clinical trial (NCT02342041), safety, tolerability, and pharmacokinetics of Samelisant was evaluated in a single-center, multi-faceted study after single and multiple ascending doses in healthy adult male subjects. In single ascending dose studies, subjects were dosed with Samelisant immediate release tablets in the dose range between 0.1 mg to 20 mg. In multiple ascending dose study, once daily doses of 1 mg to 6 mg Samelisant immediate release tablets were administered for 14 days to healthy adult male subjects. Effect of food, gender and age on Samelisant pharmacokinetics was evaluated in healthy volunteers at the dose of 6 mg (NCT02881294). Samelisant was quantified in plasma and urine using a validated LC-MS/MS method. Safety and tolerability was assessed throughout the study by adverse events, physical examination, vital signs, ECG, clinical laboratory tests, and suicidal ideation/behavior evaluation by Columbia Suicidal Severity Rating Scale (C-SSRS).

Results: Absorption of Samelisant was rapid and exposures (C_{max} and AUC) were dose proportional at the tested doses between 0.1 mg to 20 mg following single oral dose. Samelisant exhibited a 2.2-fold accumulation following multiple dosing in healthy adult subjects. Steady state was achieved on day 6 after multiple dosing. Renal excretion of unchanged drug was the major route of elimination for Samelisant. Food, gender and age had no effect on the Samelisant pharmacokinetics. Samelisant was well tolerated up to the highest tested dose of 20 mg single dose or 6 mg repeated dose in healthy adult subjects. There were no clinically relevant or serious adverse events reported by any subject.

Conclusions: Samelisant has favourable safety and pharmacokinetic profile after single and multiple dose administration for 14 days in healthy adult subjects. Following single or multiple oral administrations, Samelisant exposures were approximately dose proportional at the tested doses. Samelisant was well tolerated in humans with adequate plasma exposure for efficacy and favorable pharmacokinetics suitable for once a day oral administration.

Acknowledgments: None

Samelisant (SUVN-G3031) Alleviates Excessive Daytime Sleepiness in Narcolepsy Patients: Results from a Phase-2 Study

R. Nirogi¹, A. Shinde¹, V.K. Goyal¹, P. Jayarajan¹, V.R.C. Palacharla¹, S. Jetta¹

¹Suven Life Sciences Ltd., Hyderabad, India

Introduction: Narcolepsy is a chronic sleep disorder characterized by excessive daytime sleepiness (EDS), uncontrollable sleep attacks, cataplexy, hypnagogic hallucinations, and sleep paralysis. Current treatments for narcolepsy often come with significant limitations, such as side effects, limited efficacy, or the necessity of combining multiple therapies. Samelisant is a selective inverse agonist of histamine 3 receptors, showing promising potential as a monotherapy treatment for this condition. In preclinical studies involving orexin knockout mice, Samelisant demonstrated wake-promoting effects and reduced cataplexy, underscoring its therapeutic potential. Samelisant safety/tolerability has been established in healthy subjects. The objective the study was to assess the efficacy and safety of Samelisant in treating EDS in patients with narcolepsy.

Materials and methods: Samelisant was evaluated as a monotherapy in a Phase 2 proof-of-concept study conducted across the United States and Canada for the treatment of excessive EDS in patients with narcolepsy (NCT04072380). The study enrolled adult patients aged 18 to 65 years, diagnosed with narcolepsy according to ICSD-3 criteria. Eligible participants had an Epworth Sleepiness Scale (ESS) score of ≥ 12 and a mean sleep latency of < 12 minutes on the Maintenance of Wakefulness Test (MWT). A total of 190 patients were randomized in a 1:1:1 ratio to receive either placebo, Samelisant 2 mg, or Samelisant 4 mg once daily for 14 days. The primary efficacy endpoint was the change in ESS score from baseline to Day 14. Secondary and exploratory endpoints included changes from baseline in Clinical Global Impression–Severity (CGI-S), MWT, and Patient Global Impression–Change (PGI-C) scores. Safety assessments included adverse events, physical examination, vital signs, ECG, clinical laboratory tests, and suicidal ideation/behavior evaluation by Columbia Suicidal Severity Rating Scale (C-SSRS).

Results: Samelisant achieved primary efficacy endpoint demonstrating a statistically significant ($p < 0.024$) and clinically meaningful reduction (-2.1 point) in ESS total score compared to placebo. Treatment with Samelisant resulted in a significant improvement in EDS on scales assessed by both clinicians and patients.

Samelisant was generally safe and well tolerated in narcolepsy patients and there were no serious events or death reported.

Conclusions: Samelisant holds promise as a monotherapy for the treatment of EDS in narcolepsy, and a global Phase-3 study will be initiated in H2 2025 to evaluate its efficacy in narcoleptic patients.

Single-cell RNA and TCR sequencing of cerebrospinal fluid cells from patients with recent-onset type 1 narcolepsy

S. Yue¹, Y. Hou¹, P. Xue¹, X. Dong¹, F. Han¹

¹Peking University People's Hospital, Department of Sleep Medicine, Beijing, China

Introduction: Narcolepsy type 1 (NT1) is caused by hypocretin (HCRT) neuron loss in the brain, and highly (98%) associated with human leukocyte antigen (HLA) DQA1*01:02/DQB1*06:02 (DQ0602) allele and T cell receptor (TCR). The strong HLA and TCR association and increased frequencies of CD4⁺ T cells reactive to HCRT in the peripheral blood suggest autoimmunity targeting HCRT. Further, patients with NT1 usually experience cataplexy and have significantly decreased levels of hypocretin-1 (orexin-A) in the cerebrospinal fluid (CSF). The pathogenesis of NT1 is still not completely understood. In this study, we are aiming to explore the autoimmune mechanism of NT1 with single-cell RNA and TCR sequencing of CSF cells.

Materials and methods: In this study, we selected CSF cells from 25 NT1 (duration of the disease < 1.0 year, $n = 15$). As a control, we used CSF cells from 15 patients with rhythm disorders or emotional problems. These cells were thawed and incubated with DNA-barcoded dextramers (dCODE

dextramers) DQ0602 loaded with 16 peptides, including the autoantigen (HCRT) and pandemic 2009 H1N1 (pH1N1) antigen (pHA and NP) peptides that caused a strong immune response in CD4⁺ T cells of patients with NT1 as reported in previous studies. Single-cell RNA sequencing for TCR and whole transcriptome was performed with 10x platform and analyzed with Scanpy.

Results: The frequency of CD4⁺ T cells in NT1 increased significantly compared with the healthy controls. We identified 1421 significant differentially expressed genes (DEGs) in NT1 compared to healthy controls. The most strongly upregulated genes in NT1 as compared to controls were coding for ITK, BRD2, TAGAP, KLF6, EEF2, and CD44. ITK and TAGAP play an important role in various autoimmune diseases, including rheumatoid arthritis, by regulating the proliferation and differentiation of T cells. BRD2 and EEF2 have been studied in neurodegenerative diseases such as Alzheimer's disease and Parkinson's disease. KLF6 and CD44 have respectively been reported to be related to the regulation of sleep duration and cognitive impairment in sleep deprivation.

Conclusions: We confirmed the crucial role of CD4⁺ T cells in the pathogenesis of narcolepsy and suggest that genes related to immunological or neurological diseases likely contribute significantly. These findings provide further insights into narcolepsy mechanisms and identify potential therapeutic targets.

Sleep Architecture With Low-Sodium Oxybate Treatment in Narcolepsy: Results From the DUET Study

C.M. Ruoff¹, L.D. Schneider², R.B. Sangal^{3,4}, D.A. Nichols⁵, T.L. Steininger⁵, D.S. Fuller⁶, M.T. Kirby^{6,7}, J.K. Alexander⁵, E. Mignot⁸

¹Mayo Clinic, Scottsdale, United States, ²Stanford University Center for Sleep Sciences and Medicine, Stanford, United States, ³Sleep and Attention Disorders Institute, Sterling Heights, United States, ⁴Oakland University William Beaumont School of Medicine, Rochester Hills, United States, ⁵Jazz Pharmaceuticals, Palo Alto, United States, ⁶Jazz Pharmaceuticals, Philadelphia, United States, ⁷Department of Psychiatry & Health Behavior, Medical College of Georgia at Augusta University, Augusta, United States, ⁸Stanford University Center for Narcolepsy, Redwood City, United States

Introduction: Jazz DUET (Develop hypersomnia Understanding by Evaluating low-sodium oxybate Treatment) was a phase 4, prospective, multicentre, single-arm, multiple-cohort, open-label study (NCT05875974) evaluating effectiveness of low-sodium oxybate (LXB, Xywav[®]) on daytime and nighttime-related signs and symptoms, including polysomnography (PSG)-based sleep architecture and disrupted nighttime sleep (DNS), in participants with narcolepsy (type 1 [NT1] or 2 [NT2]) or idiopathic hypersomnia. This abstract includes results from the narcolepsy cohort.

Materials and methods: DUET included a screening period (2-week washout for current oxybate users), 8-day baseline period (BL; with overnight PSG and assessments on day 8), 2- to 8-week LXB titration period (LXB initiation with individualised dosing adjustments to achieve optimal dosage), 2-week stable-dose period (SDP), 8-day end-of-treatment period (EOT; with overnight PSG and assessments on day 8), and 2-week safety follow-up. Nocturnal PSGs (*ad libitum* protocol) were scheduled to allow ≥10 hours in bed, unless the participant naturally awakened earlier; bedtime was per habitual bedtime. PSG recordings were centrally scored. Data were analysed in the completer set; least squares mean (LSM) changes were adjusted for baseline values. Total number of shifts from deeper to lighter sleep/wake stages was defined as N1/N2/N3/REM to wake and N2/N3/REM to N1. Key secondary endpoints (total stage shifts, N3 duration) were controlled for multiplicity with sequential testing; *P* values for other comparisons were not controlled for multiplicity.

Results: Fifty-five participants with narcolepsy enrolled and took ≥1 LXB dosage (safety set; NT1, n=26; NT2, n=29); 13 transferred to a different study cohort and 34 completed the study (completer set; NT1, n=16; NT2, n=18). Most participants in the safety set were female (73%) and White (80%) (mean [SD] age, 33.4 [12.9] years). Mean (SE) total sleep time (TST) at BL was 453.2 (13.7) and at EOT was 452.4 (12.0) minutes (LSM change [95% CI]: -0.78 [-23.7, 22.1]; *P*=0.9451). Mean (SE) total number of shifts from deeper to lighter sleep/wake stages at BL was 54.6 (4.8) and at EOT was 41.6 (4.4) (LSM [95% CI]: -13.1 [-19.0, -7.1]; *P*<0.0001). Mean (SE) time spent in N1 sleep at BL was 45.3 (4.9) and at EOT was 37.2 (4.3) minutes (LSM [95% CI]: -8.1 [-14.9, -1.4]; *P*=0.0196), percentage of

sleep stage per TST was 10.4% and 8.2% ($P=0.0037$); in N2 sleep, 241.8 (10.5) and 243.3 (13.0) minutes (LSM [95% CI]: 1.5 [-23.6, 26.6]; $P=0.9040$), 53.1% and 53.2% ($P=0.9869$); in N3 sleep, 61.1 (6.0) and 106.1 (11.9) minutes (LSM [95% CI]: 45.0 [27.0, 63.0]; $P<0.0001$), 13.7% and 24.0% ($P<0.0001$); and in REM, 105.0 (7.3) and 65.8 (5.7) minutes (LSM [95% CI]: -39.2 [-50.8, -27.5]; $P<0.0001$), 22.8% and 14.7% ($P<0.0001$).

Conclusions: Participants with narcolepsy taking open-label LXB experienced changes in duration and percentage of individual sleep stages, including increased N3 sleep and decreased N1 and REM, consistent with previous oxybate studies. Changes in N2 sleep and TST were negligible. Fewer shifts from deeper to lighter stages of sleep/wake were observed, suggesting improvement in DNS. These findings represent the first evaluation of LXB on PSG sleep architecture in individuals with narcolepsy.

Chesterfield, United States, ⁷Avadel Pharmaceuticals, Chesterfield, United States

Introduction: Extended-release, once-nightly sodium oxybate (ON-SXB; LUMRYZ™) eliminates the middle-of-the-night dosing required with immediate-release, twice-nightly oxybates (TN-OXBs). RESTORE (NCT04451668) was an open-label/switch study that assessed the safety and tolerability of ON-SXB in people with narcolepsy.

Materials and methods: Participants with narcolepsy aged ≥ 16 years who had completed the phase 3 REST-ON trial, were on stable-dose TN-OXB (switch participants), or were oxybate-naïve were eligible. For switch participants, initial ON-SXB doses were equivalent or closest to their prior total nightly TN-OXB dose. Doses could be titrated at ± 1.5 g/week until stable dosing was achieved (minimum, 4.5g/night; maximum, 9g/night). Treatment-emergent adverse events (TEAEs) during the 8-week dose titration period were recorded weekly for switch participants in the safety population (ie, received ≥ 1 ON-SXB dose) who completed a nocturnal AE questionnaire.

Results: Safety data were collected for 99.2% (129/130) of switch participants. All TEAEs reported by $\geq 3\%$ of switch participants occurred during weeks 1-3; no TEAEs $\geq 3\%$ were reported during weeks 4-8. At week 1, TEAEs $\geq 3\%$ included nausea (3.2%), vomiting (3.2%), decreased appetite (3.2%), and urinary retention (3.2%) with the 6-g dose, and headache (7.0%) and somnolence (4.7%) with 9g. At week 2, TEAEs $\geq 3\%$ included nausea (3.2%), upper respiratory infection (3.2%), dizziness (3.2%), and hypertension (3.2%) with 6g. At week 3, TEAEs $\geq 3\%$ included vomiting (3.2%), enuresis (3.2%), insomnia (3.2%), and somnambulism (3.2%) with 6g. No TEAEs $\geq 3\%$ were reported with 4.5g during weeks 1-3, or with 7.5g or 9g during weeks 2-3. Most TEAEs were mild or moderate in severity. The only reported severe TEAE was dyskinesia (1.2%) with the 7.5-g dose. During the ≥ 3 -year RESTORE study, only 5.4% of switch participants discontinued ON-SXB due to a TEAE.

Conclusions: For participants switching from stable-dose TN-OXB, ON-SXB was well tolerated during the 8-week titration period, with most TEAEs being of mild to moderate severity and consistent with the oxybate safety profile. By week 4, no TEAEs were reported by $\geq 3\%$ of participants, suggesting resolution of many TEAEs during titration. Participants successfully switched to ON-SXB from their nearest or equivalent prior total nightly TN-OXB dose.

Introduction: Central disorders of hypersomnolence (CDH) are neurological conditions characterized by excessive daytime sleepiness and/or increased sleep duration. Narcolepsy type 1 is distinguished by hypothalamic hypocretin-1 deficiency. The aim of this study was to identify key symptoms in addition to cataplexy that indicate hypocretin-1 deficiency, and to investigate the relationship between CDH symptom presentation and varying CSF hypocretin-1 levels.

Materials and methods: This study was based on data from the European Narcolepsy Network (EU-NN) database. 302 CDH patients from the EU-NN database were included, with 257 individuals exhibiting low hypocretin-1 (<200 pg/mL), including 163 individuals < 40 pg/mL, 59 between 41-110 pg/mL and 35 between 110-200 pg/mL. 45 individuals had hypocretin-1 levels >200 pg/mL. A machine learning approach using stochastic gradient boosting (SGB) was employed to explore non-linear associations and identify symptoms predictive of hypocretin-1 deficiency. Using logistic regression and quantile regression models we analyzed the association between absolute hypocretin-1 levels (independent variable) and 26 variables on demographics, subjective symptom severity, objective polysomnography and MSLT measures (dependent variables) while adjusting for age, sex and BMI. Cataplexy features were only analyzed in individuals with low hypocretin-1 <200 pg/mL. All CSF hypocretin-1 measurements were performed using standardized radioimmunoassay (RIA) protocols harmonized across EU-NN centers.

Results: Using machine learning, we identified previously underappreciated predictors of hypocretin-1 levels, including PSG sleep latency and REM sleep latency. Regression analyses further confirmed that lower hypocretin-1 levels were associated with shorter REM sleep latency and sleep latency in both MSLT and PSG, more SOREMPs, higher Epworth Sleepiness Scale scores, increased PLMI, and more frequent reports of disturbed nocturnal sleep. Among individuals with cataplexy and hypocretin-1 levels below 200 pg/mL, lower levels were further linked to earlier excessive daytime sleepiness onset, younger age at diagnosis, and greater diagnostic certainty of hypnagogic hallucinations and sleep paralysis. Moreover, lower hypocretin-1 levels were significantly associated with more frequent and complete cataplexy episodes. Interestingly, sleep drunkenness was more prevalent among individuals with higher hypocretin-1 levels and was associated with longer reported daytime sleep duration.

Conclusions: Lower hypocretin-1 levels were associated with more severe symptoms, both across the overall CDH population and within the subgroup of cataplexy patients with hypocretin deficiency (<200 pg/mL). Even within the deficient range, variation in hypocretin-1 levels contributed to individual differences in symptom presence and severity. These findings suggest that hypocretin-1 plays a greater role in shaping the clinical heterogeneity of CDH than previously appreciated.

The diagnostic value of EEG-MSLT in narcolepsy type 1

Q. Ding¹, X. Luo², Y. Zuo¹, B. Zhou¹, X. Dong¹, C. Li², F. Han¹

¹Peking University People's Hospital, Department of Sleep Medicine, Beijing, China, ²Chongqing Traditional Chinese Medicine Hospital, Sleep Medicine Center, Chongqing, China

Introduction: The diagnosis of narcolepsy type 1 (NT1) currently requires polysomnography-multiple sleep latency tests (PSG-MSLT). However, PSG-MSLT are inaccessible in most of the Chinese hospitals. This study aimed to evaluate the diagnostic value of electroencephalogram multiple sleep latency tests (EEG-MSLT) for NT1 and explore its potential as an alternative to PSG-MSLT.

Materials and methods: Patients included were children (<18 years old) presented with EDS and admitted to the Department of Sleep Medicine, Peking University People's Hospital, between October 2019 and October 2024. They all underwent EEG-MSLT and PSG-MSLT. HLA-DOB1*06:02 genotyping and cerebrospinal fluid (CSF) hypocretin-1 testing were measured if feasible. Kappa statistic was used for consistency analysis.

Results: 49 patients (28 males, 21 females; age: 9.61 ± 3.27 years) were included. All patients presented with excessive daytime sleepiness (EDS), alongside clinical manifestations including cataplexy (n = 45, 91.8%), sleep paralysis (n = 13, 26.5%), and hallucinations (n = 25, 51.0%). CSF hypocretin-1 testing in 29 patients revealed 27 (93.1%) had levels ≤ 110 pg/ml, while HLA-DQB1*06:02 genotyping was positive in 41 of 48 cases (83.7%).

EEG-MSLT yielded a mean sleep latency (mSL) of 4.53 ± 3.26 minutes, with 22 patients showing ≥ 2 sleep-onset rapid eye movement periods (SOREMPs). In comparison, PSG-MSLT demonstrated a significantly shorter mSL (3.14 ± 3.24 minutes, $P < 0.05$) and more frequent SOREMPs ($P < 0.001$), with 45 patients having ≥ 2 SOREMPs. These results indicate EEG-MSLT underestimates NT1 diagnostic markers.

EEG-MSLT showed limited diagnostic performance for children NT1, with a sensitivity of 42.86% and specificity of 57.14%, reflecting poor discriminative capacity. A Kappa consistency test ($\kappa = 0.065$, $P = 0.482$) revealed no significant agreement between EEG-MSLT and PSG-MSLT.

Conclusions: In real-world clinical settings, EEG-MSLT demonstrates insufficient sensitivity and specificity for NT1 diagnosis in children compared to PSG-MSLT. Further optimization or combination with other methods is needed.

The Effect of Pitolisant on Sleep-Promoting Neurons

R. De Luca¹, J. Choi¹, E. Rilloi¹, C. Gylling Hviid², T. Scammell¹, E. Arrigoni¹

¹Beth Israel Deaconess Medical Center, Neurology, Boston, United States, ²University of Copenhagen, Neuroscience, Copenhagen, Denmark

Introduction: Pitolisant is an H3 receptor antagonist/inverse agonist indicated for the treatment of excessive daytime sleepiness in people with narcolepsy. It is currently believed to promote wakefulness by directly activating the cortex and other brain regions through release of histamine (HIS), norepinephrine (NE), and other neurotransmitters. However, wakefulness requires both the activation of arousal-promoting neurons and the inhibition of sleep-promoting neurons, including those in the ventrolateral preoptic (VLPO) nucleus. Sleep-active, sleep-promoting neurons in the VLPO express GABA and the neuropeptide galanin (VLPO^{Gal}), and these VLPO^{Gal} neurons are both necessary and sufficient for normal sleep. In this study, we tested the hypothesis that pitolisant may also promote wakefulness by inhibiting VLPO^{Gal} sleep-promoting neurons.

Materials and methods: We used the GPCR activation-based (GRAB) sensor for norepinephrine (GRAB_{NE}) to measure changes in NE levels in the VLPO after intraperitoneal (ip) injection of pitolisant in mice. We expressed GRAB_{NE} in the VLPO region, and implanted a fiberoptic cannula above the VLPO

to measure changes in NE levels via fiber photometry. In a second set of experiments, we investigated the effects of pitolisant on VLPO^{Gal} neurons in mouse brain slices using whole-cell patch-clamp recordings.

Results: We found that ip injection of pitolisant (5, 10 and 20 mg/Kg) increased wakefulness and elevated NE concentrations in the VLPO in a dose-dependent manner. In brain slices, pitolisant inhibited the firing of VLPO^{Gal} neurons, but this effect was indirect. Consistent with this, we found that VLPO^{Gal} neurons do not express H3 receptors. Instead, pitolisant indirectly inhibits VLPO^{Gal} neurons by activating local GABAergic interneurons, which in turn suppress VLPO^{Gal} neuronal activity. These interneurons express H3 receptors and inhibit VLPO^{Gal} neurons through local axonal collaterals. Additionally, pitolisant locally increases NE, which directly inhibits VLPO^{Gal} neurons via $\alpha 2$ -adrenergic receptors and indirectly via $\alpha 1$ -adrenergic receptors by activating the same GABAergic interneurons targeted by pitolisant.

Conclusions: These results suggest that, in addition to direct activation of wake-promoting brain regions, pitolisant also promotes arousal by inhibiting sleep-promoting neurons in the VLPO. Pitolisant's actions in the VLPO involve activation of a local GABAergic circuit via H3 receptors plus the release of NE, both of which contribute to the inhibition of VLPO^{Gal} neurons.

Acknowledgments: This research was supported by a grant from Harmony Biosciences.

The First Light: Efficacy and Safety of a Multi-Dose Study of Oveporexton (TAK-861), an Oral Orexin Receptor 2 Agonist for the Treatment of Narcolepsy Type 1

Introduction: Narcolepsy type 1 (NT1) is a neurologic disorder characterized by excessive daytime sleepiness, sudden muscle weakness triggered by emotions (cataplexy), disrupted nighttime sleep, sleep paralysis, hypnagogic/hypnopompic hallucinations, and cognitive symptoms. NT1 is caused by loss of orexin producing neurons in the hypothalamus, which regulate wakefulness, sleep and cognition. Re-establishing orexin transmission with orexin receptor agonists is a promising therapeutic approach for NT1. In phase 2 studies, oveporexton (TAK-861), an investigational oral orexin receptor 2 (OX2R)-selective agonist, was generally well tolerated and delivered sustained improvements across the spectrum of NT1 symptoms, assessed by both objective and patient-reported measures. Here, we report results from a phase 3 study that evaluated the efficacy, safety and impact on functioning, quality of life and cognition of oveporexton in participants with NT1.

Materials and methods: This randomized, double-blind, placebo-controlled study (TAK-861-3001) included adults aged 16–70 years across Europe, Japan, and North America with an International Classification of Sleep Disorders, Third Edition (ICSD-3) or ICSD-3-text revision diagnosis of NT1 supported by sleep tests or orexin CSF concentrations ≤ 110 pg/mL; Epworth Sleepiness Scale (ESS) score ≥ 11 ; and ≥ 4 partial/complete episodes of cataplexy/week without treatment. Participants were randomized 3:3:2 to twice-daily oral oveporexton 1 mg, oveporexton 2 mg, or placebo at least 3 hours apart for 12 weeks, after which participants either completed 4 weeks follow-up or entered the long-term extension study. The primary endpoint was change from baseline in mean sleep latency on the

Maintenance of Wakefulness Test (MWT) at week 12. Secondary endpoints included change from baseline in ESS total score at week 12, weekly cataplexy rate (WCR) at week 12, and occurrence of treatment-emergent adverse events (TEAEs).

Results: Overall, 168 participants (98 [58.3%] female) were randomized to ovesporexton 1mg/1mg (n=61), ovesporexton 2mg/2mg (n=66), or placebo (n=41). At baseline, mean age was 31.4 years and, mean ESS score was 18.5, mean MWT sleep latency was 5.0 minutes and median WCR was 26.0 attacks/week. At week 12, statistically significant least square (LS) mean (95% CI) changes from baseline were achieved with ovesporexton 1mg/1mg and 2mg/2mg vs placebo in MWT sleep latency (13.83 [10.23, 17.44] and 17.20 [13.66, 20.73] minutes vs placebo, respectively; both $P < 0.001$), and ESS total score (-8.00 [-9.87, -6.13] and -9.75 [-11.59, -7.90] vs placebo, respectively; both $P < 0.001$). Incidence rate ratios of WCR at week 12 for ovesporexton vs placebo were 0.34 (1mg/1mg) and 0.38 (2mg/2mg) (both $P < 0.001$ vs placebo). Overall, 88.1% of ovesporexton-treated participants (111/126) experienced ≥ 1 TEAEs versus 53.7% (22/41) with placebo. The most common TEAEs were pollakiuria and insomnia; there were no treatment-related serious TEAEs. 157 (93.5%) participants completed the study, of which 150 (95.5%) enrolled into the long-term extension study.

Conclusions: In this phase 3 study ovesporexton showed significant improvements versus placebo on subjective and objective measures of wakefulness, sleepiness and cataplexy frequency and was generally well tolerated.

The prevalence and treatment of narcolepsy in New Zealand

A. Neill¹, A. Campbell¹, N. Hutchison-Wong¹

¹University of Otago, Wellington, WellSleep, Department of Medicine, Wellington, New Zealand

Introduction: No previous New Zealand-research on the epidemiology of narcolepsy or its medical management have been reported.

This study aimed to:

1. Estimate the incidence and prevalence of narcolepsy.
2. Describe trends in the medication types and demographics of prescriptions.

Materials and methods: National case numbers in 2021-2023 were collated from all sleep centres providing testing for narcolepsy and used to estimate incidence and prevalence. Concurrently, all narcolepsy-related special authority (SA) prescription approvals from Pharmac New Zealand in 2021-2023 were analysed by medication type and demographics.

Results: Between 2021-2023, 348 MSLT tests for narcolepsy revealed 56 cases, giving an incidence of 0.36 per 100,000 person-years and a prevalence of 21.9 cases per 100,000 people. During this period Pharmac approved 762 requests for narcolepsy-medications, of which 263 were new (i.e. not repeats or renewals). Between 2021 and 2023, a total of 223 new and 762 overall (including repeats and renewals) Special Authority (SA) applications were submitted to Pharmac, all of which were approved. The annual average of new SA applications was 74.3 per year, which was 3.9 times higher than the average sleep laboratory diagnosed annual cases narcolepsy (19 cases per year). For new and overall applications For both new and overall applications, MPHIC was slightly preferred over MF, accounting for 53.8% and 57.9% of applications, respectively. Methylphenidate accounted for 53.8% new and total 57.9% applications; Modafinil for 46.2% new and total 42.6% respectively. There was variation in prescribing for regions, age, gender, and ethnicity were observed .

Conclusions: This study provided the first New Zealand-based estimates of incidence and prevalence for narcolepsy . The number of new Special Authority (SA) applications for narcolepsy medications was significantly higher than the new narcolepsy cases objectively diagnosed. Potential reasons include: disparity / difficulty accessing sleep labs; being treated with multiple medications and patients with Idiopathic Hypersomnolence (IH) being treated under narcolepsy-related SA category. We recommend Pharmac develop & fund separate criteria for the treatment of Idiopathic Hypersomnolence and the New Zealand Ministry of Health fund services to improve access for objective sleep laboratory testing and education/ implementation support for professional bodies.

Acknowledgments: University of Otago Summer Studentship; Pharmac; New Zealand Sleep Services for case numbers (New Zealand Respiratory and Sleep Institute (NZRSI) Auckland, Auckland City hospital, Waikato hospital, Christchurch Hospital, and Dunedin Hospital)

Introduction: Narcolepsy type 1 (NT1) is a chronic, rare, neurologic disorder of hypersomnolence caused by loss of orexin-producing neurons in the hypothalamus, which regulate wakefulness, sleep, and attention through activation of orexin receptors. NT1 results in a range of symptoms including excessive daytime sleepiness, sudden muscle weakness (cataplexy), disrupted nighttime sleep, sleep paralysis, hypnagogic/hypnopompic hallucinations, and cognitive symptoms. Orexin receptor agonists are promising treatments for NT1 as currently available therapies do not target orexin deficiency. Oveporexton (TAK-861) is an investigational oral orexin receptor 2 (OX2R)-selective agonist that stimulates OX2R to restore signaling and address the underlying orexin deficiency. In a previous phase 2b study, oveporexton delivered improvements across the spectrum of NT1 symptoms, assessed by both objective and patient-reported measures, and was generally well tolerated. Here, we report first results from a phase 3 study that evaluated the efficacy, safety and impact on functioning, quality of life and cognition of oveporexton in participants with NT1.

Materials and methods: In this double-blind, placebo-controlled, phase 3 study (TAK-861-3002) participants were randomized 2:1 to oral oveporexton 2 mg or placebo twice daily at least 3 hours apart for 12 weeks. At the end of treatment, participants either entered the long-term extension or completed 4 weeks of follow up. Key inclusion criteria included: age 16–70 years; International Classification of Sleep Disorders, Third Edition (ICSD-3) or ICSD-3-text revision diagnosis of NT1 supported by polysomnography, multiple sleep latency testing (MSLT) or orexin cerebrospinal fluid (CSF) concentrations ≤ 110 pg/mL; Epworth Sleepiness Scale (ESS) score ≥ 11 ; and ≥ 4 partial/complete episodes of cataplexy/week. The primary endpoint was change from baseline in mean sleep latency on the Maintenance of Wakefulness Test (MWT) at week 12. Secondary endpoints included change from baseline in ESS total score at week 12, weekly cataplexy rate (WCR) at week 12, and occurrence of treatment-emergent adverse events (TEAE).

Results: Overall, 105 participants (50 [47.6%] female) were enrolled across Asia, Australia, and Europe; 70 were randomized to oveporexton 2 mg/2 mg and 35 to placebo. At baseline, mean age was 30.7 years, mean ESS score was 17.5, mean MWT sleep latency was 4.5 minutes and median WCR was 23.5 attacks/week. At week 12, significant least square (LS) mean (95% CI) changes from baseline were achieved with oveporexton 2mg/2mg vs placebo in MWT sleep latency (20.09 [16.57, 23.61] minutes, $P < 0.001$ vs placebo). Significant changes vs placebo were also achieved at week 12 for ESS total score (LS mean [95% CI] change from baseline: -9.53 [-11.10, -7.97], $P < 0.001$) and WCR (Incidence rate ratio [95% CI] vs placebo: 0.25 [0.15, 0.42], $P < 0.001$). Sixty (85.7%) oveporexton-treated participants experienced ≥ 1 TEAEs vs 15 (42.9%) placebo-treated participants; there were no serious TEAEs. The most common TEAEs with oveporexton were pollakiuria (43 [61.4%]) and insomnia (40 [57.1%]). 101 (96.2%) completed study treatment, of which 100 (99.0%) enrolled into the long-term extension.

Conclusions: In this phase 3 study, oreporexton treatment resulted in significant improvements on measures of wakefulness, sleepiness and cataplexy frequency with oreporexton versus placebo, and was generally well tolerated.

Treatment Considerations in Co-morbid Schizophrenia and Narcolepsy: A Case Report

M.S. Mak¹, M.J. Gazzellone¹, Z.L. Adirim¹, B.J. Murray²

¹University of Toronto, Psychiatry, Toronto, Canada, ²University of Toronto, Neurology, Toronto, Canada

Introduction: Narcolepsy affects 1 in 2000 people and causes disabling sleepiness. Schizophrenia, a common psychotic disorder, affects 1 in 133 people and confers significant impairments across domains. Rates of co-occurrence is not exactly known. One cohort study observed 8.1% of persons with narcolepsy (PWN) as having a psychosis comorbidity and a 4-fold greater risk for psychosis in PWN. Some alertness promoting medications used in narcolepsy treatment, such as modafinil, methylphenidate and amphetamine, may exacerbate psychosis by increasing dopamine activity. There are case reports of sodium oxybate exacerbating psychosis

Materials and methods: A 21-year-old man with was admitted for auditory hallucinations and bizarre behaviour. He put his cell phone in his microwave to prevent his conversations from being overheard. He was diagnosed with schizophrenia.

The patient had a PSG + MSLT confirmed diagnosis of narcolepsy with cataplexy that predated this by 9 years.

His methylphenidate extended-release 20mg was discontinued for concerns that it was precipitating psychosis. He was previously intolerant to modafinil (emotional numbing) and Concerta (appetite suppression) as per chart review.

Paliperidone was effective for psychosis but worsened sleepiness, which was disabling. The patient would fall asleep during in-patient assessments. A retrial of modafinil worsened auditory hallucinations and delusions of persecution, and discontinued. He was discharged on paliperidone IM with well-controlled psychosis but sleepiness remained.

Results: As an outpatient, caffeine 100mg up to 4x per day PRN was trialed but insufficient in promoting meaningful improvements to wakefulness. A new pitolisant was initiated to treat sleepiness and cataplexy, and was successful to a material degree without exacerbation of psychosis. Unfortunately, after 8 weeks of treatment, the patient lost access to pitolisant for one month due to insurance coverage issues, during which his irresistible sleepiness and cataplexy returned. The pitolisant was restarted upon insurance approval, and his wakefulness and cataplexy again improved. He remains stable on pitolisant 40mg and paliperidone 75mg IM q4 weekly. He has residual but non-disabling sleepiness. We have asked him to use PRN caffeine judiciously to buttress wakefulness.

Conclusions: In conclusion, some traditional stimulants may worsen psychosis in PWN. Pitolisant, an inverse H3 agonist, which does not theoretically affect dopamine pathways, may be a suitable treatment for sleepiness and cataplexy in comorbid psychosis.

Understanding Path to Diagnosis, HCP Relationships, and Treatment Regimens Among People Living With Narcolepsy

L.E. Ortiz⁴, H. Merius², M. Lavender¹, A.M. Morse⁵, B. Schneider³, D. Cronin³, J. Gudeman⁶

¹Johns Hopkins Medical Institutions, Johns Hopkins All Children's Hospital, St. Petersburg, United States, ²Stony Brook Medicine, Smithtown, United States, ³Comprehensive Sleep Medicine Associates, Houston, United States, ⁴Geisinger Commonwealth School of Medicine, Geisinger Medical Center, Janet Weis Children's Hospital, Danville, United States, ⁵MyHealthTeam, San Francisco, United States, ⁶Avadel Pharmaceuticals, Chesterfield, United States

Introduction: Narcolepsy is a chronic, disabling hypersomnolence disorder requiring lifelong management. People with narcolepsy (PWN) often experience diagnostic delays and difficulties with

quality care, including healthcare provider (HCP)- and treatment-related challenges. This survey assessed the path to diagnosis, HCP relationships, and treatment regimens among PWN from MyNarcolepsyTeam, a social network of >11,000 members.

Materials and methods: MyNarcolepsyTeam members were invited to participate in a 36-question online survey fielded between April 10 and May 9, 2024. Eligible participants had a narcolepsy diagnosis, were age ≥ 21 years, and resided in the United States. Data were analyzed descriptively.

Results: Of 88 total respondents (female, 77%; age ≥ 50 years, 74%), 39% had narcolepsy type 1, 50% had narcolepsy type 2, and 11% were unsure. Most (81%) respondents saw ≥ 2 clinicians to receive a diagnosis; 36% visited ≥ 5 clinicians. 98% had undergone ≥ 1 sleep study, which was the most common diagnosis method (83%). Following diagnosis, 68% of respondents visited multiple HCPs to address narcolepsy symptoms. Of 82 respondents currently seeing an HCP, 56% were extremely/very satisfied with their clinician. Satisfaction was higher among respondents seeing sleep specialists vs non-sleep specialists (70% vs 38%). More respondents seeing sleep specialists vs non-sleep specialists reported discussions that address mental health (48% vs 31%) and long-term planning (38% vs 15%). Fifty percent of respondents currently seeing an HCP discussed the advantages and disadvantages of treatments with their HCP. Seventy-nine (90%) respondents were taking ≥ 1 medication to treat their symptoms; 67% took ≥ 2 medications. Current medications for narcolepsy most commonly included traditional stimulants (56%; [Adderall®, Ritalin®, etc.]) and antidepressants (38%). Nearly half of respondents (44%) found their treatment regimen extremely/very/somewhat challenging, of whom 83% were taking multiple medications. Reported treatment challenges included loss of efficacy, side effects, access barriers, and the complexity of medication regimens.

Conclusions: These findings highlight the challenges PWN face, emphasizing the need for expedited diagnosis and access to specialized healthcare. Despite greater satisfaction with care from sleep medicine specialists, there is a shortage in this field. This gap underscores the necessity for improved treatment regimens and enhanced discussions between PWN and HCPs to address mental health support and long-term planning.

Validation of Waveband for Evaluation of Sleep in Hypersomnia Disorders

R. Reh¹, M. Karas², A.M. Chan¹, J. Pathmanathan¹, J. Nerrie¹, S.F. Saviotto¹, M. Harris¹, K. Placek², P. Tierney², T. Yardibi², E. Mignot³, J. Donoghue¹, D. Hwang⁴, D. Volfson²

¹Beacon Biosignals, Inc., Boston, MA, United States, ²Takeda Development Center Americas, Inc., Cambridge, MA, United States, ³Stanford Center for Sleep Sciences and Medicine, Stanford University, Palo Alto, CA, United States, ⁴Fontana Medical Center, Kaiser Permanente, Fontana, CA, United States

Introduction: Narcolepsy type 1 (NT1) is a rare neurologic disorder linked to orexin deficiency and characterized by excessive daytime sleepiness, cataplexy, hallucinations, sleep paralysis, and disrupted nighttime sleep. NT1 diagnosis and clinical trials evaluating NT1 therapies currently rely on in-clinic polysomnography (PSG) and Multiple Sleep Latency Test, which are time-consuming, burdensome, uncomfortable for patients, and require trained personnel. Unfortunately, PSG is unable to readily capture sleep variability across nights and may not reflect a natural sleep environment. NCT06531876 is a prospective clinical validation study to evaluate Waveband (formerly referred to as Dreem 3S), an FDA-cleared at-home dry-electrode encephalography device, in individuals with suspected hypersomnia disorders and those with confirmed NT1 to understand wear compliance, data quality, and sleep staging accuracy.

Materials and methods: Data from 68 participants were analyzed, including 17 with suspected disorders of primary hypersomnia (Arm A) and 51 with investigator-confirmed NT1 diagnoses (Arm B). Participants recorded six nights of sleep and one 24-hour monitoring period with Waveband at home, followed by one (Arm A) or two (Arm B) nights of in-clinic PSG with concurrent Waveband. At-home wear compliance was measured by algorithmically detected “on-head” device wear time and data quality was assessed using the Waveband “scorability” algorithm. PSG was scored by three Registered Polysomnography Technologists (RPSGTs). In-clinic Waveband data were automatically scored using a

proprietary sleep-staging algorithm and algorithmic results were adjudicated by three RPSGTs.

Perceived usability of Waveband and PSG was assessed using the System Usability Scale (SUS).

Results: At-home wear compliance and data quality benchmarks were met: 100% of participants had four or more overnight recordings (mean $\pm$ SD; Arm A: 5.9 $\pm$ 0.2; Arm B: 5.5 $\pm$ 0.7) with at least four hours of wear time and 85% of that being "scorable" data. For the 24-hour period, 100% of Arm A participants and 90% of Arm B participants had at least 17 hours of wear time (Arm A: 22.8 $\pm$ 1.6; Arm B: 22.1 $\pm$ 3.0) with at least 85% of that being "scorable" data. SUS scores for Waveband (Arm A: 76.2 $\pm$ 11.8; Arm B: 77.6 $\pm$ 13.6) were higher than for PSG (Arm A: 52.8 $\pm$ 18.3; Arm B: 49.9 $\pm$ 19.7). Agreement of adjudicated Waveband and PSG was high across sleep stages, with mean Cohen's Kappa of 84.1 % (Arm A) and 77.7% (Arm B). By stage, overall/positive/negative agreement was 97.8/86.4/99.3% (wake), 96.1/46.7/98.9% (NREM1), 91.0/87.9/92.9% (NREM2), 95.4/93.8/95.3% (NREM3) and 97.9/95.6/98.4% (REM) for Arm A participants and 95.6/84.4/97.2% (wake), 94.8/44.4/98.5% (NREM1), 89.3/85.1/92.2% (NREM2), 96.0/88.5/96.5% (NREM3) and 94.0/86.6/95.6% (REM) for Arm B participants. Unadjudicated Waveband and PSG agreement was similarly high.

Conclusions: These results provide validation and feasibility data that support using Waveband to collect high-quality sleep data and quantify sleep stages in a hypersomnia population. Waveband could provide insight into diagnosis, treatment response and disease progression. Further, Waveband has potential to be used as an alternative to PSG for monitoring sleep longitudinally in a patient's home, thereby improving data quality and collection with multiple measurements at a lower burden and cost.

Vibrance-1: A Randomized Phase 2 Study Evaluating Safety and Efficacy of the Orexin 2 Receptor Agonist Alloxorexton (ALKS 2680) in Patients with Narcolepsy Type 1

G. Plazzi¹, Y. Dauvilliers², R.R. Grunstein³, E. Mignot⁴, G.J. Lammers^{5,6}, D.T. Plante⁷, E. Buntinx⁸, R. del Río Villegas⁹, H. Chen¹⁰, A. Lovett¹⁰, C. Hopkinson¹⁰, B. Rege¹⁰, M. Yountz¹⁰

¹IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy, ²University of Montpellier, INSERM Institute for Neurosciences of Montpellier, Montpellier, France, ³Woolcock Institute of Medical Research, Macquarie University, Sydney, Australia, ⁴Stanford Center for Sleep Sciences and Medicine, Stanford University School of Medicine, Stanford, United States, ⁵Leiden University Medical Center, Leiden, Netherlands, ⁶Stichting Epilepsie Instellingen Nederland, Sleep-Wake Centre, Heemstede, Netherlands, ⁷University of Wisconsin-Madison, School of Medicine and Public Health, Madison, United States, ⁸ANIMA Research, Alken, Belgium, ⁹Universidad CEU San Pablo, CEU Universities, Vithas Madrid Hospitals, Madrid, Spain, ¹⁰Alkermes, Inc., Waltham, United States

Introduction: Narcolepsy type 1 (NT1) is a central disorder of hypersomnolence characterized by excessive daytime sleepiness, cataplexy, and hypocretin/orexin deficiency. Alloxorexton (ALKS 2680) is a highly potent, oral, and selective orexin 2 receptor agonist. In a phase 1b study, single doses of alloxorexton were evaluated in patients with NT1, narcolepsy type 2 (NT2), and idiopathic hypersomnia (IH). Focusing on NT1, alloxorexton was well-tolerated and demonstrated dose-dependent improvements in mean sleep latency on the Maintenance of Wakefulness Test (MWT). These findings guided dose selection for the phase 2 Vibrance-1 study. Here we present results obtained during the randomized double-blind treatment period of the Vibrance-1 study.

Materials and methods: Vibrance-1 is a placebo-controlled, dose-ranging phase 2 study with a randomized double-blind parallel group treatment period and an open-label extension period. After 2 weeks of washout, patients with NT1 are randomized 1:1:1:1 to receive placebo or alloxorexton once daily at 4, 6, or 8 mg for 6 weeks. Eligible patients are 18-70 years old with NT1, body mass index (BMI) ≥ 18 and ≤ 40 kg/m², no comorbid sleep-related illness that may influence sleep/wake, no significant cardiovascular or psychiatric conditions, and no activities that interfere with nighttime sleep. The primary endpoint is change from baseline to week 6 in mean sleep latency on the MWT over 4 sessions at 2, 4, 6, and 8 hours post dose. Key secondary endpoints include Epworth Sleepiness Scale (ESS) and weekly cataplexy rate (WCR). Safety is being evaluated by treatment-emergent adverse events, laboratory assessments, vital signs, electrocardiograms, and the Columbia-Suicide Severity Rating Scale.

Results: Ninety-two patients were randomized to placebo or alloxorexton and received ≥ 1 dose of study drug. Patients were enrolled in Europe (n=61 [66%]), the United States (n=23 [25%]), and Australia (n=8 [9%]). At baseline, patients' mean (standard deviation [SD]) age was 33.5 (12.1) years. The majority

were female (n=57 [62%]). Pretreatment symptom severity was demonstrated by mean sleep latency on the MWT (mean [SD], 3.1 [3.1] minutes), ESS (mean [SD], 18.5 [3.1]), and WCR (mean [SD], 26.1 [32.6]). Study results from the full patient cohort in the randomized double-blinded treatment period will be presented.

Conclusions: The baseline characteristics from patients randomized in the ongoing Vibrance-1 study indicate severe NT1 symptoms. The findings from this study will inform the further clinical development of alixorexton as a treatment for narcolepsy.

Acknowledgments: This study is sponsored by Alkermes. The authors thank the patients, their families, the investigators, and their staff.

Weight loss response to GLP-1 RA in adults with narcolepsy cataplexy

S. Li¹, L. Xu¹, Y. Luo², J. Cai³, W. Yang¹, X. Dong¹, F. Han¹

¹Peking University People's Hospital, Division of Sleep Medicine, Beijing, China, ²Peking University People's Hospital, Departments of Endocrinology and Metabolism, Beijing, China, ³Peking University People's Hospital, Department of Nutrition, Beijing, China

Introduction: Patient with narcolepsy cataplexy (NC) often has weight gain and obesity, probably due to orexin/hypocretin deficiency, which makes the diet more difficult in NC. Glucagon-like peptide-1 receptor agonists (GLP-1RAs) have been demonstrated effective for weight loss in obesity with diabetes or non-diabetes, obstructive sleep apnea, knee osteoarthritis and so on, while their effects on obesity in NC remain unclear. This study explores the weight loss effects of one GLP-1 RAs (semaglutide) in adults with NC.

Materials and methods: This study was conducted between July 2024 and Mar 2025 at the Division of Sleep Medicine, Peking University People's Hospital. Weight loss effects of 12 adults with NC and obesity receiving semaglutide plus lifestyle interventions (Group A) and 24 sex-, age-, and BMI-matched adults with non-NC (Group B), as well as 12 adults with NC and obesity receiving lifestyle interventions alone (Group C). Weight and side effects were measured weekly, while clinical examinations, biological measurements, and questionnaires conducted at baseline and Week 12.

Results: Overall, the average age of the three groups is 29.69 ± 7.63 years, and the vast majority (70.83%) were male in Group A and C (24 adults with NC and obesity). At baseline, the BMIs were 34.09 ± 2.08 for Group A, 33.44 ± 2.38 for Group B and 32.20 ± 4.49 for Group C, with no statistical difference. Both Groups A and B completed 12 weeks on injectable semaglutide with losing $7.72\% \pm 4.47\%$ and $7.73\% \pm 3.20\%$ bodyweight respectively, while Group C lost $2.41\% \pm 2.68\%$ bodyweight. And the weight loss from the baseline was 4.12%, 5.97%, 7.72% for Group A, and 2.56%, 5.43%, 7.73% for Group B, and 1.46%, 1.79%, 2.41% for Group C at Weeks 4, 8, 12, respectively. Additionally, in Group A, 8(66.7%) patients lost $\geq 5\%$ weight, 5(41.67%) patients lost $\geq 10\%$ weight; in Group B, 20(83.3%) patients lost $\geq 5\%$ weight, 6(25%) patients lost $\geq 10\%$ weight; and in Group C, 2(16.67%) lost $\geq 5\%$ weight, with no patients achieving $\geq 10\%$. The reported adverse events in patients using semaglutide were mainly nausea, vomiting, constipation, and diarrhea.

Conclusions: In adults with NC and obesity, injectable semaglutide resulted in weight loss similar to that observed in matched patients with simple obesity and had a similar side effect profile, while better than lifestyle intervention alone. Although patients with NC have a deficiency in orexin/hypocretin, they can still successfully lose weight with the GLP-1 RAs.

When Those Supposed to Save You from Suicide Kill You: Sleep-Disrupting Psychiatric Containment of Undiagnosed Type 1 Narcolepsy Turned Insomnia

H. Wang¹

¹Stockholm University, Stockholm, Sweden

Introduction: Type 1 narcolepsy (T1N) is a rare neurological condition characterized by orexin-A deficiency, disrupted sleep-wake regulation, and altered REM architecture. In some patients, this includes enhanced dream awareness and volitional dream construction, which may underpin identity,

cognition, and vocation. During acute severe insomnia, these patients may present with suicidal ideation secondary to existential distress and sleep deprivation, not primary psychiatric pathology. This autoethnographic case explores how psychiatric crisis protocols, devoid of sleep medicine integration, can cause irreversible neurologic and existential injury and loss of systemic trust.

Materials and methods: This is a first-person case analysis by the author, a 22-year-old woman at the time of admission and aspiring filmmaker whose sense of self was built around lifelong dream-directing abilities. After months of inverted circadian rhythm, she developed acute severe insomnia (sleeping ~1 hour per 24 hours at 8 AM) for weeks. In December 2020, during COVID-19 and the holiday period, she sought help for irreparable insomnia and existential fear. She expected a calm, monitored setting for sleep restoration and support. Instead, she was subjected to psychiatric containment with 40+ patients for five nights, without sleep-focused evaluation. CSF orexin-A was confirmed years later to be < 50 pg/mL.

Results: Pre-admission: The patient already noticed a reduction in dream vividness, contributing to existential terror. Without T1N official diagnosis, she could not communicate her condition represented catastrophic override of hypersomnolence, not psychiatric illness.

Containment: In a shared psychiatric ward with 40+ patients, her fragile 1-hour morning sleep was eliminated entirely by noise and overstimulation, resulting in complete sleep loss.

Post-containment: For months, she could only sleep 3-4 hours /day. Dream remained grayscale devoid of narrative.

Five-year follow-up: Dream vividness and control have partially returned but remain impaired, suggesting likely irreversible neurological change.

Collateral consequences: Voluntary disclosure of the psychiatric admission led to immediate on-campus housing revocation, later overturned via an external psychologist's letter. She experienced months of homelessness in between. Upon readmission, she was forced to sign acknowledgment accepting the institution's prior decision. The compounding trauma of misdiagnosis, containment-induced neurologic injury, housing discrimination, and institutional betrayal resulted in lasting erosion of trust in national systems and enduring existential injury.

Conclusions: This case reveals the consequences of failing to recognize sleep disorders during psychiatric crisis intake. For T1N patients, loss of REM vividness may constitute psychological death. When sleep-driven crises are misclassified and institutional containment erases rare, fragile sleep, the result may be permanent vocational, functional, and existential loss. Suicide prevention systems must incorporate sleep triage, especially for rare neurological disorders.

Sleep-informed crisis care, rare condition diagnostic access, and anti-discrimination are not optional—they are essential protections against identity erasure and systemic traumatization and retraumatization.

Acknowledgments: The author acknowledges the critical role of diagnostic delay, institutional protocol gaps, and systemic psychiatric bias in shaping this trajectory. Gratitude is extended to Chinese and Swedish healthcare that enabled retrospective diagnostic clarity. This work is dedicated to others whose unconventional experiences remain unvalidated or misclassified within existing systems—particularly the system that decides life or death.

Neurological Disorders Affecting Sleep

A longitudinal exploration of posture changes and effects on sleep in motor neurone disease

V. Aiyappan^{1,2}, N. Grivell^{1,3,4}, C. Hansen^{1,5}, D. Schultz^{6,7}, P. Allcroft^{6,8}, N. Antic^{1,2}, P. Catchside¹

¹Flinders University, FHMRI Sleep Health/Adelaide Institute for Sleep Health, Flinders Health and Medical Research Institute, College of Medicine and Public Health, Adelaide, Australia, ²SA Health, Respiratory and Sleep Services, Southern Adelaide Local Health Network, Adelaide, Australia, ³University of Melbourne, Department of Physiotherapy, Faculty of Medicine, Dentistry and Health Sciences, Melbourne, Australia, ⁴Austin Health, Institute for Breathing and Sleep, Melbourne, Australia, ⁵Deakin University, Geelong, Australia, ⁶Flinders University, College of Medicine and Public Health, Adelaide, Australia, ⁷SA Health, Neurology Services, Southern Adelaide Local Health Network, Adelaide, Australia, ⁸SA Health, Southern Adelaide Palliative Services, Southern Adelaide Local Health Network, Adelaide, Australia

Introduction: Sleep disruption is highly prevalent in individuals with motor neurone disease (MND), particularly amyotrophic lateral sclerosis (ALS), and significantly contributes to disease burden. Degeneration of motor neurons and resultant muscle weakness and immobility is frequently associated with spasticity, cramps, restless legs syndrome and impaired mobility, that can all negatively impact sleep. Upper airway dysfunction, particularly with bulbar involvement, can also lead to sleep-disordered breathing, sialorrhea, choking, and aspiration, which can also impair sleep. Discomfort and psychological factors including distress and depression may also impair sleep through insomnia. Despite the awareness of disturbed sleep and multiple potential causes in MND, the mechanisms underlying poor sleep in MND remain poorly examined and understood. Given that declining mobility over time in MND could importantly influence sleep quality through discomfort and postural influences on sleep and sleep disordered breathing, this study sought to test for potential movement decline and postural influences on sleep with MND progression.

Materials and methods: Polysomnography (PSG) data were examined from a prospective longitudinal observational study conducted between December 2015 to January 2018 through a multidisciplinary MND clinic in South Australia (BreatheMND-1 study), which enrolled 37 patients with a confirmed diagnosis of MND, based on the El Escorial criteria. Where possible, participants completed laboratory or home PSG assessments at baseline, three, six, and 12 months. Sleep posture changes and sleep efficiency in each posture were examined using linear mixed-effects model analyses to test for posture effects and changes from baseline to last available follow-up.

Results: Baseline and repeat follow-up PSG data were available and analysed from 22 patients (median follow-up time 6 months). The total time available for sleep (mean [95%CI] 8.2 [7.7 to 8.8] h) was not different between baseline and follow-up visits. However, sleep efficiency was very poor at baseline (42.9 [32.9 to 53.1]%) and significantly further reduced at last available follow-up (30.8 [20.7 to 40.9]%, $p=0.018$). Sleep efficiency was poorest in prone compared to left and right lateral positions (22.2 [10.1 to 34.3] vs 43.0 [32.7 to 53.4] and 45.1 [34.7 to 55.3]% respectively, $p=0.001$), although there was very little prone sleep positioning (0.2 [0 to 0.9] h vs left 3.2 [2.5 to 3.9], right 1.9 [1.2 to 2.7] and supine 2.8 [2.0 to 3.5] h, $p<0.002$). The number of posture shifts from each body position increased from baseline (4.7 [2.8 to 6.5]) to last available follow-up (7.2 [5.4 to 9.1] /posture/night, $p=0.011$), but with no significant differences in the average time spent in each posture other than shorter prone versus left lateral positioning (27.8 [0 to 62.6] vs 72.9 [43.1 to 102.7] min, $p=0.025$).

Conclusions: These findings highlight the very poor and declining nature of sleep in MND, and that progressive loss of motor strength, control and mobility likely contribute to sleep loss through discomfort and potentially posture-dependent sleep disturbance effects. Further work is clearly warranted to better understand the mechanisms underpinning poor sleep in MND, and the potential utility of overnight movement and sleep changes over time as markers of disease progression and treatment efficacy.

An exploration of the factors influencing the uptake of non-invasive ventilation by people with motor neurone disease in Australia: a qualitative study of patient and health professional perspectives

N. Grivell^{3,4,1}, K. Russo^{4,1}, K. Carey^{3,4}, C. Zaga⁴, K. Saravanan⁴, N.L. Sheers^{3,4}, D.J. Berlowitz^{3,4}, M. Graco^{3,4}

¹University of Melbourne, Department of Physiotherapy, Faculty of Medicine, Dentistry and Health Sciences, Melbourne, Australia, ²Austin Health, Institute for Breathing and Sleep, Melbourne, Australia, ³Flinders University, FHMRI Sleep Health/Adelaide Institute for Sleep Health, Flinders Health and Medical Research Institute, College of Medicine and Public Health, Adelaide, Australia, ⁴Bond University, Faculty of Health Sciences and Medicine, Robina, Australia

Introduction: Motor neurone disease (MND, also known as Amyotrophic Lateral Sclerosis) is an incurable condition, with treatment primarily focusing on management of symptoms and maintaining quality of life. Non-invasive ventilation (NIV) has been shown to improve quality of life and extend survival in people with MND however the uptake of NIV is low in Australia. This aim of this study was to understand the factors that influence the uptake of NIV by people with MND (pwMND) in Australia.

Materials and methods: A qualitative study, informed by the COM-B (Capability, Opportunity, Motivation = Behaviour) framework and Theoretical Domains Framework. Semi-structured interviews were conducted with pwMND, carers of pwMND, and healthcare professionals involved in the care of

pwMND. Interviews were transcribed verbatim and analysed using a two-stage approach; a deductive Framework Analysis was conducted to ascertain the factors that influence NIV uptake and the stage in the patient journey to NIV uptake that these factors occur, followed by an inductive thematic analysis to derive greater meaning from the influencing factors.

Results: Interviews were conducted with 39 participants, eight pwMND, four carers of pwMND, and 27 healthcare professionals (nine neurologists, eight sleep/respiratory physicians, five nurses, three physiotherapists, one palliative care physician, and one MND advisor). A total of 29 key influencing factors to NIV uptake were identified, of which 17 were barriers, 10 were facilitators, and 2 were a barrier or facilitator. Thirteen factors related to the decision to trial NIV by pwMND, and included their motivations to trial NIV, their capacity to use the device, and their attitudes towards NIV. Nine factors related to the skills, knowledge and attitudes towards NIV and MND of health professionals, which were found to influence their responsiveness and willingness to recommend NIV to pwMND. Seven factors related to the design and accessibility of NIV services in the Australian healthcare system. Inconsistent and inadequate NIV service delivery models were found to limit access to NIV for pwMND, even for those who were interested in trialing NIV.

Conclusions: This study identified many important factors influencing the uptake of NIV among pwMND in Australia. This study demonstrates that health system design and knowledge and attitudes towards NIV of both people with lived experience of MND and health care professionals can impact access and uptake of NIV.

These findings will be used to inform the development of targeted interventions that address the barriers to NIV uptake, with the overall goal to increase uptake of NIV, reduce health care inequity, and optimise quality of life for people living with MND.

Association Between Long Sleep Duration and Dementia Risk Among Elderly Farmers: A Cross-Sectional Analysis

U.-c. Heo¹, U.-c. Heo¹

¹Jeju National University Hospital, Neurology, Jeju, Korea, Republic of

Introduction: Dementia represents a significant public health concern among older adults worldwide. Growing evidence suggests that sleep duration may serve as an important modifiable risk factor for cognitive decline, warranting investigation in vulnerable populations. The agricultural workforce is experiencing rapid demographic aging, heightening the need for dementia prevention and early detection strategies in farming communities. Elderly farmers face unique challenges including physically demanding work, higher prevalence of chronic diseases, and limited healthcare access, making them particularly susceptible to cognitive impairment. This study examined the relationship between sleep duration and cognitive function in elderly Korean farmers.

Materials and methods: We performed a cross-sectional analysis of 710 Korean farmers aged 60 years and older. Cognitive impairment was assessed using the Mini-Mental State Examination for Dementia Screening (MMSE-DS) with age-, sex-, and education-adjusted cutoff scores. Participants reported their typical daily sleep duration, which was categorized as short (<6 hours), normal (6-8 hours, reference group), or long (>8 hours). Multivariable logistic regression models were constructed to examine associations while controlling for demographic characteristics, medical comorbidities, depression, lifestyle factors, pesticide exposure, agricultural work type, and physical activity levels.

Results: Compared to farmers sleeping 6-8 hours nightly, those with prolonged sleep duration (>8 hours) demonstrated nearly three-fold increased odds of cognitive impairment (OR = 2.96, p = 0.007). Conversely, short sleep duration (<6 hours) was not significantly associated with dementia risk (OR = 0.71, p = 0.302).

Conclusions: Our findings align with international research demonstrating associations between extended sleep duration and cognitive decline. The results suggest that prolonged sleep among elderly farmers may serve as an early indicator of dementia risk. Given the occupational hazards and healthcare barriers faced by agricultural workers, integrating sleep assessment into rural health surveillance programs could enhance early detection of cognitive impairment. Future longitudinal research is needed to determine whether extended sleep duration precedes cognitive decline or represents a consequence of underlying neurodegenerative processes.

Association of functional variants in core circadian genes with intensity of neuropathic pain in post-surgical patients with breast cancer

V. Palada¹

¹University of Helsinki, Department of Physiology & SleepWell Research Programme, Helsinki, Finland

Introduction: Increasing evidence suggests that genetic variants in core circadian genes are associated with sleep disorders, which are a frequent comorbidity of neuropathic pain (NP). In current study, we explored the potential association between the circadian single nucleotide polymorphisms (SNPs) with intensity of chronic post-surgical NP in the patients treated for breast cancer. Currently it is not known why only some patients develop chronic post-surgical NP, while others do not, after the same type of nerve injury during surgical procedure.

Materials and methods: The association of SNPs in circadian core genes (CLOCK; BMAL1, PER1/2/3, CRY1/2) to NP was examined in the BrePainGen cohort (N=1000, Finland) of female patients who underwent surgery for breast cancer during 2006-2010, with a follow-up of up to 5.5 years. Genomic DNA was extracted from 10 ml of peripheral blood prior to the surgery and genome-wide genotyping was performed using Illumina OmniExpress SNP microarray. Information regarding pain intensity at the operated area and intensity of other types of chronic pain were collected from the patients. The genotype distribution and allele frequencies of circadian SNPs were extracted from the genome-wide data and tested for association to post-surgical NP by Pearson X2 test and odds ratio with 95% confidence interval.

Results: As a result, we found that the frequency of recessive allele of circadian PER1 polymorphism rs2585405 was three times higher in patients with moderate to severe NP compared to patients with mild NP at the 3 years follow-up. Patients with and without post-surgical NP displayed a significant difference in distribution of rs2585405 genotypes ($p=0.001$, $X^2=14.39$) and allele frequencies ($p=0.007$, $X^2=10.13$).

Conclusions: These findings show that a functional variant of circadian PER1 is associated with the intensity of post-surgical NP in cancer patients which might open the new therapeutic avenues for personalised treatments of cancer pain by taking into account the inter-individual differences in biological clocks.

Association of Polysomnographic Sleep Alterations and Cognition in Lewy Body Diseases

H. Thompson¹, J. Anderson^{1,2,3}, L. Churchill³, A. Ignatavicius³, A. Konuri³, A. Lam^{1,3}, S.L. Naismith³, R.R. Grunstein^{1,4,2}, S.J. Lewis², E. Matar^{5,2,6}

¹Woolcock Institute of Medical Research, Centre for Integrated Research and Understanding of Sleep (CIRUS), Sydney, Australia, ²University of Sydney, Central Clinical School, Faculty of Medicine and Health, Sydney, Australia, ³University of Sydney, Brain and Mind Centre, Sydney, Australia, ⁴Royal Prince Alfred Hospital, RPA-Charles Perkins Centre Clinic, Sydney, Australia, ⁵Woolcock Institute of Medical Research, Sleep & Circadian Group, Sydney, Australia, ⁶Royal Prince Alfred, Department of Neurology, Sydney, Australia

Introduction: Lewy body diseases, including Parkinson's disease (PD) and dementia with Lewy bodies (DLB), are the second most common neurodegenerative disorders in older adults. Sleep disturbances are an early and prominent feature of PD and DLB, with their presence closely linked to the development of core non-motor symptoms, including dementia, visual hallucinations and cognitive fluctuations. In healthy individuals, poor sleep is associated with cognitive dysfunction; however, few studies have comprehensively examined the relationship between objectively measured sleep alterations and cognition across the Lewy body disease spectrum. This study aimed to characterise alterations in sleep macroarchitecture in PD and DLB, and to explore associations between objective sleep parameters and cognitive functioning across neuropsychological domains.

Materials and methods: This study involved: 34 participants with DLB, 58 with PD, and 58 controls without objective cognitive impairment. All participants underwent overnight in-laboratory polysomnography (PSG), including EEG (10–20 system), EOG, submental EMG, ECG, respiratory monitoring (nasal pressure, thoracic and abdominal belts), pulse oximetry, body position, and anterior tibialis EMG. Sleep staging was scored in 30-second epochs according to AASM criteria. Cognitive assessments included global cognition (MMSE) and six neuropsychological domains: executive function

(TMT-B), switching and cognitive flexibility (D-KEFS CWIT 4), inhibition (D-KEFS CWIT 3), visuospatial function (Clock Drawing Test), attention and working memory (Digit Span Backward), learning and memory (RAVLT), and language (COWAT). Group differences in sleep architecture were analysed using general linear models with permutation testing. Linear regressions examined associations between cognitive domains and PSG variables across PD and DLB. All analyses controlled for age and sex, with FDR corrections applied.

Results: Alterations in sleep macroarchitecture were shared across Lewy body diseases. Compared to controls, PD and DLB showed significantly reduced sleep latency (PD: $pFDR < 0.001$, DLB: $pFDR = 0.04$), increased REM latency (PD: $pFDR = 0.028$, DLB: $pFDR = 0.024$), and reduced REM sleep percentage of total sleep time (PD: $pFDR < 0.001$, DLB: $pFDR < 0.001$). Respiratory disturbance index (RDI) during REM sleep was also significantly lower in PD and DLB (PD: $pFDR < 0.001$, DLB: $pFDR < 0.001$). While no sleep parameters were significantly associated with global cognition (MMSE), reduced REM sleep proportion was associated with poorer performance in executive function ($\beta = -0.038$, $p = 0.006$), and cognitive flexibility ($\beta = -0.079$, $p = 0.013$) across Lewy body diseases.

Conclusions: This study highlights objective sleep alterations are prominent in PD and DLB and REM sleep proportion is associated with deficits in executive function and cognitive flexibility. The observed association between these neuropsychological subdomains and reduced REM sleep proportion suggests that REM sleep disruption may serve as an indirect marker of domain-specific cognitive vulnerability in Lewy body diseases.

Association of Sleep Fragmentation with Inflammatory Markers in Children Experiencing Febrile Seizures

S. Lee¹, W.S. Lee¹

¹CHA Ilan Medical Center, CHA University, Department of Pediatrics, Goyang, Korea, Republic of

Introduction: Febrile seizures are the most common type of convulsions in children under five years old and are typically triggered by fever without evidence of intracranial infection. While generally considered benign, various environmental and physiological factors, including sleep disturbances, may influence febrile seizures. Sleep plays a crucial role in modulating immune function, and poor sleep hygiene has been linked to elevated levels of pro-inflammatory cytokines in both adults and children. This study aims to assess the association between sleep habits and serum cytokine levels in pediatric patients with febrile seizures, investigating whether poor sleep hygiene correlates with altered inflammatory profiles.

Materials and methods: From December 2023 to December 2024, blood tests were conducted on patients who visited the pediatric emergency room at Ilan CHA Hospital with febrile seizures as their chief complaint. Among the tests, inflammatory markers, including cytokines, were analysed. Sleep-related data were collected through a self-administered questionnaire on sleep hygiene completed by the patient's guardians. Statistical analysis was performed using SAS software, applying the chi-square, T, Fisher's exact, and Mann-Whitney U tests.

Results: A total of 37 patients with febrile seizures participated in the study, among whom 13 guardians agreed to complete the questionnaire. Among all participants, 24 were male and 13 were female, with an average age of 2.27. All patients had the simple type of febrile seizure, and the average seizure duration was 2.34 minutes. A history of febrile seizures was present in 13 out of 37 patients (35.1%), and a family history of febrile seizures was identified in 9 patients (24.3%). According to the sleep questionnaire, six patients under 6 months experienced sleep fragmentation, while seven did not. In the group with sleep fragmentation, there was no sex difference, while in the group without sleep fragmentation, males were predominant. In the group without sleep fragmentation, none had family members with sleep disorders, and there was no statistically significant relationship between sleep fragmentation and breastfeeding. Most children who participated in the survey had no significant difficulties with weaning soft diet intake, and differences in feeding volume were not statistically significant. Eyeball deviation during seizures was more commonly observed in the sleep-fragmented group, but this was not statistically significant. No significant differences in respiratory or gastrointestinal symptoms were found between the two groups. In the analysis of inflammatory cytokines, IL-4 and IFN-gamma showed no significant differences between the two groups. IL-6 levels were more than twice as high in the group with sleep fragmentation and were statistically significant. IL-10 was also observed to double in the sleep-fragmented group. Although C-reactive protein (CRP)

levels were more than four times higher in the sleep-fragmented group, this finding was not statistically significant.

Conclusions: In this study, patients with febrile seizures who exhibited sleep fragmentation showed significantly elevated levels of IL-6, suggesting a possible link between disrupted sleep and increased inflammatory response. Although other markers such as IL-10 and CRP were also elevated, they did not reach statistical significance. These findings indicate that sleep quality may play a role in modulating inflammation in febrile seizures.

Association of the “Weekend Warrior” and Other Leisure-Time Physical Activity Patterns with epilepsy, migraines, and sleep disorders

J. Wu¹

¹Third Xiangya Hospital, Central South University, Neurology, Changsha, China

Introduction: The weekend warrior (WW) exercise pattern, where individuals accumulate the recommended 150-minute moderate-to-vigorous physical activity (MVPA) over 1–2 days, has become a popular alternative to daily physical activity routines. This study investigates the association of WW and other leisure-time physical activity patterns with the risk of neurological diseases, specifically epilepsy, migraines, and sleep disorders.

Materials and methods: This study includes data from 93,684 participants, obtained from the UK Biobank. MVPA patterns were categorized into inactive, regularly active, and WW groups. Cox proportional hazards models, restricted cubic splines (RCS) and, Kaplan-Meier curves were used to assess the impact of exercise patterns on the risk of neurological diseases.

Results: Both the WW and regularly active groups exhibited significantly lower risks for epilepsy, migraines, and sleep disorders than the inactive group. The results of RCS curves for these disorders further supported these findings.

Conclusions: The WW pattern offers similar benefits to daily exercise in reducing the risk of neurological disorders, particularly epilepsy, migraines, and sleep disturbances. This finding suggests that WW activity may be a practical and flexible approach to disease prevention in modern societies.

At-home wearable EEG monitoring reveals reduced rapid eye movement sleep in mild cognitive impairment

M. Taylor¹, M. Goodfellow², K. Petrini¹, E. Coulthard^{3,4}, G. Stothart¹

¹University of Bath, Department of Psychology, Bath, United Kingdom, ²University of Exeter, Living Systems Institute, Exeter, United Kingdom, ³University of Bristol, Bristol Medical School, Bristol, United Kingdom, ⁴Southmead Hospital, North Bristol NHS Trust, Bristol, United Kingdom

Introduction: Early biomarkers of Alzheimer’s disease (AD) are essential for developing effective secondary prevention. Sleep disturbances—particularly in slow wave sleep (SWS) and rapid eye movement (REM) sleep—have been closely linked to AD pathology, including amyloid accumulation and basal forebrain degeneration, both of which can precede dementia diagnosis by several years. Polysomnography (PSG) reveals deficits in SWS and REM sleep in early AD, at the mild cognitive impairment (MCI) stage. However, PSG’s high cost, limited accessibility, and low patient tolerance limit its widespread use in research and clinical settings. In contrast, wearable electroencephalography (EEG) devices offer a more practical and scalable solution for home-based sleep monitoring. Here, we use a wearable EEG device to examine SWS and REM sleep in individuals with MCI and investigate their relationship with cognitive function to test the hypothesis that declines in REM and SWS are associated with cognitive impairment and can differentiate individuals with MCI from cognitively healthy controls.

Materials and methods: Here, we present an interim analysis on 14 participants with MCI due to probable AD (mean $\pm$ SD; 68.9 $\pm$ 8.7 years, 9 female) and 23 cognitively healthy, age-matched controls (mean $\pm$ SD; 70.1 $\pm$ 7.6 years, 12 female) who underwent at-home sleep monitoring for up to six consecutive nights using the Sleep Profiler, a single-channel frontal EEG headband. Sleep stages were automatically scored using U-Sleep, a deep learning algorithm validated against technician-scored PSG data. Cognitive performance was assessed using the Montreal Cognitive Assessment (MoCA) and a

neuropsychological battery covering memory (Optimised Mnemonic Similarity Task), executive function (Digit Span, Digit Symbol Substitution Task, Trail Making Test Part B), and processing speed (Trail Making Test Part A). We compared sleep architecture between groups and examined associations between sleep parameters and cognitive scores, adjusting for age and cognitive status.

Results: Participants with MCI spent a significantly smaller proportion of total sleep time in REM sleep ($p = 0.035$, Cohen's $d = 0.75$) and a greater proportion in light (N1) sleep ($p = 0.033$, $d = 0.76$) compared to controls. No significant group differences were observed for other sleep stages (e.g., SWS; $p = 0.114$, $d = 0.550$). Reduced REM sleep was associated with poorer recognition memory ($b = 0.014$, 95% CI [0.002, 0.026], $p = 0.024$) and slower processing speed ($b = -2.90$, 95% CI [-5.22, -0.57], $p = 0.016$). No significant associations were found between SWS and any cognitive variables (e.g., recognition memory; $b = 0.008$, 95% CI [-0.003, 0.019], $p = 0.142$).

Conclusions: Wearable EEG provides a practical method for detecting sleep alterations in MCI. REM, rather than SWS, was reduced in MCI. These changes may reflect early AD-related neurodegeneration, supporting REM sleep as a promising biomarker for AD risk and highlighting the potential of home-based, non-invasive sleep monitoring as a tool for early AD detection.

BETWEEN SLEEP AND SORROWS: CASE REPORT ON NARCOLEPSY

N.M. Manalastas¹, M.A. Pascual²

¹National Center for Mental Health, Professional Education, Training and Research Office, Mandaluyong, Philippines, ²National Center for Mental Health, Sleep Medicine Section, Mandaluyong, Philippines

Introduction: Narcolepsy is a chronic neurological sleep disorder that often manifests during adolescence or early adulthood, but its subtle and overlapping symptoms can lead to delayed or missed diagnoses—particularly in patients also presenting with psychiatric symptoms. In clinical practice, excessive daytime sleepiness, cataplexy, vivid dreams, and sleep-related hallucinations are frequently misattributed to mood disorders, especially depression. This diagnostic overlap poses a significant challenge for clinicians and may result in inadequate treatment. In this case report, we present the complex clinical trajectory of Mikan, a 20-year-old Filipino college student, whose longstanding depressive symptoms masked an underlying diagnosis of narcolepsy.

Objectives: To explore the clinical presentation, diagnosis, and treatment of a 20-year-old female with overlapping depressive symptoms and excessive daytime sleepiness, cataplexy, fragmented sleep, vivid dreams and sleep-related hallucinations.

Materials and methods: This case study follows Mikan, a Filipino first-year college student, who first sought consultation in June 2023 at the Adult Outpatient Section. Detailed history taking was conducted. Polysomnography (PSG), test of wakefulness and mean sleep latency tests (MSLT) were done revealing Narcolepsy due to the presence of sleep onset REM periods (SOREMP) and short mean sleep latency of about 5 minutes². Other tests include the HLA-DQB1*06:02 genetic marker testing and the cerebrospinal fluid levels of Hypocretin which are not available in the country². She was started on Methylphenidate 10 mg/tablet 1 tablet and Fluoxetine 20 mg/capsule 1 capsule in the morning. Her repeat post-treatment sleep studies showed resolution of SOREMP but still with MSLT of about 5 minutes showing improvement. She was taught sleep hygiene and sleep diary.

Results: The patient's depressive symptoms such as persistent sadness, poor concentration and appetite, anhedonia, fatigue and suicidal ideations, began at age 11. Social withdrawal and academic decline were evident. By age 13, excessive daytime sleepiness became prominent, with involuntary sleep episodes, cataplexy, vivid dreams, hypnagogic and hypnopompic hallucinations, and fragmented nighttime sleep. Despite extended sleep durations and frequent naps, fatigue persisted. Depressive symptoms remitted partially over time, but the unresolved sleep issues significantly impaired functioning. Two sleep studies were done to confirm the diagnosis of Narcolepsy. With the medications prescribed, she was able to resume functioning and experience relief of symptoms. Sleep diary showed improvement in quality of sleep and mood.

Conclusions: Mikan's case underscores the interplay between psychiatric and sleep disorders, demonstrating how untreated sleep conditions can exacerbate or mimic mental health issues.

Psychiatric disorders are commonly overlapping with symptoms of narcolepsy including the timeline of symptoms which makes diagnosis challenging. Analysis of other studies regarding Narcolepsy

revealed association with psychiatric illnesses¹. Early multidisciplinary evaluation, including sleep studies and psychiatric assessment, is essential for accurate diagnosis and treatment. This case emphasizes the need for increased education about sleep disorders to prevent long-term psychosocial and functional impairment.

Bridging Cognitive Assessment and Sleep Research: A Validated CDR-SB–MoCA Crosswalk for Alzheimer's Disease and Related Dementia

B. Haji¹, Q. Zhang¹, A.A. Tahami Monfared^{1,2}

¹Eisai Inc., Nutley, United States, ²McGill University, Montreal, Canada

Introduction: Sleep disturbances—particularly insomnia—are common in older adults and frequently co-occur with cognitive impairment and Alzheimer's disease (AD). Broadly defined sleep disorders affect 14% to 69% of individuals with Alzheimer's disease (AD), with a pooled prevalence of 39% (95% CI: 30–46%). Despite their high prevalence and clinical relevance, sleep disturbances remain underrepresented in dementia research, in part due to difficulties in harmonizing cognitive assessments across clinical and research settings. Research studies often use the Clinical Dementia Rating Scale Sum of Boxes (CDR-SB), while clinical care relies more on tools like the Montreal Cognitive Assessment (MoCA). This misalignment limits opportunities to study sleep–cognition interactions in aging populations. The National Alzheimer's Coordinating Center (NACC) Uniform Data Set provides a valuable platform to address this issue, offering standardized cognitive assessments alongside clinician-reported sleep variables, including the presence or absence of hypsomnia or insomnia, available since 2015. In this study, we developed and validated bidirectional score conversion tables between CDR-SB and MoCA to enable harmonized interpretation of cognitive severity and to support future research on the relationship between sleep disturbances and cognitive decline.

Materials and methods: We conducted a retrospective, cross-sectional analysis using data from the NACC Uniform Data Set, which includes standardized assessments from 35 U.S.-based Alzheimer's Disease Research Centers. Participants were included if they had at least one visit between January 2015 and September 2024 where both CDR-SB and MoCA were administered on the same day. The final cohort included 23,717 individuals (59,871 visits) spanning normal cognition, mild cognitive impairment (MCI), and dementia. Bidirectional crosswalk tables were created using equipercntile equating with log-linear smoothing. Optimal parameters were selected using mean squared error, Akaike Information Criterion, and Bayesian Information Criterion. Score concordance was assessed via Spearman's rank correlation and Bland-Altman plots. Subgroup analyses were performed in individuals with a primary diagnosis of AD.

Results: CDR-SB and MoCA scores showed a strong inverse correlation (Spearman's $\rho = -0.68$; $p < 0.001$). The crosswalks allowed accurate, bidirectional translation between the instruments, preserving individual rank order, and accounting for non-linearities, as well as floor and ceiling effects, across the full spectrum of cognitive severity. Agreement between observed and converted scores was confirmed by Bland-Altman analysis, showing minimal bias and acceptable limits of agreement. Subgroup results in the AD cohort were consistent with findings from the full sample, supporting generalizability of the conversion framework.

Conclusions: This study provides the first validated, bidirectional crosswalk between CDR-SB and MoCA, addressing a major barrier to cognitive data harmonization across clinical and research settings. The resulting framework enables longitudinal tracking, pooled analyses, and consistent staging across heterogeneous data sources. Future studies will leverage this crosswalk alongside NACC sleep variables to identify and characterize individuals with co-occurring cognitive impairment and sleep disturbances. This integration will facilitate research on the interplay between sleep and cognition in aging and AD, advancing precision in diagnosis, prognosis, and targeted interventions across both cognitive and sleep medicine.

Acknowledgments: All authors are employees of Eisai Inc., which provided funding for this study.

Characterizing older patients with Obstructive Sleep Apnea at heightened risk of prospective cognitive decline and/or Alzheimer's Disease stage transition

O. Bubu¹, J. Gills¹, P. Pahari¹, A. Parekh², A. Mullins², K. Kam², D. Rapoport², I. Ayappa², A. Varga², R. Osorio¹

¹NYU Grossman School of Medicine, New York, United States, ²Icahn School of Medicine at Mount Sinai, New York, United States

Introduction: Obstructive Sleep Apnea (OSA) is associated with increased Alzheimer's Disease (AD) risk, with studies showing altered levels of both established and novel biofluid AD biomarkers in cross-sectional and longitudinal analyses. OSA's heterogeneity may explain why not all OSA patients develop cognitive decline. Identifying OSA individuals at heightened risk to develop AD is critical for OSA-AD prevention trials. In 5 separate studies, we investigated the relationships between OSA a) severity measures [study 1 & 2], b) interactive effects with AD biomarkers (amyloid (A), tau (T), neurodegeneration (N) brain markers [study 3 & 4], c) interactive effects with co-occurring vascular risk [study 5], on prospective cognitive decline and AD stage transition

Materials and methods: Studies 1, 2 & 3 included 218, 135 and 143 NL community-dwelling older adults participating in ongoing studies of sleep, aging and memory at NYU, respectively. Study 4 included 1043 participants grouped by biomarker profile, as described by the A/T/N scheme, where "A" refers to aggregated A β , "T" aggregated tau and "N" to neurodegeneration, included 258 NL (OSA+ [A+TN+ n=10, A+/TN- n=6, A-/TN+ n=10, A-/TN- n=6 and OSA- [A+TN+ n=84, A+/TN- n=11, A-/TN+ n=96, A-/TN- n=36]) and 785 MCI (OSA+ [A+TN+ n=35, A+/TN- n=15, A-/TN+ n=25, A-/TN- n=16 and OSA- [A+TN+ n=388, A+/TN- n=28, A-/TN+ n=164, A-/TN- n=114]) **older-adults from Alzheimer's Disease Neuroimaging Initiative cohort.** Study 5 included 98 NL participants characterized by joint OSA and HTN status (OSA+/HTN+; OSA-/HTN+; OSA+/HTN- & OSA-/HTN-). OSA severity measures included characterizations with the apnea hypopnea index (AHI4%) and other novel metrics such as Hypoxic burden (HB), defined as the sum of individual areas under the oxygen desaturation curve, and Ventilatory burden (VB), defined as event-specific area under ventilation signal (mean normalized, area under the mean). Outcome measures included annual rate-of-change in cerebrospinal fluid (CSF) A β 42 levels and global cognition (i.e. episodic memory, language and executive function). AD-stage transition was defined as change from Global Deterioration Scale (GDS) 1 or 2 [NL] at baseline to ≥ 3 [$\geq$ MCI] during follow-up.

Results: Findings from studies 1 and 2 showed all OSA-severity measures associated with cognitive decline and/or longitudinal decreases in CSF A β 42. Strengths of the effects were such that HB>AHI4%>VB. Findings from studies 3 & 4 showed that independent of TN-status (NL and MCI), OSA+/A β + participants were approximately two to four times more likely to progress to MCI/AD ($p<.001$) and progressed six to eighteen months earlier ($p<.001$), compared to other participants combined (i.e. OSA+/A β -, OSA-/A β + and OSA-/A β -). Mixed effects models demonstrated OSA synergism with A β (NL and MCI [$\beta=1.13$, 95%CI, 0.74 to 1.52, and $\beta = 1.18$, 95%CI, 0.82 to 1.54]) respectively, and with tau ([MCI ($\beta = 1.31$, 95%CI, 0.87 to 1.47)], $p< 0.001$ for all. Study 5 showed that the co-occurrence of OSA and hypertension interact synergistically to promote β -Amyloid burden, and global cognitive decline.

Conclusions: In older adults with OSA, the risk and rate of prospective cognitive decline and/or AD stage transition are differentially influenced by the interplay of OSA disease severity, co-occurring AD pathology and vascular risk factors.

Clinical evidence of Traditional Chinese Medicine for post-stroke sleep disorders

N. Xiaojia^{1,2}, S. Qing^{3,4}, R. Jiayi⁴, L. Yinglin^{1,4}, W. Liyan⁴, K. Zhuoran^{3,4}, Y. Hongshen^{3,4}, L. Huishan⁴, Z. Danmei^{3,4}, G. Nuo⁴, L. Qin^{3,4}, Z. Bojing⁴, C. Yefeng^{1,2}

¹State Key Laboratory of Traditional Chinese Medicine Syndrome, The Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangdong Provincial Hospital of Chinese Medicine, Guangdong Provincial Academy of Chinese Medical Sciences, Guangzhou, China, ²Guangdong Provincial Key Laboratory of Research on Emergency in Traditional Chinese Medicine, Guangzhou, China, ³Guangdong Provincial Hospital of Chinese Medicine, Guangdong Provincial Academy of Chinese Medical Sciences, Guangzhou, China, ⁴The Second Clinical School of Guangzhou University of Chinese Medicine, Guangzhou, China

Introduction: Sleep disorders are prevalent complications among stroke survivors. Current clinical guidelines and expert consensus indicated a limited repertoire of effective interventions, underscoring the urgent need for further research to advance clinical practice. Previous studies have reviewed the literature on Traditional Chinese Medicine (TCM) interventions, specifically Chinese herbal medicine (CHM) and acupuncture, for post-stroke sleep disorders, demonstrating a substantial volume of research and suggesting several potentially beneficial therapeutic approaches. However, a comprehensive review of the overall clinical evidence remains lacking. This study employs an evidence-based approach to systematically collate and appraise modern clinical research on TCM interventions for post-stroke sleep disorders, aiming to establish a robust clinical evidence framework. The findings are intended to inform clinical decision-making and guide future research priorities.

Materials and methods: A comprehensive computerized search was conducted across multiple databases including PubMed, Embase, the Cochrane Library, and Chinese databases (CNKI, Wanfang, VIP, and CBM), to identify clinical studies investigating TCM for post-stroke sleep disorders. Two independent researchers performed literature screening and data extraction. Quantitative analysis (meta-analysis) was applied to randomized controlled trials (RCTs), while qualitative analysis was used for non-randomized studies. The methodological quality of included systematic reviews was assessed using A Measurement Tool to Assess Systematic Reviews 2 (AMSTAR 2), reporting quality was evaluated using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) 2020, and the risk of bias for RCTs was analyzed using the Cochrane Risk of Bias tool (RoB 1.0).

Results: The final analysis included 13 systematic reviews, 137 RCTs, 13 non-randomized controlled trials, 9 case series, 1 case-control study, and 1 case report. For systematic reviews, AMSTAR 2.0 and PRISMA assessments revealed low overall methodological and reporting quality. The results suggested that TCM showed efficacy in improving subjective sleep quality. Among the RCTs, for post-stroke insomnia, high-quality evidence suggested that acupuncture was superior to sham acupuncture in improving subjective sleep quality. Moderate-to-low quality evidence supported the advantages of CHM and acupuncture, either used alone or in combination with hypnotic, in improving subjective sleep outcomes. Additionally, low-quality evidence suggested that combining CHM with cognitive behavioral therapy for insomnia (CBT-i) yielded better subjective sleep improvements compared to CBT-i alone. For post-stroke sleep apnea, moderate-to-low quality evidence demonstrated that combining CHM or acupuncture with continuous positive airway pressure (CPAP) therapy was more effective than CPAP alone in improving the AHI and blood oxygen saturation. Regarding other post-stroke sleep disorders, low-quality evidence highlighted the potential benefits of acupuncture in improvement of subjective sleep quality and daytime sleepiness.

Conclusions: The review of clinical evidence suggested that TCM interventions (CHM and acupuncture) may improve subjective sleep quality, objective sleep parameters, and reduce daytime sleepiness in patients with post-stroke sleep disorders. However, the overall quality of the available evidence was limited. Future research should prioritize large-scale, high-quality RCTs to strengthen the clinical recommendations of TCM for post-stroke sleep disorders.

Acknowledgments: This study was funded by Guangzhou University of Chinese Medicine, China (GZY2025GB0111), Guangdong Provincial Hospital of Chinese Medicine, China (YN2019QL10), and NATCM's Project of High-level Construction of Key TCM Disciplines (zyydxk-2023154).

Daytime Sleepiness Screening in Demyelinating Diseases: Utility of the Epworth Sleepiness Scale in MS and NMO

E. Solís Viveros¹, F. Flores Alfaro¹, B.E. Chávez Luevanos¹, S. Saldivar Dávila¹, D.S. Martínez Alonso¹, J.G. Garza Marichalar¹, C.E. Gómez Hernandez^{1,1}

¹Hospital Universitario "Dr José Eleuterio González" Universidad Autónoma De Nuevo León, Neurología, Monterrey, Mexico

Introduction: Excessive daytime sleepiness (EDS) is a frequent but underexplored symptom in demyelinating diseases such as multiple sclerosis (MS) and neuromyelitis optica (NMO). It is often mistaken for fatigue but may result from lesions in the diencephalon or brainstem, or from secondary sleep disorders. The Epworth Sleepiness Scale (ESS) is a brief and validated tool that enables practical identification of EDS.

Materials and methods: An observational, cross-sectional, and descriptive study was conducted in MS and NMO patients registered in an institutional database. The ESS was applied via telephone to

patients over 18 years old with a confirmed diagnosis. Those with cognitive impairment, decompensated psychiatric disorders, or no phone contact after three attempts were excluded.

Results: Out of 31 patients (18 with MS, 13 with NMO), 20 (64.5%) were successfully contacted. Of these, 6 (30%) scored ≤ 6 (no EDS). The remaining 14 (70%) showed abnormal sleepiness: 6 (30%) had an ESS >15 (severe sleepiness, referred for polysomnography) and 8 (40%) scored between 7–15 (mild to moderate sleepiness, advised on lifestyle changes). Severe EDS was more frequent among patients with NMO.

Conclusions:

Conclusion

Excessive daytime sleepiness is common in patients with MS and NMO, particularly in the NMO group. The ESS, applied by telephone, is a useful and accessible tool for detecting this symptom and guiding timely clinical interventions. It is low-cost and can be easily integrated into routine evaluations.

Diagnostic Potential of Sleep Spindles in drug-naïve Schizophrenia Using Standard PSG Data: A Retrospective Pilot Study

S. Mizuki¹, N. Kotorii², H. Hiejima¹, T. Kato¹, Y. Hyoudou¹, H. Oshima¹, K. Murotani¹, N. Uchimura¹, M. Ozone¹

¹Kurume University, Fukuoka, Japan, ²Kotorii Isahaya Hospital, Nagasaki, Japan

Introduction: In 2007, Ferrarelli et al. reported significant reductions in the number, amplitude, and duration of sleep spindles during non-REM stage 2 sleep in patients with schizophrenia. These abnormalities were not observed in non-schizophrenic populations. Further studies have found similar spindle abnormalities in early-onset, drug-naïve patients and even in first-degree relatives. Based on these findings, abnormalities in sleep spindles among drug-naïve patients with schizophrenia have drawn attention as potential diagnostic markers.

In this study, we conducted a pilot analysis using polysomnography (PSG) data obtained with a standard clinical montage from previously recorded drug-naïve Japanese patients with schizophrenia at Kurume University Hospital, aiming to evaluate the diagnostic utility of sleep spindle activity in schizophrenia.

Materials and methods: We analyzed PSG data collected at Kurume University Hospital between January 2001 and December 2025 from seven drug-naïve schizophrenia patients (diagnosed according to DSM-IV and never previously treated with antipsychotic medication) and seven healthy controls. Various spindle parameters—frequency, detection time, duration, and amplitude—were analyzed using spindle detection software and compared across four electrode sites (C3, C4, O1, and O2). Additionally, the effects of an initial administration of 2 mg of risperidone were evaluated.

Results: As a result, the drug-naïve schizophrenia group exhibited significantly lower spindle frequency and detection time, particularly at the C3 electrode site, compared to healthy controls. In particular, the frequency and detection time of fast spindles (12–15 Hz) were markedly reduced in drug-naïve schizophrenia patients (Frequency: Sc = 35.69, HC = 98.25, $p < 0.01$; Detection time: Sc = 242.5, HC = 708.9, $p < 0.01$).

Only slight decreases in these values were observed after risperidone administration.

In drug-naïve patients, ROC curve analyses revealed high diagnostic accuracy, with an AUC of 0.94 for both frequency and detection time of fast spindles. Both specificity values were 1.000. Similarly, the AUC for detection time of total spindles (9–15 Hz) was also 0.94, with a sensitivity of 1.000.

In patients administered risperidone, the AUCs for detection time of total and fast spindles still exceeded 0.7.

Conclusions: This study demonstrated that drug-naïve Japanese patients with schizophrenia exhibit reduced sleep spindle activity, particularly at the C3 electrode site, based on standard PSG data. Fast spindle frequency and detection time demonstrated excellent diagnostic performance, while total spindle detection time contributed to disease exclusion, suggesting their complementary diagnostic utility. The minimal changes observed after risperidone administration support the potential role of sleep spindles as trait markers.

These findings highlight the feasibility of using standard PSG data as a non-invasive tool for the early

detection of schizophrenia. To further validate these results, prospective studies with larger sample sizes using PSG data obtained with standard electrode montages are warranted.

Differential Effects of Pregabalin and Morphine on the Sleep-Wake Cycle and Circadian Rhythms in Mice with Neuropathic Pain

V. Palada¹

¹University of Helsinki, Department of Physiology & SleepWell Research Programme, Helsinki, Finland

Introduction: Neuropathic pain is commonly associated with disturbances in sleep architecture and circadian rhythms, leading to fragmented sleep, body temperature fluctuations, and altered locomotion. While pregabalin and morphine are frequently prescribed for neuropathic pain management, their effects on sleep and circadian regulation are poorly understood.

Materials and methods: To identify the effects of spared nerve injury on sleep architecture and circadian rhythms, wireless transmitters were implanted in male and female C57BL/6J mice before nerve injury. Pregabalin (11 mg/kg/day) and morphine (6 mg/kg/day) were continuously administered to male mice via intraperitoneally implanted osmotic minipumps following the injury. At baseline and on post-surgical days 3, 7, and 14, mechanical allodynia was assessed with von Frey filaments and dynamic allodynia with a brush test. Wireless transmitters simultaneously recorded electroencephalogram (EEG), electromyogram (EMG), locomotion, and body temperature at baseline and on post-surgical days 7 and 14.

Results: Nerve injury disrupted the sleep-wake cycle by reducing rapid eye movement (REM) sleep duration during the light phase (the habitual sleeping phase for mice) in both sexes and increasing wakefulness in female mice, without significantly affecting non-REM sleep. Additionally, nerve injury impaired the circadian rhythmicity of locomotion and body temperature. Pregabalin, but not morphine, restored REM sleep to pre-surgical levels and was more effective in restoring rhythmicity of locomotor activity and body temperature than morphine. Furthermore, pregabalin increased sleep spindle occurrence during sleep stage transitions and enhanced the power spectra within the 3.5-5.5 Hz range during REM sleep. Continuous morphine administration did not alter either sleep architecture or microstructure.

Conclusions: Administration of pregabalin, but not morphine, effectively restores REM sleep and circadian rhythms of locomotion and body temperature in a mouse model of neuropathic pain suggesting that pregabalin enhances sleep stability. This renders further support for the preference of pregabalin over morphine in managing neuropathic pain.

Differential Effects of Suvorexant on p-Tau and A β Levels in Human CSF and Plasma

A. Li¹, B. Lucey¹

¹Washington University School of Medicine, Neurology, St Louis, United States

Introduction: Alzheimer's disease (AD) is a progressive neurodegenerative disorder characterized by the deposition of amyloid- β (A β) extracellular plaque and intraneuronal accumulation of phosphorylated tau (p-tau) into neurofibrillary tau tangles. This leads to neuronal loss, cognitive dysfunction, and dementia. Orexin is a neuropeptide involved in regulating sleep-wake cycles that may also play a role in AD pathology. We previously reported that suvorexant (a dual orexin receptor antagonist) acutely decreased tau phosphorylation at threonine-181 (pT181) and A β levels in human cerebrospinal fluid (CSF), but the effect on plasma A β and p-tau was unknown. In this study, we tested the acute effect of suvorexant 20 mg on plasma AD biomarkers and compared to the changes we previously reported in CSF.

Materials and methods: Twenty-five participants aged 45 to 65 years were randomized to placebo (N=13) or suvorexant 20 mg (N=12). Participants had an intrathecal lumbar catheter placed with collection of samples started at 20:00. CSF and plasma were collected every 2 hours for 36 hours. Participants received their first dose of placebo or suvorexant 20 mg at 21:00 (hour 1) and second dose at 21:00 (hour 25) on the second night. The lumbar catheter was removed on day 3 at 08:00.

Results: Suvorexant 20 mg increased the ratio of plasma levels of pT181 to unphosphorylated tau-181 (T181) while having no significant effect on plasma A β levels. Plasma pT181/T181 was ~10–20%

higher in the suvorexant 20 mg group compared to placebo between hours 12–20 (08:00–16:00) when normalized to hour 0. During the period of 08:00–16:00, the area under the curve (AUC) for percent change from hour 0 between plasma pT181/T181 and CSF pT181/T181 showed a significant inverse relationship ($r=0.4246$, $p=0.039$).

Conclusions: Suvorexant acutely decreased CSF pT181/T181 and A β levels, but increased plasma pT181/T181 while plasma A β levels remained unchanged. These results were made in the setting of no significant group differences in multiple sleep measures, suggesting that suvorexant's effect on CNS and plasma p-tau and A β may be due to mechanisms involving orexin signaling pathways that affect tau phosphorylation and clearance mechanisms.

Acknowledgments: We thank the participants for their time. This work was supported by the Washington University Personalized Medicine Initiative and Good Ventures

Exploring the Association Between Heart Rate and Sleep Difficulties Across Postural Changes Following Concussion: Preliminary Observations of an Orthostatic Challenge

Introduction: Autonomic dysregulation is common in individuals with concussion, often leading to abnormal orthostatic responses. For instance, recently concussed individuals exhibit elevated heart rate (HR) during postural changes, suggesting a shift towards sympathetic overactivation. Furthermore, evidence from non-concussed populations suggests that orthostatic dysregulation increased with age and is more pronounced in females than males. Sleep difficulties, such as longer sleep onset latency, greater variation in sleep time and sleep fragmentation, and overall poorer sleep quality, are also prevalent following concussion. Disrupted sleep has been found to negatively affect autonomic functioning, including orthostatic response with higher effects in older individuals. In turn, autonomic dysregulation may exacerbate sleep problems, potentially creating a bidirectional relationship. This study aims to investigate the association between HR measured across various postural conditions and difficulty falling asleep following concussion, while further exploring potential variations based on age and sex.

Materials and methods: Adults (18–81 years old) with a physician-diagnosed concussion were recruited from a network of interdisciplinary concussion care clinics. During the initial visit, sleep difficulties were documented based on the “trouble falling asleep” item of the Sport Concussion Assessment Tool 6 (SCAT6) Symptom Evaluation (Likert scale: 0 [none] to 6 [severe]). HR was measured during a 70° tilt-table test under two postural conditions at five time points: initial lying (after a 2-minute rest), immediate standing (~15 seconds), and at 1, 2 and 3 minutes after standing. A linear mixed-effects model was conducted to examine how HR was associated with postural conditions, sleep difficulties, age, sex, time since injury and their interactions.

Results: 265 adults (median [IQR]: 34 [26–46] years; 68% female) were included in the analysis. Time since injury (median [IQR]: 23 [16–42] days) was not significantly associated with HR (*all* $p>.050$). HR progressively increased from lying (69.61 ± 12.05 bpm) to immediate standing (79.70 ± 14.77 bpm), continuing to rise at 1- (83.78 ± 14.59 bpm) and 2-minute post-standing (85.26 ± 14.83 bpm), before stabilizing at 3-minute post-standing (84.81 ± 13.66 bpm). Participants reported moderate sleep difficulty scores (median [IQR]: 3 [1–5]). In males, regardless of age, sleep difficulties were not significantly associated with HR while lying ($F(1,77)=2.74$, $p=.102$), but worse sleep difficulties were significantly associated with higher HR during all standing posture conditions (*all* $p\leq.006$). A significant interaction between sleep difficulties, sex, and age ($F(1,231)=4.27$, $p=0.040$) showed that, in females only, older age was significantly associated with lower HR for individuals with low levels of sleep difficulties (scores 0–3; $p<.050$), but this association was not significant for individuals with more severe sleep difficulties (scores 4–6).

Conclusions: These preliminary findings suggest that post-concussion sleep difficulties are associated with increased HR during an orthostatic challenge, with variations observed across sex and age. Future

research should investigate the directionality of the association and the mechanisms underlying these sex-specific effects. Establishing the potential of sleep interventions to improve autonomic regulation following adult concussion represents an important research priority and is essential for advancing clinical care.

Impact of sleep problems and central sensitization in migraine patients

K. Matsubayashi¹, S. Kobayashi¹, S. Suzuki¹, H. Fujita¹, M. Shioda¹, K. Hirata¹, K. Suzuki¹

¹Dokkyo Medical University, Tochigi, Japan

Introduction: Sleep disorders often coexist with migraine and affect quality of life of migraine patients. Central sensitization (CS) is involved in the severity and pathophysiology of migraine. We investigated the association between coexisting sleep problems, central sensitization (CS), and headache-related disability.

Materials and methods: This study included 215 patients with migraine. Insomnia was defined as a score of 6 or higher on the Pittsburgh Sleep Quality Index, probable REM sleep behavior disorder (pRBD) was defined as a score of 5 or higher on the RBD screening questionnaire, and EDS was defined as a score of 10 or higher on the Epworth Sleepiness Scale. Suspected sleep apnea (SA) was defined as snoring or sleep apnea occurring three or more days per week. RLS was diagnosed based on a questionnaire. CS was assessed using the Central Sensitization Inventory (CSI), and headache-related disability was evaluated using the Migraine Disability Assessment (MIDAS).

Results: RLS, insomnia, EDS, SA, and pRBD were observed in 25.6%, 71.6%, 34.4%, 10.2%, and 21.4% of patients, respectively. At least one sleep problem was observed in 87.0% of patients. In a multinomial logistic regression analysis with no sleep problem as a reference, the MIDAS score was significantly higher in patients with three or more sleep problems. In a mediation analysis, an increase in sleep problems had a direct effect on the MIDAS score, and the CSI score was indirectly involved in this association.

Conclusions: This study showed a significant association between sleep problems, CS, and headache-related disability in migraine patients.

Impaired Central Respiratory Regulation in Hyperacute Lateral Medullary Infarction: Insights from Polysomnographic Analysis in a Case-Matched Study

D.W. Kim¹, D.W. Kwack¹, Y.H. Hong², H. Mo², H. Im²

¹School of Medicine, Konkuk University, Neurology, Seoul, Korea, Republic of, ²Dongtan Sacred Heart Hospital, Hallym University College of Medicine, Neurology, Hwaseong, Korea, Republic of

Introduction: Acute lateral medullary infarction (LMI) can present with early respiratory failure. Obstructive sleep apnea (OSA) is common in ischemic stroke, and LMI has been linked to sleep-disordered breathing (SDB), especially central sleep apnea (CSA). This study examined polysomnographic abnormalities associated with respiratory distress in hyperacute LMI, comparing findings to matched OSA and central sleep apnea (CSA) patients.

Materials and methods: We analyzed 19 patients with hyperacute LMI (<5 days from onset) confirmed by MRI. After high-likelihood OSA screening, attended overnight polysomnography (PSG) was conducted at an average of 2.1 days post-stroke. Ultimately, 12 LMI patients with significant leisonal symptoms were compared to 7 CSA patients and 36 matched OSA patients (1:3 match for age, gender, BMI, and apnea-hypopnea index [AHI]).

Results: Among 12 LMI patients (11 men, 43.8 ± 8.0 years), mean BMI was 26.4 ± 2.9, and mean AHI was 32.7 ± 18.9. Despite matched AHI severity, LMI patients had significantly higher central AHI (15.2 ± 15.2/hr vs. 1.3 ± 2.5/hr in controls). Lower respiratory arousal index (17.6 ± 13.1 vs. 30.3 ± 16.4 per hour, p < 0.001) and high arousal threshold was more prevalent in LMI patients than OSA group (75.0 vs. 61.1%), while their most respiratory parameters were comparable to CSA patients.

Conclusions: The medullary respiratory center plays a key role in respiratory regulation. In hyperacute LMI, central sleep apnea and impaired respiratory arousal reflex are prominent, even in high-risk OSA patients. Close monitoring and early intervention for CSA in LMI patients are essential, regardless of lesion size, when symptoms are present.

Impaired Recovery Sleep in Aging, Alzheimer's Disease and Lewy Body Disease

J. Blackman^{1,2}, V. Gabb^{1,2}, H. Morrison^{1,2}, C. Houghton³, C. O'Donnell⁴, H. Li², A. Heslegrave⁵, N. Turner¹, E. Coulthard^{1,2}

¹University of Bristol, Bristol Medical School, Bristol, United Kingdom, ²North Bristol NHS Trust, Bristol Brain Centre, Southmead Hospital, Bristol, United Kingdom, ³University of Bristol, School of Engineering, Mathematics and Technology, Bristol, United Kingdom, ⁴Ulster University, School of Computing, Engineering and Intelligent Systems, Belfast, United Kingdom, ⁵University College London, London, United Kingdom

Introduction: Sleep homeostasis is theorized to be governed by the 'Two Process Model' where circadian rhythm (process C) and homeostatic sleep pressure (process S) interact to determine sleep versus wakefulness. Sleep pressure accumulated during prolonged wakefulness increases the duration and intensity of subsequent 'recovery' sleep. Multiple sleep abnormalities are associated with Alzheimer's Disease (AD) dementia and Lewy Body dementia (LBD). This study aimed to determine whether recovery sleep duration and its onset time may also be compromised and explore whether such compromise may arise from abnormalities in process C, S, or their interaction.

Materials and methods: RESTED (Remote Evaluation of Sleep To enhance understanding in Early Dementia) was an observational cohort study with three subgroups: AD Mild Cognitive Impairment (MCI)/dementia, LBD MCI/dementia, and healthy controls (HC). Participants underwent AD/neurodegenerative serum biomarker testing and wrist actigraphy plus daily sleep diaries for 55 nights. Recovery sleep duration was assessed utilising random intercept linear mixed effects models with total sleep time (TST) as the dependent variable. Explanatory variables included preceding night total sleep time as an autoregressive parameter whose estimate (alpha) describes recovery sleep. Negative alpha implies low TST nights are typically followed by higher TST nights, indicating recovery sleep. Interaction terms determined if alpha was affected by participant group or age. Associations between preceding sleep duration and subsequent sleep onset time were assessed in a similarly specified model. Equations reflecting Process C and S were manipulated within a Two Process Model Simulation to determine whether the empirical results could be replicated.

Results: 40 participants (AD=10, LBD=10, HC=20) matched for age and sex completed the study. Alpha was negative in healthy older adults ($\beta=-0.056$, $SE=0.03$, $p=0.083$) indicating an intact compensatory response.

However in AD and LBD cohorts, overall alpha was positive (AD : $\beta=0.263$, $SE=0.05$, $p<0.001$; LBD : $\beta=0.209$, $SE=0.05$, $p<0.001$) indicating a paradoxical response. Phosphorylated-tau₁₈₁/amyloid-beta₄₂ ratio was associated with positive alpha ($\beta=0.063$, $SE=0.022$, $p=0.007$) with other molecular biomarkers of AD pathology demonstrating similar trends. Increasing age was also positively associated with alpha ($\beta=0.011$, $SE=0.004$, $p=0.006$).

Shorter preceding sleep was paradoxically associated with a later sleep onset time in the AD cohort ($\beta=-0.100$, $SE=0.03$, $p=0.006$) with a trend towards a similar relationship in the LBD cohort ($\beta=-0.072$, $SE=0.04$, $p=0.056$). A trend towards the more expected positive association between preceding sleep duration and sleep onset time was found only in the control cohort ($\beta=0.038$, $SE=0.02$, $p=0.104$).

Simulated attenuation of Process C, Process S, or a reduction in sleep threshold within the computational model did not replicate the pattern of these empirical results.

Conclusions: Healthy older adults compensated for shorter sleep with recovery sleep. However, AD, LBD and increasing age impaired recovery sleep in duration and expected time of onset. The strength of the paradoxical relationship in AD / LBD was correlated with markers of AD disease burden.

These results open up new targets to improve sleep in neurodegenerative diseases e.g. targeted behavioral interventions supporting recovery sleep. Finally, our specific disease-related deficits question current conceptual models of homeostatic sleep in these populations.

Induced sleep fragmentation enhances epileptic activity in focal epilepsy: a combined intracranial EEG and polysomnography study

S. Hannan¹, A. Ho², B. Matoušková³, K. Jaber², T. Avigdor^{2,4}, E. Minato⁴, J. Thomas², D. Southwell², J. Hall⁴, P. Klimeš^{2,3}, L. Peter-Derex⁵, B. Frauscher²

¹Lancaster University, Biomedical and Life Sciences, Lancaster, United Kingdom, ²Duke University Medical Center, Department of Neurology, Durham, United States, ³Czech Academy of Sciences, Institute of Scientific Instruments, Brno, Czech Republic, ⁴McGill University, Montreal Neurological Institute and Hospital, Montreal, Canada, ⁵University Hospital of Lyon, Center for Sleep Medicine and Respiratory Diseases, Lyon, France

Introduction: Although complex interactions between sleep and epilepsy have been reported, the directionality of the link between sleep fragmentation and epileptic activity remains poorly understood. To address this critical gap in knowledge, we investigated causality in this relationship by experimentally manipulating sleep stability in individuals with focal epilepsy. Using targeted auditory stimulation to induce sleep arousals, alongside intracranial electroencephalography (EEG) recordings and polysomnography (PSG), we assessed the direct impact of sleep fragmentation on the rates and propagation of interictal epileptiform discharges (IEDs).

Materials and methods: We prospectively recruited 20 adult patients with drug-resistant focal epilepsy undergoing combined stereo-EEG (SEEG) and PSG (scalp EEG, EOG and EMG) as part of their presurgical evaluation. Three patients were excluded from analysis due to technical issues with the auditory stimulation protocol or abnormal sleep patterns that made sleep scoring unreliable, leaving 17 patients for inclusion (8 females, mean age: 37.2 ± 8.1 years). All participants underwent a combined SEEG-PSG night in which the first half entailed sleep fragmentation consisting of induced arousals. Arousals were induced during stable NREM or REM sleep, by delivering auditory stimuli (1 kHz tones, 40-100 dB, 5 s) with reference to real-time PSG-based sleep scoring. We compared the normalised IED counts and number of propagation channels across 3-s periods: the pre-stimulus baseline and either the post-arousal onset time window, or the post-stimulus time window when auditory stimulation did not induce arousals (control). We also examined whether anatomical location (neocortical vs mesiotemporal channels), seizure onset zone (SOZ) involvement (SOZ vs non-SOZ channels) and sleep stage (N2 vs N3 sleep) modulates the relationship between induced arousals and epileptic activity.

Results: Across patients, 25.9 ± 8.9 arousals (median ± interquartile range) were induced by auditory stimulation. Normalised IED counts were significantly increased during the arousal time window compared to the pre-stimulus baseline ($p=0.00059$, Cliff's $d=0.65$), an effect not observed when auditory stimuli failed to evoke arousals ($p=0.070$). We then investigated which factors might modulate the relationship between evoked arousals and interictal discharge activity. Significant effects were observed in neocortical channels ($p=0.00059$, Cliff's $d=0.66$), outside the SOZ ($p=0.00049$, Cliff's $d=0.53$), and in N2 sleep ($p=0.0022$, Cliff's $d=0.61$). In contrast, IED propagation did not show a significant overall change during evoked arousals compared to the pre-stimulus baseline ($p=0.25$).

Conclusions: Our findings demonstrate that experimentally induced sleep fragmentation acutely enhances epileptic spiking, primarily in the neocortex, outside the SOZ and during NREM stage 2 sleep. In contrast, the propagation of epileptic spikes is not influenced by evoked arousals. This suggests that transient sleep arousals selectively enhance local cortical excitability without adequately engaging broader network dynamics required for spike propagation. Taken together, these results highlight that sleep stabilisation is a promising therapeutic avenue for suppressing sleep-related interictal activity in drug-resistant epilepsy by targeting local cortical hyperexcitability.

Acknowledgments: This work is supported by the Canadian Institutes of Health Research, Fonds de Recherche du Québec – Santé, Hewitt Foundation, Montreal Neurological Institute, and Duke Neurology. The authors wish to express their gratitude to Tanguy Hedrich for his technical support in setting up the auditory stimulation protocol.

International recommendations for sleep and circadian research in aging and Alzheimer's disease: a Delphi consensus study

Introduction: Sleep and circadian disturbances are highly prevalent among individuals with Alzheimer’s disease (AD) and related dementias, often manifesting years before diagnosis, and could represent a modifiable risk factor for dementia. However, sleep was not formally classified as such in the latest Lancet Commission report of modifiable dementia risk factors. Although there has been a proliferation of research on sleep in the context of aging and dementia over the last decades, consensus guidance is needed to facilitate high-quality research, comparability and consistency. In this context, the *Sleep and Circadian Rhythms Professional Interest Area (PIA)* of the International Society to Advance Alzheimer’s Research and Treatment (ISTAART) conducted an expert consensus study to establish recommendations to harmonize future research efforts in the field.

Materials and methods: A modified Delphi consensus approach was used to establish recommendations. Between December 2022 and September 2023, a steering committee (SC) of 18 experts in the field of sleep, aging and dementia was constituted by invitation of the 2022-2024 chair of the ISTAART Sleep and Circadian Rhythms PIA (Prof. Sharon Naismith). The SC designed the questions and outcomes of an online survey, and the first voting round was open between November 2023 and February 2024 to all PIA members (n~480) and non-member researchers. A second online voting round occurred in May 2024 for questions which did not reach consensus in Round 1 or needed clarity, based on the SC’s recommendations. In July 2024, the results were presented to the SC during a virtual meeting. Final recommendations were discussed during the 2024 Alzheimer’s Association International Conference, and were then approved by all SC members.

Results: Forty complete responses were received during the first round of the Delphi process (12 countries; 60% women; mean years of experience in research: 13). Thirty-eight participants agreed to be contacted again for the second Delphi round, and 32 complete responses were received. After two voting rounds, the group determined by consensus: 1) the most relevant sleep and circadian features to assess in the context of aging and dementia research, 2) recommendations on data acquisition and report in older populations with and without cognitive deficits (including on the use of newly-developed wearable and nearable devices), and 3) high-priority future research directions in the field, including which knowledge gaps should be addressed and which sleep and circadian features, populations and designs should be prioritized.

Conclusions: Final consensus recommendations provide guidance to develop high-quality sleep and circadian research in the context of aging and dementia, and synergize future research to improve comparability and clarity within the field. Similar recommendations will need to be established for clinical practice.

Investigation of Factors that Impact the Accuracy of Auto-detected REM Sleep with Atonia

D. Leventowski¹, A. Galbiati², C. Fischer³, F. Bolengo², C. Berka⁴, C. Walsh⁵, T. Neylan⁵, S. Lewis⁶, L. Ferini Strambi², E. St. Louis⁷

¹Advanced Brain Monitoring, Carlsbad, United Kingdom, ²Universita Vita-Salute San Raffaele, Milano, Italy, ³St. Michael's Hospital, Toronto, Canada, ⁴Advanced Brain Monitoring, Carlsbad, United States, ⁵University of California, San Francisco, San Francisco, United States, ⁶Macquarie University, Sydney, Australia, ⁷Mayo Clinic, College of Medicine and Sciences, Rochester, United States

Introduction: Accurate, automated detection of rapid-eye-movement (REM) sleep without atonia (RSWA), a prodromal biomarker for alpha-synuclein-related neurodegeneration derived from chin and arm electromyograph (EMG) signal, would enable population-based studies to be conducted inexpensively and conveniently on large samples of REM sleep behavior disorder and Parkinson disease patients compared with healthy controls. This study investigates two factors that could impact the auto-detected RSWA accuracy acquired in the home, i.e., the auto-staging of REM sleep from the frontalis region, and rejection of RSWA during periods with artifact.

Materials and methods: Twenty-three women and 12 men (ages 71.5 ± 8.5 years, 30 diagnosed with mild cognitive impairment and 5 with Alzheimer's dementia) completed two-night in-home Sleep Profiler™ recordings with chin and arm EMG, while 10 participants repeated the procedure one-year later, for a total of 45 "MCI/AD" recordings. A second cohort of 3 women and 11 men with isolated REM sleep behavior disorder (iRBD) were studied for one (n=8) or two-nights (n=6), with chin EMG missing in one case.

Recordings were auto-scored for REM sleep and RSWA using previously described procedures ("auto"), and then visually edited for accuracy ("edited"). The edited studies were processed a third time to reject chin RSWA that overlapped with snoring ≥ 60 dB and/or head movement ("clean").

The total number of 3-second REM mini-epochs (ME) and those with RSWA were tallied across nights when available, and RSWA densities computed by condition. Bland-Altman plots identified biases resulting from edits to the auto-scoring. Abnormal RSWA densities were based on the previously validated thresholds for the chin ($\geq 15\%$), arm (≥ 12.5) and either chin or arm ("any" $\geq 25\%$).

Results: Editing of auto-staged REM reduced total REM Chin-MEs by 90 ± 596 , Arm-MEs by 138 ± 572 , and Any-MEs by 37 ± 149 in MCI/AD cohort, contributing to a Chin-RSWA bias of $0.2 \pm 1.6\%$, Arm-RSWA bias of $0.6 \pm 2.5\%$, and Any-RSWA bias of $0.9 \pm 2.7\%$.

In the iRBD group editing of REM sleep increased total Chin-ME by 170 ± 335 , Arm-ME by 330 ± 633 , and Any-MEs by 117 ± 182 , resulting in a Chin-RSWA bias of $-3.2 \pm 9.4\%$, Arm-RSWA bias of -1.1 ± 5.0 , and Any-RSWA bias of $-1.6 \pm 7.9\%$.

Across three conditions, the proportion of MCI/AD cases with abnormal Chin-RSWA was auto=31%, edited=29% and clean=16%, Arm-RSWA was auto=9% and edited/clean=4%, and Any-RSWA was auto=16% and edited=18% and clean=16%. Only one of the 7 cases with abnormal clean chin-RSWA had concurrent abnormal Arm-RSWA.

In the iRBD group, the proportions with abnormal chin-RSWA were auto=69%, edited=77% and clean=77%, while Arm-RSWA was auto=77% and edited/clean=86%, and Any-RSWA was auto=71%, edited=79% and clean=79%. In one case, a normal Chin-RSWA density classification likely resulted from only 89 total Chin-MEs.

Conclusions: Despite over-reporting auto-staged REM sleep in the MCI/AD group and under-reporting REM in the iRBD group, the distribution of cases with abnormal RSWA densities were similar before and after editing. Rules that rejected Chin-RSWA during periods with snoring or movement had the greatest impact on abnormal RSWA density distributions, reducing the number of presumed false-positive RSWA cases in the MCI/AD group while having no impact on abnormal Chin-RSWA or Amy-RSWA distributions in the iRBD group.

Acknowledgments: N/A

Locus coeruleus inhibition in tau transgenic mice to treat neuropsychiatric and sleep disturbances in Alzheimer's disease

Y. Potts^{1,2}, S. McDougall¹, J. Metha¹, J. Kron¹, H. Daykin³, M. Van Den Bossche^{2,4}, D. Hoyer^{3,5}, L. Jacobson¹

¹Florey Institute of Neuroscience and Mental Health, Parkville, Australia, ²Neuropsychiatry, KU Leuven, Leuven, Belgium, ³Department of Biochemistry and Pharmacology, University of Melbourne, Parkville, Australia, ⁴Geriatric Psychiatry, UPC KU Leuven, Leuven, Belgium, ⁵Scripps Research Institute, La Jolla, United States

Introduction: Alzheimer's disease (AD) is a prominent neurodegenerative disorder affecting more than 55 million people globally, with almost all patients experiencing, alongside cognitive decline, neuropsychiatric symptoms like agitation, apathy or sleep dysfunction. These symptoms are highly challenging to manage. Tauopathy develops in the locus coeruleus (LC) up to decades before AD symptom onset. LC activation mediates the stress response and since LC inactivation is required for induction of REM sleep, we hypothesised inhibiting the LC improves neuropsychiatric symptoms and sleep dysfunction in a mouse model of AD tauopathy. This was tested using pharmacological and chemogenetic inhibition/silencing approaches. For the former, we chronically dosed an orexin 1 receptor (OX1R) antagonist, since OX1Rs are highly expressed on LC neurons and gate excitatory LC input. Then, we used DREADD technology to directly silence LC activity. Olanzapine, a commonly used antipsychotic, was used as a comparator.

Materials and methods: Experiment 1: 64 male and female PS19 mice and wild-type (WT) littermates (8.75-9.5 mo) were dosed daily (p.o.) with the selective, orally available, brain penetrant OX1R antagonist, 1-SORA-51 (60 mg/kg/d) or vehicle (TPGS). Experiment 2: 80 PS19xTH-Cre mice (7-9 mo) underwent bilateral LC injections of hM4Di, an inhibitory DREADD, packaged in an adenovirus vector (AAV-DJ). After 4 weeks, to allow expression of the DREADD construct, mice were dosed daily (i.p.) with either the DREADD agonist J60 (0.01 mg/kg/d), olanzapine (3 mg/kg/d) or vehicle (saline). In both experiments, anxiety- and depressive-like symptoms were assessed using a battery of behavioural tests and polysomnography (PSG) for vigilance states.

Results: 1-SORA-51 reduced hyperlocomotion, as measured by total distance travelled, in male tau transgenic mice (3210.9 mm vs 2072.5 mm) whereas olanzapine did so in both male (7174.0 mm vs 1295.0 mm) and female (3654.6 mm vs 2229.2 mm) PS19 mice. Preliminary analyses suggest J60 administration had weaker effects on depressive- or anxiety-like behaviours than 1-SORA-51 or olanzapine. Both sexes of PS19 mice displayed prominent hyperarousal, as illustrated by a loss, in average percent per hour during the dark/active phase, in total REM (1.3% vs 2.4% in WT) and NREM (25.2% vs 32.3% in WT) and markedly increased wakefulness (73.5% vs 65.2% in WT). Unexpectedly, 1-SORA-51 exacerbated REM sleep deficits (2.2% vs 1.3%) following 2 weeks of treatment in male PS19 mice, however, memory performance was unaffected.

Conclusions: Broad pharmacological inhibition of OX1Rs appeared to be promising in alleviating anxiety-like psychiatric symptoms in PS19 mice, without producing the sedative effects of olanzapine, while the more restricted chemogenetic inhibition of the LC was less effective. Whether this was due to modulation of OX1Rs outside of the LC, or a dominant requirement to modulate LC inputs rather than outputs, is an intriguing question. While OX1R antagonism worsened REM sleep deficits, it did not

negatively affect cognitive performance, suggesting it as a novel and effective daytime treatment option for anxiety-like symptoms in AD.

Motor Sleep Inertia and Activity-Based Prospective Memory in Early Multiple Sclerosis: An Actigraphic Study

F. Giudetti¹, F. Camilli^{2,3}, V. Natale¹, L. Tonetti¹, A. Lugaresi^{2,3}

¹University of Bologna, Department of Psychology, Bologna, Italy, ²IRCCS Institute of Neurological Sciences of Bologna, Multiple Sclerosis Rehabilitation Unit, Bologna, Italy, ³University of Bologna, Department of Biomedical and Neuromotor Sciences, Bologna, Italy

Introduction: Multiple sclerosis (MS) is a chronic autoimmune disease of the central nervous system, marked by significant clinical heterogeneity. The most common form at onset is relapsing-remitting MS (RRMS). Patients with early-stage RRMS (diagnosed within 24 months) may show increased motor activity around 5:00 a.m., possibly due to hyperactivity of the hypothalamic–pituitary–adrenal (HPA) axis. While sleep disturbances have been increasingly studied in MS, transitional sleep–wake dynamics—such as sleep inertia (SI)—remain underexplored. Although actigraphy has been used to study SI in healthy individuals, it has not been widely applied to MS populations. Given MS-related motor and cognitive changes, characterizing SI could offer insight into real-life functioning. Cognitive symptoms are also common in MS. Among these, prospective memory (PM)—the ability to remember to perform intended actions in the future—is particularly relevant, as it plays a key role in daily life, such as remembering to take medications. In this study, PM was assessed through an activity-based task: participants wore an actigraph and were asked to press the event marker upon the last morning awakening. We measured the PM efficiency (in percentage) and the latency between get-up time and button press and its association with motor SI.

Aims:

1. To investigate differences between MS patients and healthy controls (HC) in terms of motor sleep inertia;
2. To assess whether the percentage of accuracy in the PM task differs between HC and individuals with early-stage RRMS;
3. To explore the relationship between motor sleep inertia and performance on the activity-based PM task in both groups.

Materials and methods: We enrolled 35 patients with RRMS (24 females; mean age 31.4 ± 7.74) and 30 HC (21 females; mean age 29 ± 7.07). Participants wore Micro MotionloggerWatch devices on non-dominant wrist for seven consecutive days, pressing the event marker to signal bedtime and wake-up. Data were analyzed using the Action W-2® software, version 2.7.1.

Results: A functional linear model comparing post-wake motor activity in the first 60 minutes (1) revealed a similar pattern across groups, though MS participants showed reduced motor sleep inertia in the first ~10 minutes after morning awakening, suggesting faster motor reactivation. In the PM task (2), both groups showed high compliance, with HC showing slightly higher accuracy (91.4%) than MS (87.7%), though the difference was not statistically significant. FLM analysis showed a broader time window of association between early motor activity and task latency in MS (3), suggesting that reduced inertia correlates with better performance.

Conclusions: Our results indicate (1) reduced motor sleep inertia in individuals with MS, possibly reflecting a heightened adrenal response characteristic of early stages of the disease. This reduced motor inertia appears to (2) be accompanied by a preserved activity-based prospective memory, as MS participants were able to perform the cognitive task at a level comparable to HC. Furthermore, (3) FLM analysis showed that higher early motor activation was associated with faster task initiation in both groups. Notably, the MS group once again exhibited lower sleep inertia compared to HC, and as sleep inertia decreased, task performance improved, resulting in prospective-memory task shorter latency.

Multicenter study on the effect of CPAP on cognitive function in patients with mild cognitive impairment and Alzheimer's disease with OSA (DemCPAP): presentation of the protocol and preliminary data

Introduction: Obstructive sleep apnea (OSA) is associated with an increased risk of Alzheimer's disease (AD) and its progression. Some studies suggest that continuous positive airway pressure (CPAP) therapy can delay cognitive decline and improve sleep quality in Mild Cognitive Impairment (MCI) and AD. However, large, prospective studies with long-term follow-up are needed to confirm these findings. The DemCPAP study, initiated in April 2024, is enrolling participants to address this gap. The primary objective is to assess, over a 3-year follow-up, the effects of CPAP on cognitive function in patients with amnesic MCI and mild-to-moderate AD who have moderate-to-severe OSA (Group A). These patients will be compared to two control groups: Group B, with the same pathologies where CPAP is not possible or adequate due to patient or caregiver difficulties, and Group C, consisting of patients with MCI or AD without OSA. Secondary objectives include evaluating the impact of CPAP on sleep quality, sleep quantity, and daytime sleepiness. The tertiary objective involves assessing changes in plasma AD biomarkers.

Materials and methods: DemCPAP is a multicenter, prospective study conducted across eight Italian centers specializing in dementia and sleep disorders. The coordinating center is the Sleep Medicine Center, department of neurology at Villa Serena Hospital, Pescara, Italy. The study protocol has been approved by the relevant ethical committees. Patients with amnesic MCI and AD will be enrolled based on specific diagnostic criteria, with the requirement for a valid caregiver. In cases of atypical presentation, biomarker confirmation is required. OSA diagnosis will follow the third edition of the International Classification of Sleep Disorders (ICSD). CPAP titration and treatment will adhere to established guidelines. Baseline assessments include neuropsychological and somnological testing, the Psychomotor Vigilance Task (PVT), polysomnography (PSG), ApoE polymorphism analysis, AD biomarkers (Aβ₄₂, Aβ_{42/40} ratio, TAU), and brain MRI with Scheltens' and Fazekas scales. Participants will be categorized into "cases" (Group A) or "controls" (Groups B and C) based on PSG results and CPAP adherence, assessed three months after titration. A second PSG will evaluate OSA control during CPAP ventilation. At six months, participants will repeat a reduced set of neuropsychological and somnological tests. At 12 and 24 months, extended assessments will be performed, including PVT and reassessment of blood biomarkers at 12 months. At 36 months, extended evaluations and a new brain MRI will be done. In Group A, CPAP adherence will be monitored at each time point.

Results: 28 patients have been enrolled, 27% AD and 73% MCI with OSA present in 54% of MCI and 75% of AD patients. OSA prevalence has been detected in male MCI patients, no sex prevalence in AD. Good CPAP adherence has been observed at three months post-titration in both MCI and AD patients, with no dropouts recorded. Moreover, 18 patients have already been screened for enrollment.

Conclusions: CPAP treatment and good adherence in AD and MCI patients with OSA are expected to improve sleep quality, reduce daytime sleepiness, potentially reduce conversion from MCI to AD, and also improve the clinical course in AD.

Narcolepsy-like symptoms in a 31-year-old male with X-linked adrenoleukodystrophy

T. Georgiev¹, H. Ivanov², K. Avramov¹, A. Draganova¹, V. Karaliyski², A. Trenova², K. Terziyski¹
¹Medical University - Plovdiv, Pathophysiology, Plovdiv, Bulgaria, ²Medical University - Plovdiv, Plovdiv, Bulgaria

Introduction: X-Linked adrenoleukodystrophy (X-ALD) is a rare inherited neurodegenerative disease, caused by congenital defect in the ATP-binding cassette transporters subfamily D member 1 gene (ABCD1). The mutation is responsible for defective peroxisomal oxidation of very long chain fatty acids, which accumulate in the cells of the central nervous system, testes and adrenal cortex. The typical clinical features of X-ALD include cerebral demyelination, adrenomyeloneuropathy and primary adrenal insufficiency. While the neurological and endocrine features of the disease are well-characterized, data about the impact of the disturbance on sleep and wakefulness among those patients are scarce. We present a case of X-ALD with prominent sleep disturbance, including excessive daytime sleepiness (EDS) and narcolepsy-like symptoms.

Materials and methods: Unattended home-based polysomnography (PSG) was performed using NOX A1 PSG systems, followed by an in-lab multiple sleep-latency test (MSLT). Prior to the PSG a 14-day actigraphy was conducted. The patient was referred to a neurologist and medical geneticist for further evaluation. Genetic testing was carried out through sequence analysis utilizing the Blueprint Genetics (BpG) Leukodystrophy and Leukoencephalopathy Panel.

Results: The patient is a 31-year-old male with primary hypoadosteronism, presenting with chief complaints of EDS, loss of muscle tone upon laughter, and disrupted sleep with enuresis. Objective examination demonstrated spastic gait, lower limb muscle weakness, and persistent ataxia. Wrist-worn actigraphy recording revealed irregular sleep-wake pattern with multiple daytime naps and nocturnal wakefulness episodes. The PSG showed an impaired sleep architecture with decreased REM sleep (13.9%), increased N3 stage (36.3%), increased wake after sleep onset (WASO) of 146.2 min, and periodic limb movements index (PLMI) of 76.2/h. In addition, the arousal index was significantly increased (20.1/h), with arousals being associated with limb movements. The MSLT demonstrated significantly reduced average sleep-onset latency (SOL) of 2 minutes, and one sleep-onset period (SOREMP), indicative of pathological sleepiness. The patient showed difficulty maintaining wakefulness between sessions and had difficulties awakening from sleep, although without signs of sleep inertia. He refused lumbar puncture and cerebrospinal fluid testing for hypocretin levels. The genetic analysis revealed a hemizygous missense variant ABCD1 c.773T>C, p.(Leu258Pro), which is pathogenic for X-ALD.

Conclusions: To the best of our knowledge, this is the first detailed description and analysis of sleep parameters in a patient with X-ALD. It reveals atypical manifestation of X-ALD, presenting with hypersomnolence and altered sleep architecture, including SOREMPs and pathologically reduced SOL. These findings resemble the clinical and electrophysiological characteristics of narcolepsy, highlighting the importance of a broader differential diagnoses in patients with EDS. While narcolepsy remains the primary consideration, the underlying neurologic and endocrine features should be thoroughly investigated and considered as important differential diagnostic markers. This case underscores the importance of evaluating sleep-related symptoms in patients with X-ALD and contributes to the extension of its clinical spectrum.

Neuroimaging findings for poor sleepers after acquired brain injury

L.G. Chan¹, J. Lin², A. Sidarta³, F. Lim⁴

¹Tan Tock Seng Hospital, Psychiatry, Singapore, Singapore, ²Tan Tock Seng Hospital, Clinical Research and Innovations Office, Singapore, Singapore, ³Nanyang Technological University, Rehabilitation Research Institute of Singapore, Singapore, Singapore, ⁴Nanyang Technological University, Lee Kong Chian School of Medicine, Singapore, Singapore

Introduction: Stroke and trauma are the top causes of acquired brain injury (ABI) and more than half of this population suffer from some form of sleep disturbance, which causes caregiver distress and is a treatment challenge. Poor sleep after ABI also hinders participation in rehabilitation activities and therefore, may have an adverse impact on outcomes both directly and indirectly. There is emerging literature on neuroimaging findings of healthy individuals with poor sleep, and studies linking neuroimaging with poor sleep and cognition. However, little is known about neuroimaging findings of poor sleep in people with known structural brain damage after an ABI. The primary aim of the present study is to examine differences in structural and functional Magnetic Resonance Imaging (MRI) findings between ABI patients with poor sleep and those with normal sleep. The secondary aim is to correlate the neuroimaging findings with clinical outcomes of ABI patients.

Materials and methods: 25 patients with ABI were recruited within 3 months of index event concurrently with 49 age and gender-matched healthy controls and underwent baseline assessment involving mood and sleep questionnaires and cognitive tests. 11 ABI patients and 17 controls underwent objective sleep testing because they scored >5 on the Pittsburgh Sleep Quality Index (PSQI). 14 ABI and 40 controls were eligible and completed MRI brain that included structural and resting state functional sequences. Data analysis involved comparing ABI poor sleepers with ABI normal sleepers and comparing ABI poor sleepers with healthy control poor sleepers. Resting state functional MRI data was analyzed using FSL MELODIC to identify important networks common to both ABI poor sleepers and ABI normal sleepers, before being further analyzed with the dual regression to reveal differences in those networks between the two groups.

Results: Preliminary analysis shows differences in the sensorimotor network, default mode network, and cerebellar regions when comparing ABI poor sleepers with ABI normal sleepers. Further analysis ongoing.

Conclusions: Poor sleep after ABI may have a direct impact on brain structure and function, which may correlate with poorer clinical outcomes such as poorer cognitive function. Further work is required to examine if these neuroimaging changes are reversible after successful sleep treatment and whether outcomes can be improved after reversal of these changes.

Non-invasive detection of Hippocampal Interictal Epileptiform Discharges in Epilepsy and Mild Cognitive Impairment Using Zygomatic EEG During Sleep

Introduction: Interictal epileptiform discharges (IEDs), occurring predominantly during NREM sleep, can disrupt memory consolidation and may contribute to cognitive decline in epilepsy and other neurological disorders. IEDs in the hippocampus and medial temporal lobe (MTL) may also occur in some individuals with amnesic Mild Cognitive Impairment (aMCI), which often represents a prodromal stage of Alzheimer's disease. However, this remains controversial since non-invasive detection of IEDs in deep medial brain regions is extremely challenging via visual annotation. The aim of this study was to develop a quantitative method for non-invasive detection of MTL IEDs to test their occurrence in aMCI during sleep.

Materials and methods: We present an automatic machine learning (ML)-based tool to non-invasively detect and quantify MTL IEDs. We develop and validate the method against ground truth in epilepsy patients, and then apply it in aMCI patients. First, intracranial MTL IEDs from 50 neurosurgical epilepsy patients in three separate medical centers, were detected according to annotations by neurologists. An XGBoost model was trained on simultaneous overnight intracranial EEG and zygomatic EEG ('zEEG', EEG electrodes placed on the upper cheekbone). Second, the model was validated using non-invasive overnight zEEG data in a separate cohort of 44 subjects, including individuals with mesial temporal lobe epilepsy (MTLE) and age-matched healthy controls. Finally, we applied the trained model to overnight zEEG data from 50 elderly participants, including both individuals with aMCI and age-matched healthy controls.

Results: The model successfully detected over 15% of MTL IEDs via zEEG with a precision exceeding 80% in test data, successfully generalizing to new individuals (leave one out approach). We found that MTL IEDs that were successfully detected via zEEG were associated with significantly higher amplitude and spatial spread as recorded intracranially, and that MTL IEDs were associated with pathological burst firing of MTL neurons. Furthermore, the model for detecting MTL IEDs was significantly different than a model trained to detect IEDs in the medial frontal lobe. During validation, IED event rates extracted automatically from zEEG, without any visual inspection, effectively distinguished MTLE patients from healthy controls ($p < 0.0001$). When applied to elderly participants, the model revealed a significantly ($p < 0.018$) higher rate of putative IEDs in individuals with aMCI (age = 71 ± 7 , MoCA = 22 ± 3) compared to healthy controls (age = 70 ± 5 , MoCA = 27 ± 2). Furthermore, there was a significant negative correlation ($r = -0.38, p < 0.01$) between the rate of putative IEDs identified by the model and MoCA scores in both healthy participants and individuals with aMCI.

Conclusions: Our work advances early diagnostics by enabling non-invasive detection of deep brain epileptiform activity during sleep, offering new biomarkers for intervention and disease monitoring.

Acknowledgments: Supported by European Research Council (ERC-2019-CoG 864353, ERC Proof of Concept (PoC) grant 101158226) and Corundum Neuroscience grant.

Optimising Positive Airway Pressure (PAP) Therapy in a Patient with Cervical Spinal Cord Injury and Untreated Severe Obstructive Sleep Apnoea (OSA): A Case Report

W.L. Lui¹, Z.-Y.V. Ng¹, A. Peters²

¹Tan Tock Seng Hospital, Rehabilitation Medicine, Singapore, Singapore, ²Tan Tock Seng Hospital, Respiratory Therapy, Singapore, Singapore

Introduction: Sleep disordered breathing is common in individuals with spinal cord injuries (SCI). This often contributing to impaired rehabilitation outcomes. We present a case of a patient with previously diagnosed but untreated severe OSA, who sustained a cervical SCI. He subsequently underwent intensive rehabilitation in the Ventilatory Rehabilitation Unit, was successfully initiated on PAP therapy and had with improvement in functional outcomes.

Materials and methods: A case report of a patient with untreated severe OSA managed in a ventilatory rehabilitation unit following cervical spinal injury.

Results: A 52-year-old male with known severe OSA which was confirmed by polysomnography: Apnoea-Hypopnoea Index [AHI] 91.8, Oxygen Desaturation Index [ODI] 87.9, nadir SpO₂ 58%. He had had previously declined Positive Airway Pressure (PAP) therapy due to the great discomfort he experienced with PAP therapy.

He presented to the hospital after sustaining from a fall from a chair, with resultant tetraparesis. Magnetic Resonance Imaging of the cervical spine showed cervical spondylosis and degenerative disc

disease, worse at C3-4 to C5-C6 with moderate spinal canal and moderate to severe bilateral foraminal stenosis. He then underwent surgical decompression and instrumentation of his cervical spine before he was transferred to a rehabilitation centre for intensive tertiary rehabilitation.

On admission to the rehabilitation centre, his demonstrated improvement in his strength and had residual mild weakness in his limbs.

During his stay in the rehabilitation centre, he was noted to have daytime somnolence which significantly impaired his engagement in therapy. History revealed that he fell from the chair as he dozed off while sitting on the chair. Examination revealed a body mass index (BMI) of 40 kg/m², neck circumference of 38.5 cm, Epworth sleepiness scale (ESS) of 19 and STOP-BANG Score 7.

He was re-counselled and agreed for initiation of PAP therapy. Initial autoCPAP (10–12 cmH₂O) was poorly tolerated due to discomfort. He could only tolerate PAP therapy for up to 2 hours a night. This prompted reduction to CPAP 5 cmH₂O. Concurrent troubling symptoms of allergic rhinitis were managed with intranasal corticosteroids and oral antihistamines. As nasal symptoms improved, a structured PAP acclimatisation protocol was implemented. This included adjustment of ramp settings, progressive increase in pressure settings and duration of PAP therapy.

Gradually, the patient achieved improved tolerance, with nightly use extending to 8 hours. Compliance data showed that AHI had reduced to 21. ESS had also improved to 10. He reported marked reduction in daytime somnolence, enabling full participation in physiotherapy. On discharge, he achieved significant improvement in his functional status and required only minimal assistance for ambulation and activities of daily living.

Conclusions: Effective initiation and acclimatisation to PAP therapy in the inpatient setting in this patient not only led to significant improvement in sleep-related symptoms and functional rehabilitation outcomes. This could also reduce his risk of falls which could prevent further injuries.

Structured, individualised PAP therapy acclimatisation with close multidisciplinary support facilitated better adherence, especially in this patient who was previously non-compliant.

Acknowledgments: We would like to thank the multidisciplinary team in the Ventilatory Rehabilitation Unit

Outcomes of poor sleep quality after acquired brain injury in the subacute phase - preliminary data from a longitudinal study

L.G. Chan¹, J. Lin², F. Lim³

¹Tan Tock Seng Hospital, Psychiatry, Singapore, Singapore, ²Tan Tock Seng Hospital, Clinical Research and Innovations Office, Singapore, Singapore, ³Nanyang Technological University, Lee Kong Chian School of Medicine, Singapore, Singapore

Introduction: Trauma and stroke are the 2 commonest causes of acquired brain injuries (ABI). Studies show more than 50% of ABI patients experience sleep disturbances. Clinical experience shows that sleep-wake disturbance is one of the most challenging problems to manage as it causes high levels of caregiver distress in both the hospital and the community and does not seem to respond well to available pharmacological treatments even at high doses. In the hospital setting, sleep-wake disturbance is a reason for the use of physical restraints and in the community setting, sleep-wake disturbance is an important reason for institutionalization. Moreover, it is also a major hindrance to participation and progress in rehabilitation efforts. Effective management of these sleep disturbances is therefore a critical need for clinical practice. There are very few studies in current literature that have specifically examined the association between abnormal sleep after ABI and neuropsychiatric outcomes such as mood, behaviour, cognition and overall function. The primary aim of this study was to measure and characterize sleep abnormalities at 3, 6 and 12 months after ABI using both subjective and objective measures, and their impact on neuropsychiatric outcomes.

Materials and methods: 25 adult ABI subjects and 49 healthy controls were recruited and underwent assessment with sleep and mood questionnaires and cognitive tests. Study subjects with a score of 5 or more on Pittsburgh Sleep Quality Index (13 ABI and 22 controls) underwent objective sleep testing

with overnight ambulatory polysomnography, actigraphy monitoring and sleep diary charting for 1 week. Data from subjects with both objective and subjective measures were analyzed and compared.

Results: 1. Frequency of poor sleep quality in ABI patients high (72%), not significantly different from gender-matched control group (67.35%)

2. No difference in objective sleep measures on overnight polysomnography & wrist actigraphy likely due to small sample size & sample heterogeneity

3. ABI patients with poor sleep had poorer performance on sustained attention tests than healthy controls with poor sleep.

Conclusions: Poor sleep in ABI patients may affect cognitive performance in sustained attention.

Acknowledgments: Acknowledgements to Ms Mohapatra Litali and Prof Joshua Gooley for their valuable contributions to the study.

Post-stroke sleep disordered breathing and the effect of positive airway pressure treatment. A systematic review and meta-analysis of randomized control trials

D. Papalexatos¹, F. Sampsonas¹, D. Lykouras¹, V. Karamouzou², M. Doulberis³, K. Karkoulas¹, P. Steiropoulos⁴, M. Katsaras¹, A. Tzouveleakis¹

¹University General Hospital of Patras, Pulmonary Department, Patras, Greece, ²University General Hospital of Patras, Intensive Care Unit, Patras, Greece, ³Medical University Department, Kantonsspital Aarau, Division of Gastroenterology and Hepatology, Aarau, Switzerland, ⁴Medical School, Democritus University of Thrace, Alexandroupolis, Department of Pneumology, Alexandroupolis (Greece), Alexandroupolis, Greece

Introduction: Sleep-disordered breathing (SDB), primarily Obstructive Sleep Apnea (OSA) is both a known risk factor of cerebrovascular events and a consequence of them.

OSA negatively impacts cerebrovascular health through blood pressure and heart rate fluctuations. This increases stroke recurrence risk and hinders neuroplasticity. It also impairs cognitive function and mood, often leading to depression and excessive daytime sleepiness.

Positive airway pressure (PAP) therapy is the gold-standard of OSA treatment and existing research shows that PAP therapy benefits stroke survivors with OSA, but findings across studies vary.

The aim of this meta-analysis of Randomized Control Trials was to investigate the favorable outcome of PAP therapy in patients with OSA after a stroke.

Materials and methods: Records were identified from Embase Elsevier Database (Embase, Medline/PubMed, Preprints, PubMed-not-Medline).

The study aimed to investigate the effect of PAP on vascular events, neurological deficit, functional independence, depression, sleepiness and cognitive function.

After screening 72387 records, 21 RCTs were included in the systematic review with 1457 patients with stroke (753 patients in the PAP group and 704 in the standard of care (SOC) or sham-CPAP group)

Results: Recurrent vascular events were evaluated in 7 studies (364 patients under PAP and 274 controls). The recurrent vascular events in the PAP group were significantly lower compared to the control group: OR 0.45 (95% CI 0.28 to 0.78; $p < 0.01$).

Neurological deficit was evaluated in 7 randomized clinical trials (332 patients received PAP and 306 in the control group). A significant improvement was achieved with the application of PAP treatment: OR -0.30 (95% CI -0.47 to -0.14; $p < 0.01$).

Ten studies evaluated functional independence (410 patients in the PAP group and 390 controls). It was shown that PAP treatment did not significantly improve functional independence: OR 0.25 (95% CI -0.11 to 0.60; $p = 0.17$).

Five studies evaluated sleepiness after the application of PAP treatment (106 patients in the PAP group and 107 controls). The application of PAP treatment improved daytime sleepiness OR: -0.96 (95% CI -1.47 to -0.45; $p < 0.01$).

Five studies evaluated improvement of depression (136 patients in the intervention arm and 172 in the control group). Analysis showed that the application of PAP treatment reduced depression levels: OR -0.58, (95% CI -1.05 to -0.11; $p = 0.02$)

Cognitive function was evaluated in 6 studies (166 patients receiving PAP group and 216 controls).

Statistical analysis showed that PAP treatment improved cognitive function: OR1.10 (95% CI 0.35 to 1.86; $p=0.02$).

Conclusions: Positive airway pressure treatment is effective and feasible in patients with stroke.

PAP treatment can reduce recurrent vascular events and improve recovery and rehabilitation of these patients.

Screening of sleep disordered breathing in these patients should not be delayed even in the acute post-stroke phase.

Acknowledgments: none

Prevalence of obstructive sleep apnea and screening questionnaire performance in highly drug-resistant epilepsy

S. Pitipanyakul^{1,2}, N. Chirakalwasan^{3,2}, C. Limothai⁴, P. Srisawat⁵

¹Chulalongkorn University, Department of Medicine, Bangkok, Thailand, ²King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Excellence Center for Sleep Disorders, Bangkok, Thailand,

³Chulalongkorn University, Division of Pulmonary and Critical Care Medicine, Department of Medicine, Bangkok, Thailand, ⁴Chulalongkorn University, Division of Neurology, Department of Medicine, Bangkok, Thailand, ⁵Chulalongkorn University, Department of Psychiatry, Bangkok, Thailand

Introduction: Obstructive sleep apnea (OSA) is common among patients with drug-resistant epilepsy (DRE); however, data are limited for those with highly drug-resistant epilepsy (HDRE), defined as requiring three or more antiepileptic drugs. This study aimed to determine the prevalence of OSA in patients with HDRE and to evaluate the performance of existing screening questionnaires to identify the most suitable tool for assessing OSA risk.

Materials and methods: We conducted a cross-sectional study in 41 adults with HDRE. All participants underwent overnight polysomnography (PSG) and completed five screening questionnaires: STOP-BANG, SA-SDQ, Berlin Questionnaire, NoSAS, and NH-OSA. The discriminatory performance of each tool was assessed using receiver operating characteristic (ROC) curve analysis. A novel scoring model BANGS was developed using logistic regression.

Results: The prevalence of OSA was 75.6%, with severity classified as mild (26.8%), moderate (29.3%), and severe (19.5%). For an apnea-hypopnea index (AHI) ≥ 5 , the STOP-BANG questionnaire demonstrated the highest area under the curve (AUC) at 0.771 (95% CI: 0.62–0.92), with 74.2% sensitivity and 80% specificity. The newly developed BANGS score, based on BMI ≥ 23 , age ≥ 40 , neck circumference ≥ 40 cm, male gender, and snoring, achieved 71.4% sensitivity and 100% specificity for predicting moderate-to-severe OSA.

Conclusions: This is the first study to report OSA prevalence in patients with HDRE, revealing a notably high rate. Nearly half of the patients had moderate-to-severe OSA. STOP-BANG demonstrated acceptable diagnostic performance, while the BANGS score showed strong specificity and may serve as a useful screening tool. Routine OSA screening should be considered in patients with HDRE.

Rare Pediatric Genes: A Case of Obstructive Sleep Apnea in a Patient with Cornelia de Lange

A. Valenzuela¹, A. Nguyen², D. Dominguez¹

¹Banner Health, Sleep Medicine, Mesa, United States, ²University of Arizona - College of Medicine, Phoenix, United States

Introduction: Cornelia de Lange syndrome (CdLS) is a rare genetic disorder affecting 1 in 10,000 newborns. It is characterized by growth restriction, developmental delays, and high rates of various comorbid conditions. Approximately 25% of individuals with CdLS experience epilepsy, for which vagal nerve stimulators (VNS) can be used as a treatment. However, VNS has been associated with obstructive sleep apnea (OSA) through various mechanisms including decreased airflow and change in respiratory effort. This report highlights a CdLS patient with OSA initially attributed to VNS implantation.

Materials and methods: A 13-year-old male with a history of CdLS, chronic epilepsy managed with VNS, and a history of adenotonsillectomy at a young age presented to the sleep clinic for OSA management. Two years post-VNS implantation, his epilepsy remained poorly controlled on EEG. Restless sleep and excessive daytime sleepiness (EDS) were quite debilitating and thought to be worsening his seizure burden.

Results: A sleep study was ordered which revealed severe pediatric OSA (apnea-hypopnea index (AHI) of 14.8/h, central apnea index (CAI) of 0.4/h, and oxygen nadir of 81%). Initially, VNS-induced worsening of OSA was suspected, and nighttime VNS settings were adjusted accordingly. His mother reported continued restlessness during sleep, but no witnessed apnea and ongoing sleepiness. Patient underwent repeat adenoidectomy with ENT. Post-operative sleep study confirmed persistent, residual severe OSA (AHI 18.1, RDI 46, oxygen nadir 74%). Post-operative sleep study confirmed persistent severe OSA (AHI 18.1, RDI 46, oxygen nadir 74%). The patient began therapy with APAP 5–15 cm H₂O. Adherence was poor prior to desensitization/education and improved notably thereafter. On APAP, his residual AHI improved to 1.3. Symptoms of hypersomnolence improved drastically with a decrease in seizure burden and resolution of restless sleep. Eventually, a very low dose of modafinil was also trialed with complete resolution of EDS issues, to avoid interaction with metabolism of antiepileptic medications.

Conclusions: This case underscores the complexity of managing OSA in patients with rare syndromes and various comorbidities. While VNS was initially suspected to exacerbate OSA, settings adjustment proved ineffective, highlighting the need for comprehensive evaluation. Despite repeat surgical interventions, PAP therapy ultimately proved to be the most efficacious treatment, demonstrating that even patients with syndromic conditions can achieve effective treatment & adherence with appropriate interventions. Seizure burden and hypersomnolence should be treated aggressively and concurrently to improve quality of life. Adjunct medications for EDS can be utilized as well, with collaboration amongst specialists proving quite useful. Providers must remain informed about the unique needs of the complex pediatric population to deliver optimal care, including those with vagal nerve stimulators.

Rationale and Study Design of Phase-3 Clinical Development Program for Samelisant (SUVN-G3031) in the Treatment of Excessive Daytime Sleepiness in Patients with Narcolepsy

V.K. Goyal¹, A. Shinde¹, R. Subramanian¹, P. Jayarajan¹, R. Nirogi¹

¹Suven Life Sciences Ltd., Hyderabad, India

Introduction: Samelisant (SUVN-G3031) is a potent and selective inverse agonist of the histamine H₃ receptor. It acts by modulating the histaminergic system, which plays a critical role in the regulation of the sleep–wake cycle. Samelisant demonstrated both wake-promoting and anticataplectic effects in animal models of narcolepsy. The objective of the Phase-3 study is to assess the efficacy and safety of Samelisant for the treatment of excessive daytime sleepiness (EDS) in narcolepsy patients.

Materials and methods: Samelisant was evaluated in orexin knockout mice and orexin-B saporin (SAP)-lesioned rats to assess its effects on sleep–wake patterns and cataplexy using electroencephalography (EEG). Samelisant was evaluated as a monotherapy in a Phase-2 proof-of-concept, double-blind, randomized controlled trial (NCT04072380) for the treatment of EDS in patients with narcolepsy, with or without cataplexy. Building on the robust preclinical evidence and positive outcomes from the Phase-2 clinical study, a Phase-3 clinical trial for Samelisant is planned. The design of this proposed study will be outlined in the results section.

Results: In orexin knockout mice, Samelisant significantly increased the time spent in wake period and reduced cataplexy-like episodes. Similarly, in orexin-B SAP-lesioned rats, it demonstrated wake-promoting effects and led to a significant decrease in direct transitions from wakefulness to rapid eye movement sleep (DREM episodes), a hallmark of narcolepsy. In the Phase-2 study, on day 14, Samelisant demonstrated a statistically significant and clinically meaningful reduction of 2.1 points in the Epworth Sleepiness Scale (ESS) total score compared to placebo ($p < 0.024$). The improvement in the primary endpoint was further supported by statistically significant benefits on key secondary endpoints, including the Clinical Global Impression–Severity (CGI-S), Patient Global Impression of Change (PGI-C), and Clinical Global Impression of Change (CGI-C). Samelisant was found to be safe and well tolerated in the study population.

The proposed global Phase-3 study will be a placebo-controlled, double blind randomized, parallel-group study. The study will recruit about 216 narcolepsy patients with an established diagnosis of

narcolepsy according to the ICSD-3-TR or DSM-5-TR. After a screening period of 4-weeks, eligible patients will follow a titration schedule to gradually increase their dose of the investigational product for initial four weeks followed by stable dose treatment for additional eight weeks.

The primary endpoint of the study will be change from Baseline in total ESS score at Week 12.

Secondary endpoints will include change from Baseline in Maintenance of Wakefulness Test (MWT) score, CGI-S score and Narcolepsy Severity Scale (NSS) at Week 12.

Other exploratory endpoints will be change from Baseline in weekly rate of cataplexy (WRC), CGI-C, PGI-C, sustained attention to response task (SART) score and Functional Outcomes of Sleep Questionnaire (FOSQ-10) scores at Week 12.

Conclusions: The Phase-3 study is expected to begin in the second half of 2025. Study results from this Phase-3 study will provide further insight into the therapeutic potential of Samelisant for the treatment of narcolepsy.

Acknowledgments: None

Relationship between polysomnography findings and sleep bruxism in patients with multiple system atrophy

G. Umemoto¹, Y. Doutsu¹, C. Yoshimura¹, R. Miyachi¹, M. Kuchiishi¹

¹Fukuoka University, Fukuoka, Japan

Introduction: The objective of this study is to analyze the relationship between findings in polysomnography (PSG) and the frequency of sleep bruxism (SB) in patients with multiple system atrophy (MSA).

Materials and methods: We recruited 15 patients with neurological diseases who simultaneously underwent PSG and electromyography (EMG) of the masseter using a wearable device in Fukuoka University Hospital from August 2020 to December 2024. The breakdown of the 15 patients was as follows: 7 with MSA (5 males and 2 females; mean age, 70.3±12.1 years) and 8 with Parkinson's and related disorders (PRD; 6 males and 2 females; mean age, 70.0±13.1 years). The association between findings in PSG and the frequency of SB was analyzed. SB episodes were classified as phasic, tonic, or mixed based on the American Academy of Sleep Medicine criteria.

Results: The mean apnea-hypopnea index (AHI), sleep efficiency (SE, %), and periodic leg movement index (PLMI, /h) were 27.0±21.5, 68.4±11.7, and 52.6±48.5 in the MSA group, and 20.2±5.0, 77.7±11.1, and 4.4±3.1 in the PRD group, respectively. SB (/h), phasic (/night), and tonic (/night) episodes were 27.2±21.4, 73.2±100.7, and 33.7±11.1 in the MSA group, and 33.9±32.8, 110.9±167.3, and 15.0±13.1 in the PRD group, respectively. The frequencies of PLM and tonic episodes in the MSA group were significantly higher than those in the PRD group (p=0.02, p=0.01, respectively). The MSA group showed a significant negative correlation between SE and SB episodes (r = -0.893, p<0.01). The proportion of tonic episodes in SB was 17.6% in the MSA group, which was significantly higher than 7.4% in the PRD group (p < 0.001). There was no significant correlation between tonic episodes and PLMI.

Conclusions: These results suggest the possibility of increasing frequencies of PLM and tonic episodes, and of reducing the quality of sleep with the occurrence of SB in patients with MSA.

Rest-activity rhythm and risk of cognitive impairment: A systematic review and meta-analysis

L. Shi¹, X. Liu², C. Chen², M. Zhang³, Z. Wang², L. Lu⁴

¹Peking University Sixth Hospital, Beijing, China, ²Peking University Sixth Hospital, Beijing, China,

³Xinxiang Medical University, Department of Psychiatry, Henan Mental Hospital, The Second Affiliated Hospital of Xinxiang Medical University, Xinxiang, China, ⁴Peking University Sixth Hospital, NHC Key Laboratory of Mental Health (Peking University), National Institute on Drug Dependence and Beijing Key Laboratory of Drug Dependence, Peking-Tsinghua Center for Life Sciences and PKU-IDG/McGovern Institute for Brain Research, Beijing, China

Introduction: Although rest-activity rhythm (RAR) disruption is widely recognized as a risk factor for cognition, its influence on cognitive impairment remains unclear. The study is to evaluate the

association of RAR with cognitive impairment, including cognitive decline, mild cognitive impairment (MCI) and dementia.

Materials and methods: Two reviewers systematically searched PubMed, Embase, and PsycInfo for studies published from inception to February 2025, which were observational studies published as full-length articles in peer-reviewed journals related to the association of RAR and cognitive decline, MCI and dementia, and this review followed the Meta-analysis of Observational Studies in Epidemiology (MOOSE) reporting guidelines.

Results: A total of 11 longitudinal studies comprising 97,963 participants were included, with an average follow-up time of 4.95 years. It showed that individuals with lower amplitude (effect size, -0.062; 95% CI, -0.119 to -0.006), higher least active 5-hour period (effect size, 0.060; 95% CI, 0.014 to 0.105), higher intradaily variability (effect size, 0.015; 95% CI, 0.003 to 0.027), and phase-advanced (effect size, 0.114; 95% CI, 0.037 to 0.190) exhibited a higher risk of cognitive impairment. Lower amplitude (effect size, -0.092; 95% CI, -0.155 to -0.029), lower relative amplitude (effect size, -0.078; 95% CI, -0.116 to -0.039), and higher least active 5-hour period (effect size, 0.059; 95% CI, 0.025 to 0.093) were associated with mild cognitive impairment (MCI) and dementia. Lower amplitude (effect size, -0.006; 95% CI, -0.010 to -0.002) was associated with cognitive decline. But no association was found between either the most active 10-hour period or the midline estimating statistic of rhythm and cognitive impairment.

Conclusions: This meta-analysis found that RAR was associated with cognitive impairment. Higher amplitude and regular acrophase were protective factors for cognitive impairment, but higher least active 5-hour period increased the risk of cognitive impairment. The results suggested that a regular circadian rhythm pattern such as high-intensity exercise during daytime and a deep resting state during night could be useful in early-stage cognitive impairment management.

Acknowledgments: This work was supported by the National Natural Science Foundation of China General Project (82271527) and the Beijing Nova Program (20230484320).

Sativex (Nabiximols) on the sleep symptoms of agitated late-stage dementia patients - A study comparing questionnaire-based and wearable-based results

T.-W. Guu^{1,2}, C.P. Albertyn¹, D. ffytche^{1,3}, D. Aarsland^{1,3,4}

¹Institute of Psychiatry, Psychology, and Neuroscience, King's College London, Centre for Healthy Brain Ageing, London, United Kingdom, ²China Medical University Beigang Hospital, Division of Psychiatry, Yunlin County, Taiwan, ³Institute of Psychiatry, Psychology & Neuroscience, King's College London, UK Dementia Research Institute (UKDRI), London, United Kingdom, ⁴Stavanger University Hospital, Centre for Age-Related Medicine, Stavanger, Norway

Introduction: Sleep disturbances are common in late-stage dementia patients, especially in those co-morbid with behavioural symptoms such as agitation, causing considerable burden to their caregivers and increasing their own risk of fall. Despite non-pharmacotherapies have been suggested as the first line treatment, these symptoms are by far managed by hypnotics, sedentary antidepressants, or even antipsychotics, which at times cause more harm than benefit to these vulnerable patients. Cannabis and cannabinoids may be a feasible and safer option for sleep problems in this vulnerable population but has not been previously examined in randomised controlled trials.

Materials and methods: This study uses the data from the STAND (Sativex (nabiximols) for the treatment of Agitation & Aggression in Alzheimer's Dementia) trial, which is an 8-week (4 weeks of intervention followed by 4 weeks of observation) randomised, double-blind, placebo-controlled trial conducted in the UK. Nabiximols is a 1:1 mixture oral spray of delta-9-tetrahydrocannabinol (THC) and cannabidiol (CBD), and the trial's protocol, the feasibility study confirming the digital inclusivity of applying wearable device as an auxiliary assessment in this cohort, and the primary outcomes on agitation have been recently published. This study further evaluates nabiximols' effect on the participants' sleep.

Out of the 29 participants living with late-stage dementia, 28 (14 female) who accepted wearing the device with sufficient wearing rate (>80%) were included. The participants' sleep symptoms were assessed with the caregiver-rated sleep item score of the Neuropsychiatry Inventory-Nursing Home version (NPI-NH) at baseline, week 2 and week 4. Device-measured sleep variables, including sleep duration, onset and offset time, efficiency, Wake-After-Sleep-Onset duration and the Sleep Regularity Index (SRI), were calculated using unadjusted GGIR R package. The mean between-arms differences

were estimated using mixed linear models, adjusting for relevant covariates such as age, sex, and severity of dementia.

Results: The prevalence of sleep problem was high at baseline, regardless of the measuring tool (62.1% NPI-sleep item ≥ 4 , and 51.9% actigraphy-measured sleep efficiency $< 85\%$) and the trial group assigned; and the participants in both arms had a very low SRI throughout the trial period (Placebo: 22.3 ± 3.9 during week 1-2, and 24.2 ± 4.3 during week 3-4; nabiximols: 31.2 ± 4.2 during week 1-2, and 28.8 ± 4.7 during week 3-4). Sleep as measured by the NPI-NH sleep item was significantly improved in the nabiximols group compared to the control group from baseline to week 4 ($F_{2,24} = 5.176$, $p=0.009$). However, none of the actigraphy-measured sleep outcomes attained statistical significance between the two arms.

Conclusions: Care home-dwelling late-stage agitated dementia patients appeared to sleep poorly with very low sleep regularity, compared with people with similar dementia severity or of similar age. Despite not sufficiently powered, preliminary NPI-NH-based results of this study suggest sleep symptoms might be ameliorated following 4 weeks of nabiximol treatment. Although the improvements were not corroborated in device-based outcomes, the longitudinal and objective device-based variables provide holistic information regarding the overall circadian rhythmicity change, which might facilitate the development of novel therapeutic targets for late-stage dementia patients.

Acknowledgments: We sincerely appreciate the participation of the patients, their family, and caregivers.

Sleep AD: exploring the feasibility of a new approach to sleep research using at-home EEG remotely with people with prodromal and mild Alzheimer's

D. Woodstoke¹, T. Lemke¹, N. Woodward¹, J. Blackman¹, N. Turner¹, U. Bartsch², E. Coulthard¹

¹University of Bristol, Bristol, United Kingdom, ²University of Surrey, Guildford, United Kingdom

Introduction: Modifying sleep quality is an untapped opportunity with potential to delay progression of Alzheimer's disease (AD). Whilst in-laboratory polysomnography remains the gold-standard, the approach is expensive, burdensome and fails to capture a typical night's sleep. The future of sleep trials is home-monitoring with commercially-available electroencephalography (EEG) devices. We aim to identify the optimal approach balancing reliability, comfort, efficiency and accuracy, for AD sleep intervention trials. We previously demonstrated that EEG headbands can be utilised remotely with this cohort, and now seek greater spatial resolution. Sleep AD assessed the feasibility, acceptability and sensitivity of using 32-channel EEG sleep caps remotely. We hypothesised that this would yield behaviourally-relevant sleep neurophysiology sufficient for clinical trials.

Materials and methods: We used a single-centre prospective observational feasibility study design. Participants with Mild Cognitive Impairment or mild AD completed baseline sleep and mood questionnaires, and provided a blood sample for AD biomarker analysis. Recordings were conducted over 3 consecutive nights; researchers attended evenings and mornings to set-up and test/reset equipment. Participants completed a Sleep Consensus Diary and feedback questionnaire. We used Brain Products actiCAP slim sleep caps with 32 active electrodes, and a matching wireless EEG LiveAmp amplifier and battery pack, worn in harness. Participants completed an overnight memory task on the final evening, and had the option to wear a wrist pulse oximeter for nights 2-3.

Results: Of 62 screened, 31 were invited, and 11 recruited. Recruitment stopped early (our original target was $n=50$) when interim analysis proved conclusive. Participants had a mean (SD) age of 71.3 (9.1), 4/11 were female, mean (SD) Montreal Cognitive Assessment score was 18.9 (6.0). One participant withdrew after completing baseline measures. Two completed <3 nights due to kit discomfort. Sleep data was recorded from 10 participants over a total of 28 nights. We achieved optimal recordings on 11/28 (39%) nights; sub-optimal full recordings on 5/28 (17.9%) nights; and partial/no data on 12/28 (42.9%) nights. 91% of optimal recordings were achieved on nights 2-3. On night 1, 90% of participants reported disrupted sleep, primarily due to discomfort. On nights 2-3, sleep ratings improved but mild discomfort/sleep disruption were frequently reported. Overnight memory testing appeared feasible and well-tolerated. Experiences of wearing a pulse oximeter were mixed. Participants reported satisfaction with taking part and liked the home-monitoring approach.

Conclusions: Our approach to use 32-channel sleep caps remotely yielded just 39% of recordings with data sufficiently sensitive for micro-architectural analysis. Data completeness was below expectations and insufficient for intervention trials. Despite iterative set-up improvements, ground/reference signals

were frequently lost due to cap movement or adherence loss; real-time adjustments were not possible remotely. The 3 consecutive night design aimed to provide an adjustment night prior to more typical sleep on subsequent nights. Whilst partially successful, the scheduling was onerous for researchers. Despite withdrawals, feedback was unanimous that the concept of home-monitoring was appealing. We consider the approach of EEG home-monitoring with this cohort worth repeating, if we can develop a reliable and comfortable set-up with an alternative device.

Acknowledgments: Many thanks to our participants and funder Rosetrees Trust.

SLEEP CHANGES AFTER ACQUIRED BRAIN INJURY AND ITS IMPACT ON RECOVERY OUTCOMES - A SCOPING REVIEW OF THE LITERATURE

E.Y.H. Leung¹, J. Lin², L.G. Chan³

¹Singapore General Hospital, Department of Internal Medicine, Singapore, Singapore, ²Tan Tock Seng Hospital, Singapore, Singapore, ³Tan Tock Seng Hospital, Department of Psychiatry, Singapore, Singapore

Introduction: Background

While sleep and Acquired Brain Injuries (ABI) have an intimate relationship, there are limitations to elucidating the underlying aetiology of sleep disturbances and the effects of sleep on ABI outcomes. Differing disease trajectory, iatrogenic influences and the numerous challenges in sleep research further confound the relationship between sleep and ABI.

Objective

To summarize the research findings of the relationship between acquired brain injury (ABI) and sleep, and the relationship between post-ABI sleep disturbances and ABI outcomes as well as the methodological limitations that would affect the applicability of the results.

Materials and methods: Design

A scoping review was conducted from research published within 5 years from 2019-2023.

Methods

Sources of evidence were PubMed, Cumulative Index of Nursing and Allied Health Literature (CINAHL), Cochrane and Embase. MeSH terms used were “**sleep [title] AND stroke [keywords] OR brain injury [keywords]**” in PubMed and adapted accordingly to other search engines. Studies were included if they met the criteria: Adult sample >21 years old; Papers with objective or subjective measures of sleep; Papers published within 5 years from 2019-2023; Papers that measured sleep **after** stroke or brain injury; Unpublished papers (conference abstracts); Translated papers (official translations from other languages); Observational or epidemiological quantitative studies.

Results: Results

The search yielded 4336 articles. After 1472 duplicates were removed, 2864 abstracts were screened. 93 articles were found to meet the inclusion criteria. There were ample descriptions of sleep disturbances measured both subjectively and objectively occurring after stroke, but no convincing elucidation of the extent of causality and causal mechanisms of stroke and disturbed sleep.

There are also convincing correlations between sleep disturbance and poorer stroke outcomes, however the findings suffer from a lack of clarity of which type of sleep disturbance causes which specific outcome and the lack of a plausible causal mechanism.

There is a clear relationship between TBIs and sleep related disorders and symptoms. The wide variety of sleep measures and their combinations allowed for a greater breadth of evidence but the heterogeneity in measures used, and methodologies poses a challenge for direct comparison between studies.

There is also a general direction towards sleep disturbances having significant effects on patient outcomes, of particular interest would be the time taken to recover post-TBI. Patients were also more likely to experience psychological issues like depression and anxiety with poor sleep.

Conclusions: Conclusion

Future research and interventional trials can only proceed after the dilemma between small low-powered studies using precise but resource-heavy measurements and large high-powered studies using imprecise measurements can be satisfactorily resolved, and there is more detailed understanding of post-ABI sleep pathophysiology in humans.

Acknowledgments: We would like to give special thanks and credit to two Year 4 Medical Students from the Lee Kong Chian School of Medicine, Mr Andrew Chua Tiong Oon and Mr Tan Bing Rui for their great contributions to this scoping review.

Sleep Disturbances and Cognitive Functions in Dementia with Lewy Bodies and Alzheimer's Disease

Y. Cho¹, K. Brown³, K. Wilson³, D. Tsuang²

¹Veterans Affairs Puget Sound Health Care System, MIRECC, Seattle, United States, ²University of Washington, Seattle, United States, ³VA PUGET SOUND HEALTH CARE, Geriatric Research Education and Clinical Center (GRECC), Seattle, United States

Introduction: Sleep impairment is prevalent in individuals with Dementia. Dementia with Lewy Bodies (DLB) and Alzheimer's Disease (AD), two most common subtypes of dementia, have different pathogenesis and course. Cognitive decline in DLB is characterized by early visual-spatial and executive dysfunction, with memory being relatively preserved initially, alongside symptoms like fluctuating attention and visual hallucinations. AD presents with early memory loss due to hippocampal involvement, with visual-spatial and executive impairments emerging in later stages. Here, we hypothesize that sleep disturbances and cognitive functions manifest distinctly in these two neurodegenerative conditions due to their unique pathological mechanisms.

Materials and methods: Participants diagnosed with DLB (n=8) and AD (n=10) underwent assessments using the Repeatable Battery for the Assessment of Neuropsychological Status (RBANS) and wore Sleep Profiler™ EEG Sleep Monitors for two consecutive nights at baseline, 6-month follow-up, and/or 12-month follow-up. All paired data were aggregated across subjects for analysis. Sleep metrics such as sleep efficiency, REM sleep percentage, and non-REM hypertonias (NRH) were evaluated. Linear mixed models with a random intercept were applied to assess the relationship between three sleep metrics RBANS subdomain scores. Four models were used to examine the association between 1) sleep efficiency and immediate memory, 2) REM sleep and delayed memory, 3) NRH and attention, and 4) NRH and visuospatial scores, adjusting for age, dementia subtype, and interactions between dementia subtype and sleep metrics.

Results: In the DLB group, higher sleep efficiency was associated with lower immediate memory scores (beta = -0.7, 95% CI -1.2, -0.1, p=0.02), while higher NRH was linked to better attention (beta = 0.9, 95% CI 0.1, 1.7, p=0.03). No significant associations were found between the sleep metrics and RBANS subdomains for the AD group. However, the difference in the association between sleep efficiency and immediate memory between the two dementia groups was statistically significant (p = 0.04), suggesting different sleep-cognitive interactions across dementia types.

Conclusions: The direction of the associations in DLB were opposite of what we predicted. Future studies with larger samples and information about the relationship between longitudinal changes in sleep metrics and cognitive function are necessary to determine whether repeated objective sleep metrics would provide clinically relevant digital sleep biomarker for dementia.

Sleep EEG Characteristics in People with Parkinson's Disease Dementia: A Retrospective Polysomnographic Analysis

W.-P. Hong^{1,2,3}, Y.-S. Liao⁴, S.-F. Liang⁴, C.-Y. Lin^{5,3}

¹National Cheng Kung University Hospital, Department of Neurology, Tainan, Taiwan, ²National Cheng Kung University Hospital, Alzheimer's Dementia Research Centre, Tainan, Taiwan, ³National Cheng Kung University Hospital, Sleep Centre, Tainan, Taiwan, ⁴National Cheng Kung University, Department of Computer Science and Information Engineering, Tainan, Taiwan, ⁵National Cheng Kung University Hospital, Department of Otolaryngology, Tainan, Taiwan

Introduction:

Dementia prevalence is rising worldwide, with one new case every three seconds and projected global costs of USD 2 trillion by 2030. In Taiwan, 7.54% of adults ≥65 years (about 319,000 cases) are

affected. About 26% of community-dwelling patients experience sleep disturbances, which increase agitation, caregiver burden, and cognitive decline. Insomnia and sleep apnea elevate Alzheimer's and vascular dementia risk (RR 1.49 and 1.47), likely through neuroinflammation, impaired glymphatic clearance, and disrupted sleep–wake cycles. EEG studies show accelerated background slowing in dementia, with increased 8 Hz power and reduced entropy in Alzheimer's disease. Sleep EEG features—architecture, spindles, slow oscillations, coherence—differentiate dementia or MCI from controls, though subtyping remains limited.

This retrospective study (2020–2023) analyzed polysomnographic data from dementia patients at our Sleep Medicine Center to (1) characterize demographics and sleep physiology, (2) strengthen clinical practice, (3) identify research opportunities, and (4) promote cross-disciplinary collaboration.

Materials and methods: This exploratory study included patients with dementia or cognitive impairment confirmed by neurologists/psychiatrists at our hospital. Diagnoses were cross-referenced with ICD-10 codes, and all cases verified in electronic records. Two subprojects were undertaken:

1. Basic Sleep Physiology: Extracted demographics (sex, age, education, dementia type) and polysomnographic measures—total sleep time, latency, stage distribution (N1–REM), sleep events, oxygen saturation, mean heart rate, and periodic limb movement index. Data were de-identified and analyzed descriptively and by ANOVA across subgroups.

2. Sleep EEG Analysis: EEG signals from frontal, central, and occipital regions were processed with computer science support, involving pre-processing, feature extraction, classification, and post-processing. Patterns were compared across dementia subtypes.

Results: Of 46 identified cases, 33 unique remained after excluding duplicates. Records showed 24 cognitively normal individuals, 4 with subjective cognitive decline, 3 with Parkinson's disease (PD), and 2 with epilepsy. The three PD cases were included for further analysis. Preliminary spectral mapping revealed EEG differences across groups, suggesting sleep EEG may serve as a biomarker of dementia-related changes.

Conclusions: Spectral EEG analysis showed group-level differences between PD and controls. PD patients demonstrated altered delta activity and more pronounced theta power changes. Within-group analysis revealed that controls had no significant alpha–beta differences, whereas PD patients showed marked beta reduction relative to alpha. This alpha–beta imbalance may reflect impaired transitions between wakefulness and light sleep, linked to basal ganglia and cortical degeneration. Elevated Theta abnormalities are consistent with prior studies connecting Theta oscillations to cognition and memory, possibly underlying decline and disease progression in PD. These findings reinforce the value of sleep EEG for distinguishing PD dementia from normal aging and for monitoring progression.

This exploratory study highlights spectral EEG features as potential biomarkers for PD dementia. Future directions include predictive modeling of dementia progression, integrating subjective sleep measures with physiological data for risk scores, and applying machine learning to automate dementia subtyping. Despite limitations, the study demonstrates the value of institutional datasets in advancing early diagnostic tools and stratification strategies for dementia care.

Acknowledgments: The author thanks Dr. Ying-Siou Liao, Prof. Sheng-Fu Liang, and Prof. Cheng-Yu Lin for their help.

Sleep Efficiency and Short-Term Topographic Memory in Stroke Survivors: Preliminary Results

P. Srijiithesh¹, S. Mythirayee¹, R. Makal¹, R. Vibha¹, R. Yadav¹, K. Keshav², B. Raju³

¹National Institute of Mental Health and Neurosciences, Neurology, Bangalore, India, ²National Institute of Mental Health and Neurosciences, Clinical Psychology, Bangalore, India, ³International Institute of Information Technology, Cognitive Science Lab, Hyderabad, India

Introduction: Sleep plays a critical role in memory and learning tasks. About 90% of stroke patients have sleep disturbances. We have previously demonstrated differential effects of sleep efficiency based on the territory of stroke. This study aimed to assess short term topographical memory consolidation using the Four Mountain Task (4MT) in stroke patients compared to age-matched controls, pre- and post-sleep.

Materials and methods: Ischemic stroke patients (3 months old, chronic phase) and healthy volunteers, underwent the 4MT before and after an overnight polysomnography. The 4MT evaluates short term topographic memory by asking participants to recognize previously seen landscapes with four mountains. Reaction times and accuracy were recorded. Correlation between sleep efficiency and post-sleep task performance was analyzed.

Results: A total of 14 stroke patients and 14 controls were included in the study. The mean age of stroke patients was 47.3 years (SD: 8.4), while controls had a mean age of 44 years (SD: 9.39). Males comprised 50% of the stroke group and 57.1% of the controls. Reaction times improved after sleep in both groups (Patients: 4305 ms to 3920 ms; Controls: 3720 ms to 3345 ms), suggesting sleep-dependent memory improvement. Accuracy remained stable in patients and improved slightly in controls. No significant group differences were noted in overnight change scores. A significant negative correlation ($p = -0.48$, $p = 0.01$) was observed between sleep efficiency and post-sleep reaction time across all participants, suggesting that sleep dependent memory improvement.

Conclusions: Short term topographical memory benefit from sleep in stroke survivors, with reaction time improvements linked to better sleep efficiency. These findings suggest that preserving sleep quality may support cognitive recovery post-stroke.

Acknowledgments: We thank all study participants and the clinical neurophysiology sleep lab team. This work was supported by extramural DST grant (IIIT-H/IHub/Project/Healthcare/2021-22/H2-003).

Sleep Microarchitecture Disruptions in Ischemic Stroke: Insights from Polysomnography

S. Mythirayee¹, P.R. Srijithesh¹, R. Yadav¹, D.V. Seshagiri¹, G. Kumar², PN. Ravindra², S. Jitender³, K. Bindu²

¹National Institute of Mental Health and Neuroscience, Neurology, Bangalore, India, ²National Institute of Mental Health and Neuroscience, Center for consciousness studies, Neurophysiology, Bangalore, India, ³National Institute of Mental Health and Neuroscience, Neuroimaging and Interventional Radiology, Bangalore, India

Introduction: Sleep microarchitecture, including spindles, K-complexes, and slow waves, plays a critical role in neuroplasticity and recovery. However, alterations in these features following stroke remain underexplored. This study aimed to compare sleep microarchitecture features in ischemic stroke patients versus healthy controls and to identify lesion locations associated with disrupted sleep parameter using voxel-based lesion-symptom mapping (VLSM).

Materials and methods: Ischemic stroke patients (within one month of onset) and healthy controls underwent overnight polysomnography (PSG). Sleep EEG was manually scored using AASM manual 2023 and microarchitecture was analyzed using the YASA toolbox. Spindle features (count, density, amplitude, duration, frequency) and K-complexes were extracted during Stage N2. Slow-wave features (amplitude, slope, duration) were analyzed during Stage N3. REM parameters were also assessed. VLSM analysis was performed in 25 stroke patients using manually segmented lesion masks co-registered to MNI space. Non-parametric mapping with FDR correction ($p < 0.05$) was applied.

Results: Thirty ischemic stroke patients (mean age: 51.4 ± 10.2 years; 20 males, 10 females) within one month of onset and thirty age- and gender-matched healthy controls (mean age: 50.8 ± 9.6 years; 20 males, 10 females) underwent overnight polysomnography (PSG). Stroke patients had significantly lower spindle density (mean: 0.49/min vs. 0.83/min, $p < 0.01$) and amplitude (mean: 11.2 μV vs. 15.4 μV , $p = 0.02$) compared to controls, particularly over fronto-central channels. Spindle count was also reduced (mean: 147.3 vs. 235.7, $p = 0.01$), with decreased average duration (mean: 0.75 s vs. 0.89 s, $p = 0.03$). During N3 sleep, stroke patients exhibited lower slow wave amplitude (mean: 59.2 μV vs. 78.5 μV , $p = 0.01$) and slope (mean: -1.47 $\mu V/ms$ vs. -2.18 $\mu V/ms$, $p = 0.01$). REM density showed a trend toward reduction (mean: 1.9/min vs. 2.6/min, $p = 0.07$). VLSM analysis revealed that reduced sleep efficiency correlated with lesions in the right dorsolateral prefrontal cortex ($Z = 4.85$, 672 voxels), right superior frontal gyrus ($Z = 4.32$), right anterior cingulate cortex ($Z = 4.10$), left inferior parietal lobule ($Z = 3.95$), and right insular cortex ($Z = 3.82$).

Conclusions: Stroke survivors demonstrate disruptions in sleep microarchitecture, particularly in spindles and slow waves. Alterations in sleep efficiency are linked to lesions in frontal and parietal regions regulating attention and arousal. Disruptions of microarchitecture could be a potential biomarker for sleep alterations post stroke.

Acknowledgments: We thank all study participants and the clinical neurophysiology sleep lab team. This work was supported by extramural ICMR SRF student grant (3/1/2/163/Neuro/2021-NCD-1).

Sleep Misperception in Epilepsy Patients with Nocturnal Spiking

D. Toutant¹, G. McLeod², M. Ng¹

¹University of Manitoba, Winnipeg, Canada, ²University of Calgary, Calgary, Canada

Introduction: Patients with epilepsy frequently experience comorbid insomnia, complicating both conditions. Accurate sleep assessment in this population is crucial for treatment but potentially confounded by spike rate provoking awakenings leading to increased sleep fragmentation. This study enlists three sleep assessment methods (electronic self-report sleep diary, actigraphy, and high-density (hd)EEG-PSG) in patients with epilepsy and insomnia to evaluate the effect of spikes on subjective sleep perception and objective actigraphy measurements compared to the gold standard hdEEG-PSG.

Materials and methods: Participants with focal epilepsy and insomnia underwent hdEEG-PSG “adaptation” and “baseline” sleep recordings 1 week apart. Epileptic spike rate was manually annotated by an epileptologist (MCN). Patients also completed insomnia severity index (ISI) questionnaires, electronic sleep diaries, and actigraphy (Actigraph-wGT3X-BT). hdEEG-PSG was recorded using the 10-10 system and scored using modified AASM criteria in 10-second epochs within SleepWorks (Natus). The parameters of ‘wake after sleep onset’ (WASO), ‘awakenings’, ‘time in bed’ (TIB), ‘total sleep time’ (TST), ‘sleep latency’ (SL), and ‘sleep efficiency’ (SE) were provided by Actilife (Actigraph) software and SleepWorks post-scoring. Sleep diary parameters were based on answering the question of “In total, how long were you awake during the night?” for WASO, duration between participants’ recollection of lights out to last awakening for TIB, TIB minus SL minus WASO for TST, $TST/TIB \times 100$ for SE, and awakenings were taken directly from diary response. Misperception was calculated as $(|X - hdEEG-PSG| / 0.5(X + hdEEG-PSG)) \times 100$ where X is the diary or actigraphy value.

Results: Ongoing recruitment has yielded 5 participants to date – 2 of whom have been fully analyzed (50% female). Patient 1 (P1) had 383 spikes (49.3/hour). P2 had 648 spikes (108.7/hour). P1 had severe insomnia (ISI=22.9). P2 had moderate insomnia (ISI=17.7). Excluding the first night effect (i.e. “adaptation”) and compared to hdEEG-PSG (100%), respective diary and actigraphy responses were severely misperceived for both WASO (P1 136.4%, 35.4%; P2 142.9%, 79.1%) and awakenings (P1 189.4%, 160.7%; P2 182.7%, 174.5%). In contrast, P1 had only below 10% misperception on sleep diary vs. hdEEG-PSG for TST (5.8%) and SE (6.8%); and actigraphy vs. hdEEG-PSG for SE (6%). Similarly, P2 diary vs. hdEEG-PSG for TIB was 5.3%, TST 8.6%, and SE 3.3%; and actigraphy vs. hdEEG-PSG for TIB was 3.9%, TST 9.1%, and SE 5.2%.

Conclusions: Our ongoing research demonstrates that misperception of WASO and awakenings is exacerbated in people with insomnia and epilepsy compared to other sleep parameters when recorded via electronic diaries and actigraphy vs. gold standard hdEEG-PSG. While P2 with moderate insomnia was able to perceive more parameters concordant with hdEEG-PSG than P1 with severe insomnia, P2 was still unable to perceive WASO and number of awakenings precisely. Of note, both subjective diaries and objective actigraphy were unable to correctly identify the number and total duration of awakenings during sleep. Given that epileptic spikes may disrupt sleep quality and continuity, this begs the questions of whether (1) the high nocturnal spike rates in our epilepsy patients preferentially and covertly increase WASO and awakenings, and (2) actigraphy is properly attuned to measuring sleep in those living with epilepsy.

Sleep Research in Children with Autism Spectrum Disorder

A.J. Schwichtenberg¹, A. Janis¹, M. West¹

¹Purdue University, Human Development and Family Science, West Lafayette, United States

Introduction: Sleep problems are a common comorbidity for children with autism spectrum disorder (ASD) and research in this area has a relatively long history. Within this review, we first outline historic patterns in the field of sleep and ASD. Second, we conducted a systematic update and coded these studies based on their alignment with historic patterns.

Materials and methods: To identify articles for this study, we built and executed comprehensive searches in the bibliographic databases PubMed, PsycINFO (EBSCOhost platform), and Web of Science Core Collection. The search strategy combined terms related to autism and sleep. The “autism” keywords searched included *autism*, *autistic*, *Asperger’s*, and *pervasive developmental disorder not otherwise specified (PDD-NOS)*. The “sleep” keywords included *sleep*, *sleeping*, *circadian*, *waking*, *night*, *melatonin*, *clock gene*, and *rest*. Controlled vocabulary terms for these keywords were included for each database, as appropriate.

Results: Research on ASD and sleep over the past two decades has primarily focused on four principal areas: (1) documenting the prevalence and types of sleep problems, (2) sleep problem treatment options and efficacy, (3) how sleep problems are associated with other behavioral, contextual, or biological elements, and (4) the impact of child sleep problems on families and care providers. The systematic update in this paper includes empirical studies published with terms for sleep and ASD within the title, keywords, or abstract. In sum, 60 studies fit the inclusion/exclusion criteria and most fit within the historic patterns noted above. Notable differences included more global representation in study samples, studies on the impacts of COVID-19, and a growing body of work on sleep problems as an early marker of ASD. The majority of studies focus on correlates of sleep problems noting less optimal behavioral, contextual, and biological elements are associated with sleep problems across development for children with ASD.

Conclusions: Recommendations for future directions include continued expansion of global and age representation across samples, a shift toward more treatment and implementation science, and studies that inform our mechanistic understanding of how sleep and ASD are connected.

Sleep spindles and slow oscillations predict amyloid beta, tau pathology, and cognition in persons with mild to moderate Alzheimer’s Disease

A. Paez^{1,2,3}, S. Gillman^{1,3}, S. Bakian Dogaheh^{1,3}, A. Carnes⁴, F. Dakterzada⁴, F. Barbé⁵, T.T. Dang-Vu^{1,3}, G. Piñol Ripoll⁴

¹Concordia University, Sleep, Cognition, and Neuroimaging Laboratory, Dep. of Health, Kinesiology, and Applied Physiology, Montreal, Canada, ²University of Oxford, Nuffield Department of Primary Care Health Sciences, Oxford, United Kingdom, ³Centre de Recherche de l’Institut Universitaire de Gériatrie de Montréal, Montréal, Canada, ⁴Unitat Trastorns Cognitius, Clinical Neuroscience Research, Santa Maria University Hospital, IRBLleida, Lleida, Spain, ⁵Translational Research in Respiratory Medicine (TRRM), Hospital Universitari Arnau de Vilanova-Santa Maria, Biomedical Research Institute of Lleida (IRBLleida), Lleida, Spain

Introduction: Sleep plays vital roles in brain-health and cognition, including regulating clearance of β -amyloid (A β) and tau proteins that hallmark Alzheimer’s disease (AD). There is a bidirectional relationship between sleep and AD. Changes in sleep physiology can predate cognitive symptoms by decades in AD. Sleep assessments including features of NREM sleep correlated with AD pathology or cognitive decline offer the potential for early, non-invasive screening for AD risk before the onset of clinical symptoms and provide novel therapeutic targets to slow AD progression. However, the majority of available research has investigated associations between NREM sleep physiology and AD pathology or cognition in healthy older adults, but far less is known about *these in persons who already have AD*. It remains unclear which sleep characteristics predict cognitive and neurodegenerative changes after AD onset. Our research addresses these important knowledge gaps for the role of sleep physiology in AD and AD progression.

Materials and methods: Using data from a prospective cohort study of mild-to-moderate AD (n=60, 30 female, mean age 74.7) in Lleida, Spain, we analysed non-rapid eye-movement sleep spindles and slow oscillations (SO) at baseline and their associations with baseline amyloid-beta and tau, and with cognition from baseline to three-years follow-up.

Participants underwent overnight polysomnography (PSG), blood and cerebrospinal fluid draws for amyloid-beta 42, phosphorylated (pTau-181) and total-tau at baseline, and neuropsychological assessment at baseline, 12, 24 and 36 months with the Mini-Mental Status Examination (MMSE), California verbal learning test (CVLT), Rey-Osterrieth Complex Figure Test (ROCF), Alzheimer’s Disease Assessment Scale–Cognitive Subscale (ADAS-Cog).

PSG was scored along American Academy of Sleep Medicine guidelines. Spindle and SO detection were performed using in-house, open-source software packages developed at Concordia University, following Moelle (2011) recommendations for spindles and Staerens's (2015) recommendations for SO. Associations between SO and spindle and SO duration, density, power, amplitude, AD biomarkers, and cognition from baseline to 36 months were investigated with false discovery rate-adjusted generalised linear models, controlling for age, sex, apnoea-hypopnea index.

Results: We found previously unreported associations between spindle characteristics, biomarkers, and cognition in persons with AD. Higher spindle and SO density, duration, amplitude and power predicted significant changes in amyloid-beta 42 ($\beta = 69.3$, $p = 0.001$), phosphorylated (pTau-181) ($\beta = 7.92$, $p = 0.001$) and total-tau, and tau/A β 42 ($\beta = -0.52$, $p = 0.001$), clinically and statistically significantly lower Alzheimer's Disease Assessment Scale Cognitive Subscale (better cognitive performance) ($\beta = -9.0$, $p = 0.001$) and higher Mini-Mental State Examination scores (better cognitive performance) ($\beta = 15.2$, $p = 0.01$) from baseline to 36-months, and significant changes in verbal and visual memory on the ROCF and CVLT. Spindles and SO activity also mediated the effect of pTau181/a β 42 on cognition (41-81%), while pTau181/a β 42 moderated the effect of spindles and SO on cognition.

Conclusions: Our findings demonstrate that spindle and SO activity during sleep constitute predictive and non-invasive biomarkers of neurodegeneration and cognition in AD patients and novel treatment targets for delaying cognitive decline and AD progression. Sleep microarchitecture can, therefore, also provide novel therapeutic targets for preserving brain-health in older adults at risk of AD or in the early stages of AD.

Slow-wave-heart rhythm coupling during sleep in older adults with and without mild cognitive impairment: effects of phase-locked acoustic stimulation

I. Filchenko¹, M. Wunderlin², M.H. Schmidt¹, C.L.A. Bassetti¹, M. Züst²

¹Bern University Hospital (Inselspital) and University of Bern, Department of Neurology, Bern, Switzerland, ²University Hospital of Old Age Psychiatry and Psychotherapy, University of Bern, Bern, Switzerland

Introduction: Cognitive dysfunction is a hallmark of neurodegeneration, which is often associated with both cardiac autonomic dysfunction and reduced slow-wave (SW) activity (Chen et al., 2023). Therefore, slow-wave-heart rhythm (SW-HR) coupling, although largely underexplored, may be a promising biomarker for cognitive decline and a therapeutic target. Phase-locked acoustic stimulation (PLAS) of SW activity improves cognition in older adults (Wunderlin et al., 2023). However, little is known about the effects of PLAS on SW-HR coupling. We investigated SW-HR coupling in older adults with mild cognitive impairment (MCI) and without MCI. We further described how PLAS, compared to a sham intervention, affects SW-HR coupling in older adults with mild cognitive impairment (MCI) and without MCI.

Materials and methods: This is a secondary analysis of a partially randomized controlled trial (Wunderlin et al., 2023) including 57 older adults (age: 70.2 ± 4.5 years, 64% women) with MCI (16 participants, 28%) and without MCI (41 participants, 72%), who underwent a baseline nocturnal sleep assessment using high-density EEG (128 electrodes) and full polysomnography. No-MCI group was randomized to three-night PLAS (27 participants, 47%) or sham stimulation (14 participants, 25%), whereas the MCI-group received only three-night PLAS. Three groups were matched by demographics and apnea-hypopnea index. SW-HR coupling was quantified using previously described (Fabus et al., 2024; Naji et al., 2018) and newly conceptualized metrics. We compared SW-HR coupling between the groups and over time within groups on the level of individual electrodes, if applicable. The significance level was set at $\alpha = 0.05$.

Results: This is the first study to comprehensively characterize the cortical topography of brain-heart interactions. Temporal SW-HR coupling was bidirectional and predominantly involved latero-posterior regions. HR was moderately associated with SW amplitude in occipital and right insular regions and weakly with SW globality. At baseline, compared to no-MCI, the MCI group had significantly lower temporal coherence across all cortical areas and weaker coupling of HR with SW amplitude in central regions not reaching statistical significance. In both MCI- and no-MCI group, PLAS significantly decreased temporal SW-HR coherence in fronto-central and posterior regions. In MCI group, PLAS significantly decreased SW-amplitude-HR coupling in posterior and right insular regions. HR coupling with SW-globality followed the overall directional trends without reaching statistical significance.

Conclusions: Our findings extend previous observations implicating posterior and insular brain regions in cardiac autonomic functioning during sleep. The MCI group showed a reduced SW-HR coupling at baseline, suggesting early dysregulation of neurocardiac integration in central frontal networks. PLAS, while reported to enhance the coupling between SW and sleep spindles (Wunderlin et al., 2023), seemed to reduce SW-HR coupling in our analysis, particularly in MCI, which may be related to the limited physiological reserve in response to external modulation. PLAS-induced shifts in autonomic dynamics warrant further investigation of long-term physiological outcomes.

Acknowledgments: None

Subjective-objective sleep discrepancy in older adults with Alzheimer's disease and Lewy body disease

V. Gabb^{1,2,3}, J. Blackman^{1,2,3}, H. Morrison^{1,2}, N. Turner¹, E. Coulthard^{1,2,3}

¹University of Bristol, Bristol, United Kingdom, ²North Bristol NHS Trust, Bristol, United Kingdom,

³NIHR Bristol Biomedical Research Centre, Bristol, United Kingdom

Introduction: Sleep fragmentation and reduced total sleep time have been reported in aging and neurodegenerative conditions such as Alzheimer's disease (AD) and Lewy body disease (LBD). Such relationships are reliably demonstrated in polysomnography studies, but less consistent patterns are found in studies utilising self-report measures, particularly in cognitively impaired populations potentially subject to recall bias. Here, we aimed to examine the presence and utility of sleep discrepancy (the discordance between subjective and objective measures of sleep) in AD and LBD compared to healthy older adults.

Materials and methods: Adults aged 50 or older with mild cognitive impairment or dementia due to probable AD or LBD and age-matched cognitively unimpaired older adults were enrolled in a prospective cohort study measuring sleep across eight weeks. Subjective sleep quality and subjective estimates of core sleep parameters (total sleep time, sleep efficiency, and sleep latency) were derived from a baseline Pittsburgh Sleep Quality Inventory (PSQI) and compared to mean values of objective parameters derived from 8 weeks of wrist actigraphy complemented by daily digital sleep diaries. The resulting discrepancies were compared across cohorts before being used to predict cohort membership (AD, LBD, or control).

Results: 40 participants (mean age 71 years; probable AD = 10, probable LBD = 10, controls = 20) completed the study, providing a mean of 53 nights of actigraphy per participant. Mean PSQI subjective sleep quality ranked from best to worst in the AD, control and then LBD cohorts, with mean LBD sleep quality significantly worse than AD. However, participants with both AD and LBD generally overestimated their total sleep time and greater sleep efficiency subjectively compared to actigraphy (i.e., underestimated their sleep disturbance). Participants with AD also underestimated their sleep latency. Higher objective sleep efficiency was associated with better subjective sleep quality in the controls, but not in individuals with AD or LBD. Sleep discrepancy for total sleep duration, sleep efficiency, and sleep latency, combined with self-reported subjective sleep quality, discriminated between participant groups with 80% accuracy and was more accurate than subjective or objective measures alone.

Conclusions: Caution is warranted when relying on subjective measures in patients with mild cognitive impairment or dementia due to underestimation of sleep disturbance compared to objective parameters. However, subjective measures combined with wrist actigraphy and digital sleep diaries may have diagnostic utility and provide a more comprehensive profile of sleep than either subjective or objective measures alone. Wrist actigraphy and digital sleep diaries offer a low-cost and convenient pragmatic way to measure naturalistic sleep in older adults with and without cognitive impairment and could be useful in clinically as well as in research settings.

Acknowledgments: The authors sincerely thank all participants and their relatives and partners who supported their participation. Funding was received from BRACE, Alzheimer's Research UK, Bristol & Weston Hospitals Charity, David Telling Charitable Trust, NIHR Bristol Biomedical Research Centre, and philanthropic donations.

The interplay between orexin, neurodegeneration, cognition and sleep microarchitecture in mild to moderate Alzheimer's Disease

A. Paez^{1,2,3}, G. Piñol Ripoll^{4,5}, S. Bakian Dogaheh^{1,3}, S. Gillman^{1,3}, A. Carnes⁴, F. Dakterzada⁴, F. Barbé⁶, T.T. Dang-Vu^{1,3}

¹Concordia University, Sleep, Cognition, and Neuroimaging Laboratory, Dep. of Health, Kinesiology, and Applied Physiology, Montreal, Canada, ²University of Oxford, Nuffield Department of Primary Care Health Sciences, Oxford, United Kingdom, ³Centre de Recherche de l'Institut Universitaire de Gériatrie de Montréal, Montréal, Canada, ⁴Unitat Trastorns Cognitius, Clinical Neuroscience Research, Santa Maria University Hospital, IRBLleida, Lleida, Spain, ⁵Alzheimer's Disease and Other Cognitive Disorders Unit, Neurology Service, Hospital Clínic de Barcelona, Fundació de Recerca Clínic - Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain, ⁶Translational Research in Respiratory Medicine (TRRM), Hospital Universitari Arnau de Vilanova-Santa Maria, Biomedical Research Institute of Lleida (IRBLleida), Lleida, Spain

Introduction: Cerebrospinal fluid (CSF) orexin levels are higher in MCI and AD and associated with sleep deterioration, increasing risk of cognitive decline and Alzheimer's disease (AD) progression. Orexin-A is a key sleep-wake cycle regulator. Dual orexin receptor antagonists improve sleep in AD and insomnia and may reduce tau and A β deposition in older adults. However, little research has investigated associations between sleep microarchitecture, orexin, neurodegeneration biomarkers, cognitive decline, or mental health in AD. Using data from a prospective cohort study of mild-to-moderate AD (n=60, 30-female, mean age=74.7), we analysed non-REM sleep spindles, slow oscillations (SO), and their associations with CSF orexin, AD biomarkers, cognition, and mental health over three years. Participants underwent polysomnography (PSG) and CSF draws for β -amyloid (A β), ptau181, total tau, orexin, and other biomarkers and at baseline, neuropsychological assessment with the Alzheimer's Disease Assessment Scale-Cognitive Subscale (ADAS-Cog) and Neuropsychiatric Inventory (NPI) at baseline and 12 months, and Mini-Mental Status Examination (MMSE) at baseline, 12, 24, and 36 months. PSG was scored along American Academy of Sleep Medicine guidelines. Spindle and SO detection were performed using in-house, open-source software packages developed at Concordia University, following Moelle (2011) recommendations for spindles and Staresina's (2015) recommendations for SO. Associations between SO and spindle characteristics (duration, density, power, amplitude) and orexin, A β 42 and tau at baseline, and baseline orexin and cognition from baseline to 36 months were investigated with false discovery rate-adjusted generalised linear models, controlling for age, sex, apnea-hypopnea index.

Materials and methods: Using data from a prospective cohort study of mild-to-moderate AD (n=60, 30-female, mean age=74.7), we analysed non-REM sleep spindles, slow oscillations (SO), and their associations with CSF orexin, AD biomarkers, cognition, and mental health over three years.

Results: We found previously unreported, predictive associations between SO, duration, density, amplitude, and CSF orexin. Orexin also predicted increased ptau181, total-tau, ptau/A β 42, total-tau/A β 42. Increased orexin predicted worse cognitive performance (higher ADAS-cog, lower MMSE) from baseline to 36-months and increased neuropsychiatric symptom severity (NPI) from baseline to 12 months. Orexin also moderates relationships between spindles, SO, cognition, and mental health.

Conclusions: Orexin levels are associated with neurodegeneration biomarkers and cognitive deterioration in AD and moderate relationships between sleep microarchitecture and cognitive changes over time. Orexin may thus constitute a potential target for sleep-related interventions for cognition in neurodegenerative disorders. Sleep microarchitecture, through its associations with orexin and other important biomarkers of brain health, can also provide novel therapeutic targets for preserving brain-health in older adults at risk of AD or in the early stages of AD.

Other

Acoustic Properties of Healthy Vs. OSA Patients

N. Berick¹, D. Braverman², I. Braverman¹, I. Shochat¹

¹Hillel Yaffe Medical Center, Otolaryngology, Hadera, Israel, ²Tel Aviv University, Tel Aviv, Israel

Introduction: OSA and snoring are prevalent conditions affected by the vocal tract anatomy and physiology. These changes may provide non-invasive markers for diagnosing and differentiating

between OSA and healthy individuals. Comprehensive evaluation of acoustic variations across postures and their clinical implications remains elusive.

Materials and methods: We analyzed audio recordings from 59 patients stratified into three groups: OSA (n=20, 288 recordings), Snoring (n=20, 150 recordings), and Healthy (n=19, 150 recordings). Each patient provided five phonemes (/a/, /i/, /u/, /m/, /n/) in sitting and supine postures, totaling 588 recordings. Acoustic parameters, including fundamental frequencies (FFT and pYIN), vocal stability (jitter, shimmer), spectral characteristics (spectral centroid, flatness), and formant frequencies (F1, F2, F3), were analyzed. Positional effects and group-level differences were evaluated using statistical methods. Machine learning models, including k-Nearest Neighbors (KNN), were applied to assess the diagnostic accuracy of acoustic markers.

Results: The mean fundamental frequency (FFT) across all recordings was 111.29 Hz (± 43.67 Hz), ranging from 8.36 Hz to 194.52 Hz. The mean fundamental frequency (pYIN) was 131.67 Hz (± 22.04 Hz), with a range of 86.32 Hz to 350.25 Hz. Measures of vocal stability indicated a mean jitter of 0.24% ($\pm 0.10\%$) and a shimmer of 3.51% ($\pm 1.81\%$). Spectral features revealed a mean spectral centroid of 1056.14 Hz (± 349.20 Hz), while the mean spectral flatness was 0.0002 (± 0.00036), indicative of tonal characteristics. Formant frequencies averaged F1 = 500.12 Hz (± 120.45 Hz), F2 = 1500.32 Hz (± 220.87 Hz), and F3 = 2500.45 Hz (± 300.14 Hz). Supine recordings exhibited a slightly higher mean spectral centroid compared to sitting, suggesting subtle positional effects. MFCCs, capturing detailed frequency characteristics, exhibited variability, with MFCC1 ranging from -20.45 to 30.15 and MFCC12 from -47.09 to 39.05.

Significant group-level differences were observed in spectral flatness ($F=37.95$, $p<0.001$) and MFCC1 ($F=104.25$, $p<0.001$), with OSA showing distinct patterns compared to Snoring and Healthy groups. Positional effects, particularly MFCC1 mean delta ($F=4.22$, $p=0.020$), further distinguished OSA from others. Among nasal sounds, /m/ demonstrated greater discriminatory power (F_2 , $F=4.84$, $p=0.0096$). The KNN model exhibited superior classification performance (test accuracy: 94%), highlighting the potential of these features for OSA diagnosis.

Conclusions: Acoustic features, particularly MFCC1 and spectral flatness, provide promising markers for distinguishing OSA. Positional changes amplify these distinctions, underscoring the relevance of dynamic assessments. Future research should refine feature extraction and explore larger datasets to enhance diagnostic precision.

A Cross-Sectional Pilot Study on the Craniofacial Markers of Obstructive Sleep Apnea in a South Indian Population

S. Vinod Kutty¹, M.S.R. Chowdary², Y. S², S.H. Shankar³, R. Gupta⁴, P. T¹

¹All India Institute of Medical Sciences, Mangalagiri, General Medicine, Mangalagiri, India, ²All India Institute of Medical Sciences, Mangalagiri, Radiodiagnosis, Mangalagiri, India, ³S S Sparsh Hospital, Pulmonary critical care and sleep medicine, Bangalore, India, ⁴All India Institute of Medical Sciences, Rishikesh, Psychiatry, Rishikesh, India

Introduction:

Obstructive Sleep Apnea (OSA) is a prevalent disorder that results in intermittent upper airway obstruction during sleep, leading to fragmented sleep and systemic effects. Specific anatomical features can predispose individuals to this condition by affecting the patency and stability of the upper airway. Variations in cranial base and maxillary length can influence upper airway morphology and contribute to OSA. Most studies on craniofacial anatomy and OSA have been conducted in Western or East Asian populations. There is a need for research focused on the Indian population to account for ethnic and genetic variations in craniofacial morphology, which can help identify specific risks for obstructive sleep apnea.

Materials and methods:

Study design: Cross-sectional descriptive study

Primary Objective:

To identify craniofacial markers associated with symptomatic obstructive sleep apnea (OSA) in a South Indian population.

Secondary Objective:

To assess the relationship between anthropometric measurements (BMI, waist-hip ratio, neck circumference) and craniofacial markers in patients with symptomatic OSA.

Sample size estimation: Pilot study with thirty patients.

Sampling strategy: Consecutive sampling

d. Inclusion criteria:

- Adults > 18-years of age
- Symptomatic and asymptomatic newly diagnosed OSA individuals were determined by ESS and STOP-BANG scores.
 1. Symptomatic OSA Group: Participants with ESS >7, and diagnosed with OSA confirmed by Level 3 PSG.
 2. Asymptomatic OSA Group: Participants with ESS <7 and no symptoms, though mild OSA may be detected via PSG.

e. Exclusion criteria:

1. Prior treatment for OSA(surgical/PAP therapy)
2. History of craniofacial surgery or trauma
3. Pregnancy

Craniofacial imaging : MRI scan, where in single sequence of T1 SPACE 3D imaging / T1 MPRAGE with a single CT screening image was done.

- Soft palate length (mm)
- Tongue length (mm)
- Retropalatal Distance (Anteroposterior and transverse in mm)
- Retroglossal Distance (Anteroposterior and transverse in mm)
- Submental fat (mm)
- Hyoid – Sella Distance
- Hyoid – Nasion Distance
- Hyoid – Supramental distance.

These measurements were analyzed by the radiologist and correlated with indices of OSA severity.

Results: In the 26 patients included in this analysis, 18 had ESS>7 and 8 had ESS <7.

Continuous variables were described as median and IQR, while the Categorical variables were expressed as proportions.

Mann U test was used to compare the groups. Correlations were assessed using the Kendall Taus test. Majority of the patients were male. There was no statistically significant difference between the baseline characteristics of the two groups.

There was a positive correlation between tongue length, submental fat and the neck circumference.

There was a significant correlation between the hyoid to sella distance and neck circumference.

However this is a pilot study. The present study will be used to power further work exploring the various craniofacial measurements and its impact on the evaluation and management of OSA

Conclusions: There are previous studies performed in caucasian, asian and specifically north indian populations with OSA. However, there are racial and regional differences in craniofacial features. These are likely to have a differential impact on the presentation and course of illness in patients with OSA. Further studies are aimed at developing scientific knowledge in this area of sleep medicine research in India.

An Estimate of Waste Produced by CPAP Treatment in the United States

L. Donahue¹, T. Morgenthaler²

¹McGaw Medical Center of Northwestern University, Neurology/Sleep Medicine, Chicago, United States, ²Mayo Clinic Center for Sleep Medicine, Division of Pulmonary and Critical Care Medicine, Rochester, United States

Introduction: Obstructive sleep apnea (OSA) is a global public health concern, affecting up to 1 billion people worldwide. While continuous positive airway pressure (CPAP) remains the primary treatment for moderate to severe OSA, it is resource-intensive and generates considerable material waste. In the United States, where an estimated 4.8 million patients are treated with CPAP, the broader healthcare system produces 5.9 million tons of solid waste and 665 million metric tons of CO₂-equivalents annually. The environmental footprint of sleep medicine—particularly CPAP therapy—has not been quantified. The purpose of this study was to inform this discussion by estimating the total solid waste produced by the treatment of moderate-severe OSA with CPAP in the US over a 10 year period.

Materials and methods: We modeled waste generation under a steady-state CPAP-treated population (4.8 million or 24 million patients), assuming an annual 15% exit and entry rate to maintain population stability. Each new patient was assigned a CPAP machine at initiation; existing users contributed waste from ongoing consumable use. Waste calculations included machine and accessory weight (masks, tubing, filters) based on typical published product specifications. We evaluated scenarios by varying mask type distributions (even split of full face, nasal and nasal pillow masks; representative split based on CMS data), tubing type (heated tubing; simple tubing), and machine replacement schedule (every 5 years; every 7 years) to create total waste estimates.

Results: The solid waste associated with the treatment of the 4.8 million patients currently diagnosed with moderate-severe OSA in the US over a 10 year period ranged from 88.718 kilotons to 104.453 kilotons depending on model parameters. The highest amount of waste was produced when patients used climate line tubing and replaced their machine every 5 years, regardless of mask mix (104.408-104.453 kilotons); waste was reduced by 15% when patients used simple tubing and replaced their machines every 7 years (88.718-88.763 kilotons). 64.6% of all waste produced during the 10 year treatment period was due to supply refills (masks, tubing, water reservoirs).

Conclusions: The treatment of OSA with CPAP is a resource-intensive therapy that produces significant plastic and electronic waste, contributing to environmental degradation. Over 10 years, U.S. CPAP use generates ~100 kt of solid waste—less than insulin therapy (~1,019 kt) or hemodialysis (~10,452 kt), but far more than laparoscopic surgery (~25.9 kt). These estimates reflect only the mass of discarded materials and do not capture the full carbon footprint, which would also include upstream emissions from manufacturing, energy use, and transportation. Nevertheless, equipment choices can meaningfully reduce waste. Extending the usable lifespan of CPAP machines and selecting lighter components—such as simple tubing—could reduce total waste by up to 16 kt, or approximately 16% over a decade. These findings highlight the importance of improving medical device durability and advancing circular economy strategies to mitigate the environmental impact of long-term therapies in sleep medicine and beyond.

A Pilot Study of Sleep Measurements in Japanese Infants

H. Kojima¹, S. Kiyama², E.Y.Y. Lau³, C.-H. Tseng⁴

Introduction:

Sleep in early life is crucial for healthy brain development. Nevertheless, the majority of existing studies have focused on adults and school-aged children, and surprisingly little is known about the role of sleep in infants' perceptual, social, and cognitive development. The current study was conducted to serve as a pilot to validate measures of sleep for infants as a foundation for future investigations of the associations between infant sleep and social-cognitive development.

Materials and methods: Twelve infants aged between 2-12 months ($M = 7.82$, $SD = 3.9$; 5 female and 7 male) from Sendai city, Japan, participated in the study. Their sleep was continuously monitored for at

least over a week (min. 7 nights, 8 days) using an actigraphy (Micro Motionlogger®, Ambulatory Monitoring Inc.) with their sleep data analysed by the Sadeh algorithm, with metrics such as total sleep time (TST), sleep efficiency (SE) and wakefulness after sleep onset (WASO) derived. All parents completed the Brief Infant Sleep Questionnaire-Revised (BISQ-R) online and those who habitually tracked infant sleep with a diary were invited to share the records.

Results:

83.33% of the participants reported having a regular habit of tracking their infant's sleep. According to actigraphy measurements, on average, infants spent 52.78% ($SD = 4.38$) of their time asleep. The sample's mean nighttime sleep duration per night was 10 hours 30.76 minutes ($SD = 61.83$) and napping duration per nap was 1 hour 20.39 minutes ($SD = 34.47$). Average nighttime SE was at 92.54% ($SD = 4.10$), and WASO was 50.16 minutes ($SD = 35.74$). 75% of parents underestimated durations of nighttime sleep, at around 3.90% (i.e. 24.60 minutes, $SD = 5.17\%$). However, parents were equally as likely to overestimate and underestimate durations of naps - where on average, parents overestimated the durations of naps by 2.16% (i.e. 1.74 minutes, $SD = 10.96\%$). With nighttime and daytime sleep combined, 75% of parents underestimated their infant's sleep duration, at around 4.36% (i.e. 236.94 minutes, $SD = 6.06\%$). Correlational analysis revealed that better actigraphic sleep efficiency (SE) was positively correlated with healthier parent-reported sleep patterns (BISQ-R infant subscale), $r = .746$, $p = .013$. Parents' sleep monitoring confidence positively correlated with average napping durations per nap, both measured by the actigraphy, $r = .756$, $p = .030$, and reported by the parent, $r = .688$, $p = .028$, suggesting that parents' higher sleep monitoring confidence was associated with longer naps of their infants.

Conclusions: We showed that parental reports relative to actigraphy underestimates nighttime sleep frequency and duration and overestimates daytime sleep duration. A key component of the BISQ-R was found to significantly correlate with objective measures of infant sleep. This pilot work is promising and lays a foundation for future work in the relationship between infant sleep and social-cognitive development, reinforcing the value and potential of parent-reported infant sleep data.

Acknowledgments: This study was supported by EdUHK Department of Psychology's Departmental Research Grant (#R2389), Tohoku University's Ensemble Project Grant and the Research Institute of Electrical Communication's Cooperative Research Project Programme.

A Quest for a Histaminergic or Orexinergic Biomarker for Sudden Infant Death Syndrome

Y. Zhao¹, G.-F. Cui², S. Plancoulaine¹, M. Bersoult¹, Y.-P. Hou¹, Y. Dauvilliers³, A. Guyon⁴, M. Comajuan⁴, D. Meyronet⁵, A. Jouvet⁵, B. Kugener⁶, M. Thieux¹, P. Robert⁷, J.-S. Lin¹, P. Franco⁴

¹University Lyon 1, INSERM U1068, CRNL, Lyon, France, ²Chinese Academy of Sciences, The Brain Cognition and Brain Disease Institute, Translational Research Center for the Nervous System, Shenzhen Institute of Advanced Technology, Shenzhen, China, ³CHU Montpellier, INSERM U1061 and Sleep Unit, Department of Neurology, Gui de Chauliac Hospital, Montpellier, France, ⁴University Lyon 1, Pediatric Sleep Unit, Mother and children Hospital, HCL & INSERM U1068, CRNL, Lyon, France, ⁵University Lyon 1, Service de pathologie et de neuropathologie, Centre de biologie et pathologie Est, Groupement hospitalier Est, Hospices civils de Lyon, Lyon, France, ⁶University Lyon 1, SIDS Reference Center, Women and Children Hospital, HCL, Lyon, France, ⁷Bioprojet Biotech, Saint-Grégoire, France

Introduction: Sudden infant death syndrome (SIDS) is defined as the death of an infant under one year of age which occurs during the sleep and remains unexplained after a complete evaluation of death scene, infant history and postmortem investigation. In industrialized countries, SIDS is still the leading cause of post-neonatal death (between one month and one year). The occurrence of SIDS during sleep at a specific developmental period, especially between 2 and 6 months of age, suggests an association with a dysfunction in the maturation of sleep-wake regulation particularly the brain arousal systems. Indeed, polysomnographic recordings have shown that SIDS victims exhibit altered arousability, characterized by fewer arousals at the end of the night and an increased prevalence of incomplete arousals compared to age matched healthy infants. SIDS risk factors, for example, ventral sleep position, bed-sharing, overheating, infections, ante or postnatal cigarette exposure, prematurity have shown to decrease the arousability from sleep. Therefore, the present study investigates whether the

Orexin (Ox) and Histaminergic (HA) systems, two major wake-promoting systems, are altered in SIDS victims.

Materials and methods: In the first part of this study, we evaluated Ox and HA levels in CSF between infants died of SIDS, infants died of known causes (ED) and healthy control infants (C) still alive. CSF samples for Ox measures were collected from 61 controls, 38 SIDS cases and 32 infants died of ED. In the second part, we attempted to assess whether Ox and HA cell numbers are altered in SIDS. 11 SIDS and 8 ED were cell counted in the postmortem posterior hypothalamus following immunocytochemistry of Orexin -A (Ox-A) and histidine-decarboxylase (HDC, the HA synthesizing enzyme). We subdivided the HDC- and Ox-ir neuronal populations into rostral, central and caudal parts in order to quantify their respective cell number and then compare them between SIDS patients and ED control subjects.

Results: Ox levels were not statistically different in dead infants compared to controls infants, and in SIDS compared to ED. However, the decrease in Ox values in controls was not observed between the age of 0-2 months to 2-6 months in died infants ($p=0.02$), explaining higher Ox values between 2-6 months in deceased infants compared to controls ($p=0.04$). The CSF samples for HA measurement were collected from 42 other controls and 52 other SIDS cases. Compared to healthy controls, the HA and its direct metabolite *trans*-methylhistamine (*t*-MeHA) levels were extremely high in SIDS victims likely due to a postmortem cell release. More Ox-ir neurons were found in rostral ($p=0.04$) and caudal ($p=0.03$) subdivisions in SIDS compared ED controls but not in central subdivision ($p=0.60$). However, no difference was observed in terms of their morphology or in the number of HDC-positive neurons in SIDS patients compared to controls in either rostral, medial and caudal parts of the posterior hypothalamus.

Conclusions: Although no dysfunction of these systems was directly demonstrated, the elevated orexin cell counts and CSF levels in SIDS infants suggest an increased orexin release prior to death, potentially due to prolonged or repeated stressors such as hypoxia.

Are occupational therapists' sleep education and professional development needs being met in Aotearoa New Zealand?: Preliminary survey findings

D. Muller¹, F. Graham², C. Cunningham³, TL. Signal¹

¹Massey University, Sleep/Wake Research Centre, Wellington, New Zealand, ²University of Otago, Department of Medicine, Wellington, New Zealand, ³Massey University, Research Centre for Hauora and Health, Wellington, New Zealand

Introduction: Healthy sleep plays an important role in recovery from illness and injury and in positive rehabilitation outcomes. Good sleep health is also vital for mental and physical health, waking functioning and engagement in purposeful activities, all of which are encompassed in occupational therapy's scope of practice. However, recent US research suggests that most occupational therapists receive little, if any, in the way of undergraduate education on sleep and have limited access to sleep-focused continuing professional development to support their practice. The aim of our study was to investigate how much sleep-focused education and professional development occupational therapists in Aotearoa New Zealand (NZ) currently receive, to help identify unmet needs and inform future sleep education and resource development.

Materials and methods: We developed an online survey in Qualtrics (with a paper-based option) informed by previous international research and adapted for the NZ context. The survey was disseminated via formal and informal occupational therapy networks. Inclusion criteria was being a registered occupational therapist currently practising in NZ. Questions included whether participants received education about sleep in their entry-level occupational therapy programme (yes/no) and, if so, how many hours, plus whether sleep was incorporated in postgraduate occupational therapy studies they had engaged in. Therapists were also asked to report the number of sleep related continuing professional development/education hours they received in the past 2 years and whether occupational therapists in NZ should be better prepared to evaluate and treat sleep after graduation from entry-level occupational therapy programmes (yes/no).

Results: The sample ($n = 116$) comprised 7% Māori (Indigenous) and 93% non-Māori participants with a mean (SD) age of 43.3 (14.1) years. Most (92%) respondents identified as female (8% male), and one fifth had been practising for either 5 years or less (23%) or for more than 30 years (21%). Less than one fifth (18%) of participants reported receiving sleep education in their entry-level occupational therapy

training and, of those who did, 26% estimated this to have been a total of 1 hour, 21% estimated this to have been for 2 to 3 hours and 53% could not remember how much time was dedicated to sleep. Of the 37% of participants who had undertaken postgraduate occupational therapy studies, 13% reported this including a sleep component. Over half (56%) of respondents reported receiving no sleep-related continuing professional development in the last 2 years, 29% received 1 to 2 hours, 9% received 3 to 4 hours, and 7% received 5 or more hours. All participants (100%) who answered the question on whether occupational therapists should be better prepared to evaluate and treat sleep after graduating (n = 101) responded 'yes'.

Conclusions: Preliminary survey findings indicate a need to support occupational therapists via enhanced sleep education and resources spanning the course of therapists' careers. Future research to understand facilitators and barriers to implementing undergraduate and postgraduate sleep education and continuing professional development initiatives is warranted.

Acknowledgments: Thank you to all survey participants, our study advisory group and the Health Research Council of New Zealand for funding support (HRC: 23-906).

Association between sleep disturbances and cryptogenic ischemic stroke in young adults

T. Sarkanen^{1,2}, A. Kervinen², L. Tulkki³, J. Huhtakangas⁴, P. Jäkälä⁵, J. Putaala³

¹Tampere University Hospital, Tampere, Finland, ²University of Tampere, Tampere, Finland, ³Helsinki University Hospital, Helsinki, Finland, ⁴Oulu University Hospital, Oulu, Finland, ⁵Kuopio University Hospital, Kuopio, Finland

Introduction: Incidence of cryptogenic ischemic stroke (CIS) in young adult is increasing, as are sleep problems including insomnia, poor sleep quality and sleep apnea. We analyzed the association of sleep disturbances, perceived stress and CIS in a large multicenter study.

Materials and methods: Altogether 337 patients (median age 40.6 years, 45.1% women) with a recent CIS and 337 sex- and age-matched stroke-free controls were included. Responses to the Basic Nordic Sleep Questionnaire (BNSQ), Pittsburgh Sleep Quality Index (PSQI), and Epworth Sleepiness Scale (ESS)—assessing condition prior stroke—were analyzed. A conditional logistic regression model adjusting for depression, obesity, smoking, physical inactivity, snoring, and stress at work or home was used to assess associations between sleep problems and CIS.

Results: Compared to controls, patients reported more frequent difficulties falling asleep on ≥ 3 days/week (72.7% vs. 47.8%, $p=0.002$), awaking too early in the morning (76.3% vs. 47.8%, $p<0.001$), and poor subjective sleep quality (68.5% vs. 46.8%, $p<0.001$). In conditional logistic regression analysis, poor subjective sleep quality (BNSQ item 6) was independently associated with CIS (OR 2.62, 95% CI 1.03–6.65, $p=0.042$). A combination of stress and total sleep time of 5-6 hours or less showed a strong but statistically trend-level association with CIS (OR 8.05, 95% CI 0.95–68.37, $p=0.056$). Stress alone (OR 1.93, 95% CI 1.10–3.38, $p=0.022$) and current smoking (OR 2.03, 95% CI 1.01–4.06, $p=0.046$) were also significantly associated with stroke. No significant differences were observed in global PSQI or ESS scores between the patients and controls.

Conclusions: Poor subjective sleep quality, stress, and smoking were independently associated with cryptogenic ischemic stroke in young adults. Short sleep together with stress showed a very strong but statistically borderline significant association with CIS. These findings highlight the relevance of modifiable sleep and psychosocial factors in the risk profile of young stroke patients. Association with sleep, stress and stroke risk warrant further investigation.

Association Between Sodium Intake and Risk of Hypertension, Heart Failure, Stroke, and Myocardial Infarction: A Systematic Literature Review and Meta-analysis

C. Drachenberg¹, B. Singh², S. Attri², R. Dubey², S. Mettam³, J.K. Alexander¹, M. Whalen⁴, L. Pinto¹, L.A. Surkin⁵

¹Jazz Pharmaceuticals, Palo Alto, United States, ²Pharmacoevidence, Mohali, India, ³Jazz Pharmaceuticals, Oxford, United Kingdom, ⁴Jazz Pharmaceuticals, Philadelphia, United States,

⁵CardioSleep Diagnostics, Greenville, United States

Introduction: Substantial evidence supports a strong relationship between excess sodium consumption and increased cardiovascular morbidity and mortality risk. Accordingly, US and international health and nutritional guidelines recommend limiting dietary sodium intake to reduce the risk of cardiovascular disease. Certain medications can contribute to sodium consumption in excess of recommended limits (<2300mg/day for most adults); for example, some narcolepsy medications contain up to 1640mg of sodium per nightly dosage. This up-to-date systematic literature review (SLR) and meta-analysis qualitatively and quantitatively evaluated the relationship between sodium intake and the risk of hypertension (HTN), stroke, heart failure (HF), and myocardial infarction (MI).

Materials and methods: A comprehensive SLR was conducted using Embase®, MEDLINE®, CENTRAL®, conference proceedings, and clinical trial registries to identify evidence published up to 7 December 2023. Study selection, data extraction, and risk of bias assessments (Cochrane RoB2.0 and Newcastle-Ottawa Scale) were conducted manually by two independent human reviewers. For title and abstract screening, one human reviewer was replaced with an artificial intelligence-based tool (GPT-4). Discrepancies were resolved by a third human reviewer. Studies meeting prespecified PICOS criteria, including observational or interventional designs assessing associations between higher vs lower sodium levels (variably defined across studies) and the incidence of HTN, stroke, HF, or MI in adults (≥18 years) were eligible for meta-analysis. Pooled effect estimates were derived using STATA v18.5 SE. Both fixed-effects and random-effects models were applied to eligible studies in base-case and subgroup (sodium levels assessed via 24-hour urine excretion) analyses. Statistical heterogeneity and publication bias were assessed using the I-square statistic and funnel plots, respectively.

Results: The SLR included 145 studies reporting HTN, stroke, HF, and MI; low risk of bias was observed in most studies. Higher sodium/salt intake was significantly associated with increased risk of HTN (83/102 studies), stroke (15/30), HF (6/7), and MI (3/13). The 74 studies (HTN=59; stroke=9; HF=5; MI=4) eligible for meta-analysis demonstrated that higher sodium intake was significantly associated with increased odds/risk of HTN (odds ratio [OR]: 1.56, 95% confidence interval [CI]: 1.44–1.68), stroke (hazard ratio [HR]: 1.63, 95% CI: 1.28–2.09), HF (HR: 1.48, 95% CI: 1.14–1.94), and MI (OR: 2.97, 95% CI: 1.81–4.86). Subgroup analyses of studies using 24-hour urine excretion to measure sodium were comparable to those observed in the base case for HTN (OR: 2.48, 95% CI: 1.66–3.71) and HF (HR: 1.41, 95% CI: 1.15–1.73). A directionally similar trend to the base case was observed for stroke (HR: 1.39, 95% CI: 0.85–2.30) and MI (OR: 2.62, 95% CI: 0.92–7.46). Statistical heterogeneity was low in MI, moderate in stroke and HF, and high in HTN studies. Funnel plots showed no asymmetry in MI, possible asymmetry in stroke and HF, and substantial asymmetry in HTN studies.

Conclusions: This current SLR and meta-analysis are consistent with and expand the robust evidence base that higher sodium intake is significantly associated with increased risk of HTN, stroke, HF, and MI. Findings support clinical and health authority recommendations to limit sodium intake to mitigate cardiovascular risk.

Association Between Sodium Intake and Systolic and Diastolic Blood Pressure: A Systematic Literature Review and Meta-analysis

C. Drachenberg¹, B. Singh², S. Attri², R. Dubey², S. Mettam³, J.K. Alexander¹, M. Whalen⁴, L. Pinto¹, L.A. Surkin⁵

¹Jazz Pharmaceuticals, Palo Alto, United States, ²Pharmacoevidence, Mohali, India, ³Jazz Pharmaceuticals, Oxford, United Kingdom, ⁴Jazz Pharmaceuticals, Philadelphia, United States,

⁵CardioSleep Diagnostics, Greenville, United States

Introduction: US and international health organisations, including the USDA, AHA, ACC, and WHO, recommend limiting dietary intake of sodium (<2300 mg/day for most adults) to protect cardiovascular health. Chronic use of certain medications can lead to substantially higher sodium consumption, with some narcolepsy treatments containing up to 1640 mg of sodium per 9 g nightly dosage. Despite the well-established evidence that excess sodium intake is directly linked to increased blood pressure, the majority (89%) of US adults consume more sodium than the recommended 2300 mg/day limit. This systematic literature review (SLR) adds to previous SLRs by using more expansive criteria and provides an up-to-date meta-analysis to qualitatively and quantitatively evaluate the relationship between sodium intake and systolic and diastolic blood pressure (SBP; DBP).

Materials and methods: A comprehensive SLR was conducted using Embase®, MEDLINE®, CENTRAL®, conference proceedings, and clinical trial registries to identify evidence published up to 7 December 2023. Study selection, data extraction, and risk of bias assessments (Cochrane RoB 2.0, Newcastle Ottawa Scale) were conducted by two independent reviewers. For the title and abstract screening, one human reviewer was replaced with an artificial intelligence-based tool (GPT-4). Any discrepancies were resolved by a third human reviewer. Studies meeting prespecified PICOS criteria, including observational or interventional designs with ≥ 2 years of follow-up assessing the association between higher vs lower sodium levels (variably defined across studies) and SBP/DBP in adults (≥ 18 years), were eligible for meta-analysis. Pooled effect estimates were derived using STATA v18.5-SE. Both fixed-effects and random-effects models were applied to eligible studies in base-case and subgroup (sodium levels assessed via 24-hour urine excretion) analyses. Statistical heterogeneity and publication bias were assessed using the I-square statistic and funnel plots, respectively.

Results: Fifty-seven studies were included in the SLR irrespective of duration of follow-up; low risk of bias was observed in most studies. Higher sodium/salt intake was significantly associated with an increase in SBP (39/57 studies) and DBP (37/55). Across studies with ≥ 2 years of follow-up eligible for meta-analysis ($n=27$), higher sodium intake was significantly associated with increases in SBP (weighted mean difference [WMD], change from baseline [CFB]: 3.39, 95% confidence interval [CI]: 1.73–5.05 [$n=15$]; WMD, absolute mean difference [AMD]: 4.21, 95% CI: 2.52–5.90 [$n=23$]) and DBP (WMD, CFB: 1.61, 95% CI: 0.61–2.61 [$n=13$]; WMD, AMD: 1.81, 95% CI: 1.30–2.32 [$n=20$]). Subgroup analyses of studies measuring sodium levels with 24-hour urine excretion were similar for AMD in SBP (WMD, AMD: 2.69, 95% CI: 0.43–4.96 [$n=10$]) and DBP (WMD, AMD: 1.33, 95% CI: 0.40–2.26 [$n=10$]), confirming the robustness of the findings. Statistical heterogeneity was high for SBP and DBP; the funnel plot showed moderate asymmetry, suggesting potential publication bias.

Conclusions: This current SLR and meta-analysis confirm and further strengthen the evidence base for the relationship between higher sodium intake and increased blood pressure. Findings underscore the importance of reducing sodium consumption, as recommended by clinical and health authority guidelines, to manage blood pressure and protect cardiovascular health.

Associations between napping habits with mood and insomnia symptoms in young adult nappers of Hong Kong

H. Kojima¹, R.W. Sun², H.Y.D. Ma¹, S.-H. Cheung³, S.F. Cheung⁴, C.H. Hui³, E.Y.Y. Lau¹

¹The Education University of Hong Kong, Department of Psychology, Tai Po, New Territories, Hong Kong, SAR of China, ²Tung Wah College, School of Arts and Humanities, Kowloon, Hong Kong, SAR of China, ³The University of Hong Kong, Department of Psychology, Pokfulam, Hong Kong, SAR of China, ⁴University of Macau, Faculty of Social Sciences, Taipa, Macao, SAR of China

Introduction: While the links between nighttime sleep and mental health are increasingly recognised with converging evidence, the effects of daytime naps remain unclear, with mixed conclusions on whether they are beneficial or detrimental to our mood. This study aims to establish how common napping is among young adults in Hong Kong and to examine whether differences in their napping habits are associated with mood and insomnia symptoms.

Materials and methods: As a part of the Formation and Transformation of Beliefs in Chinese online panel survey study, 1374 young adults (79% female, 82.39% students) aged 18–35 years ($M=22.83$) completed a self-reported questionnaire of their napping patterns across three dimensions (duration, timing, and frequency; as a multiple choice question), negative mood states (Depression Anxiety Stress Scale-21), and insomnia symptoms (Insomnia Severity Index).

Results:

More than half (61.21%) of the participants were considered nappers, who took at least one nap per week. This prevalence was similar between students (61.22%) and workers (61.16%). Paired t-tests revealed significantly higher stress levels, $t(1222.8)=2.788$, $p=.005$, and insomnia symptoms, $t(1191.3)=2.789$, $p=.005$, in non-nappers than nappers, while depression and anxiety levels showed no significant differences between the two groups. ANOVA tests examined the differences in sleep and mood symptoms among nappers with varying napping duration, frequency, and timing. There was a significant effect of napping duration on depression, $F(3,837)=5.989$, $p<.001$, anxiety, $F(3,836)=4.448$,

$p=.004$, stress, $F(3,836)=7.294$, $p<.001$, and insomnia, $F(3,837)=5.329$, $p=.001$. Post hoc Tukey analysis showed that individuals who napped for > 2 hours had higher levels of depression ($p<.001$), anxiety ($p=.003$), stress ($p<.001$), and insomnia ($p=.008$) compared to those who napped for 30-60 minutes. They also had higher anxiety ($p=.012$) and stress ($p<.001$) levels compared to those who napped for < 30 minutes, and higher stress ($p=.027$) compared to those who napped for 1-2 hours. Napping frequency was associated with insomnia symptoms, $F(3,837)=3.395$, $p=.018$, with those napping > 6 times a week reporting more insomnia symptoms than those napping once ($p=.049$) or 4-5 times a week ($p=.015$) - but no significant mood symptom associations. Nap timing showed no significant relationship with depression or anxiety levels, but was significantly associated with insomnia, $F(6,833)=4.818$, $p<.001$, and stress levels, $F(6,833)=2.554$, $p=.019$. Those who napped between 12:00-12:59 reported higher insomnia symptoms than those who napped before 12:00 ($p=.026$) and after 13:00 ($p<.001$). Higher stress levels were reported for those who take naps at 15:00-15:59 compared to 13:00-13:59 ($p=.028$).

Conclusions: Napping was found to be common among young adults in Hong Kong. Non-nappers had significantly more insomnia and mood symptoms than nappers. Sleep and mood symptoms among nappers varied with nap duration, frequency, and timing, with habits such as napping for over 2 hours, more than 6 times per week, or around midday each being linked to negative effects on mood and insomnia.

Acknowledgments: As pilot work for a project supported by the Health and Medical Research Fund, Health Bureau, HKSAR (EdUHK#22232031), data was drawn from a completed longitudinal study, funded by General Research Fund, Research Grants Council, HKSAR (EdUHK#18611419).

Auditory sleep modulation to treat depression

P. Henckaerts¹, K.D. Fehér¹, E. Hertenstein¹, C.L. Schneider¹, M. Angelillo¹, C. Nissen^{1,2}

¹Department of psychiatry, Faculty of medicine, University of Geneva, Geneva, Switzerland,

²Department of psychiatry, Geneva University Hospitals (HUG), GenevaSW, Switzerland

Introduction: Major depressive disorder (MDD) is a leading cause of reduced quality of life due to illness worldwide. Recent studies suggest that selectively suppressing slow wave sleep (SWS) may induce rapid antidepressant effects. This project examines the impact of SWS suppression (without sleep deprivation) on depressive symptoms, sleep patterns, and brain activity, using auditory stimulation and high-density EEG during sleep. It also tests a synaptic plasticity model of therapeutic sleep deprivation in MDD, assessed via tDCS and TMS protocols.

Materials and methods: The study is a single-centre, doubled-blinded, randomized, sham controlled, repeated measures within-subject (stimulation and sham) clinical trial including 30 patients with MDD and 30 healthy controls (project-ID 2023-01804). Participants take part in four sleep laboratory nights (adaptation, baseline, stimulation and sham in counterbalanced order) and a daytime follow-up assessment. We test the hypothesis that auditory-closed loop suppression of slow wave sleep improves depressive clinical symptomatology (Montgomery-Åsberg Depression Rating Scale, MADRS) compared to sham stimulation and explore indices of brain plasticity.

Results:  A total of 16 participants (14 healthy controls (age = 37.8 ± 5.8 , $f = 8$) and 2 subjects with MDD (age = 41.5 ± 2.5 , $f = 2$) have been included so far in the study and analysis. Results show effect on the healthy controls. Stimulation led to a significant reduction of SWS by about 50%, with an associated increase in sleep stage N1, without significant changes in neither wake duration nor in arousal indices across vigilance states, other changes in architecture across the night. The continuity of SWS as well as wake was reduced. SWA as well as the number of SWs were reduced during SWS, without changes in any other frequency band nor changes in any vigilant state apart from N3. While SWA propensity dissipates across undisturbed sleep, it stayed constant across the night during stimulation, as reflected by a higher accumulation rate of SWE in the second half of the night as compared to sham.

Additionally, TMS and tDCS protocols revealed reduced long-term potentiation (LTP-like) inducibility and increased synaptic strength following a night of SWS suppression compared to an undisturbed night.

Conclusions: Preliminary results of the study demonstrate feasibility and potential efficacy of the protocol. The ongoing study aims to inform future treatment developments.

A Workforce Planning Model for Sleep Medicine Specialist Training Using Mathematical Optimization

F. Meng¹, G.Y. Ang¹, C.P. Lee², J.A. Abisheganaden^{1,3,4}

¹National Healthcare Group, Health Services and Outcomes Research, Singapore, Singapore, ²OUE Healthcare Group, O2 Lung Centre, Singapore, Singapore, ³Tan Tock Seng Hospital, Department of Respiratory and Critical Care Medicine, Singapore, Singapore, ⁴Nanyang Technological University, Lee Kong Chian School of Medicine, Singapore, Singapore

Introduction: Obstructive sleep apnea (OSA) affects about 30% of Singapore's adult population, yet it remains largely underdiagnosed. With anticipated increases in diagnosis and treatment rates, proactive workforce planning for sleep medicine specialists is essential. This study develops a mathematical model assessing the training requirements for sleep physicians to meet the projected demand for OSA treatment.

Materials and methods: Training as a sleep medicine specialist takes 13 years: 6 years of medical school, 3 years of junior residency, 3 years of senior residency, and 1 year of a sleep fellowship. We estimated the demand for sleep physician full-time equivalents (FTEs) using two approaches considering Singapore's projected population: (1) a patient-to-physician ratio based on a South Korean study, OSA prevalence and diagnosis rates in Singapore, and (2) population-to-physician ratios from the US, Australia, and South Korea. A mathematical model was created to estimate required training numbers of sleep physicians, factoring in current sleep physician data and the national retirement age.

Results: Currently, 42 sleep physicians (aged 39-62, mean age 49.6) operate at 0.2 FTE across various departments in Singapore. To meet projected demands for 2043-2062, we assessed training needs from 2025 to 2034. Using a patient-to-physician ratio with a 30% diagnosis rate and 0.5 FTE for new physicians, projected training requirements are 11 (2025-2028), 7 (2029-2031), and 8,12,14 for 2032-2034. If FTEs increase to 0.7, the needs decrease to 8 (2025-2028), 6 (2029-2030), and 5, 4, 11, 10 for 2031-2034.

Conclusions: These findings can aid policymakers in planning sleep medicine specialist capacity to address Singapore's future OSA demand.

Costs and benefits of a Meta and tiktok public campaign to promote the usage of a sleep hygiene phone app

F. Pecune¹, J. Coelho^{1,2}, P. Philip^{1,2}

¹University of Bordeaux, CNRS, Sanpsy, UMR6033, Bordeaux, France, ²CHU de Bordeaux, Sleep Medicine Service, Bordeaux, France

Introduction:

Social media platforms are a great source of medical information for a general audience. Unfortunately the quality of information is poorly controlled and many instagram or tiktok accounts do not provide reliable links to validated apps or scientific content. Moreover, while social media campaigns are often evaluated for visibility and engagement, their actual cost-effectiveness and impact on health-related behaviors remain underexplored. Leveraging their reach and engagement potential, we developed a targeted social media campaign to promote the use of a mobile application designed to support sleep hygiene. This study examines both the costs and benefits of such a campaign, assessing its ability to drive adoption and sustained use of a sleep hygiene app in a real-world context.

Materials and methods: KANOPEE, a free sleep hygiene app, was made available on the Google Play Store and Apple App Store. A grant from the French Regional Health Agency funded a social media campaign, which ran from January 11, 2023, to May 30, 2025. The campaign consisted of paid ads on META platforms (Facebook, Instagram, Messenger) and TikTok, with short video content explaining the consequences of poor sleep hygiene and the benefits of using KANOPEE. Ads targeted adults aged 18 and older, regardless of gender. Due to GDPR restrictions, these campaigns were traffic-oriented, meaning they were optimized to maximize redirection to the app's download pages without being able to link it to an actual download.

Results:

The total cost of the campaign was €30,000. It reached 14,414,918 people and generated 139,937 redirections to the app download pages, at an average cost-per-click of €0.21. Notably, the cost per redirection varied by platform and operating system: Android users were reached at a lower cost (€0.17) compared to iOS users (€0.60). All age groups were exposed to the campaign, but engagement was highest among individuals aged 55 and older. META platforms primarily reached this senior audience, while TikTok proved more effective in engaging younger demographics.

Conclusions: This study demonstrates that targeted social media campaigns can serve as a cost-effective strategy to promote evidence-based mobile health tools such as KANOPEE. With more than 14 million individuals reached and nearly 140,000 redirections to app download pages, the campaign highlights both the scalability and demographic specificity of digital outreach. Importantly, platform/device-related differences in cost-efficiency underscore the need for tailored strategies when allocating resources. While GDPR-related constraints limited direct measurement of downloads and app use, these findings suggest that social media constitutes a promising avenue to increase awareness and potential adoption of sleep hygiene interventions at the population level.

Cross-cultural comparison of the association between childcare arrangements and nap duration at age 3.5 in the Quebec (ELDEQ) and French (ELFE) birth cohorts

E. Touchette¹, E. Reynaud², G. Fréchette-Boilard¹, G. Forest³, R. Pétrin³, M.-H. Pennestri^{4,5,6}, S. Mazza⁷, A. Rey⁷, S. Plancoulaine⁸

¹Université du Québec à Trois-Rivières, Québec city, Canada, ²INSERM, CRNL, Bron, France,

³Université du Québec en Outaouais, Gatineau, Canada, ⁴Hôpital du Sacré-Cœur de Montreal, Montreal, Canada, ⁵McGill University, Montréal, Canada, ⁶Hôpital en Santé Mentale Rivière-des-Prairies, Montréal, Canada, ⁷Université Claude Bernard Lyon 1, CRNL, Bron, France, ⁸Université Claude Bernard Lyon 1, INSERM, CRNL, Bron, France

Introduction: Nap duration varies across preschool years. No study has investigated associations between childcare arrangements and nap duration between cohorts from different cultural background. Our objective was to examine whether childcare arrangements (1-unstructured with family members, 2-semi-structured in family daycares, 3-structured in a center-based childcares or schools) are associated with nap duration at 3.5 years old.

Materials and methods: Data are based on maternal reports from ELDEQ (n=1950) and ELFE (n=12236). Multinomial logistic regression models were adjusted for child (sex, age, breastfed, nighttime duration, bedtime), maternal (immigrant status, age, education) and family characteristics (siblings, income).

Results: In Quebec, 30% of children attended a structured childcare arrangement compared to 73% of children in France. At 3.5 years old, 37% in Quebec Vs 8% in France took no nap or <1h, 52% in Quebec Vs 58% in France napped from 1h to 2h, and 11% in Quebec Vs 34% in France napped ≥2h. Compared to children in a structured childcare arrangement, children in an unstructured arrangement had 3.26 (Quebec, 95%CI=2.25-4.71) or 5.03 (France, 95%CI=4.26-5.93) times the odds of taking no nap or a short one and children in a semi-structured arrangement had 1.83 (Quebec, 95%CI=1.32-2.53) or 2.16 (France, 95%CI=1.60-2.93) times the odds of taking no nap or a short one compared to children who napped from 1h to 2h. In France, children in an unstructured arrangement had 2.95 (95%CI= 2.65-3.29) times the odds of taking a long nap and children in a semi-structured arrangement had 3.41 (95%CI=2.93-3.97) times the odds of taking a long nap compared to children who napped from 1h to 2h.

Conclusions: Attending a childcare arrangement other than a structured one is associated with short nap duration (Quebec and France) or long nap duration (France) at 3.5 years old compared to children who napped from 1h to 2h.

Development of search strategies for meta-research related to sleep

G.N. Pires¹, E.S. Arnardóttir^{2,3}, J.M. Saavedra^{2,4}, S. Tufik^{1,5}, W.T. McNicholas^{6,7}

¹Universidade Federal de São Paulo, São Paulo, Brazil, ²Reykjavík University, Sleep Institute, Reykjavík, Iceland, ³Reykjavík University, Department of Computer Science, Reykjavík, Iceland, ⁴Reykjavík University, Physical Activity, Physical Education, Sport and Health Research Centre, Sports Science Department, Faculty of Social Sciences, Reykjavík, Iceland, ⁵Instituto do Sono / Associação Fundo de Incentivo à Pesquisa, São Paulo, Brazil, ⁶University College Dublin, School of Medicine and the Conway Research Institute, Dublin, Ireland, ⁷St Vincent's Hospital Group, Department of Respiratory and Sleep Medicine, Dublin, Ireland

Introduction: Although the number of systematic reviews and meta-analysis published in sleep medicine has been increasing, there is a growing concern regarding their overall reliability and external validity. Recent meta-epidemiological studies demonstrate that the average methodological quality of sleep-related systematic reviews is often poor, therefore impairing the process of evidence synthesis. Developing reliable search strategies is a challenging aspect of systematic reviews, often resulting in methodological biases and impacting their overall quality. Using standardized search strategies is an alternative to prevent methodological biases and increase the quality and reproducibility of systematic reviews. The current study aimed at developing a series of search filters for meta-research in sleep medicine.

Materials and methods: First, a comprehensive list of sleep disorders, conditions, and related topics for which search filters was created. The list included all disorders, isolated symptoms and normal variants disclosed on the International Classification of Sleep Disorders (3rd edition, text revision – ICSD-3-TR), as well as emergent or proposed disorders, and sleep-related conditions not primarily related to a disorder. In some cases, more than one search filter was developed for a single sleep disorder, in order to provide different levels of sensitivity and specificity. All search strategies were design specifically for a PubMed search, by combining controlled vocabulary (Medical Subject Headings terms – MeSH) and free terms, encompassing the disorder name, alternative nomenclature (as disclosed by the ICSD-3-TR), entry terms listed on MeSH, and clinical experience. Each search filter was developed based on an iterative process, being tested, modified and retested until a reasonable sensitivity and specificity is achieved.

Results: In total, 71 sleep-related conditions were listed for the development of search filters. This includes 40 sleep disorders listed in ICSD-3-TR (16.9%), 3 proposed sleep disorders (sexsomnia, upper airway resistance syndrome, and restless sleep disorder – 4.2%), 7 isolated symptoms (9.9%), 6 sleep-related medical or neurological disorders (listed in ICSD-3-TR appendix A – 8.5%), 3 additional conditions (sleep deprivation, chronotype and dreaming – 4.2%), and 12 supracategories, composed by the combination of two or more filters into a conceptual topic (16.9%). In total, 91 search filters were created, as some sleep disorders resulted in more than one search filter. Due to the number and length of the search filters, they cannot be disclosed in the current abstract (for instance, most have more than 100 words and the longest one has 311 words). However, all these search filters are already publicly available at Open Science Framework (<https://osf.io/tdqyp/>).

Conclusions: Efforts towards methodological standardization in sleep-related systematic reviews are needed to ensure the quality and reliability of these studies. Utilizing standardized search filters is an effective way to enhance their accuracy, transparency, and reproducibility. These search filters are valuable supporting tools for researchers aiming at developing their own systematic reviews on sleep medicine.

Does self-reported sleep duration reflect actigraphy-reported sleep duration in male youth soccer players?

P. Figueiredo¹, J. Barreira², F.Y. Nakamura², R. Pimenta^{3,4,5}, J. Brito^{6,5}

Introduction: Adequate sleep is essential for health, athletic performance, and recovery, particularly for young athletes facing the demands of continuous practice and competition. However, young athletes often obtain less sleep than recommended. While objectively tracking sleep using devices can be costly for most sports organizations, many rely on self-reported sleep as part of daily wellness assessments. Thus, it is important to determine the accuracy of self-reported sleep indices, as this may influence their effectiveness as part of a monitoring system. This study aimed to compare the agreement between daily self-reported and actigraphy-based sleep duration in male youth soccer players.

Materials and methods: Forty-eight young male soccer players (mean $\pm$ SD, age: 16.7 ± 0.9 years) reported their perceived sleep duration and completed sleep diaries daily while also wearing an actigraphy device for 35 consecutive days (a total of 1,116 individual actigraphy observations and 917 self-reported observations were collected). The reliability and agreement between objective and subjective measures of sleep were estimated. Agreement between measurements was assessed using Bland-Altman limits of agreement, with acceptable limits of agreement set at <30 minutes.

Results: The mean objectively measured sleep duration per participant over the investigated period was $06:41 \pm 00:33$ h, with a coefficient of variation of 16.1%, while the mean self-reported sleep duration per participant over the same period was $07:48 \pm 00:35$ h, with a coefficient of variation of 12.0%. The mean time in bed was $08:11 \pm 00:33$ h, with a coefficient of variation of 14.9% per participant. Results indicated a disagreement between objective and subjective sleep duration, with a mean bias of -1:00 h (95% Confidence Interval (CI): -1:09 to -00:57 h), indicating an overestimation of self-reported sleep duration by 01:00 h and a potential disagreement range of over 2:30 h, as the 95% limits of agreement ranged from -2:09 to 0:15 h (95% CI: lower -02:32 to -02:12 h and upper 00:09 to 00:28 h), suggesting considerable individual variability in agreement. When comparing the time in bed against the perceived sleep duration, data demonstrated a mean bias of 00:28 h (95% CI: 00:21 to 00:35 h), while the limits of agreement ranged from -00:46 to 01:43 h (95% CI: lower -00:56 to -00:39 h and upper 01:36 to 01:53 h).

Conclusions: The current results suggest that coaches and practitioners working with youth soccer players should interpret and use self-reported sleep indices with caution. Self-reported sleep duration appears to align more closely with the objective time in bed than with the actual sleep duration. Thus, when possible, other methods for sleep monitoring should be considered, either alone or in combination with self-reported measures.

Dyslipidemia and obstructive sleep apnea in men with androgenetic alopecia: an analysis from the EPISONO study

E.M.S. Xerfan^{1,2}, M. Rodrigues Souza^{1,2}, P. Araujo³, S. Tufik^{1,2}, M.L. Andersen^{1,2}

¹Universidade Federal de São Paulo (UNIFESP), Departamento de Psicobiologia, São Paulo, Brazil,

²Instituto do Sono, Associação Fundo de Incentivo à Pesquisa (AFIP), São Paulo, Brazil, ³Universidade Federal da Bahia, Departamento de Biorregulação, Instituto de Ciências da Saúde, Salvador, Brazil

Introduction: Androgenetic alopecia (AGA) is a non-scarring hair disorder, and the most common cause of hair loss in adult men. This condition is primarily driven by genetic predisposition and androgen activity, related to a higher conversion of the testosterone into its active metabolite, dihydrotestosterone (DHT), by the enzyme alpha-5-reductase. Emerging evidence suggests that AGA is associated with metabolic dysfunction, worse sleep quality and sleep disorders, but the causality to its pathogenesis remains unclear. Chronic and systemic inflammatory conditions, such as diabetes, dyslipidemia, hypertension, and obstructive sleep apnea (OSA) should be considered in individuals with AGA. The aims of this study were to examine the hormonal, metabolic, and sleep profiles of adult men with AGA and their potential relevance as risk factors to this hair condition.

Materials and methods: This cross-sectional case-control study used data from the 4th edition of the São Paulo Epidemiological Sleep Study (EPISONO). Participants self-reported AGA, completed sleep questionnaires, underwent polysomnography, and provided blood samples for laboratory analysis. To this study, the questionnaires Pittsburgh Sleep Quality Index (PSQI), Epworth Sleepiness Scale (ESS) and Insomnia Severity Index (ISI) were considered. A first analysis of the whole included sample was performed, followed by a propensity score matching (PSM), that was applied to match AGA and non-AGA groups in a ratio of 1:1 by age (caliper=0.2).

Results: From the total EPISONO sample of 769 participants aged 20 to 80 years, 317 were men. Among these, 307 answered the question related to AGA, with 64 self-reporting AGA and 243 reporting no diagnosis. Before PSM, the AGA group was older, with larger neck and waist circumferences, lower serum testosterone, higher triglycerides, and reduced high-density lipoprotein (HDL) cholesterol. Diabetes, metabolic syndrome, and moderate-to-severe OSA were more prevalent in individuals with AGA. After PSM, 64 age-matched pairs were analyzed. Very-low-density lipoprotein (VLDL) cholesterol and triglycerides levels remained elevated, and dyslipidemia was more frequent in the AGA group. Univariate logistic regression identified elevated triglycerides levels as a consistent predictor of AGA before and after PSM. Regarding sleep, no significant differences were found in PSQI, ESS, or ISI scores between groups before or after PSM. Moderate-to-severe OSA was associated with AGA prior to matching.

Conclusions: This study reinforces the link between AGA and lipid metabolism, with elevated triglycerides as a potential marker of this hair condition. The association between AGA and moderate-to-severe OSA before PSM analysis suggests that there is a complex interplay between AGA and metabolic factors. These results highlight the importance of early metabolic screening and sleep evaluation in individuals with AGA, and the need for further research in respect of OSA and its pathophysiological link with this hair condition.

Educational and Community Health Outcomes Following a Pediatric Sleep Medicine Education Program for Physicians in South Asia

K.B. Reddy¹, S.M. Hawkins², B. Hughes², S. Simon²

¹Shishuka Children's Specialty Hospital, Bangalore, India, ²University of Colorado Anschutz Medical Campus, Pediatrics, Aurora, United States

Introduction: The global practice of pediatric sleep medicine has been limited in large part to a lack of training opportunities. In India, 70-90 million children are conservatively estimated to have sleep problems, with potential for significant negative impact on growth, development, neurobehavioral outcomes, and academic performance. Unfortunately, a recent poll of general pediatricians across India revealed low levels of sleep-related knowledge, and 93% of pediatricians report no training in pediatric sleep during their medical education. Due to this immense need, the Diploma in Pediatric Sleep Medicine (DPSM) was started in 2022 to offer a formal training program in pediatric sleep for physicians across India. However, the impact of the DPSM program on provider knowledge, competence, performance, and community health is unknown.

Materials and methods: An electronic survey was created based on the Moore Framework for Assessing Learners and Evaluating Instructional Activities and sent via a messaging application to all participants who completed the DPSM program through December 2024. The Assessment of Sleep Knowledge in Medical Education (ASKME) questionnaire evaluated sleep medicine knowledge. Participants rated their satisfaction with the educational program on a 5-point scale from strongly disagree to strongly agree. Perceptions of pediatric sleep medicine competence and knowledge prior to and after completing the DPSM were queried on a 10-point scale from no competence/knowledge to fully competent/knowledgeable. Participants reported on their clinical practice and changes in patient and community health prior to and after the DPSM. Descriptive statistics (N, % and mean $\pm$ SD) are reported, and paired-sampled t-tests compared competence and knowledge ratings prior to and after completing the program.

Results: Out of 139 learners, 126 provided full responses to the survey. Average score on the ASKME was $74.9 \pm 10.7\%$. Participants predominantly agreed or strongly agreed that the setting, delivery, and instructional techniques and materials for the DPSM were beneficial (74.6% - 97.7%). Self-perceived knowledge and competence in pediatric sleep medicine was significantly improved after completing the

DPSM compared to before (competence before= 3.6 ± 2.7 , after= 7.4 ± 1.6 ; knowledge before= 3.8 ± 2.6 , after 7.4 ± 1.8 ; p 's<0.001). Nearly 90% of participants reported opening their practice to pediatric sleep patients and 35% began interpreting pediatric polysomnography following the DPSM.

Participants predominantly agreed or strongly agreed that the health of pediatric patients in their practice (84.7%) and in their community (80.6%) have improved because of the DPSM.

Conclusions: Pediatric sleep-related competence and knowledge increased in physicians in India who completed the DPSM. Further, access to pediatric sleep clinical care and polysomnography reportedly increased and community health was rated as improved for pediatric patients in India due to the DPSM.

Acknowledgments: No funding was obtained for this study. We would like to thank the faculty and participants in the DPSM program.

Effect of elinzanetant in reducing polysomnographic wakefulness after sleep onset in postmenopausal women: Results from the Phase II NIRVANA exploratory study

H. Joffe¹, C.N Soares², F.C Baker³, P.M Maki⁴, M. Bajbouj⁵, G. Zammit⁶, C. Caetano⁷, U. Krahn⁸, H. Shalhoub⁹, F. Kramer⁹, H.-S. Radcliffe¹⁰, C. Seitz^{9,11}

¹Brigham and Women's Hospital, Harvard Medical School, Boston, United States, ²Queen's University, Kingston, Canada, ³SRI International, Menlo Park, United States, ⁴University of Illinois Chicago, Chicago, United States, ⁵Center for Affective Neuroscience, Charité, Berlin, Germany, ⁶Clinilabs Drug Development Corporation, Eatontown, United States, ⁷BAYER Consumer Care AG, Basel, Switzerland, ⁸BAYER AG, Wuppertal, Germany, ⁹BAYER AG, Berlin, Germany, ¹⁰BAYER PLC, Reading, United Kingdom, ¹¹Institute of Clinical Pharmacology and Toxicology, Charité Universitätsmedizin, Berlin, Germany

Introduction: Sleep disturbances are a common and disruptive symptom of menopause affecting even women with infrequent or less severe vasomotor symptoms (VMS). Elinzanetant, a dual neurokinin (NK)-1 and NK-3 receptor antagonist, has previously demonstrated improvements in sleep disturbances based on favorable patient-reported outcomes (PROs) from the OASIS studies. The Phase II NIRVANA exploratory trial aimed to further evaluate the effect of elinzanetant on objectively measured sleep parameters in postmenopausal women with moderate-to-severe VMS using polysomnography (PSG), in addition to PROs. This abstract reports the effect of elinzanetant in improving PSG-measured wakefulness after sleep onset (WASO) at week 4 (primary endpoint) and week 12 (secondary endpoint).

Materials and methods: In this randomized, double-blind trial, 110 women experiencing menopause (mean [standard deviation] age 54.8 [4.6] years) with PSG-measured wakefulness after sleep onset (WASO) ≥ 30 minutes and ≥ 20 moderate-to-severe self-reported VMS per week were randomized to elinzanetant 120 mg (n=55) or placebo (n=55) once daily for 12 weeks. In-lab PSG assessments were conducted at baseline, week 4, and week 12 over two consecutive nights per time point. The primary and secondary endpoints were changes from baseline in WASO at weeks 4 and 12, respectively, analyzed using a mixed model with repeated measures. No hypotheses were planned to be tested. A prespecified analysis with log transformation was applied to address deviations from the normality assumption. Least squares geometric mean ratios (LSGMR) are therefore reported. To assess the overall treatment effect across all time points and account for substantial night-to-night variability, a post hoc random coefficient model was applied to all individual night data over the 12-week treatment period.

Results: At baseline, median WASO was 72.0 minutes (quartile [Q]1, Q3: 48.0, 90.3) for elinzanetant and 76.8 minutes (Q1, Q3: 54.0, 102.5) for placebo. At week 4, LSGMR to baseline was 0.68 (unadjusted 90% confidence interval [CI]: 0.59, 0.77) for elinzanetant and 0.94 (0.82, 1.08) for placebo, representing a 28% greater reduction in WASO with elinzanetant compared with placebo (unadjusted 90% CI (13%, 41%). At week 12, LSGMRs were 0.67 (0.57, 0.79) for elinzanetant and 0.76 (0.65, 0.90) for placebo, representing a 12% greater reduction with elinzanetant compared with placebo (unadjusted 90% CI (-11%, 30%). Night-to-night variability was notable, with WASO differing by at least 60 minutes in 15% of consecutive nights. The random coefficient model showed an 18% greater reduction in WASO with elinzanetant compared with placebo (unadjusted 95% CI: 5%, 30%), equating to an absolute reduction of approximately 13 minutes across the 12-week treatment period based on a WASO baseline assumption of 75 minutes.

Conclusions: A relative reduction in WASO was seen for elinzanetant compared with placebo, which was more pronounced at week 4 than week 12. The magnitude of improvement, while modest, is

relevant given the prevalence of sleep disturbances and the lack of therapies with efficacy confirmed by PSG in postmenopausal women. In line with the PROs from the pivotal OASIS trials, these findings support the effect of elinzanetant for menopause-related sleep disturbances.

Acknowledgments:

This study was sponsored by Bayer.

Effect of elinzanetant on sleep continuity and sleep architecture in postmenopausal women with sleep disturbances: post hoc analysis of the Phase II pilot study NIRVANA

C.N. Soares¹, H. Joffe², F.C. Baker³, P.M. Maki⁴, M. Bajbouj⁵, G. Zammit^{6,7}, C. Caetano⁸, U. Krahn⁹, H. Shalhoub¹⁰, F. Kramer⁹, H.-S. Radcliffe¹¹, C. Seitz^{10,12}

¹Queen's University, Kingston, Canada, ²Brigham and Women's Hospital, Harvard Medical School, Boston, United States, ³SRI International, Menlo Park, United States, ⁴University of Illinois Chicago, Chicago, United States, ⁵Center for Affective Neuroscience, Charité, Berlin, Germany, ⁶Clinilabs Drug Development Corporation, Eatontown, United States, ⁷Icahn School of Medicine at Mount Sinai, New York, United States, ⁸BAYER Consumer Care, Basel, Switzerland, ⁹BAYER AG, Wuppertal, Germany, ¹⁰BAYER AG, Berlin, Germany, ¹¹BAYER PLC, Reading, United Kingdom, ¹²Institute of Clinical Pharmacology and Toxicology, Charité Universitätsmedizin, Berlin, Germany

Introduction: Sleep disturbances are prevalent and burdensome in women experiencing menopause and vasomotor symptoms (VMS). While elinzanetant, a dual neurokinin (NK)-targeted therapy (NK-1 and NK-3 receptor antagonist), has demonstrated improvements in patient-reported sleep outcomes in prior OASIS studies, the Phase II NIRVANA pilot trial was the first to evaluate the effect of elinzanetant on polysomnographic (PSG) measures of sleep as a primary endpoint in postmenopausal women with moderate-to-severe VMS. The prespecified primary endpoint (change from baseline in PSG wakefulness after sleep onset [WASO] at week 4) and secondary endpoint (change from baseline in PSG WASO at week 12) are reported separately. This abstract focuses on exploratory PSG-derived outcomes of sleep continuity and architecture.

Materials and methods: In this randomized, double-blind trial, 110 women experiencing menopause (mean [standard deviation] age: 54.8 [4.6] years) with PSG-confirmed sleep disturbances (WASO ≥ 30 minutes) and ≥ 20 moderate-to-severe VMS per week were randomized to elinzanetant 120 mg (n=55) or placebo (n=55) once daily for 12 weeks. In-lab PSG was performed at baseline, week 4, and week 12 over two consecutive nights at each time point. All exploratory endpoints, including changes in sleep continuity (number of awakenings, arousal index) and sleep architecture (duration of N1, N2, N3, rapid eye movement [REM], and total non-REM sleep) were prespecified to be analyzed using descriptive statistics. To assess the time-averaged treatment effect across all time points and account for substantial night-to-night variability, a post hoc random coefficient model was applied to all individual night data over the 12-week treatment period.

Results: The number of awakenings was reduced more with elinzanetant than with placebo (least squares [LS] mean difference: -1.8 awakenings; 95% confidence interval [CI]: -2.8, -0.9) over the 12-week treatment period. The arousal index was also reduced more with elinzanetant compared with placebo (LS mean difference: -4.1 events/hour; 95% CI: -6.0, -2.2). Total time spent in non-REM sleep was greater with elinzanetant than with placebo (LS mean difference: 17.6 minutes; 95% CI: 9.0, 26.2). Elinzanetant increased N2 sleep duration (LS mean difference vs. placebo: 31.1 minutes; 95% CI: 21.0, 41.2) and decreased N3 sleep duration (LS mean difference vs. placebo: -14.9 minutes; 95% CI: -22.3, -7.5). Small differences were observed for N1 sleep duration (LS mean difference: -0.5 minutes; 95% CI: -4.0, 3.1) and REM sleep duration (LS mean difference: 0.8 minutes; 95% CI: -4.7, 6.4).

Conclusions: In this post hoc analysis, elinzanetant demonstrated a greater numerical advantage in objective measures of sleep continuity and selected sleep architecture parameters in postmenopausal women with VMS compared with placebo. Notably, elinzanetant reduced awakenings and arousals to a greater extent than placebo, complementing findings from the pivotal OASIS studies using patient-reported outcomes and supporting its potential for menopause-related sleep disturbances. Elinzanetant also increased non-REM sleep (primarily N2), while decreasing N3 sleep, which should be investigated further.

Effects of the Midnight Sun and daily step during data collection in polar Environment on Sleep Parameters: A Pilot Study

A. Marcotte¹, A.-A. Parent¹

¹Université du Québec à Rimouski, Health Sciences, Rimouski, Canada

Introduction: The midnight-sun period experienced near the Arctic Circle disrupts circadian rhythms and may alter sleep quality and architecture. This study examined how a 1- to 2- month field season under midnight-sun conditions influences the objective and subjective sleep of master's students during data collection.

Materials and methods: Two research teams, each comprising four master's students (1 man, 3 women; 27 ± 3 y), conducted environmental fieldwork on Bylot Island. Participants wore actigraph watches to record total sleep time, REM sleep, light sleep, deep sleep, number of sleep cycles, sleep efficiency, and daily step count across three periods: 1) Two weeks before departure (baseline), 2) During the expedition (42 ± 14 d), 3) One week after return (post-expedition). Weekly questionnaires: the Insomnia Severity Index (ISI) and a sleep appreciation scale (SAS)—reported subjective sleep perception over the same periods. Because of the small sample size, we used a Quade nonparametric ANCOVA with Bonferroni correction to compare baseline to each week of the expedition and to the post-expedition period. Wilcoxon tests compared baseline to the expedition average. The relationship between daily step count and sleep parameters was analyzed with Pearson's correlation.

Results: SAS differed significantly between baseline and the expedition average (55 ± 5 vs. 63 ± 11 ; $F(7,6) = -4.167$, $p = 0.037$) and between the end of the expedition and post-expedition (64 ± 14 vs. 61 ± 10 ; $F(7,6) = 4.333$, $p = 0.030$). The ISI increased in the first week of the polar environment compared to baseline (6 ± 3 vs. 9 ± 6 ; $F(7,6) = -2.667$, $p = 0.033$), but the average ISI across the expedition did not differ from baseline. Sleep data showed a significant reduction in total sleep time during the expedition compared to baseline (444 ± 26 vs. 421 ± 13 min; $Z = -2.028$, $p = 0.043$). No significant changes were observed for REM sleep percentage (22 ± 2 vs. $21 \pm 1\%$; $Z = -1.633$, $p = 0.102$), deep sleep percentage (16 ± 4 vs. $16 \pm 3\%$; $Z = -1.134$, $p = 0.257$), sleep efficiency (93 ± 2 vs. $94 \pm 1\%$; $Z = -1.394$, $p = 0.163$), or number of cycles (5 ± 1 vs. 5 ± 0 cycles; $Z = -1.732$, $p = 0.083$). Pearson's correlations revealed a moderate negative relationship between daily step count and total sleep time ($24\ 235 \pm 6\ 858$ steps vs. 425 ± 30 min; $r = -0.423$, $p = 0.016$) and between step count and deep sleep percentage ($24\ 235 \pm 6\ 858$ steps vs. $16.8 \pm 3.2\%$; $r = -0.359$, $p = 0.044$). No other sleep measures correlated significantly with step count.

Conclusions: Midnight-sun conditions seem to impair sleep perception during the initial transition into and following the polar environment and reduced average total sleep time across the expedition. Other sleep indices remained stable, likely reflecting the relatively short exposure to Arctic light and/or participants' sleep-management strategies. Furthermore, higher daily step counts were associated with reduced total sleep time and deep sleep, suggesting that increased fieldwork demands further compromise sleep under data collection in polar environment conditions.

Acknowledgments: We extend our sincere gratitude to all participants, as well as to our colleagues at Boreas and the Centre d'Études Nordiques, whose invaluable support made this project possible.

Effects on quality of life and daytime sleepiness between patients treated with CPAP versus CPAP alternatives

K. Shivanessh¹, G. Liang Chye¹, K. Fang Juin², J. Lye Chen Chen², O. Hui Yan³

¹Universiti Malaya/ Faculty of Medicine, Otorhinolaryngology, Head and Neck Surgery, Kuala Lumpur, Malaysia, ²Universiti Malaya, Faculty of Medicine, Kuala Lumpur, Malaysia, ³Hospital Sultanah Nora Ismail, Otorhinolaryngology, Head and Neck Surgery, Batu Pahat, Malaysia

Introduction: Obstructive sleep apnea is the most common sleep related breathing disorder characterised by recurrent episodes of partial or complete airflow obstruction during sleep. If left untreated, it is associated with increased morbidity and mortality. Continuous Positive Airway Pressure (CPAP) remains the primary treatment for most OSA patients due to its efficacy in maintaining airway patency during sleep. However, poor patients compliance to CPAP therapy is a significant barrier to its long-term success, often due to discomfort or inconvenience. In recent years, various surgical

interventions have emerged as a promising alternatives for OSA treatment, particularly for patients who are intolerant to CPAP. We would like to compare the improvement in the quality of life and daytime sleepiness of patients with OSA between those treated with CPAP therapy and those treated with CPAP alternatives.

Materials and methods: We conducted a pilot study in the Otorhinolaryngology clinic of University Malay Medical Centre. Patients aged 18 to 80 years old who were diagnosed with OSA of all levels, received interventions in the form of CPAP or CPAP alternatives were recruited to participate in the study. 48 patients completed the Epworth Sleepiness Scale (ESS) and the Calgary Sleep Apnea Quality of Life Index (SAQLI) questionnaires pre and post intervention (within the span of 2 weeks to 2 months).

Results: Both CPAP and CPAP alternatives were effective in improving patient outcomes, as shown by significant reductions in daytime sleepiness (ESS) and improvements in sleep-related quality of life (SAQLI) from pre- to post-treatment within each group.

Comparison between groups, no statistically significant differences were found in Post ESS ($p = 0.429$) or Post SAQLI scores ($p = 0.551$). The magnitude of improvement in sleepiness and quality of life was similar across both treatments. Although the CPAP group demonstrated slightly higher mean Post SAQLI scores, this difference was small and not clinically meaningful.

Conclusions: This preliminary study concluded that there is improvement in the quality of life and daytime sleepiness of patients with OSA treated with CPAP and CPAP alternatives. Though short term improvements are comparable between the two groups of patients, future studies need to be done to assess long term improvement of both arms, compliance of patients to CPAP therapy as well as the long term effectiveness of CPAP alternatives, such as surgical interventions and mandibular advancement devices.

Efficacy of Intraoral Negative Air Pressure (iNAP) Therapy in Adolescents with Obstructive Sleep Apnea: A Prospective Exploratory Study

Z. Song¹, J. Zhang¹, J. Shao¹, J. Huang¹

¹Department of Otolaryngology-Head and Neck Surgery, Eye, Ear, Nose, and Throat Hospital of Fudan University, Shanghai, China

Introduction: The diagnosis and treatment of obstructive sleep apnea (OSA) in adolescents are currently underestimated globally. This prospective study evaluated the effects of the Intraoral Negative Air Pressure (iNAP) Therapy on physiological parameters and subjective experiences in adolescent OSA patients, exploring treatment response differences by OSA severity.

Materials and methods: The iNAP Sleep Therapy System consists of five main components: a console, saliva container, saliva absorbent, flexible polymer tubing, and soft polymer oral interface. It creates and automatically maintains a negative oral pressure gradient. This pulls the tongue and soft palate forward, preventing respiratory events to improve sleep and user quality of life. This prospective study enrolled 13 adolescents (11 males, 2 females; aged 10-17 years), following 2 dropouts from 15 initially recruited who met inclusion criteria (Obstructive Apnea Hypopnea Index [OAHI] > 1 /hour) and underwent a feasibility test. Participants were categorized as severe (OAHI > 10 /hour, n=5) or non-severe (OAHI 1-10 /hour, n=8). All received iNAP therapy with polysomnography (PSG) at baseline, day 1 (Tx1), 1 week (Tx2), and 1 month (Tx3). Key parameters included sleep architecture, OAHI, lowest oxygen saturation (Lowest SpO₂), maximum apnea duration, Oxygen Desaturation Index (ODI), supine AHI, and questionnaire-assessed stress, quality of life (QoL), and daytime sleepiness. Paired t-tests (pre-post) and correlation analyses were performed.

Results: Regarding sleep architecture, overall sleep efficiency improved, N2 sleep decreased ($p < 0.05$), N3 sleep increased (Tx1, $p = 0.043$; Tx3, $p = 0.003$), and REM/NREM respiratory events significantly

reduced. Overall, OAHl significantly decreased at Tx1 and Tx3 ($p < 0.05$). Maximum apnea duration significantly shortened at Tx1 ($p = 0.006$) and Tx3 ($p = 0.009$). Lowest SpO_2 significantly increased at Tx2 ($p = 0.031$) and Tx3 ($p = 0.008$). ODI (Tx1, $p = 0.047$; Tx2, $p = 0.013$) and supine AHI (Tx1, $p = 0.013$; Tx2, $p = 0.044$) also significantly decreased. Improvement in OAHl ($\Delta OAHl = \text{Baseline OAHl} - \text{Tx OAHl}$) showed a strong and progressively strengthening negative correlation with improvement in NREM OAHl (Tx1: $r = -0.81$; Tx2: $r = -0.89$; Tx3: $r = -0.91$). Furthermore, OAHl improvement demonstrated strong correlations with reductions in supine AHI, shorter maximum apnea duration, and increased Lowest SpO_2 . At Tx3, 76.9% of all patients achieved $>50\%$ OAHl reduction. This rate was 100% in the severe group. In the non-severe group, 62.5% achieved $>50\%$ OAHl reduction at both Tx1 and Tx3. Both groups showed significant post-treatment OAHl improvement at Tx1 and Tx3 ($p < 0.05$). The severe group had a 4-8% significant increase in Lowest SpO_2 across all treatment stages ($p < 0.05$) and ODI improvement at Tx2 ($p = 0.036$). The non-severe group had significant maximum apnea duration reduction at Tx1 ($p = 0.042$) and Tx3 ($p = 0.036$). Questionnaire data showed improvements in OSA-18 QoL ($p = 0.08$) and total questionnaire scores ($p = 0.096$) approached statistical significance.

Conclusions: This exploratory study suggests Efficacy of Intraoral Negative Air Pressure (iNAP) Therapy in Adolescents with Obstructive Sleep Apnea: A Prospective Exploratory Study has positive therapeutic effects in adolescents with OSA, with efficacy potentially differing by OSA severity.

Feasibility, acceptability, and appropriateness of a brief sleep disorder education video for healthcare students presenting with sleep disturbance

A. Reynolds¹, C. Dunbar¹, N. Lovato¹, K. Nguyen¹, J. Fitton¹, G. Robertson¹, K. Loffler¹, K. Sansom¹, G. Harvey¹, A. Vakulin¹, G. Micic¹, A. Montero¹, T.L. Sletten², S.A. Ferguson³, S.M. Rajaratnam², B.W. Brown¹, S.E. Wanstall¹, R.J. Adams¹

¹Flinders University, Adelaide, Australia, ²Monash University, Clayton, Australia, ³CQUniversity Australia, Adelaide, Australia

Introduction: Up to 40% of young adults have symptoms of a sleep disorder. More than half of these young adults have symptoms warranting clinical investigation, but are rarely identified or managed in early adulthood. Unmanaged sleep disorders pose a risk for early career professionals engaged in shift work, as these conditions often go undiagnosed for extended periods of time.

The aim of this study was to determine the feasibility, appropriateness, and acceptability of a brief, co-designed sleep disorder education video specifically for healthcare students (medicine, paramedicine and nursing) who were likely to have future shift work requirements, and determine whether participants might consider help for their sleep after viewing.

Materials and methods: Healthcare students were invited to view a 15-minute online educational video. Customised content was delivered by a practicing early-mid career professional from each cohort, and included lived experience videos of sleep disorder diagnosis and management from a young nurse and paramedic. Videos were designed to briefly introduce young adults to the experience of, as well as treatments for, common sleep disorders.

Risk for a sleep disorder was determined using multiple validated questionnaires for insomnia, obstructive sleep apnoea, sleepiness and restless legs. Post video, participants responded to a series of questions about their interest and motivation for help seeking related to sleep.

Feasibility, acceptability, and appropriateness of the video were assessed with Weiner et al's (2017) implementation measures. Averaged scores of four items for each of the three facets were between 0-5, with 5 indicating highest agreement; between-group differences were determined with Kruskal-Wallis tests.

Results: Results are from 153 healthcare students (67% female) reporting at least one risk factor for a sleep disorder; in pre-video questionnaires, 33% were unsure if they had a sleep problem, and 48% felt that they did. Most were nursing (39%) or medicine (38%) students. Less than half (42%) indicated they had considered help for their sleep to date.

Median (IQR) scores for acceptability (4.0 (1.0)), appropriateness (4.0 (1.0)) and feasibility (4.0 (0.8)) suggested high agreement for all measures, and supported the video module. Paramedic students rated the acceptability (5.0 (1.0)) and appropriateness (4.5 (1.0)) higher than medicine and nursing students ($H(2) = 8.9$, $p = 0.012$ and $H(2) = 7.4$, $p = 0.025$ respectively). No between-group differences were found for feasibility ($H(2) = 1.7$, $p = 0.42$).

Post-video, 53% of participants indicated they were considering seeking help for their sleep.

Participants could select multiple reasons for not considering help; the most common were not perceiving a problem (49%), or that it wasn't a priority right now (42%). Having no time (32%), and feeling that help seeking would be too expensive (36%), were also factors.

Conclusions: Healthcare students found a brief, co-designed sleep disorders education video to be feasible, acceptable, and appropriate for introducing sleep disorder content. Given that all participants presented with disturbed sleep, high rates of feeling there is no time, and believing sleep care will be too expensive, should be carefully considered and addressed in future health services interventions and initiatives for sleep in young workers.

Acknowledgments: This research is funded by the Lifetime Support Authority (Australia).

From Sleep to Safety: Assessing Adverse Events in Sleep Laboratory

V.K.H. Lam¹, S.Y. Chan¹, M.W.M. Yu², Y.L. Lam¹, K.Y. Chan¹, W.Y. Tiu¹, B. Or¹, J.W.Y. Chan², Y.K. Wing²

¹Li Chiu Kong Family Sleep Assessment Unit, Shatin Hospital, Psychiatry, Shatin, Hong Kong, SAR of China, ²Department of Psychiatry, Faculty of Medicine, The Chinese University of Hong Kong, Psychiatry, Shatin, Hong Kong, SAR of China

Introduction: Patients undergoing sleep studies in the sleep laboratory may encounter adverse events. Ensuring patient safety is of paramount importance for effective and safe sleep laboratory management. Data on the type and severity of adverse events would facilitate sleep technicians in anticipating potential clinical events and to equip with relevant knowledge and intervention for timely evaluation, management and prevention. This study aims to systemically review adverse events and their consequences at an university-affiliated sleep laboratory to identify risks and enhance management strategies.

Materials and methods: We conducted a retrospective review of adverse events occurring from January 1, 2022 to March 31, 2025 at the Li Chiu Kong Family Sleep Assessment Unit, Department of Psychiatry, Shatin Hospital, Hong Kong. The sleep laboratory equipped with four beds, provides both diagnostic and therapeutic evaluations for a comprehensive range of sleep disorders across all age groups. Data were extracted from medical records, sleep reports, electronic Accident and Incident Reporting System (AIRS), and Clinical Management System (general electronic health care database of Hong Kong public health care system).

Results: Among a total of 1383 overnight attended sleep studies performed during the study period, 35 adverse events (2.53%, 1 event per 39.5 sleep studies) were documented. Adverse events affected 23 (69.7%) male and 9 (30.3%) female patients with age range from 9 to 85 years old (mean age 61.8 ± 20). Two patients had two consecutive incidences within same admission day while another one had two incidences during separate admissions. Clinical background of these patients included psychiatric disorders (45.5%), hypertension (33.3%), dementia (21.2%), cardiovascular disease (18.3%), cognitive impairment (12.1%) and Parkinson disease (9.1%).

The predominant adverse events were cardiopulmonary issues (13/35; 37.1%), including cardiac arrhythmia, hypertensive crisis and chest pain. Other notable events included altered neuropsychiatric conditions (25.7%) involving nocturnal confusion and sun downing syndrome, altered mental state with suicidal risk (3.1%) and accidental falls (3.1%). The remaining events comprised miscellaneous issues (34.4%) were upper respiratory tract infection symptoms, headache, gastroenteritis symptoms, dizziness, toe injury and skin rash. The overall severity of these adverse events was relatively mild, with no major injury or death. Only one patient ($1/1383=0.07\%$) required hospitalization, while 6 patients ($6/1383=0.43\%$) required accident and emergency department attendance. The adverse events occurred more commonly among patients with dementia ($p<0.001$) and cognitive impairment ($p<0.007$). The notable occurrence of cardiopulmonary problems and altered neuropsychiatric conditions emphasizes the need for vigilant monitoring to enhance patient safety.

Conclusions: While adverse events in sleep laboratory are relatively infrequent and occurring in 2.5% of sleep studies, the findings of cardiovascular and neuropsychiatric adverse events highlight the critical need for robust risk management and adequate staff training to mitigate potential incidents and enhance prevention measures

Groups of multiple respiratory and allergic trajectories between 1 and 5.5 years of age and their associations with sleep characteristics in early life

D. Saade¹, R. Delvert², C. Raherison-Semjen^{3,4}, O. Dumas², M. Sedki², M.-N. Dufourg⁵, B. de Lauzon-Guillain¹, B. Leynaert², R. Nadif², A. Bédard², S. Plancoulaine⁶

¹INSERM, Paris, France, ²Université Paris-Saclay, INSERM, Villejuif, France, ³Bordeaux University, Bordeaux, France, ⁴CHU Guadeloupe, Pointe à Pitre, France, ⁵INED, La Courneuve, France, ⁶INSERM, CRNL, Bron, France

Introduction: Sleep troubles have been associated with respiratory and allergic health problems in children, however the time line of their association is overlooked. The current study examined the associations between: (1) sleep patterns at age 1 year and respiratory and allergic multi-trajectories between 1 and 5.5 years; (2) respiratory and allergic multi-trajectories between 1 and 5.5 years and sleep patterns at age 5.5 years in a French birth cohort.

Materials and methods: Clusters of sleep characteristics at age 1 year (nocturnal sleep duration (NSD), day sleep duration (DSD), sleep onset difficulties (SOD), night awakenings (NA)) and at age 5.5 years (NSD, SOD, NA) and respiratory and allergic symptoms multi- trajectory groups between 1 and 5.5 years (wheezing, asthma medication, eczema, allergic conjunctivitis) were identified using unsupervised methods. Associations between sleep clusters at each age and multi-trajectory groups were assessed using multinomial regressions adjusted for potential confounding factors among 9,577 children.

Results: Two sleep clusters were identified at both age 1 and 5.5 years: C1a (79.9%, age 1 year) and C1b (83.1%, age 5.5 years) characterized by adequate sleep duration and good sleep quality; C2a (20.1%, age 1 year) and C2b (16.9%, age 5.5 years) characterized by shorter sleep duration and poorer sleep quality. Four multi-trajectory groups were also identified: G1 (no/few symptoms, 44.4%), G2 (persistent non-respiratory allergic symptoms, 23.1%), G3 (transient early respiratory symptoms, 25.2%), G4 (persistent respiratory and allergic symptoms, 7.3%). Belonging to cluster C2a was associated with an increased odds of belonging to G3 (adjusted odds ratio [95% interval confidence]; 1.14 [0.99-1.31]) and G4 (1.29 [1.05-1.59]). Similar results were obtained in children without wheezing at 2 months (1.18 [1.03-1.36] and 1.28 [1.03-1.60], respectively).

Conclusions: Sleep disturbances at 1 year are associated with poorer respiratory and allergic health between 1 and 5.5 years suggesting early sleep troubles may predict these health status.

Impact of High Mandibular Plane on Surgical Outcomes of Maxillomandibular Advancement for Obstructive Sleep Apnea

F.-Y. Hsu¹, P.-F. Wang¹, S. Stellino¹, C.-H. Lin¹

¹Chang Gung Memorial Hospital, Taoyuan, Taiwan

Introduction: Maxillomandibular Advancement (MMA) is the first surgical treatment option for obstructive sleep apnea (OSA). Despite the high success rate, incomplete remission is common. The surgical design generally focused on the forward movement of the maxillomandibular complex. The impact of high mandibular plane angle on surgical outcomes remained unclear. The purpose of this study is using cephalometry to investigate the role of high mandibular plane angle and correction in maxillomandibular advancement.

Materials and methods: A retrospective review was conducted on 106 medical records of patients (33 females and 73 males) who underwent MMA. To avoid the impact of gender and obesity, 50 male patients with a BMI<26 (Kg/m²)(26 of them had the surgical cure of post-op AHI<5) were included. Cephalometry and polysomnographic indices before and more than three months after surgery were collected for analysis. The paired T-test was applied to compare measurements before and after surgery. Non-paired T-test was used to compare between groups.

Results: On average, the maxilla(at A point) and the mandible(at B point) were advanced 4.0 ±2.9mm and 13.2±3.7mm, respectively. A lower pre-op mandibular plane angle (to Frankfort horizon) of 29.3±9.8° was noted in the surgical-cure group, compared to 35.8±8.5° in the non-cure group (p=0.012). There were significant differences in the angle counterclockwise rotation between non-cure (clockwise 2.8±3.6°) and cure group (clockwise 0.39±5.67°)(p=0.034); and a significant difference in the velopharyngeal airway between the non-cure group (10.1±2.6mm) and the cure group (11.0±2.9mm)(p=0.032).

Conclusions: A higher mandibular plane angle could have a negative impact on the surgical cure of MMA surgery in non-obese male patients with OSA.

Impact of Nocturnal Air Pollution on Sleep Quality and Emergency Health Service Utilization for Respiratory and Cardiovascular Conditions in Portugal: An Ecological Analysis Using Open Data

M. Meira e Cruz^{1,2}, V. Galdes², I. Rocha², J. Belo³, J. Lage⁴, J. Winck⁵

¹Sleep Unit, Cardiovascular Center of University of Lisbon, Faculty of Medicine, Lisbon, Portugal,

Portugal, ³Escola Superior de Tecnologia de Lisboa, Instituto Politécnico de Lisboa, Health &

Technology Research Center, Lisbon, Portugal, ⁴Instituto Superior Técnico, Universidade de Lisboa,

Centro de Ciências e Tecnologias Nucleares, Lisbon, Portugal, ⁵Faculdade de Medicina da Universidade do Porto, Porto, Portugal

Introduction:

Poor air quality is a recognized risk factor for respiratory and cardiovascular diseases. Nocturnal exposure to air pollutants may further impair sleep quality, compounding health risks and increasing emergency healthcare utilization. The interplay between nighttime environmental stressors and sleep disruption remains underexplored in the Portuguese context. With this work, authors aimed to examine the association between nocturnal air pollution, sleep quality indicators, and emergency department visits for respiratory and cardiovascular complaints across multiple regions in Portugal.

Materials and methods: This ecological study combined open-access data from the Portuguese National Environmental Monitoring Network (QualAr), national health surveillance systems, and population-level sleep quality metrics from EUROSTAT and the National Institute of Health Doutor Ricardo Jorge (INSA). Hourly nighttime pollutant concentrations (PM_{2.5}, PM₁₀, NO₂, O₃, CO; 22:00–06:00) were analyzed over a 3-year period (2020–2022). Emergency visits were classified by ICD-10 codes for respiratory (J00–J99) and cardiovascular (I00–I99) conditions. Regional sleep quality indicators—including prevalence of insomnia symptoms and self-reported sleep difficulties—were used to explore potential mediating effects. Time-series and geospatial analyses assessed correlations among air pollution levels, sleep disturbances, and acute health outcomes.

Results:

Elevated nocturnal concentrations of PM_{2.5} and NO₂ were significantly associated with increased rates of emergency department visits for both respiratory and cardiovascular conditions ($p < 0.01$), with the strongest effects observed in densely populated urban areas such as Lisbon and Porto. A seasonal trend was also noted, with higher pollutant levels and emergency visit rates during colder months.

Sleep quality emerged as an important modifying factor: regions with lower average sleep quality scores and higher self-reported insomnia prevalence exhibited greater vulnerability to the adverse health effects of air pollution. Multivariate Poisson regression models revealed that each 10 $\mu\text{g}/\text{m}^3$ increase in PM_{2.5} was associated with a 6–8% increase in emergency visits, while higher sleep quality scores were independently associated with a significant reduction in visits for both disease categories ($p < 0.001$).

Interaction terms between pollutants and sleep quality were explored. Although the interaction between PM_{2.5} and sleep quality index was not statistically significant, a trend was observed suggesting that poor sleep may potentiate the effects of NO₂ exposure on cardiovascular outcomes. These findings point to a possible synergistic relationship between environmental and behavioral factors in the context of nocturnal health vulnerability.

The models explained a substantial portion of daily variability in emergency visits (pseudo- $R^2 > 0.30$), and the inclusion of sleep-related indicators improved model fit and predictive performance.

Conclusions: Nocturnal air pollution is not only linked to a higher burden of acute cardiorespiratory events but may also indirectly exacerbate these risks through disruption of sleep quality. These findings underscore the importance of integrating environmental and sleep health policies to reduce preventable emergency healthcare demand.

Acknowledgments: Data were obtained from open-access sources, including air quality metrics from the Portuguese Environmental Agency's QualAr platform, population-level sleep indicators from EUROSTAT and the National Institute of Health Doutor Ricardo Jorge (INSA), and health service utilization records from the Portuguese Ministry of Health databases. HypnosAir project (PTDC/CTA-AMB/3263/2021/BI/12M).

Insomnia, Stigma, and Depression in Tuberculosis Patients: Longitudinal Insights from a Cross-lagged Model and Growth Models

X. Liu¹, H. Li², X. Tang³

¹Sichuan University, West China Hospital, Department of Pulmonary and Critical Care Medicine, Chengdu, China, ²Sichuan University, West China Hospital, Mental Health Center, Chengdu, China, ³Sichuan University, West China Hospital, Mental Health Center/Sleep Medicine Center, Chengdu, China

Introduction: Depression is prevalent and severe in tuberculosis (TB) patients. It is often linked to insomnia, stigma, lack of social support, and other psychological factors. However, most studies are cross-sectional, which only examine correlations. The longitudinal relationships between depression and other factors are unclear.

Materials and methods: Through convenience sampling, we selected participants for a 6-month longitudinal study. Depression, insomnia, stigma, social support, anxiety, and stress were assessed at the start of treatment (T1), and after one (T2), two (T3), and six months (T4). SPSS 26.0 and Mplus 8.3 were used for data analysis. A cross-lagged model (CLM) and latent growth models (LGMs) were constructed to study longitudinal associations.

Results: In total, 266 TB inpatients were enrolled (166 men, 100 women, mean age 48.1 ± 18.0 years). The comorbid depression detection rate fell from 23.3% at T1 to 10.1% at T4. The CLM showed insomnia at T1 significantly predicted depression at T2 ($\beta = 0.341$, $P < 0.05$). Depression at T1 predicted insomnia at T2 ($\beta = 0.182$, $P < 0.05$). Insomnia at T2 predicted depression at T3 ($\beta = 0.571$, $P < 0.05$). However, depression at T2 did not predict insomnia at T3 ($\beta = 0.073$, $P = 0.165$). Insomnia at T3 predicted depression at T4 ($\beta = 0.216$, $P < 0.05$). Depression at T3 predicted insomnia at T4 ($\beta = 0.174$, $P < 0.05$). The LGM revealed social support as a significant negative predictor of depression progression ($P < 0.05$). Stigma from T1 to T4 had a positive effect on depression over the same period ($P < 0.05$). Anxiety at T1, T2, and T4 positively influenced depression ($P < 0.05$). Perceived stress at T1 had a significant impact on depression ($P < 0.05$).

Conclusions: Insomnia predicts depression in TB patients, supporting interventions that improve sleep quality. The impact of perceived stigma on depression remains significant. Enhanced social support can accelerate recovery, underscoring the need to reduce stigma and increase support in TB depression management.

Latent Profiles of Psychological Distress in Middle-Aged Men and Their Associations with Sleep Patterns and Coping

E. Kim¹

¹Ajou University, Psychology, Suwon, Korea, Republic of

Introduction: Middle-aged men in South Korea face increasing psychological distress but often underreport symptoms due to cultural expectations surrounding masculinity and emotional restraint. Hwabyung (anger-related somatization), depression, and suicidal ideation represent key markers of mental health challenges in this population. This study aimed to identify latent psychological profiles among South Korean middle-aged men based on levels of hwabyung, depression, and suicidality, and to examine how these profiles differ in terms of sleep quality, physical activity, maladaptive schema, and coping strategies.

Materials and methods: A total of 412 middle-aged men (aged 40–59) participated in the study. Standardized self-report questionnaires were used to assess hwabyung symptoms, depression, suicidal ideation, sleep quality, physical activity, early maladaptive schemas, and coping strategies. Latent profile analysis (LPA) was conducted using Mplus 8.8 to identify distinct psychological subgroups. ANOVAs and post hoc tests were performed to compare group differences in lifestyle and cognitive-emotional variables.

Results:

Four distinct profiles emerged from the LPA, including **Low Distress Group** (n = 158, 38.3%), **Hwabyung-Dominant Group** (n = 82, 19.9%), **Depressive-High Risk Group** (n = 96, 23.3%), and **General Distress Group** (n = 76, 18.5%). Significant group differences were found in sleep quality, physical activity, maladaptive schemas, and coping strategies ($p < .01$). The Hwabyung-Dominant group showed higher levels of emotion-focused coping and avoidance, whereas the Depressive-High Risk group exhibited disrupted sleep, reduced activity, and elevated maladaptive schemas (e.g., defectiveness/shame, dependence). The Low Distress group reported healthier behavioral and cognitive profiles overall.

Conclusions: This study highlights distinct distress profiles among middle-aged men and their differential impacts on sleep. While depressive symptoms and suicidality were strongly associated with severe sleep disturbance, hwabyung was linked to sleep complaints related to emotional suppression. These findings underscore the need for sleep-focused screening tools tailored to culturally specific forms of distress. Integrating mental health profiling with sleep assessment may improve early identification and intervention strategies in this underserved population.

Leveraging Electronic Health Records to Understand Sleep Issues in Young Adults with Genetic Syndromes Across Rural-Urban Continuums

O. Veatch¹, M. Sloat², Z. Woolfolk³, F. Dickinson³, A. Driggers⁴, M. Mosconi⁴, B. Baran², L. Whitehurst³

¹University of Kansas Medical Center, Kansas City, United States, ²University of Iowa, Iowa City, United States, ³University of Kentucky, Lexington, United States, ⁴University of Kansas, Lawrence, United States

Introduction: Sleep disturbances are highly prevalent comorbidities among individuals with intellectual and developmental disabilities (IDDs). Sleep interventions are a promising target for developing new therapeutic strategies, with the potential to modulate a broad spectrum of developmental outcomes. However, investigations into sleep patterns among adolescents and young adults with IDDs remain limited. This makes it difficult to draw solid conclusions regarding sleep-related issues that should be targeted. This knowledge gap is particularly pronounced in rural populations with IDDs, who may be subject to unique environmental and systemic risk factors contributing to sleep dysregulation. The present study leveraged electronic health record (EHR) data from three US states with large rural populations (Kansas, Kentucky, and Iowa) to investigate sleep disturbances across four IDD conditions.

Materials and methods: International Classification of Diseases (ICD) codes present on ≥ 2 distinct dates were used to identify patients with the following genetic syndromes: Angelman [ICD10: Q93.5], Fragile X [ICD9: 759.83, ICD10: Q99.2], Prader-Willi [PWS; ICD9: 759.81, ICD10: Q87.11], and Rett [ICD9: 330.8, ICD10: F84.2]. Individuals with multiple distinct genetic syndrome diagnostic codes were excluded. Additional ICD9 and ICD10 codes present in the EHR of individuals who were between 13–25 years old at the time of code usage were mapped to clinically meaningful groupings of ICD codes, or Phecodes. Prevalence of sleep-related Phecodes was determined and compared between individuals living in urban versus rural areas based on Rural Urban Continuum (RUC) and Rural-Urban Commuting Area (RUCA) codes.

Results: In total, there were 607 who met criteria for the EHR-defined IDDs of interest. Most patients (73–93%) had urban designations. Co-occurring codes indicating sleep-related issues were observed in between 44–56%—with many individuals having >1 different sleep-related diagnosis. Prevalent sleep-related diagnoses identified in the EHRs of these individuals included sleep apnea, insomnia, sleep related movement disorders and circadian rhythm sleep disorder. For all sites, more individuals with a

sleep-related diagnosis resided in urban versus rural areas, with no discrepancy in the types of sleep disturbances diagnosed.

Conclusions: EHR-derived data indicates that adolescents and young adults with IDD's residing in rural areas are less likely to receive care at the health centers evaluated. This highlights issues related to rural healthcare access and a need for community engagement activities to build trust and inform patients and caregivers about the importance of healthy sleep.

Managing Sleep, Fatigue, and Crew Strategies in Offshore Sailing: The Role of Chronotype, Effort, and Team Coordination

S. Ceccanti^{1,2}, S. Bruno³, P. Frumento⁴, U. Faraguna^{1,5}

¹University of Pisa, Department of Translational Research and of New Surgical and Medical Technologies, Pisa, Italy, ²University of Verona, Department of Neuroscience, Biomedicine and Movement Sciences, Verona, Italy, ³University of Wisconsin–Madison, Department of Psychiatry, Madison, United States, ⁴University of Pisa, Department of Political Sciences, Pisa, Italy, ⁵IRCCS Fondazione Stella Maris, Department of Developmental Neuroscience, Pisa, Italy

Introduction: Sleep is a vital physiological process regulating recovery and performance through complex neuroendocrine and metabolic pathways. Its disruption, frequent in endurance sports like offshore sailing, can impair both physical and cognitive functions. In regattas, sailors face prolonged wakefulness, irregular sleep patterns, and demanding environmental conditions that challenge optimal recovery. In crewed offshore races, the difficulty is amplified by the need to synchronize individual rest with collective operational demands. Despite its relevance, sleep research in sailing is limited. Early studies on solo sailors proposed polyphasic sleep strategies, but these findings may not generalize to short-duration or crewed events.

This study investigated the impact of chronotype-aligned shift strategies, fatigue, and sleep recovery during the 151 Miglia–Trofeo Cetilar 2024, a short-duration offshore regatta. We focused on the relationship between chronotype-aligned shift strategies, subjective fatigue, and regatta outcomes, with particular attention to intra-crew dynamics.

Materials and methods: Participants were monitored before, during, and after the race. Crews were divided into two groups based on boat characteristics. Prior to the regatta, participants completed questionnaires on sail characteristics, chronotype (using the reduced Morningness-Eveningness Questionnaire-rMEQ), and sleepiness (using the Epworth Sleepiness Scale-ESS), and performed the Psychomotor Vigilance Task (PVT). After the race, PVT was repeated, post-race questionnaires were collected, and actigraphy was used for 5 days to monitor sleep recovery. Data were analyzed using chi-square tests, ANOVA, t-tests, Pearson's correlations, and multivariate regression models.

Results: The sample included 65 participants (mean age = 47.15 ± 15.59 years), with an average sailing experience of 12.05 ± 13.39 years. Chronotype distribution was 20% evening, 52.3% intermediate, and 27.7% morning types. During the regatta, participants reported an average sleep duration of 5.84 ± 3.53 hours and a significant increase in subjective sleepiness post-regatta (ESS: $t = 3.34$, $p = 0.0019$). Post-regatta, a significant correlation emerged between higher perceived physical exertion and delayed Mid-sleep Point (MPS) ($r = 0.401$, $p = 0.034$), suggesting that intense effort may postpone circadian timing. However, no significant relationship was found between MSP and chronotype, nor between chronotype and physical fatigue. Crews using self-managed shift strategies and exhibiting greater intra-crew agreement on shift organization ranked significantly higher ($p = 0.005$). At the crew level, performance was significantly associated with greater chronotype heterogeneity ($p = 0.0003$), lower average age ($p = 0.03$), and higher sailing experience ($p = 0.009$), emphasizing the role of group composition and coordination.

Conclusions: This study highlights the complex interplay between sleep, physical exertion, and team dynamics in offshore crewed sailing. In this context, internal team coordination emerged as a key factor influencing performance, alongside crew-level characteristics such as greater chronotype heterogeneity, lower average age, and higher sailing experience. While physical exertion impacts MPS, individual chronotype alone does not predict fatigue. These findings suggest that optimizing intra-crew synchronization and adopting flexible, personalized rest strategies may enhance both recovery and effectiveness in endurance contexts. Beyond sailing, these results offer actionable insights for other

high-demand environments, such as emergency services, transportation, or shift-based professions, where managing fatigue, circadian alignment, and team coordination is essential to optimize performance, safety, and well-being.

Monitoring the effectiveness of pre-flight rest in ULR operations with self-reported data

M. van den Berg¹, C. Ladyman¹, M. Hughes², B. Johnston², C. Dyer², M. Kunz², T.L. Signal¹

¹Massey University, Sleep/Wake Research Centre, School of Health Sciences, Wellington, New Zealand, ²Air New Zealand, Operational Integrity and Safety, Auckland, New Zealand

Introduction: In the aviation industry, ultra-long range (ULR) operations are defined as flights that exceed 16 hours. These operations have the potential to increase fatigue-related operational and occupational health and safety risks which are managed using multiple countermeasures. Pre-trip countermeasures include a minimum 48-hour rest (including two local nights) free from all duty and advice to crew on obtaining sufficient sleep for optimal functioning and to take a pre-flight nap to reduce the duration of time awake before signing on for duty. Monitoring the use and effectiveness of fatigue countermeasures requires data, and self-reported data are low-cost and easy to collect. To evaluate the use and effectiveness of pre-duty rest on a new ULR route, cabin crew provided information about their pre-duty days, sleep, and pre-flight ratings of sleepiness and fatigue.

Materials and methods: Sleep/duty diaries were distributed to participating cabin crew at the start of a ULR trip with an early evening sign-on time (Median = 18:40). The diary included a lookback report for documenting duty periods in the week leading up to their ULR trip, a 5-point Likert scale asking how recovered they felt from their previous duty ('not at all', 'somewhat', 'very much so'), and questions about their usual sleep at home, how much sleep they obtained in the 24 hours before their ULR trip, if they took a pre-flight nap, and if so, how much nap sleep they obtained. Additionally, they were asked to rate their sleepiness (Karolinska Sleepiness Scale) and fatigue (Samn-Perelli Crew Status Check) before the flight's departure.

Results: Seventy-seven cabin crew (55 women) provided data. The majority (96%) reported having at least two consecutive days off pre-trip (median = 3 days). When asked how recovered they felt from their previous duty, 43% reported feeling "very much so", whereas 3% said "not at all". Cabin crew reported getting more sleep in the 24 hours before the ULR trip (estimated mean = 8.3 h) compared to their usual sleep at home (estimated mean = 8.0 hours), 9% reported getting less than 7 hours sleep, and 49% reported taking a pre-flight nap. Sleepiness ratings ranged between 1 – 6 (Median = 2) and fatigue ratings ranged between 1 – 5 (Median = 2). More sleep in the 24 hours before the ULR trip was associated with lower pre-flight sleepiness ratings ($F(1,73) = 4.13, p=0.0456$).

Conclusions: Using easy and low-cost data collection methods, this study found the majority of cabin crew utilise days off pre-duty to prepare for the ULR trip, but a small proportion of crewmembers may not have recovered sufficiently. The large between-individual-variability observed in all metrics is not reflected in bio-mathematical model estimates. To reduce the likelihood of insufficient recovery, crew would benefit from enhanced fatigue education to support them make good decisions about sleep at home prior ULR duty. This should be included in initial and recurrent fatigue management training.

Acknowledgments: We acknowledge the significant contribution of the participating cabin crew. This study was funded by the airline and supported by members of its Fatigue Working Group.

Natural *Plasmodium falciparum* infection is associated with enhanced slow-wave sleep in humans

E. Martinez-Albert^{1,2}, J. Bok³, J.C. Dejon-Agobé⁴, M. Smit³, M. Gmeiner³, B. Muusz³, S. Dimitrov⁵, A. Akim Adegnika^{4,6}, T. Lange⁷, B. Mordmüller³, L. Besedovsky²

Introduction: Malaria is a parasitic infectious disease threatening more than half of the world population. While the elevation of sleep-regulatory cytokines in malaria suggests that sleep might be increased, this hypothesis remained untested so far. Assessing sleep in this infectious disease is especially interesting given that sleep, and particularly slow-wave sleep (SWS), can regulate immune responses and might thus boost host defense during malaria infection. We therefore objectively assessed sleep in adults with naturally acquired, asymptomatic *Plasmodium (P.) falciparum* infection and matched controls.

Materials and methods: In this controlled observational study in Lambaréné, Gabon, we enrolled 32 asymptomatic adults with confirmed *P. falciparum* infection and 32 age- and sex-matched uninfected controls. Participants underwent two nights of polysomnography in a sleep laboratory. Blood samples were collected to quantify immune parameters and parasitemia. Polysomnography data were analyzed for conventional sleep staging and spectral power.

Results: In matched-pair analyses, asymptomatic individuals were shown to display significantly more time in SWS compared to controls—on average, approximately 20 minutes more on night 1 and 30 minutes more on night 2. Higher leukocyte and lymphocyte counts were associated with longer SWS duration, while higher parasitemia was linked to reduced SWS. EEG spectral analyses revealed decreased slow-wave activity and disrupted slow oscillation frequency patterns in participants with higher parasitemia.

Conclusions: These findings provide the first evidence that individuals with asymptomatic malaria infection show enhanced SWS, possibly reflecting an immune-mediated adaptive response, which was further associated with malaria-related parameters.

Nocturnal Sleep Duration, Afternoon Siesta, and Sleep Disturbances (OSA) in pregnant Omani women and maternal and fetal outcomes

J. Almazroui¹, M. Al Abri², N. Al Riyami³, S. Jaju⁴

¹Sultan Qaboos University, Medicine, Physiology, Muscat, Oman, ²Sultan Qaboos University, Medicine, Clinical Physiology, Muscat, Oman, ³Sultan Qaboos University, Obstetric & Gynecology, Muscat, Oman, ⁴Sultan Qaboos University, Family and Community Medicine, Muscat, Oman

Introduction: There is a common perception that sleep is distinctly disturbed during pregnancy, and most women experience numerous sleep disturbances, dramatically changing the sleep architecture. (Kryger, 2022). Consequently, a disturbed sleep pattern during pregnancy can lead to unfavorable health outcomes for the woman and their fetus (Lee et al., 2001). Research has shown that poor sleep quality is frequent during the prenatal period, with approximately 76% of pregnant women experiencing poor sleep quality (Poeira & Zangão, 2022).

In Oman, few studies have been conducted to investigate the correlation between sleep disturbances and pregnancy outcomes. Therefore, this research study aims to examine the impact of sleep disturbances, characterized by obstructive sleep apnea (OSA), sleep deprivation indicated by nocturnal sleep duration, and Afternoon siesta, on maternal and fetal outcomes in pregnant Omani women.

Materials and methods: A cross-sectional, prospective cohort study was conducted on pregnant Omani women aged ≤35 years attending antenatal clinics. The study was ethically approved by the Medical Research & Ethics Committee (MREC) of Sultan Qaboos University and the Ministry of Health (MOH) Research and Ethical Review and Approval Committee.

Participants completed the Epworth Sleepiness Scale questionnaire, underwent limited home sleep studies, and wore actigraphy devices. Maternal and fetal outcomes were monitored. Descriptive statistics and tests of association were used for data analysis.

Results: A total of 429 Omani pregnant women were included in the study, with a mean age of 31.12 years (SD = 3.80) and an average gestational age at delivery of 38.37 weeks (SD = 1.43). The result showed a statistically significant association between the presence of OSA and a higher risk of gestational diabetes mellitus (33.7%) with odds ratio OR 0.63 (95% CI: 0.41- 0.96) and a p-value of 0.034. A significant positive correlation is observed between longer night sleep duration and preterm delivery before 37 weeks ($r=0.119$, $p < 0.05$), while short night sleep duration is linked to a more fragmented sleep pattern, such as total sleep hours and the number of awakenings at night. However, afternoon napping duration did not correlate strongly or consistently with adverse maternal or fetal outcomes. Multivariate tests revealed that the number of awakenings, a measure of sleep disturbance,

significantly impacted BMI changes during pregnancy. In contrast, other sleep disturbances showed limited evidence of association with adverse pregnancy and fetal outcomes.

Conclusions: This study revealed that OSA among pregnant women in Oman may arise, which affects the health of pregnancy and induces specific outcomes, such as gestational diabetes mellitus (GDM) and preterm delivery. However, the risk of preterm delivery is heightened during pregnancy with longer night sleep duration. Screening and management of sleep disorders during pregnancy may improve maternal and neonatal health outcomes. Though extreme efforts were made to maintain maximum accuracy and precision of this study, it was subject to some limitations that hindered the generalizability of the findings.

Acknowledgments: Sincere gratitude to all those who contributed to the completion of this research paper. An extended heartfelt thanks to the direct supervisor, whose invaluable guidance and insightful feedback were instrumental throughout the research process.

Non-application of infant sleeping recommendations at 2 months in French overseas territories: Frequency and determinants using data from the ENP-DROM 2021 survey

P. Delmer¹, R. El Rafei¹, E. Lebreton¹, S. De Visme², M. Chalumeau³, F. Thouillot⁴, J. Rosine⁵, V. Demiguel¹, N. Regnault¹, S. Plancoulaine⁶

¹Santé Publique France, Saint Maurice, France, ²INSERM, Nantes, France, ³INSERM, Paris, France, ⁴Santé Publique France, Saint Denis de la Réunion, France, ⁵Santé Publique France, Fort-de-France, France, ⁶INSERM, CRNL, Bron, France

Introduction: Preliminary analysis of the 2021 French National Perinatal Survey (ENP) suggest some poorer neonatal indicators in French overseas departments and regions (DROM) in comparison to metropolitan France, particularly regarding the application of newborns' sleep recommendations. We sought to estimate the frequency and identify the determinants of the non-application of the recommendation to put infant to sleep on their backs (NAR_BackSleep), the main protective factor against sudden unexpected infant death syndrome (SUDI), in the DROM.

Materials and methods: Our study included participating mothers at baseline and 2 months follow-up of the ENP-DROM 2021 survey in Guadeloupe (n=361), Martinique (n=374) and Réunion (n=517). NAR_BackSleep was computed as yes/no using the child dorsal sleep position question asked at 2 months. For each DROM, adjusted prevalence ratios (PRa) of NAR_BackSleep were estimated by robust variance Poisson regressions on weighted data after imputation of missing data.

Results: The frequencies of NAR_BackSleep were 58.7%, 47.1% and 24.2% in Martinique, Guadeloupe and Réunion, respectively. Common determinants of increased PRa of NAR_BackSleep were young maternal age (in all DROM), and lack of advice received from a health practitioner on newborns' sleep position (in Martinique and Réunion). Higher PRa of NAR_BackSleep were also observed with lower maternal education and health literacy, greater precariousness and inappropriate birth weight in Guadeloupe; with having a female child and presence of maternal post-partum depression in Martinique and with maternal feeling to be at ease financially and sharing their bed with their child in Réunion.

Conclusions: High frequencies of non-application of the recommendation to put infant to sleep on their backs have been measured in French overseas departments and regions. The identification of common and specific determinants in each territory will enable us to strengthen perinatal promotion among specific populations in these territories to prevent SUDI.

Outcomes of Split-Night CPAP titration: Insights into Predictors and Challenges in Obstructive Sleep Apnea

Y.L. Lam¹, V.K.H. Lam¹, M.W.M. Yu², K.Y. Chan¹, W.Y. Tiu¹, B. Or¹, J.W.Y. Chan², Y.K. Wing²

¹Li Chiu Kong Family Sleep Assessment Unit, Psychiatry, Shatin Hospital, Hong Kong SAR, China, ²The Chinese University of Hong Kong, Psychiatry, Hong Kong SAR, China

Introduction: A split-night study integrates diagnostic polysomnography (PSG) and continuous positive airway pressure (CPAP) titration for patients with severe sleep apnea (OSA). According to the AAST Technical Guideline (2023), planned split-night titration is recommended based on comprehensive

clinical assessments, while unplanned titration serves as an immediate safety measure for patient presenting with severe OSA. This study aims to evaluate the efficacy of split-night CPAP titration in reducing OSA severity, identify predictors of successful titration and assess their clinical implications in routine practice.

Materials and methods: We conducted a retrospective analysis of 68 patients (7.37%) who underwent split-night sleep studies from a total 923 PSG recordings at the Sleep Assessment Unit, Shatin Hospital between November 1, 2020 to March 31, 2025. The cohort included 51 males and 17 females, aged 25 to 85 years (mean age: 57.9 ± 13.6). Patients were categorized into planned ($n=40$, 58.8%) and unplanned ($n=28$, 41.2%) split-night titrations. Data were analyzed to assess the effectiveness of CPAP titration in reducing respiratory events with success defined as an apnea-hypopnea index (AHI) of less than 10 per hour or reduction of AHI by 75% from baseline (AASM, 2021) during the second half of the night.

Results: The overall success rate for split-night CPAP titration was 72.1%. Planned titrations demonstrated a significantly higher success rate of 87.5% compared to 50% for unplanned procedures ($p=0.001$). In the failure group, subjects exhibited a significantly higher arousal index (54.7 ± 27.8 vs. 39.0 ± 26.6 , $p=0.034$), AHI (60.2 ± 27.8 vs. 41.1 ± 27.3 , $p=0.012$) compared to successful counterparts, but had shorter sleep latency (10.2 ± 9.1 vs. 25.6 ± 36.6 , $p=0.008$). The central apnea-hypopnea index (CAHI) for the failure group was comparable at baseline (7.0 ± 8.5 vs. 3.3 ± 5.5 , $p>0.05$) but significantly increased to 14.0 ± 10.0 during titration ($p<0.001$). No clinically significant differences were observed in demographic characteristics, comorbidities, mood problem or insomnia symptoms. Logistic regression analysis indicated that unplanned split-night titration was more likely to have failed titration outcome (OR: 5.106, CI: 1.261 – 20.666) and was related to more severe AHI (OR: 1.055, CI: 1.026 – 1.085).

A higher prevalence of treatment-emergent central sleep apnea (TECSA) was found in the unplanned group (CAHI: 8.7 ± 9.8 vs. 2.2 ± 4.5 , $p=0.003$). TECSA was more closely associated with severe OSA, indicated by an AHI of 61.93 ± 27 for those with TECSA compared to 40.82 ± 27 for those without ($p=0.009$).

Conclusions: In conclusion, our findings indicate that treatment-emergent central sleep apnea (TECSA) is significantly more prevalent in the unplanned group, highlighting the importance of careful monitoring in these patients. While split-night CPAP titration effectively reduces AHI and improves sleep architecture, planned split-night titration is associated with a higher success rate than unplanned procedures. This suggests that a structured pre-planned approach may enhance treatment outcomes. The higher severity of OSA in the unplanned group is associated with emergence of TECSA, likely due to elevated pressures and expedited titration techniques. Future studies should focus on the mechanisms of TECSA and better identification of clinical subjects with severe AHI for planned split night studies.

Acknowledgments: NA

Perceptions of the causes and consequences of workplace fatigue among health leaders in Aotearoa New Zealand

K. O'Keeffe¹, L. Steege²

¹Massey University, Sleep/Wake Research Centre, Wellington, New Zealand, ²University of Wisconsin-Madison, School of Nursing, Madison, United States

Introduction: Much of the research on workplace fatigue in healthcare has focused on frontline workers, particularly clinical staff. However, a recent nationwide survey of the New Zealand health workforce highlighted that workplace fatigue is a common experience for workers in all roles and that innovative solutions are needed to manage fatigue in health settings. Health leaders have a crucial role in championing fatigue management, as well as in developing policies and procedures to manage fatigue. Yet, little is known about their knowledge and understanding of fatigue or their perceptions of the role they play in fatigue risk management. We aimed to explore health leaders' understanding of workplace fatigue and fatigue risk management.

Materials and methods: National, clinical, health and safety and occupational health leaders at Aotearoa New Zealand's primary public-funded health organisation completed an anonymous online survey to capture their perceptions of workplace fatigue, including causes and consequences that are

supported by fatigue science. Leaders were asked to report the extent to which they perceived different factors contributed to fatigue on a 5-point scale from not at all to a great deal. Similarly, leaders were asked to rate whether they agreed that fatigue had specific consequences on a 5-point scale from strongly disagree to strongly agree.

Results: The survey was completed by 632 leaders in our target groups (national: n=89, clinical: n=523, OHS: n=20). A majority (87.5%) of leaders perceived work demands as contributing to workplace fatigue 'quite a bit' or 'a great deal'. While known physiological contributors, such as insufficient sleep, were perceived to contribute to fatigue to a similar extent by 74.8% of leaders, others were less well recognised. A notable proportion reported that circadian misalignment (21.4%) and extended wakefulness (15.4%) were 'not at all' contributors to fatigue. Similarly, 17.7% felt that work schedule design was 'not at all' a contributor. Many leaders (64.4%) felt that personal factors, such as workers' health status, home life and experience, were considerable contributors to fatigue. The overwhelming majority of leaders (97-100%) agreed or strongly agreed that workplace fatigue had consequences for patient health and safety, worker health and safety, and staff retention and turnover. Perceptions of causes or consequences of fatigue did not differ by type of leader.

Conclusions: Workplace fatigue is acknowledged as having significant consequences in the health sector in Aotearoa New Zealand. While most leaders acknowledge known contributors to fatigue, some may not be aware of relevant physiological contributors, including those associated with shift work. These perceptions may hinder leaders' understanding of fatigue-related risks and their participation in system-based approaches to manage those risks. Tailored support is needed for health leaders to increase their awareness.

Acknowledgments: The project was funded by the Health Research Council of New Zealand.

Pregnancy Sleep Dynamics: A Large-Scale Wearable Study

R. Adaimi¹, N. Thigpen¹, A. Clausel¹, N. Gotlieb¹, K. Patel¹, M. de Zambotti¹

¹Ouraring Inc., Science, San Francisco, United States

Introduction: Sleep disturbances are highly prevalent in pregnancy, affecting nearly half of expectant mothers and worsening as gestation progresses. Driven by hormonal fluctuations, physical discomfort, and frequent nocturnal awakenings, these disruptions peak in the third trimester. Poor sleep has been linked to adverse maternal and fetal outcomes, including preterm birth, cesarean section and prolonged labor, and increased risk of prenatal and postpartum depression. Current understanding of sleep disturbances in pregnancy is limited by a lack of continuous, high-resolution data across gestation. Most studies rely on cross-sectional assessments or self-reported measures at isolated time points, failing to capture the dynamic, longitudinal changes in sleep patterns. This large-scale, high-density, real-world study leverages wearable technology to characterize sleep patterns from preconception to postpartum across pregnancies leading to loss, preterm, and term births, while examining the influence of maternal age and body mass index (BMI). Understanding sleep patterns and their impact on maternal health is essential for developing targeted interventions to improve pregnancy outcomes.

Materials and methods: This retrospective observational study analyzed sleep data from 10,319 Oura Ring users who self-reported pregnancy between May 2023 and November 2024. Data were collected continuously over a 64-week window, spanning 8 weeks before conception to 56 weeks postpartum. Sleep parameters, including time in bed, sleep duration, sleep stages and wake time at night, were modeled using mixed-effects linear models (MixedLM), accounting for gestational week, maternal age, and BMI.

Results: Sleep patterns shifted dynamically across pregnancy. In the first trimester, time in bed, sleep duration, and wake time peaked around week 9 (+30 min, +15 min, and +15 min, respectively), likely influenced by rising progesterone. Sleep duration returned to baseline in the second trimester, though wake time remained elevated. In the third trimester, sleep worsened, with increased wake time and reduced sleep duration possibly due to increases in physical discomfort and nocturia. Postpartum, sleep deteriorated sharply, with wake time rising ~90 min and sleep duration dropping ~70 min below pre-pregnancy levels at birth. Sleep stage analysis shows decreases in deep sleep and rapid eye movement (REM) sleep, and increases in light sleep starting early in the first trimester and persisting throughout pregnancy until birth. Pre-pregnancy age and BMI did not substantially affect sleep trajectories throughout gestation.

Conclusions: Pregnancy significantly alters sleep, with notable disruptions beginning in the first trimester, stabilizing mid-pregnancy, worsening in the third trimester, and peaking postpartum. These findings highlight the dynamic nature of maternal sleep and underscore the importance of sleep health in pregnancy care. Understanding normative sleep changes can inform targeted interventions to optimize maternal and fetal health outcomes.

Preliminary evidence about the effectiveness of a digital therapy for insomnia and remote sleep monitoring in obstructive sleep apnea treatment

K. Sousa¹, J. Vallim^{1,2}, G. Pires^{1,2}, R. Bonaldi¹

¹SleepUp Tecnologia em Saúde LTDA, São Paulo, Brazil, ²Universidade Federal de São Paulo, Psicobiologia, São Paulo, Brazil

Introduction: Obstructive sleep apnea (OSA) is a prevalent sleep disorder associated with a range of health consequences. The first-line treatment for OSA is continuous positive airway pressure (CPAP), which involves the delivery of a continuous airflow to maintain airways open. Despite the well-established benefits of CPAP treatment and its high efficacy, its acceptance and compliance remain a challenge, affecting the successful treatment of OSA. Co-morbid insomnia and sleep apnea (COMISA) is a prevalent condition among patients with OSA and might lead to decreased CPAP adherence. The treatment employed in this case is an interdisciplinary approach, CPAP with cognitive behavioral therapy for insomnia (CBTi), aiming to improve insomnia symptoms and increase CPAP adherence. The objective of this study was to assess the impact of a digital CBTi platform and remote monitoring on the CPAP usage time and sleep-related outcomes.

Materials and methods:

This study evaluated CPAP usage data from 123 users of both sexes (mean age: 48.34±11.37 years) enrolled in a CBTi program combined with remote sleep monitoring (SleepUp app). Fifty-seven (46%) of the users initiated CPAP treatment in conjunction with sleep monitoring, while 66 (54%) were individuals who had been using CPAP prior to the initiation of app use. The analysis included only patients with documented CPAP usage (>0 hours) in at least 1 time point over the course of 4 epidemiological weeks of CBTi treatment. The primary outcome was the mean CPAP usage time over each epidemiological week. The secondary outcomes were self-reported sleep quality, duration, and efficiency (sleep logs).

Results:

A significant increase in the time spent using CPAP ($\chi^2=8.93$ $p=0.030$) was observed in week 4 compared to weeks 1 ($\beta=0.36$ $p=0.045$) and 3 ($\beta=0.61$ $p<0.001$). No such increase was observed in week 2 ($p=0.090$). Sleep duration was significantly higher ($\chi^2=11.45$ $p=0.010$) in week 4 than in weeks 1 ($\beta=0.64$ $p<0.001$), 2 ($\beta=0.54$ $p=0.001$), and 3 ($\beta=0.58$ $p=0.002$). No significant differences were observed in sleep quality and efficiency over the course of the 4-week CPAP treatment, neither among subjects who initiated CPAP use concomitantly with sleep monitoring or prior to it.

Conclusions: The combined use of remote sleep monitoring with OSA treatment significantly improved CPAP adherence over a 4-week interval and increased the self-reported sleep duration. The absence of a significant distinction between new and existing CPAP users indicates that digital CBTi may confer equivalent benefits to both groups. These findings underscore the potential of digital interventions to enhance compliance with CPAP therapy. However, further research is necessary to address issues related to subjective sleep perception and long-term adherence to the treatment.

We would like to thank the volunteers and the financial support of Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP).

Prevalence of Dry eye and its association with sleep quality among students of Hyderabad Central University

S. Munugala¹, M. Hasaji¹, L. Gella¹

¹University of Hyderabad, School of Medical Sciences, Hyderabad, India

Introduction: Dry Eye Disease (DED) is a condition affecting the ocular surface due to tear film alterations, with risk factors including age, gender, contact lens use, smoking, low humidity, screen time, and poor sleep quality. Symptoms like grittiness, burning, pain, blurred vision, and light sensitivity can significantly reduce quality of life and productivity, leading to economic burden.

Sleep is crucial for overall health, and disturbances such as insufficient sleep, insomnia, abnormal movements while sleeping or sleep apnea can negatively impact the ocular surface. Studies have shown that poor sleep worsens dry eye symptoms, with sleep deprivation causing changes in the lacrimal gland, lipid layer, and tear secretion, contributing to shorter TBUT and increased tear hyperosmolarity.

Materials and methods: This cross-sectional study conducted in 2023 at Hyderabad Central University involved 324 students. Approved by the Institutional Ethics Committee, informed consent was obtained from all participants. A comprehensive eye evaluation was followed by dry eye assessments, including Tear Meniscus Height (TMH), Oxford stain grading, Tear Breakup Time (TBUT), Schirmer's test, and a questionnaire via Google Forms. The questionnaire included the Standard patient evaluation of eye dryness (SPEED) and Pittsburgh sleep quality index (PSQI) scales to assess dry eye symptoms and sleep quality, respectively.

Results: A sample size of 324 was taken to find the prevalence of dry eye and its association with sleep among students of Hyderabad central university. Mean age of students is 19.5 ± 0.7 years, among them 61% were males and 39% were females. 43% were emmetropes, and 57% were myopes. Myopia was the most predominant refractive error in our study.

Prevalence of evaporated dry eye is 29%, whereas aqueous deficient dry eye is 11.3%. The reported Prevalence of dry eye using standard patient evaluation of eye dryness (SPEED) questionnaire, subjectively is 72%.

The prevalence of poor sleep quality among the population of HCU was 55%. Occurrence of DED is severe in subjects with poor sleep quality as compared to subjects with good sleep quality. Multiple regression analysis was performed to see the relation between dry eye and sleep, which showed strong positive correlation of upto 80%. Spearman's correlation between SPEED and Seven components of sleep shows that there is strong positive correlation with Component 7 of PSQI which is day time dysfunction.

Conclusions: Our study found that there is prevalence of dry eye and poor sleep quality among students of Hyderabad central university was 40% and 55% and occurrence of DED was more prevalent in poor sleepers compared to good sleepers, this shows that sleep is an independent factor DED. Addressing sleep quality may play a crucial role in reducing the burden of dry eye disease among young adults. Future studies with larger and more diverse populations are recommended to confirm these findings and to explore the effectiveness of sleep improvement interventions in the management of DED.

Acknowledgments: I would like to express my special thanks to my supervisor Dr. Gella laxmi for her guidance, suggestions and support for completing project. I would also express my sincere thanks to my friend Meena and all my classmates for encouraging and helping me out in completing this project.

Prevalence of Exploding head syndrome (EHS) does not change from year to year

U. Tsovoosed^{1,2}, Y. Sumi^{1,3}, Y. Ozeki¹, H. Kadotani¹

¹Shiga University of Medical Science, Department of Psychiatry, Otsu, Japan, ²Mongolian National University of Medical Sciences, Department of Communication Skills, Ulaanbaatar, Mongolia, ³Medical University of Innsbruck, Department of Neurology, Innsbruck, Austria

Introduction: Exploding head syndrome (EHS) is a parasomnia characterized by the perception of loud noises or explosions inside the head during sleep-to-wake transition. However, the prevalence of EHS remains unclear. It is unknown whether the prevalence has changed from year to year. Therefore, we analyzed the change in prevalence of EHS over a 5-year period.

Materials and methods: As part of the Night in Japan Home Sleep Monitoring Study (NinjaSleep study), annual questionnaire survey was conducted among government employees in Koka City, Shiga Prefecture, Japan. To assess EHS, participants were queried “When dozing off or falling asleep, have you ever felt a sudden explosion in your head (e.g., bang, bang) or had the sensation that an explosion had occurred inside your skull?” from 2020 to 2024. Approval for the study protocol (R2017-111) was obtained from the Ethics Committee of the Shiga University of Medical Science.

Results: In total, 1.9% (29/1504), 1.6% (29/1832), 2.6% (48/1873), 1.6% (29/1811), and 2.0% (28/1401) of participants answered positively to the EHS screening questionnaire. No significant differences were found in the prevalence of EHS in these five years ($p=0.187$).

Conclusions: No significant differences in the prevalence of EHS were observed during the 5 years studied. Since EHS is a little-known sleep disorder, it is possible that asking this question every year would increase the percentage of positive responses; however, no obvious change in the positive response rate was observed.

Acknowledgments: We express our gratitude to the participants of Koka City. We thank Aiko Sagara, Kazuko Awazu, and Taeko Toyoda for their assistance with the data collection. Reduction in depression outcomes following CBT for insomnia: a potential role of general and sleep-related repetitive negative thinking and behavioural activation

V. Lall¹, M. Ree¹, R. Bucks¹

¹The University of Western Australia, Psychology, Perth, Australia

Introduction: Robust evidence supports cognitive behavioural therapy for insomnia (CBT-I) as an effective treatment for individuals experiencing both insomnia and depression. However, the mechanisms by which this sleep-focused intervention exerts its antidepressant effects remain poorly understood. This study examined whether individuals participating in a CBT-I group within routine clinical settings demonstrated improvements in general repetitive negative thinking (RNT), sleep-related RNT, and behavioural activation (BA), and whether these improvements were associated with reductions in depression outcomes reflecting potential pathways through which CBT-I may alleviate depression.

Materials and methods: The study recruited 80 participants (72.5% females) aged 23 to 89 years (Mage = 56.43, SD = 15.05), of whom 41 (Mage = 47.98, SD = 14.45) were recruited from a private behavioural sleep clinic, and 39 (Mage = 65.31, SD = 9.63) from a university-based psychology clinic. All participants were received a 4 week CBT-I group program.

Results: Using latent growth modeling, we found that participants demonstrated improvements in their depression outcomes, general RNT, sleep-related RNT, and BA overtime. Furthermore, the degree of improvement in RNT differed by time of day, with participants showing greater reductions in bedtime RNT compared to daytime RNT. Our findings also revealed strong associations between the extent to which participants' bedtime and daytime sleep-related RNT improved and the extent to which their depression outcomes improved ($r = .75$, $p < .001$ and $r = .68$, $p < .001$, respectively). Due to the lack of between-person variability in improvements for general RNT and BA, our study was unable to examine their association with improvements in depression outcomes.

Conclusions: These preliminary findings suggest that sleep-related RNT may be a plausible mechanism through which CBT-I improves depressive symptoms. Our findings also supports the literature that argues insomnia-related factors, such as Sleep-related RNT, may contribute to maintenance of depression. Future studies should test the relationship between improvements in sleep-related RNT and depression outcomes using a randomised controlled trial (RCT) and employ a research design capable of determining temporal ordering.

Relationship Between Sleep Quality and Symptom Severity in Patients with Schizophrenia: A Cross-Sectional Study

F.Z. Kessam¹, E.H. Ouanouche², S. Stati³, A. Ouanass³, A. Mesfioui¹

¹Ibn Tofail University, Biology, Kenitra, Morocco, ²Higher Institute of Nursing and Health Technology Professions TANGIER, Tangier, Morocco, ³Arrazi University Psychiatric Hospital, Faculty of Medicine and Pharmacy, Mohammed V University, Rabat, Morocco

Introduction:

Sleep disturbances are common among patients with schizophrenia and may influence the severity of psychiatric symptoms. However, the relationship between sleep quality and symptom severity remains unclear. This study aimed to investigate the correlation between subjective sleep quality, assessed by the Pittsburgh Sleep Quality Index (PSQI), and the severity of schizophrenic symptoms, measured by the Positive and Negative Syndrome Scale (PANSS), in a clinical sample.

Materials and methods: A cross-sectional study was conducted on 89 patients diagnosed with schizophrenia (79 men and 10 women). Participants completed the PSQI questionnaire and were evaluated using the PANSS scale. Pearson correlation was used to assess the relationship between sleep quality and symptom severity.

Results: The mean PSQI score was 8.17 (SD = 2.11), and the mean PANSS score was 81.81 (SD = 21.49). The Pearson correlation coefficient between PSQI and PANSS scores was $r = 0.011$ ($p = 0.918$), indicating no significant linear relationship between sleep quality and severity of schizophrenic symptoms in this sample.

Conclusions: In this cohort, subjective sleep quality was not significantly associated with the severity of schizophrenia symptoms. Further research with larger samples and objective sleep assessments is warranted to explore this relationship.

Reliability and validity of the Persian version of the Chalder Fatigue Scale in Iranian populations

A. Rahimi-Golkhandan¹, Z.-B. Alemohammad¹, A. Khajeh-Mehrizi²

¹Tehran University of Medical Science, Occupational sleep research center, Baharloo hospital, Tehran, Iran, Islamic Republic of, ²Tehran University of Medical Science, Tehran, Iran, Islamic Republic of

Introduction: Fatigue refers to a lack of energy that makes it challenging to initiate or maintain voluntary activities. The Chalder Fatigue Scale (CFS) is a tool designed to assess the severity of fatigue. Studies indicate that it has strong validity and internal reliability, measuring both the mental and physical aspects of fatigue. We aimed to translate and assess the reliability and validity of this questionnaire in Iran.

Materials and methods: The translation process adhered to guidelines for cross-cultural adaptation of self-report measures. This cross-sectional study included 70 participants. The reliability of the CFS was evaluated through internal consistency and test-retest reliability. To determine test-retest reliability, each participant completed the scale twice, with a two-week interval between assessments. Construct validity was assessed using factor analysis and principal component analysis. For content validity, a form was completed by 15 experts to evaluate the relevance and necessity of the items, calculating both the Content Validity Index (CVI) and the Content Validity Ratio (CVR).

Results: The average age of the participants was 38 years, with a standard deviation of 8.52. Among the participants, 31.4% were male. The Cronbach's alpha coefficient for the CFS was 0.89. The Intraclass Correlation Coefficient for the CFS was 0.79 (95% confidence interval: 0.66–0.87, $P < 0.001$), reflecting good test-retest reliability. Factor analysis identified a two-factor solution. Content validity analysis yielded a CVI of 0.88, indicating acceptable relevance, and a CVR of 0.81, demonstrating good content validity.

Conclusions: The results indicate that the CFS is a reliable and valid tool for assessing fatigue, making it suitable for use in both research and clinical environments in Iran.

Acknowledgments: The authors are thankful to all the staff of Baharloo sleep clinic.

Scientific and Operational Strategies to Optimize Performance through “High-Quality and Adequate-Quantity Sleep” in Elite Sport: The Italian Football Experience

L. Bonamassa¹

¹Bonamassa Sleep & Performance SA, Chiasso, Switzerland

Introduction: In elite sport, optimizing recovery is as critical as training itself. Recent evidence emphasizes the pivotal role of both sleep quality and sleep duration in supporting athletic performance, cognitive function, and injury prevention. However, elite football presents unique challenges, including irregular schedules, frequent travel, and high psychological demands, which often impair sleep. This work presents a multi-level strategy developed and implemented within top-tier Italian football clubs to optimize player performance through tailored sleep science interventions, aiming to achieve both high-quality and adequate-quantity sleep.

Materials and methods:

A multidisciplinary team composed of sports scientists, sleep specialists, coaches, and medical staff collaborated to assess and improve sleep hygiene, circadian rhythm alignment, and recovery protocols. The intervention was structured according to the “**5P Method**”, a comprehensive approach to optimizing *high-quality and adequate-quantity sleep*, based on five integrated pillars:

- **Active Elements:**
 - (i) *Sleep knowledge*: structured sleep education delivered to athletes and technical staff to increase awareness and behavioral engagement;
 - (ii) *Objective data & demographic profiling*: monitoring through wearable technologies (actigraphy, HRV), sleep latency tracking, and apnea screening;
 - (iii) *Subjective data & psychographic profiling*: analysis of routines, digital behavior, anxiety levels, and individual perception of rest.
- **Passive Elements:**
 - (iv) *Sleep system*: assessment and personalization of sleep ergonomics, including mattress and pillow testing based on individual morphology and sleep patterns;
 - (v) *Sleep environment*: optimization of external conditions—light exposure, noise levels, room temperature, air quality, and reduction of electromagnetic interference (electrosmog).

Furthermore, the 5P Method was **integrated into the athletes' training and competition planning**, including:

- Sleep periodization aligned with physical and tactical workloads
- Personalized strategies for pre- and post-match recovery
- Management of jet lag and travel-related sleep disruption
- Routine screening and monitoring protocols
- Structured *power nap* strategies during training camps and competitions

These multidimensional interventions were customized to the athlete's profile and performance context, continuously monitored and refined in cooperation with club staff.

Results: Preliminary findings show significant improvements in sleep metrics, including total sleep time (+12%), sleep efficiency (+8%), and subjective sleep quality (+20%). These changes were associated with improved reaction times, reduced perceived fatigue, and a measurable decrease in injury rates. Performance data indicated a positive correlation between optimized sleep profiles and key performance indicators (KPIs) during competitive matches.

Conclusions: Implementing a structured, evidence-based sleep strategy tailored to the realities of elite football can meaningfully enhance recovery, performance, and overall player well-being. These findings support the integration of sleep science as a core component of high-performance sport programs.

Acknowledgments: The authors would like to thank the technical and medical staff of the participating Italian professional football clubs for their collaboration, as well as the athletes for their commitment and openness throughout the sleep optimization protocols. We extend our sincere gratitude to the *Italian Football Coaches Association (AIAC)* and the *Italian Football Federation – Technical Sector (FIGC)* for their institutional support and ongoing commitment to innovation and scientific advancement in

football performance. We also acknowledge the contribution of sports science and chronobiology experts who provided valuable input in designing and implementing the intervention strategies.

Sleep Disorders in a Neurological Rehabilitation Setting: Prevalence and Clinical Implications

D. Zutter¹, A. Vorster², K. Krakow¹, C. Bassetti³

¹Rehaklinik Zihlschlacht, Neurorehabilitation, Zihlschlacht, Switzerland, ²Inselspital, Universitätsspital, Swiss sleep house, Bern, Switzerland, ³Dean, Medical Faculty, University of Bern Director of Teaching and Research, Insel Gruppe, University of Bern, Bern, Switzerland

Introduction: Sleep disorders are common among neurological patients and can either trigger, exacerbate, or accompany neurological conditions. Examples include sleep-disordered breathing in stroke and dementia, REM sleep behavior disorder and insomnia in Parkinson's disease, and excessive daytime sleepiness and fatigue in multiple sclerosis. Despite their considerable impact on quality of life and rehabilitation success, sleep disorders are frequently underdiagnosed and seldom integrated into treatment plans within neurological rehabilitation settings.

Materials and methods: In this observational study, 202 consecutive patients (90 male, 112 female; mean age 67±13 years) undergoing neurological rehabilitation at the Center for Neurological Rehabilitation Zihlschlacht, Switzerland, were screened between May and October 2023. Sleep health was assessed using the 15-item self-reported Bernese Sleep Health Questionnaire (Vorster et al., 2024). The cohort included individuals with stroke, traumatic brain injury, Parkinson's disease, and multiple sclerosis.

Results: • Insomnia symptoms (≥3x/week) were reported by 26% of patients and were associated with poor sleep efficiency (<85%) in 25%.

- Sleep medication was used by 17%.
- Snoring was reported by 22%, while 15% exhibited a high risk for sleep apnea (abbreviated Stop-Bang score >4).
- Excessive daytime sleepiness was noted in 26%, and fatigue in 31%.
- Restless legs syndrome was indicated by 15% (Ferri et al., 2007).
- Parasomnia symptoms, including frequent nightmares (≥1x/week), were reported by 7–8% of patients.
- Overall, 34% of patients failed ≥4 out of 8 domains in the Sleep Health Score, suggesting multi-dimensional poor sleep quality.

Conclusions: Over one-third of neurological rehabilitation patients are affected by clinically significant sleep disorders requiring medical attention. Systematic screening and targeted treatment of these conditions may significantly improve both general health and rehabilitation outcomes. In light of the large number of patients with comorbid sleep disturbances and the relevance of sleep for overall prognosis, a comprehensive package of 25 measures was developed to improve this important aspect within the context of inpatient neurorehabilitation. These measures included, among others, the implementation of clinic-wide training for all staff members, as well as specialized training for a dedicated 'Sleep Nurse' who focuses specifically on issues related to sleep

Acknowledgments: We would like to thank all nurses, therapists and physicians of the Rehabilitation clinic Zihlschlacht who participated in the sleep improvement program.

Sleep disorders in patients with low back pain and comorbid mood disorders

L. Tingting^{1,2,3,4}, J. Sun^{5,1,2,3,4}, L. Lu^{1,2,3,4}

¹Peking University Sixth Hospital, Beijing, China, ²Peking University Institute of Mental Health, Beijing, China, ³National Clinical Research Center for Mental Disorders, Beijing, China, ⁴Key Laboratory of

Mental Health of the National Health Commission (Peking University), Beijing, China, ⁵Peking University Third Hospital, Pain Medicine Center, Beijing, China

Introduction: Low back pain (LBP) seriously impairs individual's quality of life and it is the leading cause of years lived with disability worldwide. LBP often accompanied by anxiety, depression, and sleep disorders. Although some previous studies have found a bidirectional relationship between pain and sleep, there may be a problem of mixed multi-site pain. Additionally, there may still lack of data on comorbid mood disorders (depression and anxiety) affecting sleep. Therefore, this study aims to systematically analyze the sleep characteristics across different types of LBP by combining subjective sleep data, and further explore the effects of depression and anxiety on sleep.

Materials and methods: This study was conducted using data from the UK Biobank. Participants were classified into three groups according to the duration of LBP: no LBP, acute LBP (<3 months), and chronic LBP (≥3 months). The subjective sleep data included sleep duration, getting up in morning easy, morning/evening person (chronotypes), nap during day, sleeplessness/insomnia, snoring, daytime dozing/sleeping. Covariates included age, sex, body mass index, smoking, drinking, depression, and anxiety. Multiple linear regression models were used to analyze the relationship between LBP types and sleep parameters. Continuous variables were represented by mean ± standard deviation, while categorical variables were represented by frequency and percentage. Group differences were analyzed by analysis of variance for continuous variables and chi-square tests for categorical variables.

Results: A total of 405,044 patients were enrolled, including 150,121, 11,187, and 14,621 patients with no pain, acute LBP, and chronic LBP, respectively. Comorbid depression and anxiety were significantly more prevalent in patients with chronic LBP than in those with acute LBP or no pain, with depression rates of 15.7%, 17.2%, and 20.3%, and anxiety rates of 17.9%, 20.5%, and 25.4%, respectively. Sleep duration was significantly reduced in the depression group (7.12 ± 1.09 hours) and the chronic LBP with depression group (7.09 ± 1.16 hours), compared to the no pain group (7.26 ± 0.95 hours). Besides, patients with chronic LBP showed more sleep disturbances, such as insomnia, sleep late, nap and daytime dozing, while patients with acute LBP showed more snoring. Patients with LBP comorbidity depression or anxiety significantly reduces sleep time, increases difficulty getting up in morning, sleep late, insomnia. Additionally, patients with chronic LBP without mood disorders have a higher rate of snoring.

Conclusions: LBP significantly affects an individual's sleep quality, and longer pain duration, comorbid depression and anxiety can exacerbate sleep disorders. These findings highlight the need for personalized, integrated interventions targeting both pain and mood disorders, which may better improve clinical outcomes and enhance the quality of life in patients with LBP.

Acknowledgments: We gratefully acknowledge the UK Biobank team for providing the data resource, and all the participants who took part in this project.

Sleep EEG Signatures of APOE4 in Older Adults with Subjective Cognitive Impairment

H. Mundell¹

¹The University of Sydney, Sydney, Australia

Introduction: Alzheimer's disease (AD) is the leading cause of dementia and a major global health concern. The APOE4 allele is the strongest genetic risk factor for late-onset AD. Pathological changes such as amyloid-β accumulation and tau pathology begin decades before clinical symptoms, creating a critical window for early detection and intervention. Sleep—particularly non-rapid eye movement (NREM) sleep—plays a central role in glymphatic clearance and has emerged as a promising non-invasive biomarker of early AD-related change.

Subjective Cognitive Impairment (SCI), characterised by self-reported cognitive decline without objective impairment on neuropsychological testing, is increasingly viewed as a potential early manifestation of neurodegeneration. Individuals with SCI are at elevated risk for future development of dementia. However, the relationship between APOE4 status and sleep EEG features in this group remains underexplored.

Materials and methods: Participants (N = 101) were older adults with SCI enrolled in the Healthy Brain Ageing Program. All underwent overnight in-laboratory polysomnography and genotyping. EEG spectral power was calculated for NREM sleep at six standard electrodes (C3, Cz, Fz, O1, Oz, Pz).

Relative power in delta, theta, alpha, sigma, and beta bands was derived. Linear models tested the association between APOE4 carrier status and each EEG variable, adjusting for relevant demographic and clinical covariates. Results were corrected for multiple comparisons using FDR.

Results: Seven NREM EEG features significantly differed between APOE4 carriers and non-carriers. Notably, APOE4 carriers exhibited: Decreased delta power at Oz and Pz, Increased beta power at Oz and Pz, Increased sigma power at Oz, Increased alpha power at Oz, Increased theta power at O1.

These changes were most prominent in posterior electrodes. In contrast, no significant effects were observed at frontal (Fz) or central (Cz) sites, suggesting a posterior-dominant spectral profile.

Conclusions: Individuals with Subjective Cognitive Impairment who carry the APOE4 allele exhibit a distinct pattern of NREM sleep EEG alterations, characterised by reduced slow-wave activity and increased fast-frequency power in posterior regions. These findings resemble spectral changes observed in symptomatic AD but are more spatially confined. This suggests that sleep EEG may reflect early electrophysiological disruptions in at-risk individuals, supporting its role as a potential biomarker for preclinical AD.

Sleeping while Queer: Impacts of sexual and gender identity-related concerns on sleep health in the LGBTQ+ community before and after the 2025 US presidential inauguration

S. Manuli¹, S.D. Cleary², L. Mitchell³, L. Oglesby⁴

¹George Washington University Milken Institute School of Public Health, Department of Global Health, Washington, United States, ²George Washington University Milken Institute School of Public Health, Department of Epidemiology, Washington, United States, ³the sleep lab, Dunedin, New Zealand,

⁴Project Sleep, Los Angeles, United States

Introduction: To examine the impact of sexual and gender identity-related concerns on sleep health in the LGBTQ+ community before and after the 2025 US Presidential inauguration.

Materials and methods: LGBTQ+ adult participants completed an online survey containing questions about sexual and gender identity-related concerns and their impacts on sleep health. Pre-inauguration responses were collected June 2023 to September 2024. Post-inauguration responses were collected February to March 2025. Multivariable regression was used to assess impacts of sexual and gender identity-related concerns on sleep health pre- and post-inauguration. The survey was IRB exempt.

Results: 271 members of the LGBTQ+ community completed the survey (152 pre-inauguration, 119 post-inauguration). 74% of respondents have a diagnosed sleep disorder. 94% currently experience sleep problems, and of these, 98% reported that their sleep problems impact their physical, mental, and/or emotional well-being. 80% of respondents said concerns related to their gender and sexual identity may negatively impact their sleep.

Following the 2025 US presidential inauguration, there were significant increases in respondents' concerns about finding and maintaining friendships (OR 2.15, $p=0.007$), employment (OR 1.90 $p=0.021$), housing (OR 2.04, $p=0.043$), being safe in their homes (OR 3.39, $p=0.043$) and in public (OR 1.87, $p=0.013$), being bullied or harassed (OR 2.60, $p=0.002$), having restricted civil rights (OR 3.14, $p<0.001$), losing civil rights (OR 3.57, $p<0.001$), and accessing health care (including gender affirming care) (OR 2.36, $p=0.002$).

Transgender and nonbinary respondents were also significantly more likely to have concerns about maintaining family relationships (OR 3.64, $p<0.001$), and were significantly more likely than cisgender respondents to say their concerns have probably (OR 3.54, $p=0.003$) or definitely (OR 2.63, $p=0.02$) had a negative impact on their sleep.

Conclusions: This study finds that LGBTQ+ community members are experiencing significantly higher rates of minority stress-related sleep issues than before the 2025 US presidential inauguration. These differences may be linked to a post-inauguration increase in federal anti-LGBTQ+ policies and presidential executive orders. Overall, this study provides valuable insights into factors negatively impacting sleep health in LGBTQ+ communities following the 2025 inauguration and highlights distinct differences between the impacts on transgender and nonbinary individuals and their cisgender counterparts.

The comorbidity of ischemic heart disease requiring (IHD) revascularization significantly correlates with obstructive sleep apnea (OSA)

M. Kowalik^{1,2,3}, M. Tworek^{1,2,3}, W. Wloczyk³, L. Bielecka³, M. Orawiec^{1,3}, A. Kablak-Ziembicka^{1,3}, W. Plazak³, J. Podolec^{4,3}

¹Department of Cardiac and Vascular Diseases, Institute of Cardiology, Jagiellonian University Medical College, Cracow, Poland, ²Jagiellonian University Medical College, Doctoral School of Medical and Health Sciences, Cracow, Poland, ³The St. John Paul II Hospital, Cracow, Poland, ⁴Department of Interventional Cardiology, Institute of Cardiology, Jagiellonian University Medical College, Poland, Poland

Introduction:

Obstructive sleep apnea (OSA) is a chronic condition characterised by periodic stopping or shallowing of breathing during sleep due to collapse of the soft tissues of the throat. There is evidence to suggest that OSA and ischemic heart disease (IHD) may co-occur. Chronic vascular inflammation and oxidative stress, caused by episodes of hypoxia during episodes of shallowing and nocturnal apnea, have been identified as factors that predispose patients to the development of atherosclerotic cardiovascular disease (CVD). The aim of this study was to investigate the relationship between the prevalence of IHD requiring revascularisation treatment and the severity of OSA. Furthermore, the compliance of patients with mild or severe OSA with continuous positive airway pressure (CPAP) therapy was investigated.

Materials and methods: This retrospective study was conducted between 2022 and 2024, analysing data from 70 patients with different stages of OSA and varying degrees of IHD. Demographic data, respiratory parameters obtained from a sleep polygraph examination, information on comorbidities, and eligibility for continuous positive airway pressure (CPAP) treatment were analysed. Patients were divided into two groups: those without or with mild OSA and those with moderate or severe OSA.

Results: The prevalence of ischemic heart disease necessitating revascularisation therapy (by coronary artery bypass grafting or coronary artery angioplasty) was higher in patients with a greater degree of sleep apnea (41.18% in the group with severe obstructive sleep apnoea). Moreover only 14 (40%) of the patients with moderate to severe OSA who met the criteria for CPAP therapy were using this form of therapy.

Conclusions: The incidence of IHD requiring revascularisation treatment is higher in patients with severe OSA than in those with less severe forms of the condition.

The Effects of Daytime High-intensity Swimming Training in Nighttime Parasympathetic Activity for Swimmers with Different Training Status

C.-Y. Lin¹, Y.-J. Lai², C.-P. Chu², L.-W. Wang³, C.-T. Lin³, S.-F. Liang³, T.-H. Huang²

¹Department of Otolaryngology, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan, ²Institute of Physical Education, Health and Leisure Studies, College of Management, National Cheng Kung University, Tainan, Taiwan, ³Department of Computer Science and Information Engineering, Tainan, Taiwan

Introduction: Sleep involves significant fluctuations in sympathovagal balance throughout the cycles of non-rapid eye movement (NREM) sleep and rapid eye movement (REM) sleep. Previous study demonstrated the advantage of using heart rate variability (HRV) during slow wave sleep (SWS) is that fewer external body movement or arousal which might cause abrupt HR increase and disrupt the

electrocardiography signal. The root mean square of successive normal R-R interval differences (RMSSD) was reasonably linked to vagal activity.

R-R interval and RMSSD decreased during both daytime and SWS in nighttime after supramaximal intermittent exercise in healthy individuals. Parasympathetic activity in athletes decreases during SWS but increases during wakefulness in the overload period compared to the taper period. Current studies lack objective comparisons between populations under different training conditions during sleep. Research is scarce on nighttime RMSSD performance in swimmers with varying training status under identical training volumes. This study compares sympathetic and parasympathetic activation during SWS in regular training versus recreational swimmers after five training days. We also examined psychological state and sleep architecture changes before and after training.

Materials and methods: Participants were members of the swimming team at National Cheng Kung University, Taiwan. Eligible participants were swimmers aged ≥ 20 years, free of sleep, physiological, psychological, and neurological disorders, as confirmed by a clinical physician. Exclusion criteria included late-night shift work, sports injuries within the past 6 months and long-term medication use. Participants were divided into two groups based on training load and competition participation: the recreational group (R group), consisting of swimmers from former varsity members with irregular training status (e.g. ≤ 2 days/week), and the regular training group (RT group), comprising active swimmers from varsity members with training routine of 4 or more days per week.

The study included two randomized experimental sessions, separated by at least one week: one on a training day and the other on a non-training day. HR, HRV as well as standard polysomnography (PSG) were assessed during sleep. Standard PSG was conducted for determining sleep phase while HR was measured using a wrist pulse oximeter. HR derived RR interval was further used to calculate RMSSD during N3 sleep as index of HRV.

Results: In the RT group, compared to the non-training day, REM stage, sleep efficiency, and HR in N3 increased by 3.75% ($p=0.027$), 5.89% ($p>0.05$), and 5.54 BPM ($p=0.028$), respectively, while RMSSD decreased by 16.40 ms ($p=0.028$). In the R group, REM stage, HR in N3, and RMSSD increased slightly, while sleep efficiency decreased, with no significant differences ($p>0.05$). RT group showed consistent sympathetic activation and reduced parasympathetic activity, whereas R group exhibited varied responses due to individual differences.

Conclusions: Regular trained swimmers who were capable to execute the training protocol at higher intensity demonstrated reduction in nighttime parasympathetic activity, while swimmers of recreational group showed more variability in similar measurements.

Acknowledgments: This research was funded by a grant from National Science and Technology Council (grant numbers: NSTC-112-2425-H-006-002 and NSTC 113-2425-H-006-006).

The Influence of Short-Term and Long-Term Sleep on Postural Control and Balance

S. Ceccanti^{1,2}, M. Bertucco², D. Manzoni¹, P. Frumento³, M. Di Galante⁴, U. Faraguna^{1,5}

¹University of Pisa, Department of Translational Research and of New Surgical and Medical Technologies, Pisa, Italy, ²University of Verona, Department of Neuroscience, Biomedicine and Movement Sciences, Verona, Italy, ³University of Pisa, Department of Political Sciences, Pisa, Italy, ⁴Sleepacta srl, Montacchiello, Italy, ⁵IRCCS Fondazione Stella Maris, Department of Developmental Neuroscience, Pisa, Italy

Introduction: Sleep plays a vital role in neurophysiological processes, including synaptic plasticity, motor memory consolidation, and postural control. Disrupted or insufficient sleep impairs sensory integration and increases postural instability, elevating fall risk. While the detrimental effects of sleep deprivation are well-established, the potential of short sleep episodes (naps) to enhance postural adaptation is less understood. Additionally, the influence of long-term sleep patterns and individual chronotype on postural control remains partially underexplored. This study investigated: (a) the effect of a short nap between two postural testing blocks on postural adaptation, and (b) the relationship between sleep quantity, chronotype, and postural performance in healthy young adults.

Materials and methods: 12 participants (6 males, 6 females; aged 20–25) completed two identical experimental sessions one week apart. Each session included two blocks of 10 single-leg stabilometric trials (60 s each; 90 s rest). Between blocks, participants either napped (EEG-verified) or stayed awake (quiet seated rest) for 45 minutes; conditions were counterbalanced. Sleep parameters were also monitored via wrist actigraphy for 7 nights between sessions. Chronotype and daytime sleepiness were

assessed using the reduced Morningness–Eveningness Questionnaire (rMEQ) and Epworth Sleepiness Scale (ESS), respectively.

Results: Among the 12 participants, 2 were classified as M-type, 9 as N-type and 1 as E-type, with moderate levels of daytime sleepiness ($ESS = 7.08 \pm 2.75$). EEG monitoring during the nap showed an average total sleep time (TST) of 21 minutes and a sleep efficiency (SE) of 63%. Actigraphy data indicated a TST of 6.8 hours and SE of 79.7%.

Paired t-test revealed significant post-nap changes, whereas no significant differences were observed in the wake condition ($p > 0.05$). After the nap, participants exhibited a significant increase in postural sway variability (SD_x : $p = 0.019$; SD_y : $p = 0.001$; SD_{tot} : $p = 0.001$) and in the Area of the 95% confidence ellipse derived via Principal Component Analysis ($p = 0.001$). Concurrently, there was a significant decrease in Entropy along both x ($p = 0.035$) and y axes ($p = 0.004$), suggesting a reduction in postural control complexity.

Correlation analyses showed that greater post-nap increases in sway amplitude and area were associated with higher subjective fatigue ($p < 0.05$), but not with chronotype or sleepiness. Although overall EEG-based regression models were not significant, N2 duration emerged as a predictor for some postural parameters. In contrast, actigraphy-based models revealed that actigraphic TST significantly predicted pre–post nap difference in SD_y , SD_{2D} , and Area (all $p < 0.001$, all r negative). Mixed-effects models confirmed a significant main effect of the interaction between condition (Sleep/Wake) and time (Pre/Post) for most stabilometric variables. Notably, entropy showed an opposite pattern of change compared to sway-related variables, suggesting distinct underlying mechanisms in postural control responses to sleep. A trial effect suggested potential learning across repetitions.

Conclusions: Sleep produces measurable alterations in postural control, increasing sway magnitude and reducing signal complexity. These changes appear influenced more by long-term sleep quantity than by nap-specific sleep architecture. These findings are preliminary, and further analyses are underway to validate and expand upon these initial results.

The Sleep and Wearables Operational Research for Readiness and Deployment (SWORD) Lab: A Program to Study Sleep and Circadian Science in the U.S. Military

E. Metzger¹, C. Jones¹, V. Matrosova¹, A. Pollatou¹, L. Skeiky¹, S. Gupta¹, G. Tays¹, A. Studnicki¹, S. Yalewayker¹, E. Cheraghpour¹, O. Ilori¹, M. Smith¹, M. Ceribo¹, H. Decot¹, S. Allotey-Addo¹, E. Castillon¹, J.K. Werner¹

¹Uniformed Services University, Bethesda, United States

Introduction: Insomnia is a common sleep disorder that is 2-3 times more prevalent in military/veteran United States (U.S.) Service Members (SMs) than civilians. Moreover, over half of U.S. SMs sleep less than six hours a night. Sleep deficits decrease performance, attention, and information processing, and increase risk of injury, suicidality, and chronic diseases. Sleep physiology is complex, remains poorly understood, and interventions, especially those that are noninvasive, are limited. This multi-pronged program uses wearables to capture longitudinal autonomic data, studies glymphatic correlates, seeks to further understand biomarkers and cognitive function related to sleep, investigates biofeedback-based interventions, and utilizes retrospective/large sample datasets to inform measurements. The program also aims to understand the impact of unique U.S. military exposures on sleep, such as repeated low-level blast exposure experienced during training, and also to understand novel phenomena such as local sleep in wake.

Materials and methods: Our program includes six components focused on non-invasively characterizing and modulating sleep physiology in U.S. SMs, veterans, and their families:

1. Glymphatics physiology measuring brain interstitial fluid, cerebrospinal fluid, and cerebral blood flow changes during wake and sleep via ultra-high-performance magnetic resonance imaging (MRI) and wearable functional near-infrared spectroscopy (fNIRS) headband.
2. Autonomics functioning and circadian rhythm modeling measurements via multimodal wearables worn longitudinally, with a focus on gold-standard validation.
3. Sham-controlled wearable interventions, including: a) wearable transcranial electrical stimulation headband, b) smartwatch haptic biofeedback, c) whole-body and transcranial photobiomodulation, and d) low-intensity focused ultrasound.
4. Biospecimen measurements from high sensitivity assays via blood, sweat, saliva, and microbiome.

5. Cognitive testing via high-specificity customized tasks.

6. Retrospective/large sample polysomnogram analysis to uncover novel biomarkers.

Approximately 750 participants are projected to be enrolled. To date, over 60 participants are enrolled across projects. The program includes five (5) study enrollment sites.

Results: We will present multimodal pipeline designs for review. Preliminary results will include sleep correlates with blood biomarkers, cognition, wearables, and fNIRS data. Initial assessment of wearable devices will be presented. Early validation efforts of commercial and non-commercial devices for sleep monitoring will be presented.

Conclusions: Sleep physiology remains inadequately characterized and treated, especially in far-reaching environments such as those experienced in military operations. Modulation techniques for sleep quality, or targeting specific sleep features, remain limited and often include pharmacological approaches. Our program embarks on an exciting multimodal approach to better characterize sleep physiology and even deliver therapy longitudinally in a noninvasive manner.

Tired and Wired: Sleep Deprivation Prevents Affective Renormalisation During Exposure to Ambiguous Threat

E. Sullivan¹, C. McCall¹, M. Croissant², L.-M. Henderson³, G. Schofield⁴, S. Cairney¹

¹University of York, Department of Psychology, York, United Kingdom, ²University of York, Department of Computer Science, York, United Kingdom, ³University of York, Psychology, York, United Kingdom, ⁴University of York, School of Arts and Creative Technologies, York, United Kingdom

Introduction: Sleep deprivation amplifies next-day state anxiety and impairs threat-related information processing, but little is known about how sleep loss affects the evolution of anxiety over the course of a threatening experience. Reciprocally, sleep slow wave activity (SWA) has been shown to reduce next-day state anxiety, but whether SWA influences the evolution of threat-related anxiety remains to be established. In the current study, we combined immersive virtual reality (VR) and psychophysiology to test two hypotheses: 1) sleep deprivation amplifies in-the-moment arousal responses to prolonged threats, and 2) SWA supports the resolution of anxiety during exposure to prolonged threat.

Materials and methods: Following a night of polysomnographically-monitored sleep or total sleep deprivation, N = 54 adults (mean [SD] age = 20.30 [2.27] years, 33 females) entered an immersive VR world that cycled between threatening and non-threatening environments, during which their skin conductance level (SCL) and heart rate (HR) were monitored. Participants then watched a replay of their VR experience and retrospectively rated their subjective arousal at each moment. Physiological (SCL and HR) and subjective arousal measures were averaged across the various threatening and non-threatening environments and applied to a 2 (Environment: Threatening/Non-Threatening) X 2 (Group: Restful Sleep/Sleep Deprivation) mixed ANOVA.

Results: We replicated previous studies demonstrating that self-reported state anxiety significantly increased overnight in sleep-deprived participants, while it significantly declined in those who were well-rested. Physiological arousal (based on SCL) remained elevated across the threatening parts of the VR world after sleep deprivation but not after restful sleep (where instead arousal declined over time; interaction: $p = .030$), supporting our first hypothesis. No such effect was observed in the HR data or for subjective arousal. Correlational analyses indicated that SWA was not associated with the sleep-related decline of threat-related physiological arousal, contrary to our second hypothesis.

Conclusions: Our findings indicate that a restful sleep promotes the resolution of anxiety when engaging in threatening environments for prolonged periods of time. However, this anxiolytic benefit of sleep does not appear to be dependent on SWA. More broadly, this work provides novel insight into the mechanisms through which our brains navigate threats and uncertainties in our everyday lives.

Updated Atlas and Scoring Rules for the Cyclic Alternating Pattern (CAP): A Consensus Report by the ESRS Taskforce

H. Gretarsdottir¹, L. Parrino², R. Thomas³, I. Rosenzweig⁴, O. Bruni⁵, G.B. Senel⁶, E.S. Arnardottir¹, R. Ferri⁷

¹Reykjavik University, Reykjavik, Iceland, ²University of Parma, Parma, Italy, ³Harvard Medical School, Boston, United States, ⁴King's College, London, United Kingdom, ⁵Sapienza University, Rome, Italy, ⁶Istanbul University-Cerrahpasa, Istanbul, Turkey, ⁷Oasi Research Institute-IRCCS, Troina, Italy

Introduction: The cyclic alternating pattern (CAP) is a hallmark of NREM sleep microstructure and a recognized biomarker of sleep instability. Since the 2001 CAP rules, advancements in EEG analysis, pediatric neurophysiology, and REM sleep understanding have highlighted the need for updated and standardized scoring criteria. This project, commissioned by the European Sleep Research Society, aimed to develop a revised CAP scoring framework compatible with modern standards and clinical applicability.

Materials and methods: An expert Taskforce systematically reviewed the original CAP scoring system, integrating updated AASM guidelines, newly validated EEG patterns, and structured input from pediatric and REM sleep research. Consensus-derived rules were formulated through iterative discussion and literature synthesis.

Results: Key innovations include:

- Dual amplitude and frequency criteria for defining phase A onset and offset, with $\geq 60\%$ lead concordance.
- Expanded EEG event catalog for phase A (e.g., high-amplitude slow transients, mixed-frequency transients, beta bursts).
- Formalized subtype classification with clear decision rules.
- Comprehensive pediatric adaptations, including age-specific EEG norms and developmental thresholds.
- Optional CAP scoring guidelines for REM sleep in pathological contexts (e.g., RBD, REM OSA).
- Standardized metrics for CAP quantification (e.g., CAP rate, subtype distribution, sequence characteristics).

Conclusions: The updated CAP Atlas provides a rigorous, developmentally sensitive, and clinically translatable scoring system. It enables accurate assessment of sleep instability across populations and conditions, fostering harmonized CAP use in research and clinical practice.

Parasomnia

Enhanced Phase-Amplitude Coupling Prior to Dream-Enactment Behaviors in isolated REM Sleep Behavior Disorder: A Video-Polysomnography Study

S. Date¹, Y. Sumi^{2,3}, M. Imai^{2,4}, K. Ogawa⁵, K. Fujiwara^{6,7,8}, A. Stefani³, B. Högl³, H. Kadotani²

¹Nagoya University, Graduate School of Engineering, Nagoya, Japan, ²Shiga University of Medical Science, Psychiatry, Otsu, Japan, ³Medical University of Innsbruck, Neurology, Innsbruck, Austria, ⁴Shiga Sleep Clinic, Kusatsu, Japan, ⁵Hiroshima University, Graduate School of Humanities and Social Sciences, Higashi-hiroshima, Japan, ⁶Nagoya University, Department of Materials Process Engineering, Nagoya, Japan, ⁷Hokkaido University, Research Institute for Electronic Science, Sapporo, Japan, ⁸Nara Institute of Science and Technology, Medilux Research Center, Ikoma, Japan

Introduction: REM sleep behavior disorder (RBD) is characterized by dream-enactment behaviors (DEBs), often involving motor activities and vocalizations that are sometimes violent. However, the neurophysiological mechanisms underlying these behaviors remain poorly understood. Previous studies on NREM parasomnia have suggested that mixed features of sleep and wakefulness may contribute to the occurrence of abnormal behaviors. Although similar dissociation of arousability between brain regions may be implicated in RBD, the neural information processing underlying subsequent episodic behaviors remains poorly understood. Our previous study demonstrated increased functional connectivity in the beta frequency range preceding DEBs in patients with isolated RBD (iRBD). However, no study has yet investigated cross-frequency interactions, such as phase-amplitude coupling

(PAC), leading to DEBs. In this study, we analyzed polysomnographic (PSG) data from patients with iRBD to investigate changes in PAC preceding DEBs.

Materials and methods: We analyzed EEG recordings from 30 patients with iRBD (24 males; mean age: 69.7 years) with intense, complex movements confirmed by video-PSG at Shiga University of Medical Science Hospital. EEG was recorded using six scalp electrodes (F3, F4, C3, C4, O1, and O2). Ethical approval and informed consent were obtained from all patients. The EEG data were re-referenced using the M1-M2 average before the analysis. For each patient, we compared two 60-second artifact-free REM sleep periods: (1) pre-DEB periods immediately preceding DEB onset and (2) non-DEB periods without DEBs and with minimal submental EMG activity.

PAC was computed using the Kullback-Leibler modulation index (phase: 0.5–8.0 Hz with 0.5 Hz-bin; amplitude: 10–50 Hz with 1-Hz bin). We first analyzed PAC across the average of the six electrodes to identify significant PAC clusters. Using a one-tailed cluster-based permutation test (10,000 permutations; $p < 0.05$), we identified significant PAC frequency pairs ($p < 0.005$). Frequency clusters for further analysis were defined based on the significant clusters. Subsequently, PAC was evaluated at each individual electrode to investigate topographical characteristics.

Results: We first identified increased PAC clusters in the pre-DEB periods compared to the non-DEB periods using cluster-based permutation testing across averaged electrodes. Based on their spectral features, we defined two broader clusters: low-delta (0.5–1.5 Hz)-gamma (30–50 Hz) and theta (4–8 Hz)-gamma frequency range. Next, PAC analysis at individual electrodes revealed similar patterns between left (F3, C3, O1) and right (F4, C4, O2) sites. The frontal and occipital electrodes showed comparable PAC enhancement, whereas the central electrodes exhibited fewer increases and a distinct pattern. Region-specific modulation was also observed: gamma-band amplitude was modulated by slow-wave phases in the frontal region, while beta-band amplitude was modulated in the occipital region.

Conclusions: We found significant PAC increases in low-delta-gamma and theta-gamma frequencies during the pre-DEB periods compared to the non-DEB periods. PAC enhancement may reflect activation or suppression related to visuomotor control, potentially associated with dream experiences leading to DEBs. These findings provide new insights into the neurophysiological processes preceding DEBs. Future longitudinal studies are needed to examine whether PAC changes before DEBs evolve over time and predict phenoconversion.

High-Frequency Oscillations Across Wakefulness and Sleep in NREM Parasomnia and Sleep-Related Hypermotor Epilepsy

G. Benbir Senel¹, B. Caliskan², M.K. Caliskan³, B.G. Türk¹, D. Karadeniz¹, L. Nobili⁴

¹Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Neurology, Istanbul, Turkey,

²Sancaktepe Şehit Prof.Dr. İlhan Varank Training and Research Hospital, Clinic of Neurology, Istanbul, Turkey, ³Msc Mechanical Engineer, Istanbul, Turkey, ⁴University of Genoa, Genoa, Italy

Introduction: High-frequency oscillations (HFOs) have recently been defined in patients with epilepsy as electrophysiological markers of the neuronal hyperexcitability. HFOS have become increasingly prominent in epilepsy research as their role in the pathophysiology of epilepsy has been well-established in recent years. Based on the anatomo-patho-physiological interconnections between non-rapid eye movement (NREM) arousal parasomnias and sleep-related epilepsies, we hypothesized that HFOs, namely ripples and fast ripples, may also be detected in these patients, reflecting an increased excitability in cortical-subcortical networks.

Materials and methods: Sixteen patients with NREM arousal parasomnias, fourteen patients with non-refractory SHE, and ten age- and sex-matched healthy controls were prospectively included. HFO analysis was performed in 16-channel electroencephalography in three-minute periods from wakefulness before sleep, N2, N3 and REM sleep stages in the first (first 4 hours) and second half of the night, and wakefulness after sleep.

Results: A total of 16 patients with NREM-related parasomnia, 14 patients with SHE and 10 patients in the control group were included in our study. The ripple and/or fast ripple activities were detected in 50% of the patients with NREM parasomnias, in 71.4% of the patients with SHE, and in 30% of the healthy controls ($p=0.039$). While the total numbers of ripples and fast ripples in sleep and wakefulness were significantly higher in patients with epilepsy in compared to the patients with NREM parasomnias and controls, the comparison of data obtained from the patients with NREM-related parasomnia and

control group showed that the total number of ripples was higher in patients with NP ($p=0.048$). The total number of fast ripples occurring in the second half of sleep ($p=0.061$), the total number of fast ripples occurring during the whole sleep ($p=0.049$) and the total number of fast ripples ($p=0.044$) were also significantly higher in the parasomnia group. In patients with NP, the numbers of ripple and fast ripple activities were higher in wakefulness (than those in sleep), in temporal cortical regions (than those in frontal regions), and on right-side (than those on left side) ($p<0.05$). It was observed that the patients with SHE of frontal origin was associated with higher numbers of ripples during sleep in frontal cortical areas at seizure side, while fast ripples were increased in both wakefulness but predominantly in sleep in patients with SHE of temporal origin ($p<0.001$). In control group, the overall numbers of HFOs were scarce, being higher in sleep (than those in wakefulness), in frontal cortical regions (than those in temporal regions), and on right-side (than those on left side).

Conclusions: Our study demonstrated that high-frequency oscillations can be detected in patients with NREM arousal parasomnias. It may be suggested that HFOs, which may represent physiological elements, could similarly be disrupted in pathological states, like in parasomnias and epilepsy, as evidenced by the observed differences between normal conditions. To our knowledge, this is the first study demonstrating the presence of increased HFOs in patients with NREM arousal parasomnias, and encouraging further research to better explore the role of HFOs in the pathophysiology of NREM-related parasomnias.

Knowledge and prevalence of sleep paralysis in medical students from two Latin American universities: UDES Colombia and ULA Venezuela

O. Medina-Ortiz^{1,2,3,4}, C. Cárdenas⁵, M. Amaya¹, S. Castilla¹, A. Alvarado¹, N. Medina-Sánchez⁶, Y. Fernández¹, J. Sánchez-Frank¹

¹University of Santander, Medicine, Cúcuta, Colombia, ²University Simón Bolívar, Cúcuta, Colombia,

³University of the Andes, San Cristóbal, Venezuela, ⁴Venezuelan Academic of Sleep Medicine, San Cristóbal, Venezuela, ⁵Venezuelan Academic of Sleep Medicine, Caracas, Venezuela, ⁶Metropolitan College, San Cristóbal, Venezuela

Introduction: Sleep paralysis is a state of consciousness and unconsciousness that occurs during sleep, characterized by people being able to open their eyes, but cannot move or speak. They usually experience symptoms such as shortness of breath, chest pressure, and hallucinations. Sleep deprivation resulting from long hours of study in medical students can increase the prevalence of these seizures. The objective of this study was to determine the prevalence of sleep paralysis in a group of students from two Latin American universities and their knowledge about this point.

Materials and methods: Observational, descriptive, cross-sectional study. All first- to third-year medical students from the University of the Andes (ULA) in San Cristóbal, Venezuela and the University of Santander (UDES) in Cúcuta, Colombia, were invited to participate. After signing the informed consent, a questionnaire was applied on the main symptoms of sleep paralysis and another on knowledge about the subject. Statistical analysis was performed with SPSS 22 and significance was considered less than 0.05. For categorical variables, Chi-square was used. The study was approved by the Ethics Committee of the Universidad de Los Andes.

Results: A total of 147 students were included (34.69% UDES and 65.31% ULA). The average age was 21.52 years for UDES (SD: 3.17; min: 17 and max: 35), and 25.38 years for ULA (SD: 2.71; min: 23 and max: 34) ($p<0.05$). The female sex predominated (68.63% UDES and 65.63% ULA) ($p=n.s.$). For the questions regarding knowledge of sleep paralysis, some of the answers were as follows: 1. Yes, I know what sleep paralysis is (86.36% UDES Vs 98.96% ULA) ($p=0.0051^*$). 2. It is a sleep disorder (86.27% UDES Vs 95.79% ULA) ($p=0.045^*$). For the prevalence questions, some of the answers were: 1. Have you ever felt awake while sleeping, but unable to articulate words, scream, and/or move (60.78% UDES Vs 52.08% ULA) ($p=n.s.$). 2. After a long and stressful study day, upon going to bed, have you experienced some of the sensations described above (37.25% UDES Vs 37.50% ULA) ($p=n.s.$).

Conclusions: The prevalence of sleep paralysis tends to be the same in medical students from both countries, however, students from the ULA in Venezuela have a greater knowledge about the pathology than those from the UDES in Colombia. This may be because the lead author of this study is a professor of psychiatry at that school, and he devotes several classes to sleep disorders, which goes a long way toward promoting sleep medicine education at universities.

Acknowledgments: The University of Santander, University of the Andes, University Simón Bolívar and the Venezuelan Academy of Sleep Medicine are thanked for their collaboration in carrying out this study.

Mental Experiences in Disorders of Arousal: Findings from a Two-Week Prospective Diary Study

F. Berra¹, E. Cini¹, F. Casoni², C. Leitner^{1,2}, A. Salibba¹, M. Sforza^{1,2}, P. Proserpio², L. Ferini-Strambi^{2,1}, A. Galbiati^{1,2}

¹Vita-Salute San Raffaele University, Psychology, Milan, Italy, ²IRCCS San Raffaele Scientific Institute, Clinical Neurosciences, Neurology - Sleep Disorder Center, Milan, Italy

Introduction: For decades, episodes associated with disorders of arousal (DOA) were believed to occur in the absence of mental experiences. However, recent retrospective and serial awakenings studies have challenged this view, suggesting that vivid, emotionally charged mental content may be present during these episodes. However, these findings are vulnerable to recall bias and may overrepresent atypically intense episodes. Starting from these premises, we aimed to investigate mental contents associated with parasomnia episodes using a prospective, longitudinal paradigm.

Materials and methods: To investigate mental experiences during parasomnia episodes prospectively, we developed a dedicated Event Diary, which participants were instructed to complete within 15 minutes upon awakening for 14 days. This tool was designed to systematically record the occurrence of DOA episodes and to assess the associated mental contents. Specifically, we investigated their characteristics from multiple perspectives, including perceptual, emotional, sensorimotor, and contextual aspects, as well as specific elements present within the experience. Patients also completed a battery of questionnaires, including the Paris Arousal Disorders Severity Scale (PADSS) and the Sleep Condition Indicator (SCI) to assess perceived sleep disturbances severity.

Results: 11 DOA patients (age: 29.45 ± 7.28 ; M/F: 6/5), diagnosed by a neurologist expert in sleep medicine, were enrolled, two out of them did not report any episode. The mean PADSS score was 18.44 ± 10.47 while the mean SCI score was 17.00 ± 5.07 , with the 44.44% of the sample reporting the presence of insomnia symptoms. Across 152 diary entries, 64 DOA episodes were reported.

Remarkably, over 65% of these episodes involved recollections of mental content, often described as highly realistic and emotionally intense. Higher emotional intensity was significantly associated with stronger perceived realism of the experience ($r = 0.50$, $p = 0.005$). Fear, threat, worry, and surprise emerged as the most common emotions, underscoring the disturbing nature of these experiences. Moreover, the fear intensity score positively correlated with disease severity measure by PADSS global score ($r = 0.78$; $p = 0.015$) and PADSS subscale A ($r = 0.82$, $p = 0.013$).

Furthermore, episodes involving greater sensory details and perceptions of movements were linked to stronger emotional intensity, in particular fear ($r = 0.58$; $p = 0.004$), heightened realism ($r = 0.42$; $p = 0.036$), and increased feelings of threat ($r = 0.49$; $p = 0.014$).

Contrarily to what has been reported in the literature, rarely the experience was settled in their actual sleep environment, and even more rarely they included in the scenario people, animals or objects that were really present in the room.

Conclusions: Previous retrospective studies suggested that emotional and perceptual rich mental experiences are a frequent feature of DOA episodes. However, these studies faced criticism due to potential memory and selection biases. Our daily assessment provides stronger, methodologically sound evidence supporting these findings, confirming conscious and vivid experiences during DOA episodes. Furthermore, our results highlight the clinical relevance of assessing mental content for a more comprehensive understanding of disease severity and for guiding future targeted therapeutic interventions.

Non-Rapid Eye Movement Parasomnias and Their Impact on Academic Performance in Medical University Students: A Cross-Sectional Study

F. Iftikhar¹, S. Mushtaq¹

¹Foundation University School of health sciences, MBBS, Islamabad, Pakistan

Introduction: Parasomnias are undesirable events or experiences that occur during sleep transitions, classified into rapid eye movement (REM) and non-rapid eye movement (NREM) types. NREM parasomnias (arousal disorders) include confusional arousals, sleepwalking, and sleep terrors. Despite knowing that parasomnias can negatively impact, there is a noticeable paucity of studies on parasomnias among university students. This study is the first one in Pakistan to explore the prevalence of arousal disorders, their association with sleep quality, and their impact on the academic performance of university students.

Materials and methods: University students were sampled as part of a cross-sectional investigation. The Arousal Disorder questionnaire was used to evaluate features of NREM parasomnias among the participants, and the Pittsburgh Sleep Quality Index (PSQI) was used to assess sleep quality and its characteristics. All descriptive and inferential statistical tests were conducted on IBM SPSS 26, and a $p < 0.05$ was considered statistically significant for all applied measures.

Results: The sample consisted of 319 participants of age ranging from 18-25 years [1.46 ± 0.499]. NREM parasomnias were prevalent among $n=211$ (66.1%) female participants as compared to male one $n=108$ (33.9%). Out of all, the prevalence of NREM Parasomnias included confusional arousals (49.2%), sleepwalking (15.4%), and sleep terrors (38.9%). The mean PSQI scores of the participants were 7.94 ± 3.55 , indicating an overall poor sleep quality. Sleep quality was significantly associated with prevalence of confusional arousals ($p < 0.001$), sleep walking ($p = 0.004$), and sleep terrors ($p < 0.001$). Additionally, participants' age was also significantly associated with the prevalence of confusional arousals ($p = 0.012$), with confusional arousals being more common in older age groups. Sleep quality was significantly associated with prevalence of confusional arousals ($p < 0.001$), sleepwalking ($p = 0.013$, $p = 0.004$), sleep terror ($p < 0.001$, $p = 0.001$), respectively. Sleep quality had no significant effect on students' academic performance ($p = 0.382$).

Conclusions: NREM parasomnias were fairly prevalent among university students. Poor sleep quality is strongly linked to a greater frequency of NREM parasomnias. This study focuses on NREM parasomnias among university students, which limits generalizability to non-student populations. Larger-scale studies encompassing a diverse population are warranted to ascertain the relationship between NREM parasomnias and sleep quality.

Acknowledgments: I am thankful to the university students and my coauthors who took part in this study. Their time, honesty, and willingness to share their experiences were important for the success of this research. I also received support from the faculty and the staff at Foundation University School of health sciences which offered the needed resources and handwork throughout this project. Lastly, I am truly thankful to my family and friends who have been so supportive and patient with me and their belief in me at each step of the way.

Parasomnias and Associated Factors Among University Students: A Cross-Sectional Study in Saudi Arabia

S. Alshahrani¹

¹King Abdullah Bin Abdulaziz University Hospital, Princess Nourah Bint Abdulrahman University, Neurosciences, Riyadh, Saudi Arabia

Introduction: Parasomnias are a group of sleep-related movements or emotions like sleepwalking, sleep talking, teeth grinding (Bruxism), nocturnal enuresis (sleep enuresis), sleep terrors (night terrors), sleep-related eating disorder (SRED), nightmare disorder, REM Sleep Behavior Disorder (RBD), and confusional arousals. Parasomnias are more common in children than in adults. This study aimed to estimate the prevalence of different parasomnias among university students in Saudi Arabia. Additionally, it aimed to study the relationship between different parasomnias and gender-associated sleep disorders, mental disorders, and other medical diseases, stress, substance use, and medications.

Materials and methods: This study is a descriptive cross-sectional survey-based study. The target population for this study is university students from different regions of Saudi Arabia. Parasomnia was defined as having at least one of

the 11 disorders (over the past six months). Data was collected through an online survey. The survey was distributed on different online platforms to collect data from other regions of Saudi Arabia. The study took place between August and November 2022.

Results: Among 1,296 participants, 934 (72.1%) were female, and 1,071 (82.6%) were aged 19-24 years. A total of 1054 (81, 3%) participants reported having at least one parasomnia disorder. The most prevalent parasomnias were sleep talking 656 (50.6%), nightmares 650 (50.2%), and confusional arousals 524 (40.4%). The least prevalent parasomnia was sleep-related eating disorder 98 (7.6%). Among participants, 580 (44.8%) had a family history of parasomnia, 439 (33.9%) were diagnosed with sleep disorders, 296 (22.8%) were diagnosed with mental illnesses, and 92 (7.1%) had other medical diseases.

Conclusions: Parasomnias are prevalent among university students in Saudi Arabia. Parasomnias were higher in female students and in students with a family history of parasomnia. Parasomnias in adults might be a chronic or recurrent disorder. Parasomnias are significantly associated with psychological stress, depression, and anxiety disorders.

Acknowledgments: The authors would like to acknowledge and express their sincere gratitude to the volunteers who helped with data collection, the participants for their cooperation, and the Research and Academic Accreditation Office of Princess Nourah Bint Abdulrahman University (PNU), and King Abdullah Bin Abdulaziz University Hospital (KAAUH) for their help in distributing the survey to university students. This study could not have been completed without data collection efforts.

Reliability and diagnostic accuracy of home video recording in differentiating Sleep-related Hypermotor Epilepsy from Disorders of Arousal

G. Mainieri¹, L. Licchetta¹, G. Loddo², F. Baccari¹, G. Bruschi^{1,3}, L. Taruffi³, L. Nobili^{4,5}, P. Tinuper³, L. Vignatelli¹, F. Bisulli^{1,3}, F. Provini^{1,3}

¹IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy, ²Department of Primary Care, Azienda AUSL of Bologna, Bologna, Italy, ³Department of Biomedical and Neuromotor Sciences, University of Bologna, Bologna, Italy, ⁴Child Neuropsychiatry, IRCCS, G. Gaslini Institute, Genova, Italy, ⁵Department of Neuroscience (DINOGLI), University of Genoa, Genova, Italy

Introduction: Video-polysomnography is the gold standard for diagnosing Sleep-related Hypermotor Epilepsy (SHE) and confirming Disorders of Arousal (DoA), but it is expensive and may not always capture relevant events. Home video has emerged as a cost-effective alternative for detecting sleep-related behavioral episodes, though its diagnostic reliability remains under debate. This study aims to evaluate the inter-rater reliability (IR) and diagnostic accuracy of home video in differentiating SHE from DoA among neurologists with varying expertise levels. It also examines learning effects in non-experts and identifies key diagnostic features and confounding elements

Materials and methods: Twenty-four home videos from 12 patients with confirmed SHE and 12 with DoA were selected, each showing a representative sleep-related event. A group of 18 experts in epilepsy and/or sleep medicine and 12 general neurologists/residents reviewed the videos in a full-day session, classifying each as "SHE", "DoA", or "unknown" based solely on event semiology. Inter-rater agreement was assessed using Kappa statistics before and after expert discussion. Learning effects among non-experts were evaluated using McNemar's test. Thematic analysis of participant comments was conducted to identify key diagnostic features and confounding factors

Results: Overall agreement reached 75%, with a “moderate” IR (Kappa = 0.56). Among experts, agreement was 79% with “substantial” IR (Kappa = 0.62). In general neurologists, agreement increased from 70% to 82% after training, improving IR from “moderate” (Kappa = 0.47) to “substantial” (Kappa = 0.65). Misclassification was more common in DoA cases. Thematic analysis identified abrupt onset, short episode duration, ambulatory behavior, and irregular breathing as the main confounders

Conclusions: Home video is a valid and practical tool for distinguishing SHE from DoA. Its diagnostic accuracy is high among specialists and can significantly improve in non-experts following brief training. Home video can thus serve as a valuable diagnostic aid, especially in settings with limited access to advanced neurophysiological testing, and may support both initial diagnosis and long-term monitoring

Sexomnia in a Young Adult Male. A complex case of Non-REM Parasomnia with Diagnostic and Therapeutic Challenges

M. Alshahrani¹, M. Almutairi², L. Alhomayin²

¹King Fahad Medical City, Sleep Medicine, Riyadh, Saudi Arabia, ²KFMC, Sleep Medicine, Riyadh, Saudi Arabia

Introduction: Sexsomnia, a distinct non-rapid eye movement (NREM) parasomnia, involves involuntary sexual behaviors during sleep. Although more than 100 cases have been documented in the literature, underreporting and misdiagnosis remain prevalent. Factors such as anxiety, insomnia, and other parasomnias (e.g., sleepwalking, sleep terrors) may predispose individuals to sexsomnia. Despite emerging insights, treatment options remain largely empirical and range from pharmacotherapies to behavioral interventions, including hypnosis.

Materials and methods: Materials and Methods

We present the case of a 29-year-old male with a two-year history of aberrant sexual behaviors during sleep, initially occurring daily and later reducing to three times per week. The patient underwent in-laboratory video-polysomnography, including a comprehensive electroencephalogram (EEG) and electromyogram (EMG) assessment, as well as standard cardiopulmonary monitoring. An extensive clinical evaluation was performed, including sleep questionnaires (Epworth Sleepiness Scale, STOP-BANG), MRI of the brain, and a review of psychiatric and family history. Therapeutic interventions trialed included fluoxetine, melatonin, and valerian root.

Results:

Diagnostic findings revealed normal EEG and MRI, with an apnea-hypopnea index of 2.3 events/hour and a REM respiratory disturbance index of 15.5. The patient's Epworth Sleepiness Scale score was 5, and STOP-BANG was 2, indicating no significant risk of obstructive sleep apnea. The sexsomnia episodes were exacerbated by anxiety and insomnia. Pharmacotherapy attempts (fluoxetine, melatonin) did not alleviate symptoms, whereas self-initiated valerian root supplementation resulted in a 90% reduction in episode frequency.

Conclusions: This case illustrates the multifaceted nature of sexsomnia and highlights the importance of a comprehensive, multidisciplinary approach involving sleep specialists, psychiatrists, and primary care providers. While first-line pharmacological options may be beneficial for some, nonpharmacological interventions, such as valerian root and possibly hypnosis, can offer substantial improvements. Further research is warranted to develop evidence-based guidelines, as most current management strategies rely on case reports and small

Acknowledgments: The authors wish to thank the patient for consent to share this case and the sleep disorders center staff for assisting with polysomnography and clinical evaluations. We also acknowledge the contributions of our co-authors regarding their collaborative efforts in this case report .

Transgender Identity Moderates the Association Between Nightmare Frequency and Suicidal Ideation

R.G. Virnoche¹, M.K.P. Gratton^{1,2}, G. Baber¹, N.A. Hamilton¹

¹University of Kansas, Social and Behavioral Sciences, Psychology, Lawrence, United States, ²University of Kansas Medical Center, Department of Internal Medicine, Kansas City, United States

Introduction: Frequent nightmares are known risk factors for suicidal ideation. Nightmares and suicide are both relatively understudied within minority populations. Transgender individuals experience disproportionately higher rates of sleep disturbances and suicidality, potentially due to the minority stress of transgender identity. Despite this, the intersection of transgender identity, nightmares, and suicidality has not been adequately investigated. To address this gap, we investigated the potential moderating relationship that transgender identity may play in the association between weekly nightmare frequency and suicidal ideation severity.

Materials and methods: We used the Assessing Nocturnal Sleep/Wake Effects on Risk of Suicide (ANSWERS) data set (N = 971), accessed through the National Sleep Research Resource. Nightmare frequency was measured using the 5-item Disturbing Dream and Nightmare Severity Index (DDNSI). The 25-item Columbia Suicide Severity Ratings Scale (CSSRS) was used to assess lifetime suicidal ideation severity. Linear regression was used to determine the association between nightmare frequency and suicidal ideation while controlling for both age and race. Transgender identity was then included as an interaction term.

Results: Weekly nightmare frequency was independently associated with lifetime suicidal ideation severity ($\beta = 0.14$, 95% CI: [0.09, 0.19], $p < 0.001$). Further, transgender identity moderated the relationship between weekly nightmare frequency and lifetime suicidal ideation severity ($\beta = 0.28$, 95% CI: [0.02, 0.54], $p = 0.035$).

Conclusions: Transgender individuals with higher weekly nightmare frequency appeared to be more likely than non-transgender to have higher lifetime suicidal ideation. This finding highlights a unique mental health disparity within the transgender population, emphasizing the importance of addressing sleep disturbances and their potential contribution to suicidality. Future research should explore the role of intersecting factors, such as minority stress, using larger and more diverse samples. These findings may help prioritize targeted care for transgender individuals experiencing frequent nightmares and suicidal ideation.

Pediatric

Achieving recommended sleep duration and abdominal fat deposition: a sex-specific relationship in 10-year-old children

Introduction: Sleep deprivation and obesity has been extensively studied but there is limited literature examining the link between sleep duration and abdominal adipose tissue volumes in children.

Abdominal adiposity is more closely linked to obesity-related morbidity and mortality than total body fat in adults. Additionally, within the abdominal areas, subcutaneous and visceral adipose tissues have different associations with cardiometabolic outcomes. Moreover, hormonal differences can lead to differential fat deposition in boys and girls. This study aimed to study the sex-stratified associations between attaining recommended sleep duration and abdominal fat volumes.

Materials and methods: Sleep duration (weekday and weekend) of 10-year-old children ($n=638$, 51% boys, mean age 10.2 ± 0.2 years) was caregiver reported in the GUSTO study with a subset having additional actigraphy data ($n=491$). Recommended total sleep duration was defined as ≥ 9 hours per day, as per National Sleep Foundation recommendation. Total fat mass was quantified by quantitative magnetic resonance ($n=528$). Abdominal adipose tissue volumes [superficial subcutaneous adipose tissue (SSAT), deep subcutaneous adipose tissue (DSAT) and visceral adipose tissue (VAT)] were quantified by magnetic resonance imaging ($N=377$) (mean age 10.7 ± 0.2 years). Multivariable linear regression was used with adjustment for ethnicity and maternal education.

Results: Boys whose caregiver reported sleep duration met recommendation on weekdays and weekends ($n=111$), had lower body mass index z score (BMIz) (0.34 ± 0.16 vs 0.98 ± 0.12) ($P=0.001$), lower total fat mass ($8.77 \pm 0.69\text{kg}$ vs $11.31 \pm 0.51\text{kg}$) ($P=0.002$) lower SSAT ($651 \pm 85\text{ml}$ vs $888 \pm 55\text{ml}$) ($P=0.013$), DSAT ($492 \pm 86\text{ml}$ vs $729 \pm 56\text{ml}$) ($P=0.014$) and VAT volumes ($415 \pm 51\text{ml}$ vs $557 \pm 33\text{ml}$) ($P=0.013$). Boys whose actigraphy recorded sleep duration met recommendation, had lower DSAT ($454 \pm 119\text{ml}$ vs $685 \pm 59\text{ml}$) ($P=0.077$) and VAT volumes ($352 \pm 71\text{ml}$ vs $535 \pm 35\text{ml}$) ($P=0.019$). Only boys who met sleep duration recommendation for both weekdays and weekends had significantly lower BMIz, DSAT and VAT volumes compared to boys who did not meet sleep duration recommendation all week (weekdays and weekends). Boys who met sleep duration recommendation on either weekdays or weekends ($n=142$), did not differ on BMIz, total fat mass and abdominal fat volumes, compared to those who did not meet sleep duration recommendation all week (weekdays and weekends). No significant differences were observed in BMIz, total fat mass and abdominal fat volumes in girls.

Conclusions: Boys, but not girls, who achieved the recommended sleep duration for both weekdays and weekends, have lower BMIz, total fat mass and abdominal fat volumes. Interventions to help children attain the recommended sleep duration for both weekdays and weekends may help reduce abdominal and total adiposity, especially in boys.

Acknowledgments: The study is supported by the National Research Foundation (NRF) under the Open Fund-Large Collaborative Grant (OF-LCG; MOH-000504) and the Prenatal/Early Childhood Grant (Grant No. H22P0M0001), provided by NRF and the Agency for Science Technology and Research (A*STAR), Singapore.

Altered Sleep Oscillation Dynamics: Enhanced Slow Oscillation–Spindle Coupling in Children with Dyslexia

A. Quercia¹, G. Lanza^{1,2}, R. Ferri¹, O. Bruni³

¹Oasi Research Institute-IRCCS, Department of Neurology and Sleep Research Center, Troina, Italy,

²University of Catania, Department of Surgery and Medical-Surgical Specialties, Catania, Italy,

³Sapienza University of Rome, Department of Human Neuroscience, Rome, Italy

Introduction: Dyslexia is a neurodevelopmental disorder characterized by difficulties in reading and language processing, often accompanied by distinctive neurophysiological patterns. Previous research has shown that children with dyslexia (DS) display atypical electroencephalographic (EEG) activity during sleep, particularly in the architecture and density of sleep spindles—brief bursts of oscillatory brain activity critical for cognitive functioning and learning. The interaction, or coupling, between sleep spindles and slow oscillations (SO)—large-amplitude, low-frequency waves prominent in non-REM sleep—has been identified as a key mechanism underlying memory consolidation and learning. However, the precise nature of SO-spindle coupling in dyslexia remains insufficiently understood. This study aims to address this gap by systematically examining SO-spindle coupling during non-REM sleep stages N2 and N3 in children with dyslexia compared to typically developing, normally reading children (NC).

Materials and methods: We recruited 10 children diagnosed with dyslexia (3 males, mean age 11.22 ± 1.30 years) and 11 age-matched, normally reading controls (6 males, mean age 11.83 ± 1.70 years). All participants underwent comprehensive overnight polysomnographic recordings to capture detailed sleep EEG data. We quantified the density of fast spindles (FS, 12–15 Hz), slow spindles (SS, 9–12 Hz), and slow oscillations (SO, ~ 1 Hz) in both fronto-central and occipital EEG derivations. Additionally, we calculated the percentage of SO-spindle coupling events, representing the proportion of spindles temporally aligned with SOs. Custom MATLAB scripts were used for signal processing and event detection. Statistical analyses included mixed ANOVA for group comparisons of spindle and SO densities, and Dirichlet regression for analyzing coupling percentages, all conducted using R.

Results: Our analyses revealed that both FS and SS densities were significantly reduced in the N2 sleep stage of dyslexic children compared to controls (adjusted $p < 0.05$). SO density was also lower in DS relative to NC, with significant differences observed in central and frontal regions during N2 (adjusted $p < 0.05$) and across all derivations during N3 (adjusted $p < 0.001$). Intriguingly, despite these reductions in absolute densities, the percentage of SO-spindle coupling was significantly higher in DS than in NC for both FS and SS during N2 and N3 ($p < 0.001$). This indicates that, although fewer spindles and SOs occur overall in DS, a greater proportion of the remaining spindles are temporally aligned with SOs.

Conclusions: The reduction in spindle and SO densities we observed aligns with previous reports linking impaired sleep oscillatory activity to deficits in cognitive and learning processes. However, the increased SO-spindle coupling percentage in DS suggests a compensatory or maladaptive reorganization of sleep dynamics. This heightened coupling may reflect an attempt by the dyslexic brain to enhance memory consolidation processes, but it could also indicate inefficient or aberrant neural mechanisms underlying sleep-dependent learning. Overall, our results provide novel insights into the sleep microstructure of dyslexia, suggesting that altered SO-spindle coupling could serve as a biomarker for disrupted cognitive processing during sleep in this population. Further research is warranted to clarify the functional implications of these findings and their potential translational value for interventions targeting sleep in dyslexia.

A novel machine learning algorithm for predicting sleep apnoea in children using oximetry

A. Kevat^{1,2}, K. Iyer^{2,3}, P. Terrill², S. Lingawi⁴, C. Kuo⁴, D. Wensley^{4,5}, S. Suresh^{1,2}, A. Collaro^{1,2}

¹Queensland Children's Hospital, Department of Respiratory and Sleep Medicine, Brisbane, Australia, ²University of Queensland, Brisbane, Australia, ³QIMR Berghofer Research Institute, Brisbane, Australia, ⁴University of British Columbia, Vancouver, Canada, ⁵BC Children's Hospital, Vancouver, Canada

Introduction: Polysomnography (PSG) is the gold standard test for diagnosing obstructive sleep apnoea in children, but resource-intensiveness limits availability. Although oximetry testing is widely available, manual scoring methodologies such as McGill oximetry scoring (MOS) have poor sensitivity (17-43%), are subject to inter-observer variation, and have decreased positive predictive value (52-71%) when applied to those with complex medical comorbidities. We hypothesised that a computerised approach to oximetry analysis could overcome these limitations. We aimed to develop and test the performance of a *novel support vector classifier (SVC) machine learning algorithm with a component for discarding of likely movement/wake artefact* that classifies the overnight oximetry as being either low risk (predicted apnoea hypopnoea index $< 5/\text{hour}$) or high risk ($\geq 5/\text{hour}$).

Materials and methods: Oxygen saturation (SpO₂) and pulse rate (PR) data were extracted and down-sampled to 0.5Hz from 3476 diagnostic PSGs performed at Queensland Children's Hospital (QCH). Children aged 2-18 years regardless of underlying comorbidity were included. 3114 (90%) PSGs were selected for model training with ten-fold cross-validation, with the remainder held out for final testing. Extracted SpO₂ and PR data were subjected to a rules-based filter, with periods of oxygen saturation $< 60\%$ or PR > 225 or < 40 discarded as likely wake/movement artefact. Additionally, all data from PSGs $< 6\text{hrs}$ in length was discarded. Thirteen SpO₂ and PR-related features were used for SVC model training using the non-discarded data. These features were a combination of desaturation measures (e.g. ODI3, D90, CT95), central tendency measures, entropy measures (e.g. PR and SpO₂ Shannon entropy), and Lempel-Ziv SpO₂ complexity. Model training was performed in MATLAB R2024a using the fitcsvm function, and optimal gamma and c hyperparameter selection using Bayesian optimisation. Model performance was then evaluated on held-out data from QCH and other PSG datasets.

Results: Testing of the SVC using data from 344 held-out PSGs performed at QCH showed a positive predictive value of 93%, negative predictive value of 90%, specificity of 99%, sensitivity of 65% and weighted F1 score of 90%. When tested on similarly extracted SpO2 and PR data from PSGs within the Childhood Adenotonsillectomy Trial (CHAT), Paediatric Adenotonsillectomy Trial for Snoring (PATS) and clinical British Columbia Children's Hospital datasets (n=1215, n=721 and n=2895 respectively) the performance of the QCH model showed specificities of 99%, 98% and 84% respectively, with sensitivities of 35%, 57% and 62% respectively.

Conclusions: A SVC machine learning algorithm can be used to predict with a high degree of overall accuracy AHI <5 or ≥5 using oximetry data obtained from children both with and without a diverse range of comorbidities. The consistently high specificity across multiple datasets suggests a strong potential for this SVC approach to identify children at high risk of obstructive sleep apnoea, supporting use in home oximetry for triaging PSG waitlists or fast-tracking likely moderate-to-severe cases for surgical intervention when timely PSG access is limited. Alternatively, a modified version of the SVC with costs/penalties applied in training in order to increase sensitivity to >90% (at the expense of specificity) has the potential to be used as a screening test.

Application of the Das-Naglieri Cognitive Assessment System in Children with Sleep-Disordered Breathing

L. Yang¹

¹Shenzhen Hospital, Southern Medical University, Shenzhen, China

Introduction: This study focuses on the application of the Das-Naglieri Cognitive Assessment System (DN-CAS) in a specific pediatric population: children with sleep breathing disorders (SDB). Although the DN-CAS has been extensively used to assess cognitive functions in children with Attention Deficit Hyperactivity Disorder (ADHD), there is limited research on its application in children with SDB. The similarities in behavioral characteristics between SDB and ADHD, such as hyperactivity, impulsivity, and learning difficulties, suggest that they may share underlying cognitive impairments. Therefore, this study aims to explore the applicability and effectiveness of the DN-CAS in children with SDB, aiming to provide guidance for their treatment.

Materials and methods: Study Participants: Children aged 6 to 12 years with SDB who were treated in our department between July 2021 and December 2022 were included in this study. Based on polysomnography results, participants were divided into mild (n=32) and severe groups (n=24). Additionally, children with severe obstructive sleep apnea syndrome (OSAS) (n=8) who underwent continuous positive airway pressure (CPAP) treatment were prospectively analyzed with a follow-up period of 2 months.

Study Design: A cross-sectional analysis and a prospective study design were adopted. All participating children underwent polysomnography and DN-CAS assessments for attention and planning functions. The applicability and effectiveness of the DN-CAS were assessed by comparing sleep parameters and cognitive functions between the mild and severe groups, as well as changes in cognitive functions in children with SDB before and after CPAP treatment.

Assessment Tool: The Das-Naglieri Cognitive Assessment System, which is based on the PASS theory and focuses on assessing individuals' abilities in planning, attention, simultaneous processing, and successive processing.

Results: Cross-Sectional Study Results: In terms of cognitive functions, although there were no significant differences in scores for attention and planning functions between the two groups, children in the severe group performed slightly worse on certain cognitive tasks.

Prospective Study Results: CPAP treatment significantly improved sleep parameters such as obstructive apnea-hypopnea index and lowest oxygen saturation in children with severe OSAS. Additionally, CPAP treatment significantly improved cognitive functions, particularly attention functions, in these children. This suggests that CPAP treatment may have potential value in improving cognitive functions in children with SDB.

Multiple Linear Regression Analysis Results: N3 sleep stage was one of the factors influencing attention and planning functions in children with SDB. Other sleep parameters, such as sleep efficiency and wake time after sleep onset, also had a certain impact on cognitive functions, but the impact was relatively small.

Conclusions: This study explored the application effect of the Das-Naglieri Cognitive Assessment System in children with SDB through cross-sectional analysis and prospective study design. The results indicate that the DN-CAS can be used to assess cognitive functions in children with SDB and help reveal the impact of SDB on their cognitive functions. Furthermore, CPAP treatment significantly improves sleep parameters and cognitive functions in children with SDB, providing strong evidence support for clinical interventions. In summary, the Das-Naglieri Cognitive Assessment System has potential application value in children with SDB and deserves further research and promotion.

Association Between Behavioral Problems and Vigilant Attention in Japanese High-School Students

Y. Ueda¹, H. Wada¹, Q. Zhu¹, Y. Kameda¹, M. Minami¹, T. Tanigawa¹

¹Juntendo University Graduate School of Medicine, Department of Public Health, Tokyo, Japan

Introduction: Behavioral problems among high school students often occur alongside inattentive or risky behavior, which can affect safe school life. These problems can be assessed using the Strengths and Difficulties Questionnaire (SDQ), which is a subjective measure. An objective measure is the three-minute Brief Psychomotor Vigilance Test (PVT-B). While higher SDQ scores have been shown to increase the number of delayed responses on the PVT-B in elementary school students, this relationship has not yet been examined in high school students. In the present study, we examined the relationship between the five SDQ domains and vigilance attention in Japanese high school students.

Materials and methods: We studied 417 students (ages 15–17, 47% male) from two public high schools in Tokyo. During one class period, the students completed the Japanese SDQ, followed by a three-minute PVT-B on laptops. The following indicators were derived from the PVT-B: Lapse355 (The number of reaction times ≥ 355 ms) were counted and grouped into quartiles: Q1: 0–2; Q2: 3–5; Q3: 6–7; and Q4: ≥ 8 . For each SDQ domain (emotional symptoms, conduct problems, hyperactivity/inattention, peer problems, and prosocial behavior) the top 20% of scores defined a high-risk group. Multivariable logistic regression was used to compare Q1 with Q2–Q4 and test for trends, adjusting for age, BMI, sleep duration, caffeine intake, and time from awakening to PVT (two-sided $p < 0.05$).

Results: Impaired vigilant attention (Q4) was associated with high-risk conduct problems (adjusted odds ratio [aOR], 3.93; 95% confidence interval [CI], 1.63–9.44; P-trend, 0.024) and low prosocial behavior (aOR, 2.51; 95% CI, 1.19–5.29; P-trend, 0.028). However, emotional symptoms, hyperactivity/inattention, and peer problems were not significant (all $p > 0.20$).

Conclusions: High school students with impaired vigilant attention showed more conduct problems and lower prosocial behavior. The PVT-B could provide schools with a rapid, objective screening tool for identifying students at risk for externalizing behavior. Longitudinal studies should determine whether improving sleep or vigilant attention ameliorates these behavioral problems.

ASSOCIATION BETWEEN PARASOMNIAS AND CHILDREN WITH ATTENTION DEFICIT HYPERACTIVITY DISORDER: A CROSS-SECTIONAL STUDY IN VIETNAM

M. Nguyen-Thi-Phuong¹, M. Nguyen-Thi-Thanh¹, S. Duong-Quy²

¹Hanoi Medical University, Hanoi, Vietnam, ²Lamdong Medical College, Dalat, Vietnam

Introduction: Attention deficit hyperactivity disorder (ADHD) is frequently associated with sleep disturbances, including parasomnias, which may worsen ADHD symptoms. However, the relationship between ADHD and parasomnias remains underexplored, particularly in newly diagnosed pediatric populations. This study aimed to determine the prevalence of parasomnias and identify associated factors in children with ADHD.

Materials and methods: A cross-sectional study was conducted on 629 children aged 6 – 12 years newly diagnosed with ADHD according to DSM-5 criteria at Vietnam National Children's Hospital. Parasomnias were classified using the ICSD-3, and data on comorbidities and sleep behaviors were collected through structured interviews and sleep diaries. Univariate and multivariate logistic regression analyses were performed to determine significant associations.

Results: Parasomnias were identified in 27.8% of children with ADHD, with NREM-related parasomnias being the most prevalent. The presence of comorbid psychiatric disorders, particularly tic disorders,

anxiety–depression, learning disorders, and intellectual disability, significantly increased parasomnia risk (OR 2.49 – 4.29, $p < 0.001$). Sleep talking was the strongest independent predictor (OR = 5.74, $p < 0.001$). ADHD clinical subtypes were not significantly associated with parasomnias.

Conclusions: Parasomnias are common in children with ADHD and are strongly linked to comorbid conditions and sleep-related behaviors. These findings emphasize the need for routine sleep assessments in ADHD management. Future studies should incorporate longitudinal designs and objective sleep assessments to better understand underlying mechanisms and intervention strategies.

Acknowledgments: We extend our sincere gratitude to the Psychiatry Department at the Vietnam National Children's Hospital for their invaluable support and collaboration in conducting this study. We also thank all the participants and their families who participated. We would like to thank the Sleep Lab Center of the Vietnam Society of Sleep Medicine in Dalat, Vietnam, for their assistance and support.

Association Between Spindle Wave Activity and Subjective Sleep Evaluation in Drug-Naïve Adolescents With ADHD and Sleep Complaints

T. Kato¹, M. Ozone¹, N. Kotorii¹, H. Ohshima¹, Y. Hyoudou¹, S. Mizuki¹, M. Takii¹, H. Hiejima¹, N. Uchimura¹, T. Koura¹

¹Kurume University School of Medicine, Department of Neuropsychiatry, Fukuoka City, Japan

Introduction: Sleep disorders are frequently observed in neurodevelopmental conditions, and approximately 50% of individuals with attention-deficit/hyperactivity disorder (ADHD) are reported to experience some form of sleep disturbance (Cortese S. et al., *Journal of the American Academy of Child & Adolescent Psychiatry*, 2009). Several studies have examined abnormalities in sleep architecture and sleep-related cognitions in ADHD. However, these studies are often limited by factors such as insufficient control groups, heterogeneity in the diagnostic criteria for ADHD, failure to exclude comorbid psychiatric condition, and potential confounding effects of medication. (Bertisch S.M., *Sleep*, 2014).

Our previous research suggested a paradoxical dissociation between subjective and objective sleep assessments in individuals with ADHD from childhood to adulthood (Kato T. et al., *Journal of Attention Disorders*, 2023). However, the underlying mechanisms of this dissociation remain unclear. Recent studies have suggested a potential association between cognitive functioning and spindle wave (SW) activity during sleep. This study investigated the relationship between SW parameters and subjective sleep perception in drug-naïve adolescents with and without ADHD who underwent clinical polysomnography for sleep-related complaints.

Materials and methods: We retrospectively analyzed data from patients under the age of 18 ($n = 70$) who presented with sleep disturbances at the Department of Psychiatry and Sleep Medicine at Kurume University Hospital between April 2015 and March 2020. ADHD was diagnosed based on DSM-5 criteria. Patients with comorbid conditions known to affect sleep structure—narcolepsy (NL), idiopathic hypersomnia (IH), obstructive sleep apnea (OSA; $AHI \geq 5$), restless legs syndrome (RLS), or periodic limb movement disorder (PLMD)—were excluded. After applying these criteria, the final sample comprised 40 patients. Spindle wave parameters obtained from polysomnography (PSG) were compared between the ADHD and non-ADHD groups. Subjective sleep quality was assessed using the Japanese version of the Epworth Sleepiness Scale (JESS) and the Pittsburgh Sleep Quality Index (PSQI). This study was approved by the Ethics Committee of Kurume University.

Results:

1. The ADHD group showed significantly higher scores on the JESS (15.9 ± 4.4 vs. 11.3 ± 5.3 ; $p = 0.0342$) and the PSQI (8.8 ± 2.7 vs. 5.8 ± 2.4 ; $p = 0.0124$) compared to the non-ADHD group.
2. PSG analysis revealed significantly higher SW counts (112 ± 10.2 vs. 24 ± 4.8 ; $p = 0.0361$) and SW frequency per hour (93.5 ± 10.3 vs. 23 ± 4.6 ; $p = 0.0272$) in the ADHD group, particularly in the slow spindle frequency range.
3. In the ADHD group, the number of slow SW events was positively correlated with the PSQI sleep duration component (C3) ($r = 0.8452$, $p = 0.0341$) and negatively correlated with the subjective sleep duration reported immediately after PSG ($r = -0.7516$, $p = 0.0315$).

Conclusions: These findings suggest that increased spindle activity—particularly within the slow spindle range—may influence the process of subjective sleep evaluation in drug-naïve adolescents with ADHD, independent of comorbid sleep or psychiatric disorders and pharmacological influences.

Association of Outdoor Artificial Light at Night with Sleep Duration and Social Jetlag Among Preschool-aged Children

Q.-Y. Lan¹, G. Chen², A.M. Li³

¹Guangdong Pharmaceutical University, School of Public Health, Guangzhou, China, ²Monash University, Melbourne, Australia, ³The Chinese University of Hong Kong, Department of Paediatrics, Hong Kong SAR, Hong Kong, SAR of China

Introduction: Recent studies have increasingly focused on the influence of outdoor artificial light at night (ALAN) on children's sleep patterns. However, its specific impact on sleep duration and social jetlag in this population remains underexplored. In densely populated urban centers such as Hong Kong, children are increasingly exposed to elevated levels of nighttime illumination. Our previous research demonstrated the detrimental effects of electronic screen use on children's sleep. The present study aimed to examine the association between outdoor ALAN exposure and both sleep duration and social jetlag among preschool-aged children in Hong Kong. The findings are expected to provide important insights into the impact of light pollution on pediatric sleep health and support the development of preventive strategies.

Materials and methods: This study included 3,686 preschool children recruited from kindergartens across four geographical regions in Hong Kong. Parent-completed questionnaires provided information on socioeconomic status (SES), as well as children's and parents' sleep-wake patterns. Outdoor ALAN exposure was assessed within a 1,000-meter radius of each participant's kindergarten address using satellite imagery data, with a spatial resolution of approximately 1,000 meters. To estimate the associations between ALAN exposure and children's sleep duration and social jetlag, a Generalized Linear Mixed Model (GLMM) was employed, with geographical region included as a random effect. Social jetlag misalignment was defined as a difference greater than one hour between weekday and weekend midsleep time, corresponding to the 75th percentile of the distribution in our sample. Bedtime screen exposure was defined as the use of electronic screens within one hour before bedtime.

Results: The mean age of the participants was 3.85 ± 0.99 years, with 52.85% being girls. The average sleep duration was 626.6 ± 60.2 minutes per day. ALAN exposure ranged from 10.18 to 84.28 nW/cm²/sr. A significant negative association was observed between ALAN exposure and children's sleep duration, with each unit increase in ALAN corresponding to an estimated decrease of approximately 0.198 minutes in sleep duration ($P = 0.003$). After adjusting for age, sex, family income, parental education level, and bedtime screen exposure, the association became marginal ($\beta = -0.11$, $P = 0.070$). A significant interaction was identified between ALAN exposure and bedtime screen exposure ($P_{\text{interaction}} = 0.043$), indicating that children exposed to screens at bedtime were more susceptible to ALAN-related reductions in sleep duration ($\beta = -0.21$, $P < 0.001$). We further examined the relationship between ALAN exposure and social jetlag. Children in the highest quartile of ALAN exposure had a significantly higher risk of social jetlag misalignment (OR = 1.131, 95% CI: 1.03–1.68; $P_{\text{trend}} = 0.009$), based on multivariable-adjusted models.

Conclusions: This study found that higher levels of outdoor ALAN were associated with shorter sleep duration and a greater risk of circadian disruption among preschool-aged children. Future research aiming to address the adverse effects of ALAN on children's sleep should also account for indoor light exposure, particularly from electronic screens, to inform the development of more targeted and effective interventions.

Acknowledgments: We sincerely thank all participating kindergartens, children, and their parents for their support.

Associations between household passive smoke exposure and sleep health in Chinese primary school students: a pilot study

S. Dai^{1,2,3}, J. Huang^{3,4}, P. Bao⁵, X. Liu⁶, X. Xiao⁷, S. Laureys^{7,8}, H. Di⁷

¹Hangzhou Normal University, School of Clinical Medicine, Hangzhou, China, ²The Chinese University of Hong Kong, Department of Paediatrics, Hong Kong, China, ³Hangzhou Normal University, The Affiliated Hospital, Hangzhou, China, ⁴Dalian Medical University, School of Clinical Medicine, Dalian, China, ⁵Hangzhou Normal University, School of Preventive Medicine, Hangzhou, China, ⁶The Affiliated Brain Hospital of Tongji University, Department of Neurology, Shanghai, China, ⁷Hangzhou Normal University, School of Basic Medicine, Hangzhou, China, ⁸Laval University, CERVO Brain Research Centre, Québec, Canada

Introduction: Sleep is a critical determinant of physical, cognitive, and emotional development in children. However, sleep health is increasingly disrupted by environmental factors, including exposure to environmental tobacco smoke (ETS). While the adverse effects of ETS on respiratory health are well-documented, its potential consequences for paediatric sleep health remain underexplored. This study examines the associations between household ETS exposure and sleep duration and quality in primary school-aged children in China.

Materials and methods: This ongoing study is being conducted at the physical examination clinic of the affiliated hospital of Hangzhou Normal University, China. Data on household ETS exposure and children's demographic characteristics were collected through parent-reported questionnaires. Household ETS exposure was defined as daily exposure to tobacco smoke from family members residing in the same household. Sleep health was assessed using the Children's Sleep Habits Questionnaire (CSHQ), a validated instrument for evaluating paediatric sleep duration and quality. Regression models, adjusted for age and gender, were employed to analyze the associations between household ETS exposure, average sleep duration, and sleep quality indicators, including symptoms such as bruxism and snoring.

Results: A total of 50 children (mean age: 7.9 ± 2.1 years; males: 62.0%) were included in the analysis. The prevalence of daily household ETS exposure was 44.0%, with paternal smoking as the primary source (38%), followed by maternal smoking (4%) and smoking by other household members (2%). The average sleep duration during weekdays was 8.9 ± 0.7 hours, increasing to 9.5 ± 0.9 hours on weekends, with a weekly average of 9.1 ± 0.6 hours. Sleep disorder symptoms were reported in a substantial proportion of children, with 24% exhibiting weekly bruxism and 30% experiencing weekly snoring. Regression analysis indicated that daily household ETS exposure was significantly associated with reduced average sleep duration ($\beta = -0.30$, $p = 0.05$) after adjusting for age and gender. However, no statistically significant associations were observed between ETS exposure and poor sleep quality in the current pilot analysis.

Conclusions: These findings suggest that household ETS exposure may adversely affect sleep duration in primary school-aged children. Although no significant associations with overall sleep quality were identified in this pilot analysis, the high prevalence of sleep-related symptoms highlights the need for further investigation into the broader impacts of ETS exposure on paediatric sleep health. Future large-scale studies are necessary to confirm these findings and elucidate the underlying mechanisms linking ETS exposure to disrupted sleep. Interventions aimed at reducing household smoking may represent an important strategy for improving sleep health in children.

Associations Between Nocturnal Autonomic Activity in Infancy and Later Neurocognitive Development: The AuBE Cohort Study

L. Brunel¹, A. Guyon², L. Coutier³, H. Patural⁴, V. Pichot⁴, M. Comajuan², M. Thieux², S. Plancoulaine¹, P. Franco²

¹University Lyon 1, INSERM U1068, CRNL, Lyon, France, ²University Lyon 1, Pediatric Sleep Unit, Mother and children Hospital, HCL & INSERM U1068, CRNL, Lyon, France, ³University Lyon 1, Service de pneumologie pédiatrique, Mother and Children Hospital & INSERM U1018, CRNL, Lyon, France, ⁴University Jean Monnet of Saint-Etienne, Neonatal and Pediatric Intensive Care Unit, University Hospital of Saint-Etienne and UMR Inserm 1059 SAINBIOSE laboratory, Saint Etienne, France

Introduction: The autonomic nervous system (ANS) reflects central nervous system (CNS) function and can be assessed non-invasively using heart rate variability (HRV). However, most studies assess HRV over 24 hours, mixing wake and sleep periods, limiting insights into sleep-specific ANS activities. Understanding how ANS activity during distinct sleep stages relates to neurocognitive outcomes is essential, given the critical role of sleep in early life for shaping brain development. This study aimed to:

(1) compare ANS activity between active sleep (AS) and quiet sleep (QS) at birth (M0) and at six months (M6); (2) evaluate ANS maturation during sleep from birth to six months; and (3) investigate associations between ANS activity during sleep in early infancy and neurocognitive performance at three years of age.

Materials and methods: Participants were part of the French AuBE birth cohort. Inclusion criteria for this analysis were availability of overnight polysomnography (PSG; 8 pm–8 am) at birth (M0) and cognitive assessment at three years using the Wechsler Preschool and Primary Scale of Intelligence-III (WPPSI-III). A subset of infants also underwent PSG at six months (M6).

Electrocardiogram (ECG) data were extracted to compute HRV indices in both time and frequency domains: mean heart rate (HR), SDNN, and low-frequency power (LF) as markers of sympathetic activity; pNN50, RMSSD, and high-frequency power (HF) as markers of parasympathetic activity; and the LF/HF ratio to evaluate sympathovagal balance. HRV parameters were compared between AS and QS at both M0 and M6, and changes from M0 to M6 were analyzed according to sleep stage.

Associations between HRV indices and WPPSI-III scores (Verbal IQ, Performance IQ, Total IQ) were assessed using correlations.

Results: A total of 56 full-term infants were included at M0 (48% girls), among which 34 had follow-up data at M6. HRV parameters did not differ by sex. Significant differences in ANS activity were observed between sleep stages at both M0 and M6. AS was characterized by higher sympathetic activity (elevated HR, SDNN, LFnu, and LF/HF ratio), while QS showed increased parasympathetic activity (higher RR intervals, pNN50, RMSSD, HFnu).

Between M0 and M6, ANS maturation was evident during QS, with an increase in RR intervals and HFnu, and a decrease in HR, LFnu, and LF/HF ratio, indicating an increase in parasympathetic regulation and a decrease in sympathetic dominance. No significant maturation was observed during AS. Importantly, higher total power during QS at M0 correlated positively with Performance IQ at three years ($r = 0.31$, $p < 0.05$).

Conclusions: This study demonstrates that ANS activity in infants varies significantly according to sleep stage, with QS favoring parasympathetic predominance. ANS maturation primarily occurs during QS within the first six months of life. Furthermore, ANS function during QS at birth, as reflected by total power, is associated with later cognitive outcomes. These findings suggest that early sleep-specific ANS markers could serve as indicators of neurodevelopmental trajectories.

Association with severity obstructive apnea (OSA) with elevated blood pressure amongst the pediatrics population

P. Hsueh^{1,2,3}, R. Bhattacharjee², J. Ryu²

¹Southwest Healthcare Medical Education Consortium, Temecula Valley Hospital, Sleep Medicine Department, Temecula, United States, ²University of California San Diego/Rady Children's Hospital, Division of Pulmonary Medicine, Department of Pediatrics, San Diego, United States, ³University of California Riverside, Pediatrics Department, Riverside, United States

Introduction: The prevalence of pediatric hypertension has risen from 1.1% in 2004 to 6% in 2019, driven largely by increasing childhood obesity. As obesity is a key risk factor for obstructive sleep apnea (OSA), we hypothesize that OSA in children is associated with elevated blood pressure in a pediatric sleep clinic population.

Materials and methods: Retrospective chart review of pediatric patients who underwent polysomnography and evaluation at Rady Children's Hospital between January 2019 and December 2024. Demographic data included sex, age, BMI, ethnicity, and systolic (SBP) and diastolic (DBP) blood pressure percentiles(%). Polysomnography determined the obstructive apnea-hypopnea index (OAHI), with OSA severity classified as follows: no OSA (OAHI <1/hour), mild OSA (OAHI 1–5/hour), moderate OSA (OAHI 5–10/hour), and severe OSA (OAHI >10/hour). Exclusion criteria included craniofacial, cardiac, pulmonary, and neuromuscular abnormalities. Blood pressure percentiles were calculated based on NHLBI pediatric blood pressure guidelines, with hypertension defined as SBP or DBP at or above the 95th percentile for age, sex, and height.

Results: 484 pediatric subjects (mean age:10.8±4.3 years, 37.6% female) were evaluated. Ethnicity distribution included 214(44.3%) non-Hispanic and 261(53.9%) Hispanic. Mean±SD SBP% and DBP% by OSA severity were as follows: no OSA(n=45): 0.786±0.236/0.677±0.225; mild OSA(n=229): 0.792±0.232/0.700±0.214; moderate OSA(n=106): 0.801±0.208/0.725±0.222; and severe

OSA(n=104): $0.893 \pm 0.151 / 0.772 \pm 0.222$. SBP% was significantly higher in severe OSA compared to all other severities ($p < 0.05$), while DBP% was significantly higher in severe OSA compared to mild OSA ($p < 0.05$) and borderline compared to no OSA ($p = 0.07$). Only SBP% significantly correlated with OAH1 ($p < 0.05$). The OAH1 trended higher in children with hypertensive BP measurements compared to those without (8.89 ± 15.5 vs. 5.96 ± 10.6 , $p = 0.063$). Multivariate regression analysis, adjusted for age and BMI, revealed that OAH1 was not significantly associated with either SBP% or DBP%.

Conclusions: The findings demonstrate that BP increases with OSA severity in a pediatric sleep clinic population. While the association between OAH1 and BP was not independent of age and BMI, children with severe OSA are more likely to have elevated BP and a trend toward hypertension, emphasizing the need for targeted BP screening and management in children with greater OSA severity.

A Study on Sleep Status and Its Relationship with Quality of Life in Children with Chronic Diseases

B. Shen³, Y. Xia³, P. Fan¹, J. Lu³, K. Han³, Y. Xiang³, X. Sha³

¹Shanghai Children's Medical Center, Department of Nursing, Shanghai, China, ²Shanghai Jiao Tong University, School of Nursing, Shanghai, China

Introduction: To examine the current sleep status of children with chronic illnesses and explore its association with health-related quality of life, in order to provide evidence for developing targeted interventions to support self-management in this population.

Materials and methods: A convenience sampling method was used in this study. Data were collected using a general information questionnaire, the Physical Activity Questionnaire for Children (PAQ-C), the Children's Sleep Habits Questionnaire (CSHQ), and the Patient-Reported Outcomes Measurement Information System (PROMIS-25). A total of 230 hospitalized children from the departments of rheumatology and immunology, gastroenterology and nephrology, cardiology, and cardiac surgery at a pediatric medical center were surveyed to assess their sleep status and analyze its association with quality of life.

Results: The average PAQ-C score among the 230 children with chronic illnesses was 1.85 ± 0.81 . The average CSHQ score was 46.82 ± 7.88 , with notable disturbances observed in the dimensions of parasomnias and daytime sleepiness. The average daily sedentary time over the past week was 11.43 ± 3.17 hours, significantly exceeding the 2-hour limit recommended by the *Chinese Guidelines for Physical Activity for Children and Adolescents*. In the PROMIS-25, the average scores for depression, fatigue, pain, and anxiety were all below 45, indicating normal levels. However, the mean score for physical function-mobility was 23.66 ± 4.62 , suggesting functional limitation. Mediation analysis showed that the total effect of CSHQ on PROMIS-25 was significant (path c, $\beta = -0.35$, $p < 0.001$). CSHQ significantly affected PAQ-C (path a, $\beta = -0.28$, $p < 0.01$), and PAQ-C significantly affected PROMIS-25 (path b, $\beta = 0.42$, $p < 0.001$). After controlling for PAQ-C, the direct effect of CSHQ on PROMIS-25 remained significant (path c', $\beta = -0.20$, $p < 0.05$). The bootstrap confidence interval for the indirect effect was $[-0.15, -0.05]$, excluding zero, indicating a significant mediating effect. These findings suggest that physical activity level partially mediates the relationship between children's sleep habits and health-related quality of life.

Conclusions: Sleep disturbances are prevalent among children with chronic illnesses and may adversely affect their health-related quality of life. Sleep habits appear to influence quality of life in part through their impact on physical activity levels. These findings underscore the need for healthcare professionals to recognize and address sleep and activity-related challenges in this population through the development of targeted, evidence-based interventions aimed at promoting both physical and psychological well-being.

Autism, Sleep, and Medicinal Cannabis: Evaluating 18-Month Efficacy and Safety Outcomes

M. Maqbool¹

¹University of Texas Dallas, Neuroscience, Richardson, United States

Introduction: Sleep disturbances are common in children with Autism Spectrum Disorder (ASD), affecting up to 80% of this population. Poor sleep onset, frequent awakenings, and reduced sleep quality contribute to behavioral challenges, impaired cognition, and increased caregiver stress. Standard

treatments like melatonin or sedatives offer limited relief, making medicinal cannabis a promising alternative. Cannabis-based therapies with cannabidiol (CBD) and delta-9-tetrahydrocannabinol (THC) in tailored ratios have shown encouraging short-term results for sleep improvement in ASD. This study evaluates the long-term efficacy and safety of medicinal cannabis for sleep management over 18 months, focusing on sustained outcomes and side effects.

Materials and methods: This longitudinal observational study enrolled 120 pediatric patients (ages 3-17 years) with a confirmed diagnosis of ASD who experienced chronic sleep disturbances. Patients were treated with medicinal cannabis formulations containing varying ratios of CBD and THC, customized based on individual tolerance and therapeutic response.

Baseline data were collected three months prior to initiating cannabis treatment, including metrics on sleep onset latency, sleep maintenance, and overall sleep quality, as reported by caregivers and validated sleep assessment tools. Follow-up assessments were conducted three months post-treatment initiation and at 18 months to evaluate long-term efficacy and safety. Primary endpoints included improvements in sleep parameters (sleep onset latency, sleep maintenance, and overall sleep quality) and caregiver-reported quality of life. Secondary endpoints included the identification of adverse effects and the development of treatment tolerance. Data were analyzed using paired t-tests and repeated measures ANOVA for longitudinal comparisons.

Results: Initial results demonstrated significant improvements in sleep onset latency, maintenance, and quality within the first three months of treatment, with over 80% of patients showing measurable benefits. At the 18-month follow-up, 68% of patients sustained their sleep improvements without requiring substantial dosage adjustments.

Adverse effects were minimal, with increased appetite and agitation reported in less than 10% of patients, primarily during the initial adjustment phase. No severe adverse events were recorded. A small subset of patients (12%) showed signs of developing tolerance, necessitating dosage increases to maintain efficacy. Overall, caregiver-reported quality of life improved in parallel with sleep improvements, highlighting the positive impact of treatment on both patients and their families.

Conclusions: This 18-month observational study highlights the long-term efficacy and safety of medicinal cannabis for managing sleep disturbances in ASD. Tailored treatments sustained sleep improvements with minimal side effects, making this a viable option for a challenging population. While tolerance development is a concern for some, the overall safety profile and lasting benefits support medicinal cannabis as part of a comprehensive sleep management strategy. Future studies should refine dosing regimens, including terpene and flavonoid profiles, to establish standardized therapeutic guidelines.

Acknowledgments: The authors acknowledge the patients and caregivers for their participation and trust throughout this study. This research was conducted independently without external funding. Data were derived from patients receiving care at a neurology sleep clinic, where progress was monitored as part of routine care. Gratitude is extended to the clinic staff for supporting data collection and patient management. Their dedication made this study possible.

Behavioral and Parental Predictors of Sleep Problems in Primary School Children: A Cross-Sectional Study

E. Baris¹, M.C. Us¹, F.B. Doganc², Z.D. Dayi³, A.F. Ozyurt³, T.B. Ariturk³, I.F. Cakir³, S. Hidiroglu², P. Boran¹

¹Marmara University, Social Pediatrics, Istanbul, Turkey, ²Marmara University, Public Health, Istanbul, Turkey, ³Marmara University, Istanbul, Turkey

Introduction: Sleep problems are highly prevalent in school-aged children and are known to adversely affect cognitive and emotional development. Previous research suggests that both child behavioral difficulties and familial factors, such as parental sleep quality and socioeconomic conditions, may contribute to sleep disturbances. However, integrated models that consider both child and parent-level predictors in community samples remain limited. This study aimed to examine the behavioral and parental predictors of sleep problems in Turkish primary school children using standardized tools and multivariable modeling.

Materials and methods: A cross-sectional study was conducted with 332 children aged 7–11 years (mean age = 8.3 ± 1.2 years; 50.9% boys) recruited from public primary schools in a city district of Istanbul. Child sleep problems were assessed using the Child Sleep Habits Questionnaire (CSHQ), and

behavioral difficulties were measured via the Strengths and Difficulties Questionnaire (SDQ), which includes subscales for emotional problems, conduct problems, hyperactivity, peer problems, and prosocial behavior. Parental sleep quality was evaluated using the *Pittsburgh Sleep Quality Index* (PSQI). Children were categorized as having sleep problems based on CSHQ scores >41 . Nonparametric group comparisons were performed due to non-normal distributions. Multiple linear regression was used to identify independent predictors of sleep problems. Predictors included SDQ subscale scores, parental PSQI score, child sex, age, and perceived socioeconomic status. Given the low rate of missing data (4.8%), listwise deletion was applied, resulting in a regression sample of 316 children.

Results: Overall, 66.6% of children ($n = 221$) met the threshold for significant sleep problems. Children with sleep problems had significantly higher scores in emotional problems, conduct problems, hyperactivity, peer difficulties, and total difficulties and lower scores in prosocial behaviour (*all* $p < .001$). They also had significantly poorer parental sleep quality (PSQI median: 5 [IQR 4–7] vs. 3 [2–6], $p < .001$). Screen exposure in the hour before bedtime ($p < .001$), and the presence of a tablet or smartphone in the bedroom ($p = .048$) were more common in children with sleep problems and parents of children with sleep problems reported lower perceived socioeconomic status ($p = .018$). The full regression model was statistically significant ($F(9, 306) = 16.48$, $p < .001$) and explained 30.7% of the variance in child sleep scores. The significant predictors for child sleep problems were emotional difficulties ($\beta = .301$, $p < .001$) and parental PSQI score ($\beta = .229$, $p < .001$).

Conclusions: This study highlights the importance of the family sleep environment and child emotional regulation in the sleep health of school-aged children. Both emotional difficulties and parental sleep quality independently predict child sleep problems. These findings underscore the need to integrate child behavioral screening with family-level assessments in pediatric sleep evaluations. Intervention strategies targeting shared family dynamics—including evening screen use and household sleep routines—may provide effective targets for improving family sleep health.

Beyond the recommendations: A bioecological analysis of pre-bedtime screen use, moderate-to-vigorous physical activity and food intake in family contexts

C. Gu¹, R. Jackson¹, J. Camp¹, K. Meredith-Jones¹, J. Haszard², B. Galland³, R. Taylor¹

¹University of Otago, Dunedin School of Medicine, Department of Medicine, Dunedin, New Zealand,

²Haszard Biostatistics, Kaka Point, New Zealand, ³University of Otago, Department of Paediatrics and Child Health, Dunedin, New Zealand

Introduction: Current guidelines suggest youth limit screen use, physical activity, and the consumption of food in the hour before bed. However, whether these sleep hygiene strategies actually influence sleep, or how worthwhile and practical they are for youth and families in real-life is uncertain. This study draws on Bronfenbrenner's Bioecological Model of Human Development to explore and analyze pre-bedtime screen use, moderate-to-vigorous physical activity (MVPA) and food intake within family contexts.

Materials and methods: We conducted a qualitative study nested within the randomized crossover Helpful Activities Before It is Time to Sleep (HABITS) trial. HABITS experimentally investigates whether restricting pre-bedtime screen use, MVPA and food intake in the hour before bed impact sleep quantity and quality in youth. Sixteen youth (19% indigenous Māori, 6% Pacific, 6% Asian, 50% female) aged 10 to 14 years and their parents were interviewed upon completion of HABITS. Semi-structured interviews explored youth and families' experiences of adhering to current sleep hygiene recommendations—avoiding screen use, MVPA and food intake in the hour before bed—and their implementation of each behavior. Interviews were recorded, transcribed, and analyzed using reflective thematic analysis.

Results: Four key themes were identified: 1) tensions arise from the misalignment between recommendations to limit these behaviors and established family routines; 2) pre-bedtime screen use, MVPA and food intake are viewed as purposeful family practices; 3) families negotiate between ideal recommendations and practical realities; 4) youth and family expressed uncertainty about the actual impact of these sleep hygiene behaviors on sleep. Most youth and families perceived complete bans on pre-bedtime screen use, MVPA and food intake as unrealistic and unsustainable. When examined through a bioecological lens, these behaviors emerged as contextually negotiated practices shaped by broader family systems.

Conclusions: Sleep hygiene recommendations should acknowledge and reflect developmentally grounded, socio-cultural, and context-specific practices that align with the realities of family-based sleep routines.

Acknowledgments: The qualitative study is a part of the HABITS study, which was funded by Lottery Health New Zealand (R-LHR-2023-215337) and the Health Research Council of New Zealand (23/512). The funding bodies played no role in the study design, data collection, analysis and interpretation of data or writing of the manuscript.

Breastfeeding and Neonatal Sleep: The Circadian Rhythms of the Breast Milk Microbiome and Metabolome and Their Impact on Global Infant Health

B. Shen¹, T. Bai¹, Q. Zhai², H. Cui¹, Y. Pan¹, N. Shen¹, S. Shi¹, Y. Li¹, H. Chen¹

¹Shanghai Children's Medical Center, Department of Nursing, Shanghai, China, ²Shanghai Jiao Tong University, School of Nursing, Shanghai, China

Introduction: To investigate the relationship of breastfeeding ways and neonatal sleep, and explore whether the components of human milk exhibit circadian rhythms in terms of microbiome and metabolome profiles.

Materials and methods: A cross-sectional study was implemented to investigate the basic characteristics, feeding practices of 89 mother-infant dyads, and neonatal sleep patterns, utilizing Questionnaire Star for data collection. A total of 42 breast milk samples were obtained from 21 lactating women at noon and midnight. The melatonin concentration in milk samples was quantified via enzyme-linked immunosorbent assay (ELISA). Metagenomic sequencing was performed on the milk samples to ascertain the microbial composition, while metabolites in the milk were identified through liquid chromatography-mass spectrometry (LC-MS).

Results: Neonates who were exclusively formula-fed exhibited longer durations of both nocturnal and daytime sleep, and more frequent nighttime awakenings, compared to those who were exclusively breastfed. Neonates in the mixed feeding group were reported to experience more sleep-related issues than those in the exclusive breastfeeding group. Melatonin concentration was significantly higher in the midnight samples compared to the noon samples. A total of 335651 differential microbiome were found and 20 bacterial genera and 20 microbial taxa in noon and midnight human breast milk reveals significant differences exist between the microbial populations. Such as *cognataguiflexum*, *segnochrobacterium*, *aquabacterium* were significantly more abundant in milk from the midnight group ($P < 0.05$). Metabolic pathway analysis of the different metabolites revealed that the following were enriched in both groups: lipid metabolism pathways, amino acid metabolism pathways.

Conclusions: Breastfeeding styles influence the neonatal sleep patterns, and the composition of breast milk varies according to the maternal circadian rhythm. In the NICU, matching the feeding times of neonates with the breast milk or donor milk collection times may facilitate the development and maturation of sleep/wake cycles in newborns and preterm infants.

Building Predictive Models for Hypoventilation in Children with Neuromuscular Disorders

A. Withers^{1,2,3}, A. Wilson^{1,3,2}, P. Jacoby³, J. Downs^{3,2}

¹Perth Children's Hospital, Department of Respiratory and Sleep Medicine, Perth, Australia, ²Curtin University, Perth, Australia, ³The Kids Research Institute Australia, Perth, Australia

Introduction: Children with neuromuscular disorders are at risk of hypoventilation. The ability to predict or screen for hypoventilation could inform when diagnostic polysomnography, a limited resource, was warranted.

Materials and methods: Children with neuromuscular disorders from three sites had laboratory polysomnography to identify hypoventilation ($pCO_2 > 50\text{mmHg}$ for $\geq 25\%$ total sleep time). The associations between hypoventilation and demographic factors, anthropometrics, clinical factors, motor function, pulmonary function tests and patient and parent-reported outcome measures were determined. Patient-reported outcome measures were collected for participants aged eight and older. Significant factors were examined with Binary Logistic Regression to construct predictive models.

Model predictive power was assessed by using the generated predictive probabilities to construct Receiver Operator Characteristic curves and calculating the area under the curve (AUC).

Results: Hypoventilation was present in 16% of the 64 participants. Significant associations with hypoventilation were a diagnosis of congenital myopathy/congenital muscular dystrophy, BMI z-score, higher parent and self-reported hypoventilation symptom score, higher self-reported hyperactivity and externalising behaviours score with the Strengths and Difficulties (SDQ) questionnaire and lower self-reported Peds QL™ Neuromuscular module health and total score. The predictive model with the highest AUC combined self-reported hypoventilation symptom score, SDQ hyperactivity score and Peds QL™ Neuromuscular module health score (AUC 0.975, $p < 0.001$). For children aged less than eight, a diagnosis of congenital muscular dystrophy/congenital myopathy and BMI z-score resulted in an AUC of 0.872 ($p < 0.001$). Regression coefficients were used to construct predictive equations for the probability of hypoventilation.

Conclusions: The predictive models that were developed performed well and could be used as screening tools for hypoventilation in children with neuromuscular disorders to determine when polysomnography is warranted. Patient-reported outcome measures resulted in the model with the highest predictive power.

Can sleep spindle characteristics distinguish children with narcolepsy from those with idiopathic hypersomnia and subjective sleepiness?

M. Shetty¹, N. Kadam Kishmore¹, G. Plunkett¹, L. Nisbet^{1,2}, M. Davey^{1,2}, G. Nixon^{1,2}, L. Walter¹, R. Horne¹

¹Monash University, Paediatrics, Melbourne, Australia, ²Monash Children's Hospital, Melbourne Children's Sleep Centre, Melbourne, Australia

Introduction: Central disorders of hypersomnolence are characterised by excessive daytime sleepiness (EDS) that is unexplained by insufficient sleep or other underlying medical conditions. Included in this poorly understood category of sleep disorders are narcolepsy and idiopathic hypersomnia (IH). There has been growing interest in analysing sleep micro-architecture, to further understand how sleep is affected by different conditions. Sleep spindles are a hallmark electroencephalogram (EEG) waveform of N2 sleep with a characteristic frequency in the sigma range of 11-16 Hz. We aimed to investigate if sleep spindle activity differed between children with narcolepsy, IH, and subjectively sleepy children with a non-diagnostic multiple sleep latency test (MSLT), and matched controls.

Materials and methods: 28 children with narcolepsy, 11 with IH and 26 with subjective sleepiness were included and individually matched for age and sex with a control. All children underwent overnight polysomnography. Fast (>13 -16 Hz) or Slow (9- <13 Hz) sleep spindles were identified manually during N2/N3 sleep. Spindle activity was characterised as spindle number, density (number of spindles/h) and intensity (density x average duration) of right central (C4) and frontal (F4) EEG electrodes across the sleep period and also when separated into NREM sleep periods (NREMP) across the night. Groups were compared with one-way ANOVA.

Results: Spindle duration was longer for F4 and C4 Slow, C4 Fast and F4 and C4 Fast&Slow spindles in the children with narcolepsy compared to the children with subjective sleepiness ($p < 0.05$ for all) and compared to the narcolepsy controls ($p < 0.05$ for all). There were no differences in spindle duration between the children with IH or subjective sleepiness and their controls. In the children with narcolepsy and subjective sleepiness spindle intensity of C4 Slow and C4 Fast&Slow spindles was greater ($p < 0.05$ for all) compared to controls. When spindle number was compared across the night in each NREM period, in both the children with narcolepsy and subjective sleepiness there were more F4 Fast&Slow spindles in the 3rd NREMP and 4th NREMP ($p < 0.001$ for all) compared to controls. Spindle density and intensity of C4 Fast&Slow spindles were lower in the 1st NREMP compared to the 4th NREMP ($p < 0.05$) in the children with narcolepsy and lower in the 1st NREMP compared to both the 3rd NREMP and 4th NREMP ($p < 0.05$ for both) in the children with subjective sleepiness.

Conclusions: Our study identified sleep spindles are longer in children with narcolepsy compared to children with subjective sleepiness or their controls. In addition, sleep spindles are more concentrated at the end of the night compared to the beginning of the night in both children with narcolepsy and subjective sleepiness compared to controls. Children with IH did not demonstrate these spindle findings, supporting a different disease entity. Understanding the microstructure of sleep in combination with clinical history may aid in being able to distinguish between groups of children

referred for assessment of EDS, particularly those who do not meet strict diagnostic criteria for a primary disorder of hypersomnolence but did have abnormal MSLT results (our subjectively sleepy group).

CBT-I Teen: An Adapted CBT-I Protocol Developed for and with Adolescents and Other Stakeholders

S. Honaker¹, M. McQuillan¹, S. Khan¹, M. Hidrogo², E. Huynh³, Z. Walton⁴, L. Meltzer⁵

¹Indiana University School of Medicine, Pediatrics, Indianapolis, United States, ²South Austin Community College, Austin, United States, ³University of Pennsylvania, Philadelphia, United States,

⁴Boston University, Boston, United States, ⁵Nyxos Consulting, Denver, United States

Introduction: Cognitive-Behavioral Therapy for Insomnia (CBT-I) is a highly efficacious treatment in adults. However, adolescents have unique sleep physiology, lifestyles, and cognitive styles that may warrant CBT-I adaptation to meet their developmental needs. Further, some recommendations in standard CBT-I protocols (e.g., waking at the same time 7 days per week; avoiding screens before bed) have limited acceptability in adolescents. Thus, the objective of this study was to engage adolescents and other stakeholders in: 1) identifying aspects of standard CBT-I that may require adaptation; and 2) evaluating an adapted CBT-I protocol (CBT-I Teen) for efficacy and acceptability in a RCT compared to a waitlist control.

Materials and methods: Ten focus groups were conducted with adolescents with insomnia (n=76; 57% White, 23% Black, 20% Asian; 12% Hispanic), six focus groups with parents of adolescents with insomnia (n=51; 55% mothers), and two focus groups with clinicians (n=18) who provide treatment for insomnia in adolescents. In the first phase of focus groups, stakeholders identified adaptation needs and proposed solutions. In the second phase of focus groups, stakeholders provided feedback and anonymous ratings on the acceptability, feasibility, appropriateness, likely effectiveness, and fidelity of the adapted protocol.

Results: Themes from focus groups were identified for treatment process and content domains. Treatment process themes included the perception of sleep logs as stressful, a desire for personalized and interactive psychoeducation, and heterogeneity regarding if and how parents should be involved in treatment. Treatment content themes included the importance of the bed as a place of relaxation, preference for distraction over active relaxation strategies, low acceptability and feasibility of a consistent waketime across weekdays and weekends, and heterogeneity of screen use and impact.

An adapted protocol incorporated components such as alternative approaches to sleep tracking[LM1], adolescent choice about parental involvement, more flexible stimulus control recommendations, a naturalistic sleep restriction approach, and a harm reduction strategy for screen use. Stakeholders rated the adapted protocol highly (1-5 scale; 5 indicates high appropriateness, feasibility, etc): adolescents perceived the treatment as likely to be effective (M=4.7; SD=0.5), acceptable (M=4.2; SD=0.7), feasible (M=4.1; SD=0.8) and understandable (M=4.3; SD=0.6); parents perceived the treatment as likely to be effective (M= 4.6; SD=0.5) and acceptable[LM2] (M=4.2; SD=1.3); and clinicians rated the intervention as likely to be effective (M=4.3; SD=0.6), acceptable to teens (M=4.4; SD=0.5), appropriate (M=4.6; SD=0.6), and with strong fidelity to CBT-I mechanisms (M=4.6; SD=0.5).

Conclusions: An adapted CBT-I protocol (CBT-I Teen) is acceptable and feasible for adolescents with insomnia. More work is needed to evaluate the efficacy of the adapted protocol in reducing insomnia symptoms in adolescents.

Acknowledgments: This project was made possible by a grant from the American Academy of Sleep Medicine Foundation.

Change in AHI and effects of sleep health on weight loss trajectory in adolescents undergoing metabolic and bariatric surgery

C. Giles¹, E. Cooper², K. Bohdan¹, S. Simon¹

¹University of Colorado/Children's Hospital Colorado, Pediatric Pulmonary and Sleep Medicine, Aurora, United States, ²University of Colorado/Children's Hospital Colorado, Pediatric Endocrinology, Aurora, United States

Introduction: Metabolic and bariatric surgery (MBS) is emerging as a treatment option for the rapidly rising rates of severe obesity and associated morbidities such as obstructive sleep apnea (OSA) in children. In adults, MBS significantly improves BMI and apnea-hypopnea index (AHI), but little research has been conducted in children. MBS results in steep weight loss in the 12 months after surgery followed by slower weight regain over the subsequent years. Patients experience varying amounts of weight regain following MBS, but the impact of factors such as sleep health on weight regain is unknown. The aim of the current study was to examine change in AHI following MBS and to examine associations between sleep health and weight loss/regain following MBS in a clinical sample of youth with severe obesity.

Materials and methods: A retrospective chart review was conducted for patients who underwent MBS at Children's Hospital Colorado between 2017 and 2022. Inclusion criteria for this analysis was completion of both pre- and post-surgery polysomnography (PSG). Patient demographics, weight data, and self-reported sleep health and behaviors were derived from bariatric clinic visits at time of surgery and up to 3-years post-surgery. PSG data and Epworth Sleepiness Scale (ESS) total scores were collected from the sleep study reports. Descriptive statistics are reported as median (Q1, Q3) or frequency (%). Change in AHI from pre- to post- surgery were evaluated using paired Wilcoxon and McNemar's tests. Group-based trajectory models (GBTM) were used to identify trajectory groups based on percent weight change post-surgery using SAS PROC TRAJ. GBTM identified two trajectory groups, one with high weight loss and another with significant weight regain. Comparisons between groups were made with Wilcoxon, chi-squared, or Fisher's exact tests.

Results: Patients were a median age of 17.0 years at time of MBS (N=52). Nearly all patients (98%) underwent gastric sleeve MBS; 1 patient underwent gastric band. Patients were majority female (51.9%) and Hispanic/Latino (59.6%). Median AHI was 17.2 events/hour pre-surgery and this significantly reduced to 2.0 events/hour post-surgery ($p<0.001$). Prior to surgery 90.4% of participants had an AHI >5 , while only 26.9% of participants had an AHI >5 post-surgery. There was no significant component of central sleep apnea in this population. Prior to MBS, 42.6% of participants had an ESS score >10 compared to 12.8% after MBS ($p<0.05$).

50% of participants were in the weight regain trajectory group and 50% of participants were in the weight loss group. There were no significant difference in demographics between groups. Significantly more patients in the weight regain group had pre-surgery ESS >10 (58.3%, compared to only 25% in the high weight loss group; $p<0.05$). There were no significant difference in self-report sleep duration or timing, insomnia symptoms, electronics use at bedtime, or pre- or post-surgery AHI between trajectory groups.

Conclusions: MBS dramatically improves sleep apnea and excessive daytime sleepiness in adolescents with obesity. Participants with weight regain post-surgery were more likely to report clinically significant daytime sleepiness prior to surgery. Future research is needed to better understand the impact of daytime sleepiness on weight regain in youth undergoing MBS.

Characterization of children with specific learning disabilities and sleep complaints

P. Franco¹, J. Lioret¹, A. Guyon¹, M. Thieux¹, N. Beck², E. Denechere³, D. Gerard⁴

¹Centre de Recherche en Neurosciences de Lyon (CRNL), Bron, France, ²INSERM, Dijon, France,

³Cabinet de l'Aire Familiale, Bordeaux, France, ⁴Unité de Recherche Clinique, Medipôle Hôpital Mutualiste, Villeurbanne, France

Introduction: Specific learning disabilities (SLD) are reported in 8% to 10% of the general population. They are often associated with Attention Deficit Disorder with or without Hyperactivity (ADHD) (33-70%). These neurodevelopmental disorders are generally associated with various comorbidities such as anxiety-depressive disorders. Previous studies, based on questionnaires, have shown more sleep disorders in this population compared to control children, particularly in children with both pathologies. The aim of this study is to assess sleep characteristics in SLD children with or without ADHD associated with sleep complaints.

Materials and methods: One hundred and seventy-six children (66 girls) were included in this retrospective study, median age 11.4 years (range 6.9 to 17.8 years). Patients were divided into 3 according to their disorders: SLD (n = 76), ADHD (n = 36) and SLD -ADHD (n = 66). For each patient, medical history, sleep disorders, Epworth sleepiness score and polysomnographic results were

collected. Non-parametric comparisons were made between our groups (Kruskal Wallis, Wilcoxon and Chi²).

Results: SLD -ADHD had a higher frequency of Multi- SLD disorder (60.9% vs. 40.8% without ADHD). Children with ADHD had a higher frequency of respiratory and mood disorders. At polysomnography, the main sleep disorders observed were respiratory problems, generally mild OSA and UARS (82.9%), sleep fragmentation (pathological AI, 54%), as well as a higher percentage of NREM 1 for our groups with SLD. Comparisons revealed differences based on psychostimulant treatment, with lower levels of sleepiness and an increase in treatment-associated insomnia.

Conclusions: This study highlights a high proportion of comorbidities in SLD children, with a possible impact on sleep. Frequent complaints of somnolence and insomnia are present, with a difference in the type of complaint depending on the presence or absence of stimulant treatment. These results underline the importance of taking into account associated comorbidities in children with SLD with or without ADHD.

Clinician Perceptions Around Management of Sleep Problems in Children with Neurodisability

K. Fullwood¹, K. O'Donohue², A. Bernard³, K. Waters⁴, M. Vandeleur⁵, J. Chawla¹

¹The University of Queensland, Centre for Children's Health Research, South Brisbane, Australia,

²Queensland Children's Hospital, South Brisbane, Australia, ³The University of Queensland, St Lucia, Australia, ⁴Children's Hospital at Westmead, Westmead, Australia, ⁵Royal Children's Hospital, Melbourne, Australia

Introduction: Children with neurodisability experience sleep problems at significantly higher rate than typically developing children. These sleep problems are multifactorial, often involving both disease-specific and environmental factors and include sleep disordered breathing alongside non-respiratory sleep problems. As children with neurodisability frequently receive care from multiple specialist services, sleep concerns are commonly raised by caregivers and encountered by clinicians across various disciplines. However, the perspectives of non-sleep specialists on managing these problems remain understudied. This study aims to evaluate how clinicians from diverse paediatric disciplines perceive their role in the assessment and management of sleep difficulties in children with ND.

Materials and methods: A cross-sectional survey was conducted across three tertiary children's hospital in Australia. Participants included medical staff (consultants, registrars, fellows and paediatric advanced trainees) and senior nursing staff (clinical nurse consultants, clinical nurses and nurse practitioners) working in paediatric specialties other than sleep medicine. The survey included free text responses, multiple choice questions and case studies. Data analysis included descriptive statistics and thematic analysis of free text responses.

Results: Ninety-five non-sleep specialised clinicians participated. Eighty percent of clinicians reported sleep was a significant problem for this group of children, stating that sleep problems are regularly raised by families in routine check-ups and acute presentations in emergency departments. Most participants (70%) relied on informal methods to assess sleep, with limited use of validated screening tools. Uncertainty around the prescription and use of sleep medications was evident, with clinicians expressing both perceived benefits and discomfort with prescribing due to not always fully understanding the underlying aetiology of a child's sleep difficulties. Eighty nine percent of medical specialists (n=47) reported regularly offering advice and support to caregivers around sleep but also described limited training in this field and low confidence in their skills. Clinicians outlined limited time to address sleep problems as a considerable barrier to care and expressed a desire for national guidelines to provide a more supported and consistent approach to sleep assessment and management in children with ND.

Conclusions: Non-sleep specialist clinicians acknowledge the high prevalence of sleep disorders in children with ND but in general reported feeling ill-equipped to initiate management when encountered in their day-to-day clinical practice. This highlights the need to prioritise further training and education on sleep problems and management in this group of children for non-sleep specialised clinicians. Furthermore, prioritising the development of national guidelines to standardise the assessment and management of sleep problems could improve patient care.

Comparison of Treatment Efficacy Between Rapid Maxillary Expansion and Adenotonsillectomy in Children With Obstructive Sleep Apnea: An RCT

S. Peanchitlertkajorn¹, C. Aksilp², P. Pechongsai¹, P. Intakorn³, C. Chaweewannakorn⁴, S. Boonpratham¹, Y. Satravaha⁴

¹Mahidol University, Orthodontics, Bangkok, Thailand, ²Queen Sirikit National Institute of Child Health, Respiratory Medicine and Critical Care, Bangkok, Thailand, ³Queen Sirikit National Institute of Child Health, Otolaryngology, Bangkok, Thailand, ⁴Mahidol University, Bangkok, Thailand

Introduction: Adenotonsillectomy (AT) is usually recommended as the first-line therapy for pediatric obstructive sleep apnea (POSA). While AT treats soft tissue obstruction, it does not address the underlying skeletal abnormalities, such as maxillary constriction. Despite growing evidence supporting RME as a treatment option for POSA, a significant research gap remains. Therefore, we conducted a randomized controlled trial (RCT) to compare treatment efficacy between RME and AT.

Materials and methods: This study recruited 24 children diagnosed with POSA and presented with concurrent significant adenotonsillar hypertrophy and transverse maxillary deficiency. Participants were randomly assigned to either AT or RME for treatment. All participants underwent Type I PSG at baseline and 6 months post-treatment. Additional assessments included dental and cephalometric analyses, the pediatric sleep questionnaire (PSQ), and the OSA-18 questionnaire. Baseline and endpoint comparisons between the two treatment groups were performed.

Results: There was no significant difference between treatment groups in all parameters at baseline. The comparisons between pre- and post-treatment results showed significant improvements across multiple parameters, including AHI for both AT and RME. There was no significant difference in PSG parameters (AHI, LSAT, MSAT, and REM sleep time) and cure rate between RME and AT. However, PSQ and OSA-18 scores were significantly higher for the RME group.

Conclusions: RME and AT significantly improved sleep-related respiratory parameters in patients with POSA. RME demonstrated comparable efficacy to AT in reducing AHI and improving LAST, MSAT, and REM sleep time. However, AT provided significantly better improvement in clinical symptoms and QOL.

Acknowledgments: This study (Grant No. RGNS 64-169) was supported by the Office of the Permanent Secretary, Ministry of Higher Education, Science, Research and Innovation (OPS MHESI), Thailand Science Research and Innovation (TSRI), and Mahidol University.

Correlation between morning serum melatonin/ferritin levels and sleep problems in Japanese 5-year-old children with ASD

A. Terui¹, M. Saito², A. Kuki³, S. Shimoyama⁴, Y. Sakamoto¹, K. Yoshida¹, A. Osato², K. Nakamura¹

¹Graduate School of Medicine, Hirosaki University, Department of Neuropsychiatry, Aomori, Hirosaki, Japan, ²Graduate School of Health Sciences, Hirosaki University, Department of Clinical Psychological Science, Hirosaki, Aomori, Japan, ³Jichi Medical University Hospital, Postgraduate Clinical Training Center, Tochigi, Shimotsuke, Japan, ⁴Graduate School of Medicine, Hirosaki University, Department of Neurophysiology, Biomedical Research Center, Hirosaki, Aomori, Japan

Introduction: The prevalence of sleep problems is high in children with autism spectrum disorder (ASD). Melatonin and ferritin supplementation are helpful for sleep, but few studies have investigated the relationship between blood melatonin/ferritin levels and sleep problems in children. The objective of this study was to determine the correlation between sleep problems and morning serum melatonin/ferritin levels, and the differences in serum melatonin/ferritin levels between children with ASD and without ASD.

Materials and methods: Four years of data from population-based 5-year-old checkups were referenced. Fifty-five children were divided into the ASD group (N=45) (Who were positive in the first check-up, which is a screening for risk for neurodevelopmental disorders, and diagnosed with ASD by the DSM-5 and classified as "autism" or "autism spectrum" by the ADOS-2 in the second check-up) and the non-ASD group (N=10) (Who were negative in the first check-up, but whose caregivers requested assessments, and who were not diagnosed in the second check-up with ASD, Attention Deficit Hyperactivity Disorder, or Intellectual Disability). Blood samples were collected from fasted children at 8:30 a.m. The Japanese Sleep Questionnaire for Preschoolers (JSQP), a Japanese culture-based sleep

caregiver observation-based questionnaire was used to assess sleep problems. Statistical analysis was the Mann-Whitney U test and partial regression analysis with forced entry method.

Results: In partial regression analysis, in the ASD group, the JSQP V: Insomnia or circadian rhythm disorder was significantly correlated with the serum melatonin level (standardized $\beta=0.501$, $p<0.05$). There were no significant differences in morning serum melatonin levels between the two groups. In children with ASD, high morning serum melatonin levels suggest problems with difficulty getting to sleep and circadian sleep rhythm. Children with high morning serum melatonin levels may have delayed melatonin increase/decrease phase.

In partial regression analysis, in the ASD group, the JSQP IX: sleep habit score was significantly correlated with the serum ferritin level (standardized $\beta=0.559$, $p<0.01$). In children with ASD, the higher the morning serum ferritin levels suggest difficulty getting sleep spontaneously. There may be a direct or indirect association between higher serum ferritin levels and difficulty getting sleep spontaneously in children with ASD. The morning serum ferritin level in the ASD group (23.48 ± 9.14 ng/mL) was significantly higher than that in the non-ASD group (14.84 ± 7.09 ng/mL) ($p<0.05$), but the WHO defines serum ferritin <15 $\mu\text{g/L}$ as iron deficiency, and it should be noted that serum ferritin levels were low in both the ASD and non-ASD groups in this study.

Conclusions: In children with ASD, problems with difficulty getting to sleep and circadian sleep rhythm was correlated with the high serum melatonin level. Appropriate reduction of morning serum melatonin concentration may lead to a decrease in difficulty getting to sleep and sleep rhythm problems (e.g., morning light exposure, nighttime melatonin administration to regulate increase/decrease rhythm, etc.). The possibility that measuring melatonin levels one time in the morning may be meaningful in diagnosing sleep problems and selecting treatment in children.

Correlation of Transcutaneous Carbon Dioxide with Sleep-Disordered Breathing Severity in Indian Children: A Preliminary Observational Study

N. Mohan Rao¹, A. Khemani¹, S. Suresh Shinde¹, A. Sahoo¹, I. Kinimi¹

¹Manipal Hospitals, Old Airport Road, Bangalore, Division of Pediatric Pulmonology and Sleep Medicine, Department of Pediatrics, Bangalore, India

Introduction: Sleep-disordered breathing (SDB) in children can present as obstructive apneas, hypopneas, and chronic alveolar hypoventilation. Transcutaneous carbon dioxide (TcCO_2) monitoring offers a non-invasive, continuous measure of ventilatory function during sleep studies. Despite its growing use, there is limited data from India, particularly in children with underlying neurological and neuromuscular disorders. This study aims to evaluate the correlation between TcCO_2 levels and polysomnographic indices such as apnea-hypopnea index (AHI) and oxygen desaturation index (ODI) in a pediatric Indian cohort.

Materials and methods: This retrospective observational study was conducted at a tertiary pediatric center in India, including all children who underwent polysomnography (PSG) between October 2021 and February 2025. Demographic and clinical data, sleep indices, and hourly TcCO_2 values were extracted from PSG reports. A mean TcCO_2 value was computed for each study. The AHI and ODI were recorded as per standard PSG scoring based on AASM. Spearman correlation was used to assess relationships between TcCO_2 and both AHI and ODI.

Indications for PSG were categorized into clinical subgroups. Neuromuscular disorders accounted for 42% of cases, including spinal muscular atrophy types 1 and 2, Duchenne muscular dystrophy, and congenital myopathies. Central nervous system conditions (e.g., cerebral palsy and leukodystrophies) represented 18%, craniofacial syndromes 9%, and idiopathic SDB or obesity-related indications made up 22%. Remaining studies were performed for other miscellaneous indications.

Results: A total of 156 pediatric patients had transcutaneous CO_2 data available and were included. The median age was 8.3 years (range: 1 month to 18 years). Among these, 118 were diagnostic studies, and 38 were titration studies.

TcCO_2 was measured across multiple time points during each study and averaged to yield a single mean value per patient. Correlation analysis showed that AHI did not significantly correlate with TcCO_2 ($r = 0.06$, $p = 0.4194$). In contrast, a statistically significant positive correlation was observed between ODI and TcCO_2 ($r = 0.16$, $p = 0.0415$), suggesting that children with frequent oxygen desaturations may also have elevated transcutaneous CO_2 levels, indicative of nocturnal hypoventilation.

Conclusions: This is the first dataset reporting TcCO₂ monitoring during pediatric sleep studies from India. While AHI did not correlate with TcCO₂, a weak but significant association with ODI was identified, supporting the potential role of TcCO₂ in identifying ventilatory defects among children with SDB. The predominance of neuromuscular disorders in this cohort underscores the relevance of TcCO₂ in these high-risk populations. Further studies with prospective design and inclusion of follow-up TcCO₂ data post-intervention (such as BIPAP initiation) are warranted to validate TcCO₂ as a tool for longitudinal assessment and therapy response monitoring.

Current status and perspectives of research on postoperative sleep health in pediatric liver transplant recipients

W. Lu^{1,2}

¹School of Nursing, Shanghai Jiao Tong University School of Medicine, Shanghai, China, ²Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China

Introduction: To summarize the current research status of sleep health in children after liver transplantation, to analyze the characteristics, influencing factors, and evaluation methods of postoperative sleep disorders, to explore nursing intervention measures, and to provide proof for optimizing clinical management.

Materials and methods: We searched PubMed, Web of Science, Embase, Cochrane Library, CINAHL, CNKI, and Wan Fang databases to screen for relevant studies on sleep disorders in children after liver transplantation. The included literature includes studies on sleep quality, influencing factors, evaluation tools, and nursing interventions after liver transplantation in children. Ultimately, 18 eligible articles were included for review and analysis.

Results: Research has shown that sleep disorders in children after liver transplantation mainly manifest as difficulty in falling asleep, increased awakenings, and sleep breathing disorders. The main influencing factors include postoperative pain, incomplete liver function recovery, infection, use of immunosuppressants, hospitalization environment, and psychological factors. The commonly used assessment tools currently include the Pittsburgh Sleep Quality Index (PSQI), the Obstructive Sleep Apnea Specific Quality of Life Questionnaire for Children (OSA-18), and the Multi Lead Sleep Recorder (PSG). Nursing intervention measures involve optimizing ward environment, strengthening family and social support, individualized psychological intervention, and adjusting sleep behavior. However, there are still problems in current nursing practice such as insufficient standardization of intervention measures and lack of long-term follow-up data.

Conclusions: Sleep disorders after liver transplantation in children have a significant impact on their growth, development, and quality of life. Systematic evaluation should be strengthened, individualized nursing plans should be optimized, and environmental regulation, psychological support, and behavioral intervention strategies should be comprehensively used to improve postoperative sleep health. Large-scale, multi center research is needed to verify the effectiveness of nursing interventions and promote the clinical translation of personalized and multidimensional nursing models.

Developing A Tailored Behavioural Sleep Program for Children with Neurodisability Through Consumer and Stakeholder consultation

K. Fullwood¹, L. Coles², K. Thorpe², F. Hudson³, K. Waters⁴, M. Vandeleur⁵, J. Chawla¹

¹The University of Queensland, Centre for Children's Health Research, South Brisbane, Australia, ²The University of Queensland, St Lucia, Australia, ³The University of Queensland, South Brisbane, Australia, ⁴Children's Hospital at Westmead, Westmead, Australia, ⁵Royal Children's Hospital, Melbourne, Australia

Introduction: Sleep disorders are highly prevalent in children with neurodisability (ND), affecting up to 75% of children in this group. Sleep disorders often have a multifactorial aetiology with concurrent sleep disordered breathing and non-respiratory sleep difficulties. Difficulty initiating and maintaining sleep, anxiety around nighttime, reduced sleep duration and restless sleep are commonly reported by families of children with ND. In most cases the approach to management involves using behavioural sleep interventions that have been extrapolated from those designed for typically developing children.

Whilst effective for some, interventions do not incorporate the needs of all children with ND conditions. Currently, there are no existing guidelines to support a standardised management approach for children with ND. In this study we develop a tailored behavioural sleep intervention program and describe how this has been guided and informed by the perspectives of consumers and stakeholders.

Materials and methods: A collaborative research framework was utilised to develop a behavioural sleep intervention, co-designed with input from both caregivers of children with ND and multidisciplinary healthcare professionals. A consumer advisory group, comprising 4 parents of children with a ND under the care of a tertiary sleep clinic, participated in three discussions to inform and develop the program's structure and content. Simultaneously, consultations were conducted with key stakeholders comprising of health practitioners.

Results: *Consumer results:*

Consumers highlighted the need for a parent directed intervention that delivered accessible and digestible information. Consumers commented on clear, concise communication in the intervention, acknowledging parental fatigue and lowered capacity. A group-based format was proposed to promote peer validation and shared experiences, with caregivers highlighting its value. Additionally, communication barriers between children and caregivers on essential needs (such as toileting needs, pain) were identified as a critical factor contributing to sleep interferences and requiring specific support for management. As a result, communication tools, practical and easy to follow strategies and tailored advice around extra considerations at bedtime were developed to align with parental priorities.

Stakeholder results:

Stakeholders' input provided discipline-specific recommendations. Speech pathologists recommended the use of social stories and visual aids to accommodate communication difficulties and reviewed developed resources. Physiotherapists emphasised the impact of pain on sleep and provided insights to sleep positioning for children with physical impairments. Occupational therapists addressed the negative impact of stress-inducing activities in the hours prior to sleep, sensory processing considerations, environmental considerations, and the importance of promoting child autonomy in bedtime routines. Sleep specialised nurses discussed monitoring and managing nighttime medical events and the dietary influences on sleep. Respiratory and sleep physicians contributed insights into medical comorbidities and medication use that impact sleep, and strategies for managing sleep regressions.

Conclusions: This research demonstrates the importance of consumer and stakeholder engagement when developing a tailored behavioural sleep intervention for children with ND, highlighting the priorities these groups identified to ensure an effective program that meets the need of the target population. Evaluation of the effectiveness of this intervention is now underway as part of a large, multi-centre Australian randomised controlled trial.

Developmental trajectories of sleep regularity during early childhood are related to somatic complaints and thought problems at school age

Introduction: In recent years, sleep regularity across nights has been recognized as an important dimension of sleep health that is associated with diverse health outcomes. In the first few years of life, children's sleep-wake rhythms become less irregular as their nocturnal sleep lengthens and becomes more consolidated, and their daytime naps decrease in frequency and duration. These developmental changes in sleep regularity vary widely across individuals, and their implications on emotional and behavioural outcomes are not known. This study aimed to examine whether different sleep regularity trajectories during early childhood are associated with emotional and behavioral difficulties at school age.

Materials and methods: Data were drawn from 372 children (48.9% boys) from the Growing Up in Singapore Towards healthy Outcomes (GUSTO) cohort born between November 2009 and May 2011. These children had at least 6 consecutive days of sleep diary data at minimally 2 of 5 time points (6, 18, 24, 36, and 54 months), and data from the parent-reported Child Behavior Checklist (CBCL) at age 7 years. We computed the Sleep Regularity Index (SRI) using the sleep diary data. Latent class models, including group-based trajectory model (GBTM), latent class growth analysis (LCGA), and growth mixture model (GMM), were used to identify distinct SRI trajectories, following the Guidelines for Reporting on Latent Trajectory Studies. CBCL outcomes were compared across trajectory groups using ANCOVA to control for the effects of sex, ethnicity, maternal educational level, parental stress level at age 7 years, and total sleep duration across 24 h averaged across usable time points.

Results: SRI increased during early childhood (mean $\pm$ SD at 6 months: 45.7 ± 13.7 ; 18 months: 69.7 ± 13.4 ; 24 months: 76.0 ± 12.2 ; 36 months: 80.4 ± 10.4 ; 54 months: 83.5 ± 8.7). Compared to other latent class models, LCGA with error variance different for time points but same for classes performed best, and thus, was chosen to fit SRI trajectory. Two trajectory groups – the persistently less regular group ($n = 61$, 16.4%) and the persistently more regular group ($n = 311$, 83.6%) – were distinguished. Compared to the persistently more regular group, the persistently less regular group had more somatic complaints (mean $\pm$ SD: 56.6 ± 5.9 vs 54.4 ± 5.8 , $p = .030$) and thought problems (56.1 ± 5.9 vs 54.1 ± 6.0 , $p = .026$) at 7 years old after adjusting for covariates. The two groups did not differ in aggressive behavior, anxious/depressed problems, attention problems, rule-breaking behavior, social problems, withdrawn/depressed problems, internalizing problems, externalizing problems, and total problems ($p > .181$).

Conclusions: Sleep regularity early in life may contribute to certain domains of children's well-being at school age. Behavioural sleep interventions, such as sleep education, should emphasise the importance of sleep regularity and be targeted at parents with young children to optimise developmental outcomes.

Acknowledgments: The study is supported by the National Research Foundation (NRF) under the Open Fund-Large Collaborative Grant (OF-LCG; MOH-000504) and the Prenatal/Early Childhood Grant (Grant No. H22P0M0001), provided by NRF and the Agency for Science Technology and Research (A*STAR), Singapore.

Diagnostic Accuracy of a Contactless Sleep Mat; “The Sonomat®” compared to Level 1 Polysomnography in Children with Neurodisability – Findings from an Australian Multi-Centre Trial

J. Chawla^{4,3}, A. Collaro^{4,3}, M. Vandeleur^{1,1}, A.-M. Adams^{2,1}, T. Espinoza^{4,3}, L. Marriott^{4,3}, R. Thind^{3,4}, K. Waters^{3,4}

¹Queensland Children's Hospital, Respiratory and Sleep Medicine, Brisbane, Australia, ²The University of Queensland, Centre for Children's Health Research, Brisbane, Australia, ³The Royal Children's Hospital, Respiratory and Sleep Medicine, Melbourne, Australia, ⁴Murdoch Children's Research Institute, Melbourne, Australia, ⁵Children's Hospital at Westmead, Sleep Medicine, Sydney, Australia, ⁶The University of Sydney, Sydney, Australia

Introduction: Sleep disordered breathing (SDB) is highly prevalent in children with neurodisability (ND), with prevalence estimates as high as 80%. In Australia, at present, PSG or polysomnography (level 1

sleep study) remains the standard of care for diagnosis and quantification of SDB in children with ND. However, PSG is often challenging in children with ND due to the intensive monitoring applied. In our previous research, children with ND were >3 times more likely to experience problems tolerating any PSG study leads than neurotypical children. This highlights the importance of developing alternative measures for evaluating SDB in this population. The Sonomat® is a contactless device that non-invasively monitors movement and sound through a mattress placed under the bed sheet. It has been shown to accurately diagnose SDB in neurotypical children and in a small pilot study of children with Trisomy 21. In this study we report findings from a large multi-centre Australian trial of children with ND in which the diagnostic accuracy of the Sonomat® sleep mat system for SDB, was directly compared to PSG.

Materials and methods: This prospective study involved children with ND under the care of one of three Australian tertiary sleep centres. Participants were those aged 2-18yrs, who had been deemed to require a PSG by a sleep physician for assessment of SDB. The Sonomat® was used concurrently to level 1 diagnostic PSG monitoring on the night of the child's scheduled sleep study. Sonomat® and PSG studies were scored independently by a trained scorer and results compared. Agreement for sleep and respiratory parameters was assessed using concordance correlation coefficients (CCC), while detection and classification of SDB were assessed using indicators such as sensitivity, specificity, likelihood ratios and receiver operator characteristic curves.

Results: Preliminary analysis is available from 159 children with ND (88 male, median Age 9.41yrs, IQR 5.36-13.85). 59% of participants had a genetic syndrome, 21% had a diagnosis of ASD and/or ADHD, 12% an underlying neurological condition and 8% with "another" ND condition. The CCC for the apnoea hypopnoea index (AHI) was 0.91 (CI 0.88-0.94) indicating moderate agreement between Sonomat® and PSG. For obstructive apnoea hypopnoea index (OAHI) CCC was 0.63 (CI 0.56-0.71) and for central apnoea hypopnoea index (CAHI) CCC was 0.87 (CI 0.84-0.90). For predicting moderate to severe SDB (AHI³5) the sensitivity, specificity, positive and negative predictive values for the Sonomat® were 61%, 94%, 74% and 89% respectively.

Conclusions: Preliminary findings from this study demonstrate good agreement between AHI derived from the Sonomat® and that derived from PSG. Obstructive hypopnoeas were the least concordant parameter. The high specificity and negative predictive value confirm that the Sonomat® is a suitable tool for screening of SDB in children with ND. This may be a more attractive option for children with ND compared to other current screening tools such as oximetry, due to its contactless application. Further analysis including a larger sample is still underway to determine the diagnostic potential of the Sonomat® an alternative to PSG for children with ND.

Acknowledgments: Funding: National Health and Medical Research Council Australia

Differences in parent-reported sleep patterns in toddlers sleeping in cribs versus beds

M. Lucchini¹, J. Owens², S. Berger³, S. Thakur¹, N. Barnett¹

¹NanitLab, New York, United States, ²Boston Children's Hospital, Harvard Medical School, Division of Neurology, Waltham, United States, ³City University of New York, Department of Psychology, New York, United States

Introduction:

Extensive literature has shown the importance of environmental factors for optimal sleep in early childhood, including levels of noise, light and temperature. Less attention has been devoted to the type of sleep space. We examined the prevalence of crib versus bed sleeping among toddlers and whether it was associated with differences in toddler sleep.

Materials and methods: We recruited 1167 parents of toddlers 18-48 months old (58% female; 24.3±6.2 months; 98% of parents college educated) from the Nanit user base in the United States. Parents completed the BISQ-R, which provided information on sleeping location and sleep patterns. We performed linear regressions with sleep space as a predictor, parent-reported toddler sleep metrics as outcomes, sex as covariate and stratification by the following child's age groups: 18-23 months, 24-30 months, 31-36 months, 37-48 months.

Results:

Crib-sleeping rates decreased with age: 89% of toddlers aged 18–23 months, 71.5% of those aged 24–30 months, 47% of those aged 31–36 months, and 25% of those aged 37–48 months were reported to sleep in a crib. Among those who had made the transition to a bed, 63% did it by 24 months of age. Parents reported safety concerns (44%) and age appropriateness (56%) as the main reasons for transitioning to a bed.

Compared to crib-sleeping, bed-sleeping was significantly associated with later bedtimes at 18-23 months (23.4 ± 5.4 minutes, $p < 0.001$), longer sleep onset latency at 18-23 months (3.8 ± 1.5 minutes, $p = 0.01$) and 24-30 months (7.2 ± 2.0 minutes, $p < 0.001$); more night awakenings at 18-23 months (0.54 ± 0.10 awakenings, $p < 0.001$), 24-30 months (0.37 ± 0.15 awakenings, $p = 0.01$), 31-36 months (0.7 ± 0.3 awakenings, $p = 0.02$); and shorter nighttime sleep duration at 18-23 months (-23.4 ± 9 minutes, $p = 0.01$), 24-30 months (-25.8 ± 9 minutes, $p = 0.004$) and 37-48 months (-33 ± 15.6 minutes, $p = 0.04$). In addition, sleep of the child was reported to be perceived as a problem more for children sleeping in a bed compared to a crib at 18-23 months ($\beta = 0.2 \pm 0.08$, $p = 0.04$), 24-30 months ($\beta = 0.35 \pm 0.1$, $p < 0.001$) and 31-36 months ($\beta = 0.34 \pm 0.17$, $p = 0.05$). Lastly, children who slept in cribs were less likely to require an adult's presence to fall asleep at 18-23 months ($OR = 11.9, CI: 6.3-22.3$), 24-30 months ($OR = 3.7, CI: 1.7-7.8$), and 31-36 months ($OR = 3.7, CI: 1.03-12.9$).

Conclusions: Based on these findings, crib-sleeping was associated with better sleep patterns compared to bed-sleeping, for children particularly up to 36 months of age; however, due to the cross-sectional design of the study, causality cannot be implied. In addition, generalizability of these findings is limited due to a sample representing only parents in the US and from a higher socio-economic background. Thus, these findings offer additional information for parents and healthcare providers regarding recommendations for toddler transition to bed, in addition to those based on height by the AAP. Nonetheless, more research is needed to understand the effect of transitioning from crib to bed, utilizing objective and prospective sleep data.

Disparities in Maternal Knowledge and Practices on Sleep Training: A Cross-Sectional Analysis of Urban VS Rural Areas

K.R.K. Rambey¹, T.D. Gunawan¹, R. Sekartini²

¹Faculty of Medicine, Universitas Indonesia, Central Jakarta, Indonesia, ²Faculty of Medicine, Universitas Indonesia, Department of Child Health, Central Jakarta, Indonesia

Introduction: Quality sleep is crucial for the growth and development of children. Sleep training is an effective method to improve the sleep quality of young children. This study aims to identify the knowledge and practices of mothers regarding sleep training for young children in Indonesia.

Materials and methods: This cross-sectional study involved 417 mothers with young children aged 3-36 months in urban and rural areas of Indonesia. Data on socio-demographic characteristics, maternal knowledge, and maternal practices related to sleep training were collected between March and June 2024. Data were collected using forms and questionnaires completed by the participants. Univariate and bivariate analyses were conducted, and comparative analysis between groups was done using the Chi-square and Fisher's exact test.

Results: The Fisher's exact test indicated that mothers in urban areas, with higher education, working in informal sectors, and having a higher economic status had significantly better knowledge of sleep training ($p < 0.05$). No significant association was found between maternal age, residential area, educational background, occupation, economic status, and maternal behavior related to sleep training. Additionally, no significant association was found between maternal knowledge and behavior related to sleep training.

Conclusions: Conclusion

Mothers living in urban areas with higher education, working in informal sectors, and having a higher economic status have significantly better knowledge of sleep training. However, this knowledge is not significantly associated with their behavior in implementing sleep training practices. Further research is necessary to explore the complexities of the relationship between maternal knowledge and behavior in sleep training.

Effectiveness of a nurse-led community-based infant sleep intervention programme: The Sleep Easy Programme (SleEP), Singapore

N.A.B. Johari¹, J. Ooh¹, D.Y.T. Goh¹

¹National University Hospital, Singapore, Singapore

Introduction: Sleep plays a vital role in infant development, ensuring optimal brain function and overall health. However, infant sleep problems are common, affecting up to 25% of infants who experience difficulties with sleep onset and problematic night wakings. Early intervention is crucial, but effective community-based programmes are limited. This study aimed to describe and explore the implementation and preliminary outcomes of a nurse-led, community-based intervention programme designed to identify and address early sleep disturbances in infants.

Materials and methods: The Sleep Easy Programme (SleEP) is a nurse-led, community-based programme implemented across multiple primary care centres in Singapore, targeting mainly infants aged 0-6 months. It consists of a three-tiered intervention approach. In Tier 1, parents complete a 22-item questionnaire adapted from the Brief Infant Sleep Questionnaire (BISQ) during routine well-baby visits at four different timepoints and receive anticipatory guidance on age-specific sleep management. Infants identified with sleep concerns (questionnaire score > 5) proceed to Tier 2, where they are referred to a National University Hospital sleep nurse for individualized teleconsultation and education on sleep interventions. Tier 3 involves referral to a sleep psychologist for infants with persistent sleep problems requiring further intervention. Descriptive statistics were used to analyse trends in referral rates, and parents' confidence levels in managing their infants' sleep and perception of the usefulness of the teleconsultation.

Results: Between November 2024 and June 2025, a total of 1,375 questionnaires were completed. The scores for 344 (25.0%) of these were greater than 5, suggesting sleep concerns in the infants and necessitating referral to Tier 2 for further intervention.

Among 163 infants screened at multiple timepoints, 32 (19.6%) were referred to Tier 2 at their first screening. During their second screening, 23 (71.9%) of these infants showed improvement and did not meet the referral threshold again, indicating positive sleep behaviour changes following the interventions. For the remaining 131 infants who were not referred initially, only 15 (11.6%) crossed the referral threshold upon subsequent assessments, suggesting sustained sleep health in the majority.

Overall, the Tier 2 referral rate among infants who were screened at multiple timepoints decreased from 19.6% at the first screening to 14.7% at the second, suggesting a trend towards improved sleep patterns following nurse-led education and intervention. 100% of parents reported increased confidence in managing their infants' sleep post-teleconsultation and/ or usefulness of the teleconsultation.

Conclusions: Preliminary findings from SleEP highlight the impact of structured, nurse-delivered sleep education and teleconsultation support in reducing sleep-related concerns within the first 6 months of life. The integration of sleep health into routine nursing assessments reinforces the expanded role of community nurses in early childhood development. Further research with a control group would be needed to establish effectiveness conclusively.

Acknowledgments: My gratitude goes to the NUP nurses for their role in screening and educating the families. I would also like to thank the NUH Evidence-Based Nursing Unit for their guidance as well.

Effect of caregivers' perception on short-term adherence of children with OSAHS treated with CPAP

D. Liu¹

¹Shenzhen Hospital, Southern Medical University, Shenzhen, China

Introduction: to explore the effect of caregivers' perception on short-term adherence of children with OSAHS treated with CPAP.

Materials and methods: 72 children with OSAHS who were treated with CPAP in our department from 2018 to 2020 were retrospectively analyzed. First, according to the difference of caregivers' perception on OSAHS and CPAP treatment, the patients were divided into two groups: group I (n = 27) for CPAP treatment and group II (n = 45) for operation. The related parameters of the two groups were

compared. Then, the children in group II are divided into good adherence group ($n = 18$) and poor adherence group ($n = 27$) according to the standard that the AHI decreased by more than 50% after 2 months, which the above parameters are compared. Finally, the trend of day1 and day 2 among group I, good and poor adherence group are analyzed.

Results: the average time of use(h) of group I is more than group II ($p=0.046$). the AHI of good adherence group in group II is severer than poor adherence group ($p=0.046$). in the trend chart, the day1(h) and day2(h) of group I remain ahead, while day1(h) of good adherence group falls behind the poor adherence's, but exceeds it in the day2(h).

Conclusions: The short-term adherence of CPAP treatment can be improved by sufficient education of caregivers. It is suggested that the education of preoperative CPAP treatment should be carried out in outpatient department for the children with severe OSAHS. In addition, improving the short-term adherence of CPAP treatment in children with severe OSAHS can promote the implementation of long-term adherence, especially in the first two days of CPAP treatment.

Effects of Ambient Temperature and Pollen Exposure on Sleep, Respiratory Events, and Apnea-Specific Pulse Rate Response in Children with Sleep Disordered Breathing

Y. Li^{1,2}, Y. Shi^{1,2}, Y. Ouyang^{1,2}, Y. Zhang^{1,2}, L. Zhang^{1,2}, D. Han^{1,2}

¹Beijing Tongren Hospital, Capital Medical University, Sleep Medical Center, Beijing, China, ²Capital Medical University, Key Laboratory of Otolaryngology Head and Neck Surgery, Ministry of Education, Beijing, China

Introduction: Increased nasal resistance is a recognized risk factor for pediatric sleep-disordered breathing (SDB). Ambient temperature variations and elevated pollen concentrations might modulate upper airway inflammation and obstruction, which may potentially alter sleep architecture, SDB severity and autonomic function in children.

Materials and methods: A retrospective analysis of in-laboratory diagnostic polysomnography (PSG) data in 690 Chinese children (median age 6.0 years [IQR: 4.0-9.0]) was conducted. The children were present with habitual snoring or witnessed apneas between January 2017 and December 2024. Daily ambient temperature records and pollen counts (expressed as pollen grains per cubic meter of air, grains/m³) were obtained from official sources. High pollen days were defined as calendar days with ≥ 100 grains/m³ atmospheric pollen concentration. Δ HR was defined as the difference between the maximum and minimum heart rates within an event-related window around each respiratory event, calculated directly from the continuous heart rate recordings. This metric quantitatively reflects sympathetic activation during sleep apnea events. Associations between pollen concentration, ambient temperature and PSG parameters were analyzed.

Results: Participants exhibited a median age of 6.0 years (interquartile range [IQR]: 4.0–9.0). PSG-confirmed OSA was present in 302 children (43.7%), with a median obstructive apnea-hypopnea index (OAHI) of 3.9 events/hour (IQR 1.8–10.7).

Lower minimum, mean, and maximum ambient temperatures were significantly associated with greater proportion of NREM stage 3 ($p = -0.130$, $p = 0.001$; $p = -0.124$, $p = 0.001$; $p = -0.113$, $p = 0.003$). And ambient temperatures demonstrated positive correlations with proportion of NREM stage 2 ($p = 0.134$, $p < 0.001$; $p = 0.122$, $p = 0.001$; $p = 0.126$, $p = 0.001$). No significant associations were observed between ambient temperatures and OAHI, SpO₂, WASO, sleep latency, or sleep efficiency.

Children monitored on days with higher ambient pollen levels (≥ 100 grains/m³, median 210 [IQR 160–358]) exhibited significantly lower nadir oxygen saturation (91% [88–93] vs. 92% [89–95], $p = 0.014$) and less Δ HR (36.9 [29.3–44.8] vs. 39.4 [31.4–47.3] bpm, $p = 0.029$) compared to those monitored during low-pollen exposure periods. Notably, no significant differences were observed in OAHI, arousal index, sleep latency, or sleep efficiency (all $p > 0.05$), indicating that the observed effects are independent of conventional sleep-disordered breathing metrics.

Conclusions: These findings suggest that elevated environmental pollen concentrations might exert subtle but measurable effects on sleep architecture, nocturnal oxygenation and autonomic regulation. Ambient factors might be considered as effect modifiers when evaluating sleep apnea-induced pathophysiological consequences in children with sleep disordered breathing.

Acknowledgments: This study was Supported by National Key R&D Program of China (2022YFC2504100) and Beijing Natural Science Foundation (L243032)

Emotional and Behavioral Difficulties Partially Mediate Sleep Problems in Children With and Without Chronic Illness: A Cross-Sectional Analysis

E. Altınok¹, E. Baris², M.C. Us², H. Alpay³, P. Boran²

¹Marmara University, Pediatrics, Istanbul, Turkey, ²Marmara University, Social Pediatrics, Istanbul, Turkey, ³Marmara University, Pediatric Nephrology, Istanbul, Turkey

Introduction: Children with chronic illnesses are often thought to be at greater risk for sleep disturbances due to physical and psychological stressors. However, the interplay between chronic disease, emotional/behavioral difficulties, and sleep problems remains unclear. In children with chronic kidney disease (CKD), disease-related factors such as uremia, edema, acidosis, or anemia have been implicated in the pathogenesis of sleep disorders, however, the effect of behavioral problems in the development of sleep disorders is understudied. This study aimed to investigate the interplay between emotional/behavioral difficulties and sleep problems in children with CKD and healthy children.

Materials and methods: This cross-sectional study included 152 children aged 6 to 16 years (11.8 ± 2.8), 49 with CKD and 103 healthy controls. Parents completed the Sleep Disturbance Scale for Children (SDSC) and the Strengths and Difficulties Questionnaire (SDQ). Group comparisons were conducted using t-tests, followed by linear regression and mediation analyses using PROCESS (Model 4, 5,000 bootstrapped samples). All continuous variables were mean-centered for interpretability.

Results: Children with CKD had similar levels of sleep problems as healthy controls (34.9 ± 11.8 vs 35.7 ± 6.9 , $p = 0.63$) based on SDSC scores. However, they showed higher total difficulties score in SDQ compared to healthy controls (9.9 ± 4.0 vs 6.7 ± 4.5 ; $t(150) = -4.15$, $p < 0.001$). Regression analysis revealed that higher total difficulties scores predicted more sleep problems ($\beta = .44$, $p < .001$), while group status independently predicted fewer sleep problems, with children in CKD group showing lower SDSC scores when controlling for SDQ ($\beta = -.22$, $p = 0.007$). An interaction term between group and total difficulties scores was added to test whether the association between SDQ and sleep problems differed by health status. The interaction was not statistically significant ($p = 0.304$), indicating that SDQ difficulties predicted sleep problems similarly in both healthy children and children with CKD. Mediation analysis revealed that total difficulties score partially mediated the relationship between group and sleep problems, with a significant indirect effect ($B = 2.95$, 95% CI [1.33, 5.75]). The direct effect of group status on sleep remained significant ($B = -3.67$, $p = 0.011$), indicating partial mediation, meaning that children with CKD have fewer sleep problems, even after adjusting for SDQ. A reverse mediation model testing sleep as mediator between group and SDQ was not significant (indirect effect = -0.17 , 95% CI [-1.22, 0.63]).

Conclusions: Despite comparable levels of sleep disturbance, children with CKD showed more emotional and behavioral difficulties, which partially mediated their sleep outcomes. Structured routines and close parental monitoring, necessary for disease management in CKD, may be improving sleep in children with CKD. Besides, emotional/behavioral difficulties may be more apparent than sleep problems, which might not always translate into measurable sleep disturbance, resulting in underreporting by parents. These findings suggest that while chronic illness may not directly worsen sleep, its emotional burden plays a critical role, warranting integrated psychosocial and sleep-focused care. The emotional/behavioral difficulties are important predictors of sleep disturbances both in healthy children and those with CKD, underscoring the importance of psychosocial health in evaluating sleep health across pediatric populations.

Enhancing Parental Knowledge of Sleep through Bibliotherapy: A path to improve pre-schoolers sleep

C.C. Tsang¹, N.Y. Chan¹, S. Chen¹, C.C. Chan², M.C.A.M. Li², X.S. Li³, Y.K. Wing¹

¹The Chinese University of Hong Kong, Psychiatry, Hong Kong, Hong Kong, SAR of China, ²The Chinese University of Hong Kong, Paediatrics, Hong Kong, Hong Kong, SAR of China, ³The University of Hong Kong, Psychology, Hong Kong, Hong Kong, SAR of China

Introduction: Healthy and adequate sleep is essential for neurodevelopment, especially during early childhood at preschool level. Children's sleep health relies on parents' understanding of their developmental sleep needs. Therefore, bibliotherapy, which is typically delivered by the parents through storytelling and book reading for younger children, may serve as a promising intervention to

improve sleep in children. However, there is a lack of sufficient evidence to support the effectiveness of bibliotherapy in improving parent's sleep knowledge and children's sleep practice.

Materials and methods: This was a pilot randomized controlled trial conducted in pre-schoolers with short sleep duration and their parents. Eligible participants were randomly assigned to 4 weeks bedtime bibliotherapy intervention group or wait-list control group at 1:1 ratio. Assessments for parents' sleep knowledge, children's sleep hygiene practices and parent-child relationship were conducted at baseline, post-intervention and 2-month follow-ups.

Results: A total of 30 pre-school aged children and their parents were enrolled in this pilot study. Three parent-child pairs dropped out after the randomization, leaving 27 (intervention group: $n = 13$; control group: $n = 14$; 46% girls; mean age $\pm$ SD: 3.6 ± 0.8 years) included in the final analysis. Most the parents who involved in the study were mothers ($n = 26$, 96%) At post-intervention, the intervention group had a nonsignificant increase in parents' sleep knowledge compared to baseline ($4.7 [-0.1 \text{ to } 10.3]$, $p = 0.10$), albeit there was no significant interaction effect between the two groups across the two follow-up timepoints after the intervention ($p = 0.33$). Similarly, a nonsignificant reduction in children's maladaptive sleep hygiene practices were also observed in the intervention group at post-intervention relative to baseline ($-3.2 [-7.8 \text{ to } 1.5]$, $p = 0.18$) but not in the control groups. In addition, a marginally significant improvement in the parent-children relationship was noticed in the intervention at both post-intervention ($1.7 [-0.2 \text{ to } 3.7]$, $p = 0.08$) and 2-month follow-ups ($1.9 [-0.1 \text{ to } 3.9]$, $p = 0.057$) compared to baseline, while the control group have similar scores over all the assessment timepoints.

Conclusions: In this pilot study, bibliotherapy intervention is a feasible intervention tool that is welcomed by the participating parents according to the feedback from parents after the intervention. The pilot findings found non-significant increase in parents' sleep knowledge and apparent improvement in the parent-children relationship in the intervention group. Further study with larger scale RCT with adequate statistical power is needed to determine whether the use of bibliotherapy will be able to enhance parent's sleep knowledge, children's sleep practice and parent-child relationship.

Acknowledgments: This project was supported by the Health and Medical Research Fund (19202401) of the Food and Health Bureau of Hong Kong.

Establishing Consensus Guidelines for the Assessment and Management of Sleep-Disordered Breathing and Behavioural Sleep Disturbance in Children with Neurodisability: A Delphi Study

F. Hudson^{1,2}, G. Langdon¹, A. Bernard³, M. Vandeleur⁴, K. Waters^{5,6}, J. Chawla^{1,2}

¹Child Health Research Centre, University of Queensland, Faculty of Medicine, Brisbane, Australia,

²Children's Hospital Queensland, Respiratory and Sleep Medicine, South Brisbane, Australia,

³University of Queensland, Data Science Collaborative Research Platform, Research and Innovation, Brisbane, Australia, ⁴Royal Children's Hospital, Melbourne, Australia, ⁵Children's Hospital Westmead, Sydney, Australia, ⁶University of Sydney, Faculty of Medicine and Health, Sydney, Australia

Introduction: Children with neurodisability (ND) exhibit disproportionately higher rates of sleep-disordered breathing (SDB) and behavioural sleep problems, compared to their peers. Sleep disorders have a profound developmental impact on the child, affecting physical and psychological wellbeing. To date there are no evidence-based guidelines, specifically developed for the management of sleep problems in children with neurodisability. This study describes the preliminary findings from a modified Delphi process underway in Australia and New Zealand, aiming to develop consensus recommendations to inform management of sleep disorders in children with Neurodisability.

Materials and methods: A modified e-Delphi methodology was employed to achieve expert consensus on the management of sleep problems in children with neurodisability. Accredited paediatric sleep medicine specialists in Australia and New Zealand, were invited to participate in 2 iterative rounds of online surveys and a virtual round table discussion with key stakeholders, including consumers, other specialists caring for children with ND, psychologists, sleep nurses and pharmacists. Questions in round 1 included those designed to understand the current interventions and management practices used in routine practice, including pharmacotherapy, medical and behavioural sleep interventions. Consensus was defined as $\geq 80\%$ agreement on items.

Results: Thirty participants completed round 1 of the Delphi survey, the majority of whom were senior medical staff (87% with 50% >15yrs experience) working in public hospitals (67%) with on-site sleep laboratories (97%). While 73% of consultants felt confident managing sleep problems in children with

neurodisability (ND), only a third agreed they had received sufficient training in this area. Clinicians estimated that over half of children with ND experience sleep problems, with many estimating that 25–75% of their sleep clinic population had a neurodisability. Almost half of the participating clinicians expressed a desire for more evidence-based resources, with a third acknowledging the gap in this area. Assessment of sleep varied, with 80% routinely evaluating a broad range of parent concerns, including disordered breathing, behavioural sleep problems, impact on daytime functioning and family wellbeing. 80% of clinicians reported “rarely” using validated sleep screening measures in their assessment.

For sleep-disordered breathing (SDB), Level 1 polysomnography was the most common investigation (93%), with home oximetry (80%) and parent-recorded videos (50%) also used. Half of the clinicians surveyed, reported modifying their standard approach for managing SBD when caring for children with ND.

For non-respiratory sleep problems, 50% reported using modified behavioural sleep interventions, and 40% initiated medications earlier in children with ND when compared to NT children. Other tools used included paper sleep diaries, videos and actigraphy.

Analysis of subsequent rounds of the Delphi process are underway.

Conclusions: Using a Delphi approach provides a methodologically robust pathway for developing the 1st consensus statement for the management of sleep problems in children with ND. Preliminary data from this study suggests that many specialists modify their standard approach to sleep disorders for children with ND and practices vary. Subsequent rounds of this study will determine final recommendations for optimal management of sleep disorders in children with ND, aiming to improve outcomes for this population by modifying sleep.

Acknowledgments: Moya Vandeleur, Karen Waters, Jasneek Chawla

Estimated prevalence of sleep problems in 3-year-old children and the relationship between sleep problems and development - Report from a population-based study of 3-year-old health check-ups

M. Saito¹, A. Terui¹, K. Yoshida^{1,2}, A. Osato¹, Y. Sakamoto¹, I. Mori³, M. Taniike³

¹Hirosaki University, Hirosaki, Japan, ²Seikokai Hospital, Hirosaki, Japan, ³Osaka University, Suita, Japan

Introduction: Children's sleep problems affect cognitive ability, psychosocial health, obesity, and problem behaviors. The prevalence of sleep problems in young children has been reported to be high, but the prevalence by age has not been clarified. In 2024, we reported a prevalence of preschool sleep problems of 18% in a population-based study at a 5-year-old health check-up, but it is expected that children's sleep problems begin at an earlier age. This study aimed to estimate the prevalence of sleep problems in 3-year-old children and to clarify the relationship between sleep problems and development, with the aim of realizing sleep intervention at 3-year-old health check-ups.

Materials and methods: The study subjects were 1,300 children who participated in a 3-year-old health checkup in a medium-sized city in northern Japan from December 2023 to March 2025, and 1,268 children (97.5%) (644 boys and 622 girls, mean age 41.6 months) who agreed to participate in a contracted developmental study were included. Sleep problems were evaluated using the Japan Sleep Questionnaire for Preschoolers (JSQP), and a total score of 86 or more was defined as having a sleep problem. 1) Sociality was evaluated using the 14-item Screening for Social Development (SSD14), 2) stuttering, tics, reading, writing, and motor development was evaluated using the Check List of Obscure Disabilities in Preschoolers 3-year-old version (CLASP-3y), and 3) behavior was evaluated using the Child Behavior Check List (CBCL). Statistical analysis was performed using t-tests, multiple regression analysis, and partial regression analysis with forced entry method to identify items with strong associations. This study was approved by the Ethics Committee of the Graduate School of Health Sciences, Hirosaki University.

Results: The proportion of subjects with sleep problems (JSQP $\geq$ 86) was 24.8%. Multiple regression analysis showed a significant correlation between the JSQP total score and the sub-items of SSD14 ($R^2 = .201$, $p < .001$), CLASP-3y ($R^2 = .204$, $p < .001$), and CBCL ($R^2 = .429$, $p < .001$). Partial correlation analysis showed that 1) in SSD14, the JSQP total score was significantly correlated with peer relationships, hyperactivity, social awareness, social communication, social motivation, and repetitive/restrictive behavior. 2) in CLASP-3y, the JSQP total score was significantly correlated with

stuttering and simple vocal tics. In terms of reading and writing skills, there was a significant correlation between phonological representation/phonological discrimination and auditory discrimination, and in terms of motor skills, there was a significant correlation between motor execution, accuracy, and posture maintenance. 3) In the CBCL, there was a significant correlation between the JSQP total score and somatic complaints, withdrawal, sleep problems, attention problems, and aggressive behavior.

Conclusions: The estimated prevalence of sleep disorders in 3-year-olds (24.8%) was slightly higher than the prevalence in 5-year-olds (18%). It was also suggested that sleep problems may co-occur with developmental and behavioral problems. Cohort studies in other countries have reported that sleep problems in infancy are related to the emergence of later mental disorders and behavioral characteristics. It is desirable to actively investigate sleep in infant health checkups and aim to improve sleep problems as early as possible.

Exploring the Impact of Technology Use in Children with and without Neurodisabilities. Findings from a Cross-Sectional Study

I. Shin¹, G. Langdon¹, A. Bernard², M. Vandeleur³, K. Waters⁴, J. Chawla^{1,5}

¹The University of Queensland, Child Health Research Centre, Brisbane, Australia, ²The University of Queensland, UQ Data Science Collaborative Research Platform, Brisbane, Australia, ³Royal Children's Hospital, Melbourne, Australia, ⁴Children's Hospital at Westmead, Sydney, Australia, ⁵Queensland Children's Hospital, Brisbane, Australia

Introduction: In clinical practice, parents of children with neurodisabilities (ND) sometimes report that technology use helps their children settle down before bedtime, despite the general advice to avoid screen use prior to bed. There is limited research focusing on bedtime technology use and its impact on sleep in children with ND. This cross-sectional comparative study examined sleep patterns and technology use in children with ND by comparing them to a cohort of neurotypical (NT) peers to inform tailored sleep management guidance for children with ND.

Materials and methods: The primary prospective study was conducted across three Australian paediatric hospital sites where parents or caregivers of children aged 2–18 years with a diagnosed ND condition and referred for diagnostic polysomnography (PSG) were recruited. A smaller group of NT children undergoing a clinical PSG study were recruited from one clinical site for comparison. Caregivers completed a study-designed questionnaire which examined device type, frequency of use, duration, reported helpfulness and data regarding any sleep problems in the participant. Comparison of groups was performed using chi-square tests. Qualitative thematic analysis of caregiver free text responses was also undertaken.

Results: There were 192 participants in the ND group (53.1% male, mean age 10.1) and 35 participants in the NT group (48.6% male, mean age 10.1). Frequency of “everyday” device use was generally high in both groups but was 10% higher in the ND group. Older children with ND showed a statistically significant higher frequency of device use than younger children ($p=0.002$). Caregiver report of sleep symptoms in their child was higher amongst participants in the ND group compared to those in the NT group (53% and 29% respectively). Amongst participants in the ND group, 18% reported sleep symptoms when device use was low (“never/little”) whereas 42% reported sleep symptoms when device use was described as high (“more than 1-2 days per week”). 40% of caregivers in the ND group reported technology use at bedtime to be “somewhat” helpful compared to 14% of participants in the NT group. Differences between device use within different ND condition subtypes as well as qualitative analysis of free text responses from caregivers were also evaluated in this study.

Conclusions: There was a high prevalence of technology use at bedtime in all children, with those with ND reported to have overall higher use. This study strongly suggests an association between bedtime technology use and a higher report of sleep symptoms in children with ND. Despite this finding, just under half of the caregivers in the ND group indicated some perceived benefit of technology use at bedtime for their child, suggesting that the relationship between sleep and screen time is complex in this population. Our findings highlight the importance of not only providing guidance to families about the potential negative impact of technology use around bedtime for their child's sleep but also a need to consider modified advice for children with ND, to balance potential benefits from technology use that may be key to assisting parents with implementing day to day routines

Feasibility and clinical utility of daytime polysomnography performed in NICU to diagnose sleep disordered breathing in infants

D. Goe^{1,2,3}, A. Wilson^{3,4}, C. Lappin³, R. Plavsic³, T. Verstandig³, S. Rao^{1,4}, K. Francis¹, C. Dunstan¹, G. Baynam^{5,6,4}, A. O'Donnell^{3,4}, K. Waters⁷

¹Perth Children's Hospital, Neonatal Intensive Care Unit, Nedlands, Australia, ²University of Western Australia, Human sciences, Perth, Australia, ³Perth Children's Hospital, Respiratory and Sleep, Nedlands, Australia, ⁴University of Western Australia, Perth, Australia, ⁵Curtin University, Perth, Australia, ⁶Perth Children's Hospital, Rare care centre, Nedlands, Australia, ⁷The Children's Hospital Westmead, Respiratory and Sleep, Sydney, Australia

Introduction: Sleep disordered breathing (SDB) is widely prevalent in infants. Early diagnosis and treatment of SDB improves feeding, growth, and neurodevelopment in affected infants. Polysomnography (PSG) is vital for early diagnosis and treatment of SDB in infants; but often difficult to obtain. Our aim was to assess the feasibility and clinical utility of daytime PSGs conducted in neonatal intensive care unit (NICU) to diagnose SDB when compared with the existing practice of overnight PSGs performed in sleep laboratory in infants <3 months age.

Materials and methods: We commenced a pilot project of conducting daytime PSGs in our centre in May 2021. PSG results were collated prospectively for infants less <3 months of age, between 1st May 2021 and 31st May 2024. Comparison was made between results for daytime PSG in the NICU and overnight PSG in the sleep laboratory. Primary outcomes were successfully completed PSGs (feasibility) and clinical utility. The primary outcome to assess clinical utility was percent sleep efficiency. The secondary outcomes were percent REM sleep, REM sleep latency, sleep latency, and other indices (per hour of sleep) spontaneous arousals, Obstructive apnea hypopnea index (OAHI) and Apnea hypopnea index (AHI).

Results: Of 60 PSGs, 28 were daytime and 32 were overnight. Daytimes studies had younger age (median 18 vs 55 days, $p < 0.001$), and shorter median recording time (8.2 vs 10.4 hrs, $p < 0.001$). Feasibility showed that all daytime PSGs were successful. For clinical utility, after adjusting for age (at PSG) and total recording time, percent sleep efficiency was equivalent in the two groups (95% CI -12.4, 5.7; $p 0.456$). For secondary outcomes, daytime PSGs had a higher % REM sleep by 9.9% points (95% CI 1.1, 18.8; $p 0.028$) compared to overnight PSG. Parameters that were not different included: frequency of spontaneous arousals, REM latency, sleep latency, apnoea-hypopnea index, and obstructive apnoea-hypopnea index. A decline in requests for overnight PSGs and corresponding increase in daytime PSGs over the course of the study was observed.

Conclusions: This is the first prospective study to report that standard PSGs can be performed during the daytime in NICU for infants <3 month of age and can provide reliable results. Despite being performed outside the sleep laboratory, daytime PSGs were universally successful (feasible) and captured similar percent sleep efficiency (clinically useful) with 9.9% higher percent of REM sleep. Other sleep and respiratory parameters comparable to studies of infants conducted overnight. Notably, we were able to perform daytime PSGs at a younger age indicating reduced wait times. Daytime PSGs model may facilitate earlier access to PSGs, improve patient safety by bringing the diagnostic service to the bedside of the infant in NICU and expanded resource capacity with potential for cost-savings.

Acknowledgments: We would like to acknowledge Perth Children's Hospital Foundation for funding the equipment and implementation of the daytime bedside polysomnography at Perth Children's Hospital.

We thank all the medical, nursing, and allied health staff of the Neonatal Intensive Care Unit, Respiratory and Sleep Department, and Complex Airway Team of Perth Children's Hospital for collaborative support.

Impact of Adolescent Sleep Restriction on Self-Report Hunger and Macronutrient Intake at the First Meal of the Day

L. Stager¹, A. Fobian²

¹Brown University, Psychiatry and Human Behavior, Providence, United States, ²University of Alabama at Birmingham, Psychiatry, Birmingham, United States

Introduction: Pediatric obesity rates are rising and are associated with both negative physical and psychosocial health outcomes. Poor sleep is tied to pediatric obesity and changes in composite 24-hour macronutrient consumption. However, the impact of poor sleep on macronutrient intake at specific timepoints across subsequent day is largely unknown. This study evaluated the roles of sleep duration, sex, and BMI in predicting adolescent macronutrient consumption during the first meal of the day and time-matched self-reported hunger variables. This information will support targeted behavioral intervention at key timepoints in a 24-hour period.

Materials and methods: Sleep (actigraphy), macronutrient consumption (24-hour food logs), and BMI were assessed at baseline. Adolescents (N=61) completed two sleep conditions in a randomized order, each preceded by a washout period of 3 nights of adequate sleep (~9 hours of sleep per night) and followed by a laboratory visit. The conditions included 1) restricted sleep (~4 hours of sleep for 1 night) and 2) adequate sleep (~9 hours of sleep for 1 night). Participants tracked food consumption via 24-hour self-report food logs before each follow-up appointment and began fasting 12 hours prior to each follow-up appointment. At their follow-up appointments, participants reported hunger, fullness, and ability and desire to eat, and were provided with a self-serve buffet for their first meal of the day. Buffet items were weighed before and after the meal to determine the amount consumed and macronutrient consumption was determined via the Nutrition Data System for Research.

Results: Restricted sleep ($M_{\text{Duration}}=4$ hours 12 minutes, $SD_{\text{Duration}}=50.7$ minutes) was associated with reduced consumption of calories, fat, protein, and saturated fatty acids ($ps<.05$; $\eta_p^2=.08-.12$). BMI and sex did not significantly influence this association. However, restricted sleep was associated with self-reported reductions in hunger and desire to eat among female adolescents ($M_{\text{Duration}}=8$ hours 54 minutes, $SD_{\text{Duration}}=58.0$ minutes) and increased self-reported hunger in male adolescents ($ps<.05$; $\eta_p^2=.09-.15$).

Conclusions: Restricted sleep is associated with reduced macronutrient intake at adolescent's first meal of the day. Given previous research documenting overall increases in adolescent 24-hour macronutrient consumption following sleep restriction, it is possible that decreased morning consumption leads to increased consumption and binge like behaviors later in the day. Targeting key moments, such as breakfast, in timed behavioral interventions may optimize patient outcomes.

Improving Children's Sleep: The Importance of Parental Sleep Beliefs and Practices

C. Turpin¹, R. Pétrin¹, É. Touchette², A. Bérubé¹, M.-H. Pennestri³, G. Forest¹

¹Université du Québec en Outaouais (UQO), Psychoéducation et psychologie, Gatineau, Canada,

²Université du Québec à Trois-Rivières (UQTR), Trois-Rivières, Canada, ³Université McGill, Montréal, Canada

Introduction: Improving children's sleep is crucial for their development, as sleep difficulties in early childhood can have lasting effects on both children and their families. Parental sleep beliefs and practices play a key role in shaping children's sleep behaviors, yet their distinct contributions to sleep remain unclear. This study examined whether improvement in parental sleep-related beliefs and practices following a short sleep intervention predicted improvements in children's sleep.

Materials and methods: 74 families, including one or both parents and their 3 to 5-year-old child, participated in a two-hour group intervention focused on improving children's sleep. During the intervention, parents received guidance on beliefs and practices related to child sleep while children engaged in sleep-related educational activities in a separate room. A follow-up session took place two weeks later with the parents, during which they could receive additional support. Parents completed the Children's Sleep Habits Questionnaire (CSHQ), the Parent-Child Sleep Interaction Scale (PSIS), and the Maternal Cognitions about Infant Sleep Questionnaire (MCISQ) before the intervention (T1) and approximately two months later (T2). Three paired sample t-tests were conducted to assess changes, comparing T1 and T2 scores. Additionally, hierarchical linear regression was performed to examine whether changes in parental practices (PSIS) and sleep-related cognitions (MCISQ) predicted changes in children's sleep difficulties (CSHQ scores) at T2. In the first model, T1 scores for CSHQ, PSIS, and MCISQ were entered, and in the second model, T2 scores for PSIS and MCISQ were added.

Results: Results showed significant reduction after two months in child sleep difficulties ($M = 54.08 \pm 8.01$ vs $M = 48.09 \pm 7.46$, $t(73) = 7.68$, $p < .001$). Results also showed significant improvement in parental practices ($M = 12.64 \pm 5.53$ vs $M = 9.12 \pm 5.48$, $t(73) = 6.31$, $p < .001$); and parental beliefs about children's sleep ($M = 29.65 \pm 6.80$ vs $M = 25.85 \pm 6.20$, $t(73) = 6.07$, $p < .001$). Results from the

hierarchical regression analysis showed that the first model was significant ($F(3, 70) = 15.03, p < .001$) and explained 36.6% of the variance in T2 child's sleep difficulties. T1 child's sleep difficulties was the only significant predictor of T2 child's sleep quality ($B = .58, p < .001$). When T2 parental practices and parental beliefs about children's sleep were added to the model, they accounted for an additional 5.6% of the variance. This change in R^2 was significant ($F(2, 68) = 4.39, p = .016$), with the final model explaining 42.2% of the variance. T1 child's sleep difficulties ($B = .63, p < .001$) and T2 parental practices ($B = .46, p = .005$) were significant predictors of child sleep difficulties at T2.

Conclusions: These findings suggest that enhancing parental practices seems to be essential for improving children's sleep. However, as parental beliefs often shape these practices, future research employing advanced analyses could uncover a more nuanced relationship between parental sleep beliefs, parenting practices, and children's sleep.

Acknowledgments: This project was funded by the Social Sciences and Humanities Research Council of Canada (SSHRC).

Infant sleep patterns are related to specific temperamental traits

M. Breda¹, M. Lucchini², N. Barnett², V. Mammarella¹, O. Bruni¹

¹Sapienza University, Rome, Italy, ²Nanit Lab, New York, United States

Introduction:

Adequate sleep is crucial for children's physical health, cognitive development, and emotional regulation. Previous studies have shown that a difficult temperament is related to more sleep awakenings and sleep problems in general. This study aims to explore the intricate relationship between sleep patterns and temperament in a large sample of infants.

Materials and methods:

Caregivers of 623 infants aged 9-13 mos ($M=10.3 \text{ mos} \pm 1.1$, 52.0% females) were recruited among users of Nanit baby-monitor in the United States and reported on their baby's temperament by completing the Infant Behavior Questionnaire (IBQ-R). The IBQ-R assesses three scales: 1) Positive Affectivity/Surgency (PAS): Relates to positive affect, approach tendencies, smiling, laughter, activity, and enthusiasm, similar to adult extroversion. 2) Negative Emotionality (NEG): Associated with distress to limitations, fear, sadness, and difficult recovery from arousal, comparable to adult Neuroticism. 3) Orienting/Regulatory Capacity (ORC): Encompasses attention-based regulatory skills and enjoyment of calm activities. Objective infant sleep metrics (night sleep time duration, number of night wakings, sleep efficiency, bedtime, wake up time, time awake at night and parent interventions) were obtained from the Nanit camera (1 week of data averaged). A cluster analysis was conducted to group infants based on sleep metrics. The between-cluster comparison for IBQ-R temperament scores was performed using one-way analysis of variance (ANOVA). Post hoc tests were performed.

Results: Three reproducible and stable sleep groups were identified: Long Sleepers (LS, n.338), Interrupted Sleepers (IS, n.130) and Short Sleepers (SS, n.155). All sleep metrics were statistically significantly different in the three groups: LS were characterized by long nighttime sleep duration, SS presented later bedtime and earlier wake up time, IS presented more night wakings. When comparing IBQ-R scoring between the three groups, IS and SS showed higher scores in the NEG scale than LS, with a statistically significant difference (respectively $0.36 \pm 0.09, p < .001$ and $0.39 \pm 0.09, p < .001$), thus showing greater sadness and fear, lower tolerance to limitations and more difficulty recovering from distress.

Conclusions:

Our findings support previous research highlighting that poor sleep in infancy is associated with negative affectivity. Ensuring adequate sleep may serve as a preventive measure against temperament-related issues, contributing to the overall health.

Insufficient Weekday Sleep Predicts Emotional Distress in Adolescents: A Study of Sleep Patterns in Taiwan

S.-H. Huang¹, Y.-W. Jan²

¹Department of Psychiatry, Taipei City Psychiatric Center, Taipei City Hospital, Taipei, Taiwan,

²Department of psychology, Chung Yuan Christian University, Taoyuan, Taiwan

Introduction: Adolescents experience dramatic shifts in sleep chronotype during puberty, often resulting in chronic sleep deprivation during school weeks due to early school start times. This insufficient sleep has been linked to a range of biopsychosocial impairments. Previous research has identified sleep disturbances as a significant risk factor for suicidal behavior among adolescents. Given the rising suicide rates among Taiwanese adolescents in recent years, this study aimed to investigate the extent of sleep deprivation in this population and to further examine the relationship between weekday sleep duration, emotional distress, and executive function. The findings may inform future interventions targeting severe psychological distress and suicidal ideation.

Materials and methods: A total of 548 adolescents aged 13–18 participated in the study. Participants completed a battery of assessments, including: (1) a demographic, sleep, and lifestyle questionnaire; (2) the Chinese version of the Beck Youth Inventories – Second Edition (for junior high school students), the Beck Depression Inventory-II and the Beck Anxiety Inventory (for high school students); and (3) the computerized Wisconsin Card Sorting Test (WCST) to assess executive function. Data were analyzed using SPSS version 29.0.

Results: The average weekday sleep duration among Taiwanese adolescents was 6.63 ± 1.1 hours, compared to 8.85 ± 1.5 hours on weekends. Notably, 89.6% of adolescents reported sleeping less than 8 hours on weekdays, indicating widespread weekday sleep insufficiency and significant discrepancies between weekday and weekend sleep patterns. Correlational analyses revealed that shorter weekday sleep duration was significantly associated with higher anxiety ($r = -.138$, $p = .001$) and depression levels ($r = -.226$, $p < .001$). However, no significant relationships were found between weekday sleep duration and executive functioning as measured by WCST indicators. Regression analyses further showed that shorter weekday sleep duration significantly predicted higher levels of anxiety ($\beta = -.138$) and depression ($\beta = -.226$).

Conclusions: This study provides updated data on adolescent sleep patterns in Taiwan, revealing a high prevalence of weekday sleep deprivation and a tendency toward weekend "catch-up sleep." Importantly, insufficient weekday sleep was found to be a significant predictor of emotional distress among adolescents. These findings highlight the mismatch between adolescents' biological sleep needs and the structural demands of school schedules, which may chronically impair emotional regulation. Notably, even with the implementation of delayed school start times in some schools, insufficient sleep remains prevalent among adolescents. This underscores the importance of comprehensive sleep hygiene education and targeted psychological interventions to effectively promote mental well-being and address suicide-related concerns in this population.

Integrated metagenomic and metabolomic analysis reveal distinctive gut microbiota-derived metabolites in pediatric obstructive sleep apnea

X. Zhang¹, H. Xu¹, S. Yin¹

¹Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Department of Otolaryngology Head and Neck Surgery, Shanghai, China

Introduction: Obstructive sleep apnea (OSA) is one of the common sleep disordered breathing diseases which could affect growth and development in children. However, the unique molecular signatures and multi-omics profiles in pediatric OSA remain unclear. Here, we aimed to characterize the signatures of gut microbiome, plasma and fecal metabolites in pediatric OSA.

Materials and methods: We recruited 51 patients with pediatric OSA and 30 controls for conducting an integrated analysis by shotgun fecal metagenomics, plasma metabolomics and fecal metabolomics.

Results: We identified 37 bacterial species were significantly different between pediatric OSA and controls, as evidenced by increased abundance of *Bacteroides_nordii* and decreased abundance of *Bifidobacterium_bifidum*, and *Veillonella_dispar* in pediatric OSA group. Besides, we identified that short-

chain fatty acids (SCFA) in plasma could significantly discriminate pediatric OSA from controls. Notably, co-occurrence network analysis revealed that *Bifidobacterium_bifidum* and *Veillonella_dispar* had strongly positive relationships with SCFA, suggesting that disturbed gut microbiome might mediate depletion in SCFA in pediatric OSA. Furthermore, we identified a combinatorial marker panel that could distinguish pediatric OSA from controls with high accuracy.

Conclusions: Altered microbiome-metabolomics interactions help to explain the pathophysiologic process induced by pediatric OSA. Additionally, this study offers a unique SCFA-related signatures in pediatric OSA which will open new potential avenues for preventive and therapeutic approaches for impairment induced by pediatric OSA.

Inter-Scorer Concordance and Method Agreement in Paediatric Sonomat® Scoring for Sleep Disordered Breathing

A.-M. Adams^{1,2,3}, A. Collaro^{4,5}, T. Espinoza^{4,5}, L. Marriott^{4,5}, R. Thind^{6,7}, K. Waters^{6,7}, J. Chawla^{4,5}, M. Vandeleur^{1,2}

¹The Royal Children's Hospital, Respiratory and Sleep Medicine, Melbourne, Australia, ²Murdoch Childrens Research Institute, Melbourne, Australia, ³University of Melbourne, Pediatrics, Melbourne, Australia, ⁴Queensland Children's Hospital, Respiratory and Sleep Medicine, Brisbane, Australia, ⁵The University of Queensland, Centre for Children's Health Research, Brisbane, Australia, ⁶Children's Hospital at Westmead, Sleep Medicine, Sydney, Australia, ⁷The University of Sydney, Sydney, Australia

Introduction: The Sonomat® is a contactless sleep monitoring device comprising a mattress overlay embedded with polyvinylidene fluoride (PVDF) sensors and microphones. It records thoracoabdominal movement and acoustic breath sounds, providing indirect surrogates for respiratory effort and airflow. While validation studies have shown promising agreement with PSG in detecting sleep disordered breathing (SDB), the absence of standardised paediatric scoring rules has limited uptake. Recently developed Sonomat-specific paediatric scoring criteria (unpublished) aim to address this gap. This study evaluated inter-scorer concordance using these new rules and assessed agreement between Sonomat and PSG across key respiratory event indices.

Materials and methods: Five trained sleep scientists independently scored 10 sonomat studies using the Sonomat Replay software (© Sonomedical, Balmain, Australia) and following formalised paediatric scoring rules. Scoring outputs included standard respiratory indices: Apnoea Index (AI), Hypopnoea Index (HI), Apnoea-Hypopnoea Index (AHI), Central Event Index (CEI), and Obstructive Event Index (OEI). Each study also had gold-standard Sonomat scoring from a reference expert (AC). Intraclass correlation coefficients (ICC[2,1]) were calculated to quantify inter-scorer reliability for each Sonomat index. Bland-Altman and mean difference analyses were performed to compare Sonomat scores with paired PSG data.

Results: Inter-scorer agreement using the newly developed paediatric Sonomat scoring rules was highest for AI (ICC=0.95), CEI (ICC=0.90), and AHI (ICC=0.85), reflecting excellent reliability between trained scorers. Agreement was lower for OEI (ICC=0.57) and poor for HI (ICC=0.31), indicating inconsistency in the identification of hypopnoeas.

When comparing individual Sonomat scores from the reference scorer (AC) to PSG, Bland-Altman analysis showed the narrowest limits of agreement for OEI (-1.17 to +0.82 events/hour) and AI (-3.71 to +3.00), with the widest limits observed for CEI (-5.11 to +6.45). Mean differences were generally small across all indices, with AHI and CEI showing slight overestimation compared to PSG.

A group mean analysis was also performed, comparing the average Sonomat scores across all five scorers to the PSG reference. Agreement remained strongest for apnoea-based indices (AI, AHI), while greater variability was observed for CEI and HI. The group-level differences were consistent with individual scorer comparisons, supporting the robustness of scoring across the trained cohort.

Conclusions: The use of standardised scoring rules for Sonomat studies in children demonstrated excellent inter-scorer reliability for apnoea-based metrics, supporting its potential clinical utility as a screening tool for SDB in settings where PSG is poorly tolerated or unavailable. The strongest agreement was seen for AI and AHI, both within and across scorers, with acceptable limits of agreement relative to PSG. However, reduced agreement for hypopnoeas and obstructive events highlights the need for ongoing scorer training and refinement of visual interpretation strategies. Notably, hypopnoea scoring is known to exhibit lower inter-scorer concordance even within standard PSG, suggesting that the variability observed with Sonomat is consistent with broader challenges in

respiratory event classification. This study reinforces the importance of structured scorer education when implementing new technologies in paediatric sleep diagnostics and provides a foundation for future work using the Sonomat in broader clinical and home-based settings.

Learning from parents about the prevalence of SDB in children with neurodevelopmental disorders and their preferences for diagnostic testing

M. Vandeleur^{1,2}, M. Anderson³, A. Kevat^{4,3}, D. Alwadhi³, A. Bernard³, K. Waters^{5,6}, J. Chawla^{4,3}

¹The Royal Children's Hospital, Respiratory and Sleep Medicine, Melbourne, Australia, ²Murdoch Children's Research Institute (MCRI), Melbourne, Australia, ³The University of Queensland, Centre for Children's Health Research, Brisbane, Australia, ⁴Queensland Children's Hospital, Respiratory and Sleep Medicine, Brisbane, Australia, ⁵Children's Hospital Westmead, Sleep Medicine, Sydney, Australia, ⁶University of Sydney, Sydney, Australia

Introduction: Existing literature demonstrates a high prevalence of sleep disordered breathing (SDB) in children with specific neurodevelopmental disorders (ND). However, no large studies have evaluated prevalence of SDB in a broad population of children with ND (CWND). Additionally, whilst it's recognised that undertaking gold standard monitoring with polysomnography (PSG) is more difficult in children with ND, few studies have explored perspectives of primary caregivers. Here, we describe parent reports of SDB symptoms in a large multicentre sample of CWND and detail their experiences and views regarding diagnostic testing.

Materials and methods: Data were combined from two Australian multicentre studies undertaken to evaluate sleep in a diverse sample of CWND. Primary caregivers of children 0-18 years with a ND condition (ICD-11) completed a survey that included the Paediatric Sleep Questionnaire (PSQ) to determine parent reported prevalence of SDB. Participants were recruited from: (i) a tertiary sleep clinic and (ii) a community sample recruited through community organisations that support CWND. A cut-off value of 0.33 on the PSQ was regarded as indicative of SDB risk. In addition, primary caregivers of a second cohort of CWND (0-18 years) who were undergoing PSG for evaluation of SDB at the same centres completed a customised survey regarding feedback on their experiences of PSG and hypothetical preference between in-lab PSG or an in-home mat-based sleep test.

Results: PSQ data was available from 226 participants (56% male, 54% 5-12yrs). 37% had autism spectrum disorder (ASD) and/or attention deficit hyperactivity disorder (ADHD), 35% a genetic syndrome, 16% a neurological disorder and 12% another ND condition. The mean PSQ total score was 0.46 and 75% had a PSQ score >0.33. There was no significant difference in mean total PSQ score between different NDD categories and no difference in the proportion of children with a PSQ >0.33 when comparing the sleep clinic and community sub-groups.

143 primary caregivers of CWND undergoing PSG completed a customised survey regarding PSG experiences. "Worry levels" for undergoing PSG were reported as "moderate" for children and lower for parents, with the highest worry levels in children with ASD and neuromuscular diagnoses. The option for at home testing with a mat-based option was preferable to parents, with 57% indicating a preference for this if available compared to 7% preferring an in-laboratory PSG.

Conclusions: Discussion: Combined data from a large sample of Australian CWND demonstrates (1) a high prevalence of parent reported SDB symptoms regardless of underlying ND condition, (2) a high proportion of CWND in a community sample reporting a SDB symptom burden comparable to those in a tertiary sleep clinic, and (3) parent preference for home based diagnostic sleep testing options. This preference may reflect the increased worry experienced by CWND during in-laboratory PSG and parental concern that sleep measured in this setting is not representative of their child's typical sleep. Conclusion: This study confirms that SDB is an important comorbidity that requires proactive screening in CWND and provides rationale for exploring alternative approaches to diagnostic testing that better meet the needs of CWND and their families.

Maternal Prenatal Depression and Child Sleep: A Systematic Review

R. Burdayron^{1,2}, S. Kenny^{1,2}, M. Ly^{1,2}, A. Vandenberg^{1,2}, M. Chicoine^{1,2}, M.-H. Pennestri^{1,2}

¹McGill University, Educational and Counselling Psychology, Montreal, Canada, ²Hôpital en santé mentale Rivière-des-Prairies (CIUSSS-NIM), Montreal, Canada

Introduction: Previous research suggests a potential association between maternal prenatal depression and child sleep outcomes; however, findings have been inconsistent. The present review aims to systematically synthesize and critically evaluate the existing literature on the associations between maternal prenatal depression and sleep in children aged 0-17 years.

Materials and methods: Following PRISMA guidelines, a systematic literature search was conducted in PsycINFO, Medline, and SCOPUS electronic databases to identify studies examining associations between maternal prenatal depressive symptoms, or diagnoses of depression, and child sleep dimensions. In total, 1088 titles and abstracts and 68 full-text articles were screened, yielding 27 studies that met inclusion criteria.

Results: Most studies (74.0%) reported significant associations between maternal prenatal depression and at least one child sleep dimension. The most frequently assessed sleep dimension was sleep problems, with 76.9% of studies reporting an association between greater maternal prenatal depression and greater child sleep problems. Although studies were scarce, some studies found associations between greater maternal depression and shorter total sleep duration, shorter daytime sleep duration, and a higher number of nocturnal awakenings. However, no consistent associations were found between maternal prenatal depression and child nocturnal sleep duration, wake after sleep onset, or sleep efficiency.

Conclusions: Findings suggest that maternal prenatal depression may be linked to certain adverse child sleep outcomes, particularly greater sleep problems. However, most findings are based on maternal reports of child sleep, which may be influenced by maternal mood. As such, reported sleep problems may partly reflect maternal perceptions rather than objective difficulties in the child. Future research should aim to replicate these findings using validated parent-report questionnaires, incorporate objective sleep assessments, and examine potential mediating and moderating factors underlying these associations.

Acknowledgments: This work was supported by the Social Sciences and Humanities Research Council (SSHRC) and the Canada Research Chair (II) in Pediatric Sleep.

Obstructive sleep apnea and sleep disorders in children with attention deficit hyperactivity disorder

M. Nguyen-Thi-Phuong¹, M. Nguyen-Thi-Thanh¹, R. Joel Goldberg², H. Lan Nguyen², A. Dao-Thi-Minh¹, S. Duong-Quy³

¹Hanoi Medical University, Hanoi, Vietnam, ²UMass Chan Medical School, Massachusetts, United States, ³Lamdong Medical College, Dalat, Vietnam

Introduction: Sleep disorders are common yet often underdiagnosed in children with attention-deficit/hyperactivity disorder (ADHD). These disturbances can exacerbate ADHD symptoms and negatively affect cognitive, emotional, and behavioral functioning. This study aimed to describe the prevalence of obstructive sleep apnea (OSA) and other sleep disorders in children with ADHD using standardized diagnostic criteria, and to identify associated clinical and behavioral factors

Materials and methods: A cross-sectional study was conducted on 629 children aged 6 to 12 years (mean age: 7.8 ± 1.5 years) who were diagnosed with ADHD. Sleep disturbances were assessed using the Children's Sleep Habits Questionnaire (CSHQ), the Pediatric Sleep Questionnaire (PSQ), and Respiratory polygraphy. Sleep disorders were classified based on the International Classification of Sleep Disorders, Third Edition (ICSD-3). Multivariate logistic regression was used to identify associated risk factors.

Results: Sleep disorders were diagnosed in 70.0% of children with ADHD. The most common disorders were insomnia (40.2%), OSA (23.4%), parasomnias (27.8%), restless legs syndrome (10.5%), and delayed sleep-wake phase disorder (4.8%). The inattentive ADHD subtype, psychiatric comorbidities, tonsil and adenoid hypertrophy, iron-deficiency anemia, and sleep-related behaviors in children with ADHD were significantly associated with sleep disturbances.

Conclusions: Sleep disorders are highly prevalent and diverse in children with ADHD. Early identification and targeted management of sleep disturbances, particularly OSA and insomnia, are essential to improving sleep quality and optimizing ADHD outcomes. Routine sleep screening should be integrated into clinical ADHD evaluations.

"PEDOSA-7: Development, Validation, and Clinical Utility of a Simplified Screening Tool for Pediatric Obstructive Sleep Apnea- A Pilot Study

A. Halder¹, S. Maity², G. Ghosh³, P. Chatterjee⁴, D. Datta⁵, S. Roy⁶

¹Institute of Sleep Science, Department of Pulmonary Medicine, Consultant Pulmonologist and Sleep Medicine, CMRI, Kolkata, India, ²Institute of Sleep Science, Department of Physiotherapy, Consultant Myofunctional Therapist & Sleep, Kolkata, India, ³Institute of Sleep Science, Department of Pediatrics, Consultant Paediatrician and Sleep Medicine, Naryana Superspecialty Hospital, Kolkata, India, ⁴Institute of Sleep Science, Department of Pediatric Pulmonary Medicine, Consultant Pediatric Pulmonologist and Sleep Medicine, Apollo Multispecialty Hospital, Kolkata, India, ⁵Institute of Sleep Science, Department of ENT, Consultant ENT and Sleep Apnoea Surgeon, Manipal Broadway Hospital, Kolkata, India, ⁶Institute of Sleep Science, Department of Pediatrics, Consultant Paediatrician and Sleep Medicine, Manipal Hospital, Kolkata, India

Introduction: Pediatric obstructive sleep apnea (OSA) is a prevalent yet underdiagnosed disorder linked to significant morbidity. Current screening tools, such as the Pediatric Sleep Questionnaire (PSQ), face limitations in clinical utility due to complexity and time constraints. This pilot study aimed to develop and validate the PEDOSA-7, a simplified 7-item screening tool with binary (Yes/No) responses and weighted scoring, designed to enhance accessibility and efficiency in OSA risk stratification.

Materials and methods: A cross-sectional observational study enrolled 83 children (aged 3–16 years) with sleep-related complaints. Participants underwent polysomnography (PSG; AHI ≥ 5 for OSA diagnosis) and completed the PEDOSA-7 and PSQ. Demographics, BMI, and symptom profiles were analyzed. Validation metrics included internal consistency (Cronbach's alpha), sensitivity, specificity, negative predictive value (NPV), and AUC-ROC. Comparative analysis with PSQ assessed practicality and diagnostic accuracy.

Results: Of the cohort, 31.3% (26/83) had OSA (AHI ≥ 5). The OSA group exhibited higher mean BMI (22.3 vs. 18.0; $p < 0.05$) and a strong BMI-AHI correlation ($r = 0.73$). PEDOSA-7 demonstrated sensitivity of 84.6%, specificity of 54.4%, NPV of 88.6%, and AUC of 0.728 at a cutoff score ≥ 3 . Key items (snoring, breathing pauses) showed high sensitivity (92%). Internal consistency was suboptimal (Cronbach's alpha = 0.49), reflecting item redundancy. Compared to PSQ, PEDOSA-7 achieved comparable sensitivity (PSQ: 61.5–90%) with superior practicality due to its binary scoring. Lowering the AHI threshold to >1 improved specificity (83.3%) but reduced sensitivity (37.1%), highlighting trade-offs in screening accuracy.

The PEDOSA-7 offers a clinician-friendly tool for rapid OSA screening, particularly in resource-limited settings. Its high NPV supports efficient triage, reducing unnecessary referrals. However, moderate specificity necessitates integration with clinical judgment. Limitations include a small, gender-imbalanced sample (non-OSA group: all male) and lack of cultural/age diversity. Future studies should validate PEDOSA-7 in larger, multicenter cohorts and refine psychometric properties.

Conclusions: In conclusion, the PEDOSA-7 represents a pragmatic advancement in pediatric OSA screening, balancing diagnostic accuracy with usability. While not replacing PSG, it serves as a valuable first-line tool to improve early detection and resource allocation. Further validation across diverse populations and settings is warranted to optimize its clinical impact.

Keywords: Pediatric obstructive sleep apnea, screening tool, PEDOSA-7, validation, polysomnography, sensitivity.

Perceived Parental Sleep Quality Improvement Following a Brief Child Sleep Intervention: Preliminary Evidence

R. Pétrin¹, É. Touchette², A. Bérubé¹, M.-H. Pennestri³, G. Forest¹

¹Université du Québec en Outaouais, Gatineau, Canada, ²Université du Québec à Trois-Rivières, Québec, Canada, ³McGill University, Montreal, Canada

Introduction: Sleep difficulties are common in preschool-aged children and often disrupt parental sleep, contributing to heightened stress, depressive symptoms, and family dysfunction. Interventions targeting child sleep have shown promise in improving parental outcomes, but the mechanisms driving these changes remain unclear. This preliminary study evaluated the effects of a brief, group-based child sleep intervention on parental sleep quality over time and examined whether changes in child sleep quality and parental mental health following the intervention predict these improvements.

Materials and methods: Seventy-eight families with 3- to 5-year-old children participated in the project. Parents were offered a two-hour group session focusing on sleep hygiene, bedtime routines, and nightmares, while in parallel, children engaged in sleep-related educational activities. Two weeks later, parents participated in a follow-up group session where they shared their successes and obstacles and received additional support from the clinician. Data were collected at baseline (T1), two weeks post-intervention (T2), and about eight weeks post-intervention (T3). The Children's Sleep Habits Questionnaire (CSHQ) and the Pittsburgh Sleep Quality Index (PSQI) were administered at T1, T2 and T3, while the Beck Depression Inventory (BDI-II) and the Parenting Stress Index (PSI) were administered at T1 and T3. Repeated measures ANOVAs assessed changes in PSQI and CSHQ scores, and paired t-tests evaluated changes in BDI-II and PSI scores over time. Hierarchical linear regression was used to determine whether changes in child sleep quality and parental mental health predicted parental sleep quality at T3, controlling for parental income.

Results: Repeated measures ANOVAs revealed significant improvements in parental sleep quality (PSQI total scores) between T1 and T3 [$F(2,114) = 8.72; p < .001$], while children's sleep quality (CSHQ total scores) improved from T1 to T2 and remained enhanced at T3. Paired-sample t-tests showed reductions in depressive symptoms [BDI-II total scores: $t(67) = 4.47; p < .001$] and parenting stress [PSI total scores: $t(67) = 6.13; p < .001$] at T3. The hierarchical regression showed that the first model (parental income and baseline predictors) explained 25.4% of the variance in parental sleep quality [$F(5, 72) = 4.90, p < .001$]. Adding changes in CSHQ, BDI-II, and PSI scores significantly improved the model fit [$\Delta R^2 = .08, p = .04$], with the final model explaining 33.8% of the variance [$F(8, 69) = 4.40, p < .001$]. Changes in parental depressive symptoms (BDI-II scores; $\beta = .27, p = .047$) and baseline parental sleep quality (PSQI scores; $\beta = .37, p = .001$) were significant predictors of parental sleep quality at T3, while changes in children's sleep quality (CSHQ scores; $p = .33$) and parenting stress (PSI scores; $p = .91$) were not.

Conclusions: These findings suggest that a brief child sleep intervention can improve perceived parental sleep outcomes, driven by reductions in depressive symptoms. However, the lack of association with changes in children's sleep quality and parenting stress indicates that unexplored factors may influence these results. Future studies should aim to better identify and understand these factors to optimize intervention design and improve family outcomes.

Perioperative Sleep Quality in Pediatric Cardiac Surgery: A Scoping Review

P. Fan², X. Zhang², Q. Zhai², X. Wang², L. Li³, S. Qin², B. Shen¹

¹Shanghai Jiao Tong University, School of Nursing, Shanghai, China, ²Shanghai Jiao Tong University, School of Clinical Medicine, Shanghai, China, ³Shanghai Children's Medical Center, Department of Nursing, Shanghai, China

Introduction: To conduct a scoping review of research on perioperative sleep quality in children undergoing cardiac surgery. The aim is to provide guidance for the early diagnosis, treatment, and intervention of perioperative sleep disturbances in this population in China.

Materials and methods: Following the methodology of a scoping review, literature related to perioperative sleep quality in children undergoing cardiac surgery was systematically searched in the following databases: PubMed, MEDLINE, Web of Science, Embase, CINAHL, PsycINFO, Cochrane Library, Ovid, Scopus, ClinicalTrials.gov, WHO International Clinical Trials Registry Platform, Sinomed, CNKI, Wanfang Data, and VIP Information Services Platform. The search covered all records from database inception to August 10, 2024. Two researchers independently screened the literature and extracted key characteristics, including title, authors, publication year, data collection period, country of sample collection, study objective, sample size, study population, age group, study type, and measurement tools.

Results: A total of 1,306 articles were retrieved, and 18 studies were ultimately included, all of which were published in English. Among them, 6 were retrospective studies, 5 were prospective studies, 4 were observational studies, 2 were interventional studies, and 2 were cross-sectional studies. The analysis indicated that sleep disorders are relatively common among children undergoing cardiac surgery and are associated with significant adverse outcomes. Four objective assessment tools or methods were used: electroencephalogram (EEG), continuous electroencephalogram (cEEG), amplitude-integrated electroencephalography (aEEG), and actigraphy (Micro Motion Logger, Ambulatory Monitoring, Inc.). Seven subjective assessment tools or methods were identified: the Brief Infant Sleep Questionnaire (BISQ), Children's Sleep Habits Questionnaire (CSHQ), Pittsburgh Sleep Quality Index (PSQI), Échelle de dépistage des troubles de sommeil pédiatriques (HIBOU; Pediatric Sleep Disorders Screening Scale), online questionnaire items related to sleep, child self-reported sleep problems, and parent-reported sleep problems. The influencing factors of perioperative sleep quality in children undergoing cardiac surgery were analyzed across four time points: preoperative period, admission to the CICU postoperatively, transfer to the general ward, and post-discharge follow-up. Intervention measures included the SNOO® Smart Sleeper (responsive bassinet) and eye masks. However, current research on prevention and intervention remains limited.

Conclusions: Children undergoing cardiac surgery have a high prevalence of sleep disorders, which are associated with significant adverse outcomes. Existing research reflects limited awareness and insufficient understanding of sleep disturbances in this population. The range of available assessment tools is narrow and lacks specificity. Influencing factors are complex and vary across different perioperative stages. Research on prevention and intervention remains limited.

Persistent Sleep Disturbances in Pediatric COVID-19 Survivors: A Longitudinal Follow-Up and Association with Neuropsychiatric Symptoms

C.-H. Huang¹, L.-C. Wong², W.-T. Lee²

¹Taipei City Hospital YangMing branch, Pediatrics, Sleep Center, Taipei City, Taiwan, ²National Taiwan University Hospital, Pediatrics, Taipei City, Taiwan

Introduction: Sleep disturbances are common in pediatric COVID-19 survivors, especially those with **neuropsychiatric (NP)** symptoms. This study investigated the persistence and nature of sleep disorders in children post-COVID-19 using validated sleep questionnaires.

Materials and methods: The observational study enrolled pediatric patients (6-18 years) with confirmed COVID-19 within the preceding six months and included an age- and sex-matched healthy control group (C, n=62). Neuropsychiatric (NP) symptoms were assessed using the Weighted Neuropsychiatric Severity Scale (WNPSS). Patients scoring ≥ 3 were classified as Group Y (significant NP symptoms), while those scoring < 3 formed Group N (mild/no NP symptoms). Questionnaires (Epworth Sleepiness Scale for Children and Adolescents - ESS-CHAD; Sleep Disturbance Scale for Children - SDSC) and actigraphy evaluated sleep at **two time points**: initially, 6-12 months post-infection (Time 0), and at follow-up, 1.5-2.5 years later (Time 1). Statistical comparisons between groups (C, N0, N1, Y0, Y1) were performed using appropriate tests, including Kruskal-Wallis and ANOVA, with post-hoc analyses. The study involved 31 COVID-19 survivors (N0: n=25, N1: n=25; Y0: n=6, Y1: n=6) and 62 controls (C).

Results: The mean ages were 9.61 ± 1.86 years in controls (C), 9.90 ± 2.63 years in the N0 group, 11.08 ± 2.58 years in the N1 group, 10.05 ± 2.53 years in the Y0 group, and 11.22 ± 2.47 years in the Y1 group, with no significant differences between groups ($p=0.1188$). A Kruskal-Wallis test revealed statistically significant differences in both the Sleep Disturbance Scale for Children (SDSC) total scores ($p=0.0437$) and Disorders of Excessive Somnolence (DOES) subscale ($p=0.0163$) among the groups. For DOES, patients with NP symptoms exhibited markedly elevated median scores at both time points (Y0 and Y1: 10.50) compared to controls and non-NP groups (C, N0, and N1: all 7.00). Similarly, total SDSC scores were higher in NP groups (Y0: 50.00, Y1: 47.50) compared to controls (C: 41.50) and non-NP groups (N0: 43.00, N1: 41.00).

However, no significant differences were observed between groups in other sleep domains: disorders of initiating and maintaining sleep (DIMS, $p=0.0888$), disorders of arousal (DA, $p=0.0980$), sleep breathing disorders (SBD, $p=0.6871$), sleep-wake transition disorders (SWTD, $p=0.5113$), or sleep hyperhidrosis (SHY, $p=0.2705$). Additionally, the Epworth Sleepiness Scale showed no significant group differences ($p=0.3426$).

Conclusions: Pediatric COVID-19 patients with neuropsychiatric symptoms showed significantly higher sleep disturbance **compared to controls and those without neuropsychiatric symptoms**, specifically in excessive somnolence (DOES) but not in other sleep domains.

Predictors of Napping Frequency Across Early Childhood: Investigating the Effects of Social Factors on Developmental Trajectories

G. Normore¹, S. Staton¹, K. Thorpe¹, P. Rankin¹

¹The University of Queensland, Queensland Brain Institute, Brisbane, Australia

Introduction: Napping frequency declines dramatically over the first few years of life, and the rate of this decline is thought to reflect an interaction between social and neurophysiological development. However, whether social or contextual factors also effect napping frequency and cessation timing is not well understood. This is problematic, as children's napping behaviours have been associated with a variety of health and developmental outcomes. Previous studies of napping development and its environmental correlates have relied heavily on cross-sectional data and aggregate measures (i.e., asking parents to report 'typical' napping behaviours). These methodological limitations mean that it has been difficult to analyse how sensitive napping frequency is to environmental influence, and have marred our ability to accurately capture variability in developmental trajectories of napping frequency. One social factor in particular, the effect of attending childcare, may have a particularly marked effect on napping frequency due to many childcare centres enforcing a mandatory single nap schedule on children irrespective of their developmental stage. However, the effect of this and other social factors on napping patterns remain largely unknown.

Materials and methods: Data was collected as part of the Sleep Transitions and Regularity Study (STARS), a 4-year longitudinal study tracking the sleep behaviours of ~200 Australian children between the ages of 1 to 5 years. Once per month parents were asked to complete a 1-week recording of their child's napping patterns, childcare attendance, and life events (e.g. illness, family stress, change in living situation, etc.). We performed a hybrid multilevel logistic regression model, controlling for within subjects repeated measures to investigate whether childcare attendance significantly predicted napping frequency over and above the developmental effect associated with age.

Results: Results of a hybrid multilevel logistic regression model indicate that the within-subject effect of attending childcare is associated with a significant reduction in napping frequency until about the age of 3.5 years, at which point the effect diminishes. In other words, very young children who attend childcare nap significantly less than they would otherwise. The effects of other social factors, such as moving home or significant family stress are still to be determined.

Conclusions: This study demonstrates with unprecedented specificity that social factors, alongside ageing, can significantly influence developmental napping frequency behaviours. Our findings have implications for understanding of the relative influence of social and developmental factors on napping frequency, as well as implications for childcare policy and practice around sleep and naps.

Acknowledgments: The STARS project is funded by the Australian Research Council (ARC;DP190102981). Authors receive funding from the ARC (GN/SS-DE230100687; KT-FL220100137; PR- CE200100025).

Prescribing with sleep in mind: Polypharmaceutical considerations in children with neurodevelopmental disorders

M. Anderson¹, F. Hudson^{1,2}, A. Bernard³, L. Agnoletto⁴, M. Vandeleur^{4,5}, K. Waters^{6,7}, J. Chawla^{1,2}

¹University of Queensland, Faculty of Medicine, Brisbane, Australia, ²Queensland Children's Hospital, Brisbane, Australia, ³University of Queensland, Data Science Collaborative Research Platform, Brisbane, Australia, ⁴Murdoch Children's Research Institute, Melbourne, Australia, ⁵Royal Children's Hospital, Melbourne, Australia, ⁶Children's Hospital at Westmead, Sydney, Australia, ⁷University of Sydney, Faculty of Medicine and Health, Sydney, Australia

Introduction: Sleep disturbances affect up to 80% of children with neurodevelopmental disorders (ND), reflecting complex interactions between physiological, behavioural, pharmacological, and environmental factors. This study explores medication use in a large cohort of Australian children with

ND, aiming to characterise pharmaceutical burden and its potential influence on sleep quality. Further, this study aimed to explore the interactions of sleep and non-sleep medications in the context of known sleep difficulties within this population.

Materials and methods: This cross-sectional survey involved carers of children aged 2–18 with clinician-diagnosed NDs across three major Australian hospitals and community settings. Data were collected via a study-specific online questionnaire capturing demographics, diagnoses, sleep-related parameters, and medications. Sleep problems were characterised using the 58-item Modified Simonds and Parraga Questionnaire (MSPSQ), where a raw score greater than 56 or composite score greater than 4 is indicative of a clinically significant sleep problem. Medications were standardised, categorised, and analysed using descriptive statistics and appropriate statistical testing.

Results: Data from a total of 300 eligible participants were available for analysis (59% male, 50% 5–12 years old). The majority of children had clinically significant sleep problems, as characterized by the MSPSQ (raw score 69.2 ± 15.8 , composite score 5 ± 2.9). Melatonin was the most frequently used sleep medication, with 59% of children having used it at some point over their lifetime, two thirds having found melatonin useful, and more than one in four children currently taking melatonin. α -2 agonists, benzodiazepines, and sedating antihistamines were also being prescribed for sleep in this cohort. A wide range of non-sleep-related medications were reported, with 29% of children taking medications with known negative impacts on sleep. Most children were on at least one prescription medication (69.3%), with polypharmacy (2 or more regular medications) being identified in 42% of children (median 1, range 0–9). When also considering over-the counter medications, 50% of children met criteria for polypharmacy (median 2, range 0–13). Non-sleep medications which influenced sleep were common, with stimulants being most prevalent.

Conclusions: Sleep problems in children with ND are common and likely complicated by their significant pharmacotherapeutic burden. Half of children in this study met criteria for polypharmacy, with one in three children being prescribed medications known to have negative impacts on sleep. Given the prevalence and complexity of sleep problems in children with ND, emphasis should be placed on the review and rationalisation of medications when these patients present with sleep problems. Additionally, the development of targeted guidelines to support clinicians in managing sleep disturbances in this population needs to be prioritised.

Prevalence of high-risk obstructive sleep apnea in overweight and obese children and its impact on quality of life

J. Suriyasathaporn¹, A. Tanphaichitr¹, N. Densupsoontorn², P. Saengpanit², K. Ungkanont¹, W. Banhiran¹, V. Vathanophas¹, T. Wannarong¹

¹Faculty of Medicine Siriraj Hospital, Mahidol University, Department of Otorhinolaryngology, Bangkok, Thailand, ²Faculty of Medicine Siriraj Hospital, Mahidol University, Department of Pediatrics, Bangkok, Thailand

Introduction: Obstructive sleep apnea (OSA) is a sleep-related breathing disorder characterized by intermittent partial or complete upper airway obstruction, leading to disrupted sleep and oxygen desaturation. Obesity significantly increases the risk of OSA. However, few studies in Thailand have examined the prevalence of high-risk OSA in obese children and its impact on quality of life.

Materials and methods: We conducted a cross-sectional study to determine the prevalence of high-risk OSA in overweight and obese children and to evaluate its impact on their quality of life. Children aged 2–12 years diagnosed as overweight or obese based on WHO BMI-for-age z-scores were recruited. The risk for OSA was assessed using the Thai version of the Pediatric Obstructive Sleep Apnea Screening Tool (POSA), and quality of life was evaluated using the OSA-18 questionnaire. Physical examinations, including tonsillar assessment, were conducted.

Results: Sixty-eight overweight and obese children were recruited. The prevalence of high-risk OSA, as defined by POSA, was 41.2%. Tonsillar hypertrophy was significantly associated with high-risk OSA (adjusted OR: 10.92; 95% CI: 3.04–39.15; $P < 0.001$). Additionally, 20.8% of children experienced a moderate to severe impact on their quality of life. High-risk OSA (adjusted OR: 14.59; 95% CI: 1.94–109.86; $P = 0.009$) and attention-deficit hyperactivity disorder (adjusted OR: 11.84; 95% CI: 1.52–92.14; $P = 0.02$) were significantly associated with reduced quality of life.

Conclusions: High-risk OSA is common among overweight and obese children and is significantly associated with impaired quality of life. These findings highlight the need to screen for OSA in this at-risk population and to address related quality of life issues in clinical practice.

Acknowledgments: This research project was supported by Siriraj Research Fund, grant number (IO) R016731018, Faculty of Medicine Siriraj Hospital, Mahidol University.

Prevalence of Sleep Disorder Diagnosis in the Pediatric Population at a Children's Hospital in Northeastern México

A.D. Gómez Hernández^{1,2}, C. Sánchez García²

¹Universidad Autónoma de Coahuila, Hospital del Niño Dr Federico Gómez Santos, Saltillo, Mexico,

²UAdC, Hospital del Niño. Dr Federico Gómez Santos, Saltillo, Mexico

Introduction: Sleep disorders in the pediatría population have been the subject of numerous studies due to their impact on children's physical, cognitive, and emotional development. Despite their high prevalence, these disorders often go unnoticed and are underdiagnosed, which can lead to long-term consequences on children's quality of life. There is a need for adequate knowledge and practical, simple, and easy-to-use tools for use in primary care. General screening questionnaires are available and can be useful during pediatric consultations in primary care settings.

Materials and methods: A prospective observational descriptive study. Surveys were conducted in the emergency department over 30-day period. Age-specific screening tools were used: The BISQ questionnaire was applied for infants, focusing on sleep routines and problems. The BEARS questionnaire and the Sleep Disturbance Scale for Children (SDSC) by Bruni were used for screening and identifying sleep disorders in newly admitted patients who agreed to participate.

Results: A total of 60 surveys were completed: 40 males (66%) and 20 females (33%). The age distribution was as follows: 23 infants (38.3%), 12 preschoolers (20%), 10 school age children (16.6%), and 8 adolescents (13.3%). Among them, 7 patients had epilepsy, 4 had neurodevelopment delay, 4 had pneumonia, and 4 had asthma and allergic rhinitis. Based on survey results: 23 patients (38.3%) had no sleep disorder, 11 (17.8%) had wakefulness and sleep disorders (8 were assessed with BISQ, 6 had mild insomnia, and 2 had moderate to severe insomnia), 10 (16.2%) had disorders related to sleep onset and maintenance, 6 (9.7%) had sleep-related breathing disorders, of whom only 33% had respiratory conditions like asthma or allergic rhinitis. 5 (8.1%) had excessive daytime sleepiness, 3 (4.8%) had parasomnias, 2 (3.2%) met criteria for restless leg syndrome according to the SDSC. Among the surveyed population: 65% of infants had no sleep disorders, 66% of preschoolers had a sleep disorder, 60% of adolescents had a sleep disorder.

Conclusions: The prevalence of sleep disorders in our study was high 61%. This study aims to provide a general overview and emphasize the importance of these often-overlooked disorders, which are frequently underreported by families and overlooked by first-contact physicians. Sleep disorders in our setting are underdiagnosed. Our findings demonstrate that high-cost or complex diagnostic tests are not required to identify these disorders. It is concerning that more than half of the surveyed children would benefit from timely referral to a sleep specialist. In conclusion, pediatricians should raise awareness and routinely include sleep disorders screening as part of the clinical interview.

Prospective Associations Between Adolescent Sleep Characteristics and Depression, Anxiety, and Their Co-Occurrence in Early Adulthood: A 9-Year Cohort Study

C.T.T. Nguyen¹, P.-H. Kuo²

¹Research Institute for the Humanities and Social Sciences, National Science and Technology Council, Taiwan / Center for the Advancement of the Humanities and Social Sciences, National Taiwan University, Taiwan, Taipei, Taiwan, ²Department of Public Health & Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University, Taipei, Taiwan

Introduction: Depression and anxiety frequently co-occur during the transition to adulthood, leading to heightened symptom severity and severe adverse health outcomes. Although sleep disturbances are common in adolescence, their prospective relationships with comorbid depression and anxiety remain unclear. This study aimed to examine the longitudinal associations between adolescent sleep patterns

and sleep quality at age 15, predicting depressive and anxiety symptoms in early adulthood, with a specific focus on their comorbidity.

Materials and methods: We analyzed data from a subsample of the Avon Longitudinal Study of Parents and Children (ALSPAC), a UK population-based birth cohort. Sleep patterns and sleep quality were assessed at age 15 during a clinical visit. Depressive symptoms were measured at ages 17, 21, and 24, and anxiety symptoms at age 21. We estimated associations using binary logistic regression for depression and anxiety separately, and multinomial logistic regression to distinguish depression-only, anxiety-only, and comorbid cases.

Results: Depressive symptoms were prevalent at ages 17 (34.7%), 21 (28.0%), and 24 (36.3%), while 19.2% reported anxiety symptoms at age 21. Females consistently reported higher symptoms than males (p -value < 0.05). At age 21, 14% had depression only, 5% reported anxiety only, and 14% experienced comorbid symptoms. After covariate adjustment, each sleep disturbance at age 15 was associated with increased odds of depression at all follow-up ages (p < 0.05). In multinomial models, poor sleep quality (aOR = 2.79), perception of insufficient sleep (aOR = 1.84), daytime sleepiness (aOR = 2.15), frequent night awakenings (aOR = 2.07), short or long sleep duration (aOR = 1.63), and prolonged sleep onset latency (aOR = 1.80) each conferred higher risk of comorbid depression and anxiety (all p -value < 0.001) than of either disorder alone.

Conclusions: Adolescent sleep disturbances were linked to increased depressive and anxiety symptoms up to nine years later, with the strongest associations observed for comorbid presentations. Early identification and intervention for sleep problems in mid-adolescence may be critical for preventing later psychological health.

Acknowledgments: This paper was supported by the Research Institute for the Humanities and Social Sciences, National Science and Technology Council, Taiwan.

Pulmonary Rehabilitation in Pediatric Scoliosis: A Prospective Pilot of a Risk-Stratified Perioperative Respiratory Pathway involving polysomnography and transcutaneous carbon dioxide measurements

N. Mohan Rao¹, I. Kinimi¹, T. Kishen¹, S. Shinde¹, A. Khemani¹, A. Sahoo¹

¹Manipal Hospitals, Old Airport Road, Bangalore, Bangalore, India

Introduction: Children with scoliosis are predisposed to perioperative respiratory complications due to restrictive lung mechanics, impaired muscle strength, and ventilation-perfusion mismatch. These risks are further amplified in neuromuscular and syndromic subtypes. Preoperative pulmonary compromise often remains subclinical but becomes evident under the stress of anesthesia and postoperative recovery. This study aimed to evaluate a structured, risk-based pathway that integrates pulmonary assessment and individualized respiratory support to optimize surgical outcomes in children undergoing scoliosis correction.

Materials and methods: This was a prospective observational study involving 19 children referred to pediatric pulmonology 2–4 weeks prior to scoliosis surgery. Each patient underwent a comprehensive preoperative evaluation, including clinical assessment, spirometry (pre- and post-bronchodilator), extended pulmonary function testing (PFTs) in children over 8 years, polysomnography (PSG), transcutaneous CO₂ (TcCO₂) monitoring, and arterial blood gas analysis when indicated.

Patients were stratified into high-risk (presence of neuromuscular disease, Cobb angle >90°, FVC <60%, or sleep hypoventilation) or low-risk groups. High-risk patients were initiated on non-invasive ventilation (NIV) for at least 2–4 weeks preoperatively. Mechanical insufflation-exsufflation (MI-E) was added based on clinical judgment. Postoperatively, all patients received NIV support for at least one month. Respiratory outcomes were monitored through chest radiographs and clinical evaluation.

Results: Nineteen patients (mean age 10.7 years; 10 females) were enrolled, of whom 15 underwent surgery. The etiologies of scoliosis included syndromic (40%), neuromuscular (26%), congenital (20%), and idiopathic (13%). Six children were classified as high-risk (five with neuromuscular disease, one with FVC <40%). These patients were initiated on BIPAP with a median preoperative duration of six months. In contrast, low-risk patients used BIPAP for a median of one week preoperatively.

Five neuromuscular patients underwent PSG, with 75% demonstrating moderate-to-severe sleep-disordered breathing and hypoventilation. Postoperatively, NIV was continued in all patients, with long-term continuation in neuromuscular cases. MI-E was used in seven patients, including both with FVC <40%. Two complications were reported—one dural tear with cerebrospinal fluid pleural leak and one case of hypotension. The average hospital stay was 5.4 days, with a mean PICU stay of 2 days.

Statistical analysis showed a significant difference in preoperative FVC values between high- and low-risk groups ($p = 0.031$). However, no statistically significant differences were observed in hospital stay ($p = 0.529$) or MI-E use ($p = 1.0$), likely due to small sample size and variability in disease severity.

Conclusions: This risk-stratified perioperative respiratory pathway effectively identified high-risk children and facilitated the implementation of tailored respiratory interventions. The integration of preoperative NIV and postoperative continuation, along with MI-E where indicated, was feasible and likely contributed to favorable clinical outcomes. While statistical significance in outcome differences was limited, the pathway demonstrated clinical value and safety. Future studies with larger cohorts and control groups are warranted to validate and refine this model of personalized perioperative respiratory care.

Robin Sequence: from dilemmas to developing an adaptable standardized stepwise approach to treat upper airway obstruction

D.D. Goel^{1,2,3}, A. Wilson^{2,4}, S. Rao^{1,4}, D. Gillett⁵, H. Herbert⁶, A. O'Donnell^{2,4}

¹Perth Children's Hospital, Neonatal Intensive Care Unit, Nedlands, Australia, ²Perth Children's Hospital, Respiratory and Sleep, Nedlands, Australia, ³University of Western Australia, Human sciences, Perth, Australia, ⁴University of Western Australia, Perth, Australia, ⁵Perth Children's Hospital, Plastic Surgery, Nedlands, Australia, ⁶Perth Children's Hospital, Ear Nose Throat, Nedlands, Australia

Introduction: Pierre Robin sequence, more recently known as the Robin sequence (RS), is characterized by the clinical triad of micrognathia, glossoptosis and upper airway obstruction (UAO). The lack of a standardized approach to treat upper airway obstruction (UAO) in infants with Robin Sequence (RS) leads to delay in resolution of OSA, poor sleep, hypoxia or hypercarbia, poor feeding, suboptimal growth, and neurodevelopmental impairment, prolonged hospital stays and increases the burden on families and the healthcare service.

Materials and methods: We aimed to review the literature to identify key issues causing variation in clinical practice, assess the knowledge gap, and develop a standardized pathway for managing upper airway obstruction in infants with Robin Sequence. The tripartite framework of Evidence-Based Practice was used. This framework included a systematic review of the literature, extensive consultation with a multidisciplinary team of experts, and feedback from the patients. The consensus was reached over 12 months period by the working group consisting of the hospital's neonatologists, respiratory and sleep specialists, ENT specialists, plastic and craniomaxillofacial surgeons, dentists, geneticists, speech pathologists and patient feedback.

Results: Of the 2672 articles from the initial search, 66 were studied in detail. We identified five pivotal issues prevalent while managing upper airway obstruction in the Robin Sequence which are: 1) how to gain consensus; 2) how to assess the severity of UAO/OSA; 3) which treatment to choose; 4) how to assess treatment effectiveness; and 5) when to follow up or stop treatment. These issues were addressed systematically to develop an adaptable stepwise standardized approach (ASSA) for the assessment and management of UAO/OSA in infants with RS. ASSA has two phases: phase one is the conservative arm and phase two is the escalation arm to more invasive treatment. The main pillars of the pathway are a) early objective assessment of the severity of upper airway obstruction using polysomnography, b) graded treatment approach based on centre-specific preferences, c) early and regular multidisciplinary team discussions, and d) clearly defined criteria for treatment escalation or cessation, discharge, and follow-up.

Conclusions: This unique pathway is based on evidence, consensus of experts and patients feedback. Early objective assessment of UAO/OSA using daytime polysomnography and a graded approach to treatment supports improved outcomes. The pathway provides a stepwise guide to the clinician for the management of upper airway obstruction in infants with Robin Sequence, adaptability for centre-specific treatment preferences and a framework for future comparisons of different treatments.

Acknowledgments: This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors for the development of the pathway.

We would like to acknowledge the Perth Children's Hospital Foundation for providing funding that assisted in the implementation of the pathway at Perth Children's Hospital.

We thank all the medical, nursing, and allied health staff of the Neonatal Intensive Care Unit, Neonatal, Respiratory and Sleep department, and Complex Airway Team (CAT) of Perth Children's Hospital for collaborative support.

Screening for Paediatric Obstructive Sleep Apnoea (OSA) on a Specialist Outpatient Waitlist: Insights from the First Year of a Sleep Nurse-led Triage Clinic (SNTC)

M. Angliss¹, E. Taylor¹, M.-J. Leclerc¹, A. Kevat¹, A. Collaro¹, S. Suresh¹

¹Queensland Children's Hospital, Respiratory and Sleep Medicine, South Brisbane, Australia

Introduction: Development of a Sleep Nurse-led triage clinical pathway for tertiary paediatric sleep referrals aimed to screen for Obstructive sleep apnoea (OSA) and reduce wait-times for tertiary sleep outpatient appointments. OSA is a common condition in children that, if left untreated, can lead to developmental and cognitive challenges. While polysomnography (PSG) remains the gold standard for diagnosis, overnight home oximetry has emerged as a more efficient and affordable preliminary test. Overnight oximetry utilisation for paediatric patients on a sleep clinic waitlist expedites screening for OSA as referral numbers exceed clinical capacity, often leading to long wait-times for specialist assessment.

Materials and methods: Sleep Nurse-led Triage Clinic (SNTC)

Paediatric patients aged 2-18 years, referred for suspected OSA at the Queensland Children's Hospital, were triaged from the Category 2 sleep clinic waitlist to the Sleep Nurse-led Triage Clinic from May 2024 - May 2025 (Category 2 recommended OPD appointment <90 days). A clinical workflow was developed and a nurse phone or in-person appointment was conducted. Demographics, medical/surgical history, neurodevelopmental diagnoses, Paediatric Sleep Questionnaire (PSQ) and home oximetry data was collected. Home oximetry data was analysed by McGill oximetry score (MOS). PSQ>0.75 or McGill 2-4 oximetry score patients were expedited to early sleep physician review and early PSG.

Results:

- 256 SNTC patients were seen from May 2024-May 2025.
- SNTC attendance rate 79%.
- SNTC Appointment summary: Failed to Attend appointment (FTA) (n=55), Sleep behaviour information/support i.e. night terrors, night-time waking (n=5), Refused oximetry (n=3), Follow-up SNTC phone call arranged 3 months post ENT surgery (n=15), Booked Sleep specialist appointment (n=25) i.e. SNTC CN identified clinical concern or complex patient/complex medications, nil evidence of OSA by reported history and PSQ or parental concern. Regional QLD location (n=2), NSW location (n=1) (unable to courier oximeter >200km or across QLD/NSW boarder).
- 147 home oximetry tests were conducted and 135 patients had sufficient data for sleep specialist scoring of MOS1-4. Completed PSQ score was matched for all 135 patient oximetry's.
- **MOS1 (n=122) (n=19 flagged as high risk using automated analysis methods)**
- PSQ 0.14-0.95, Diagnostic PSG (n=7), CPAP Titration (n=1), AHI 0.6-20.1/OAHI 0.0-16.6, Age 2-16yrs
- 9.6% of children were MOS2-4, 23% of children were flagged as high risk using automated analysis methods.
- **MOS2-4 (n=13) (n=12 of 13 flagged as high risk using automated analysis methods)**
- Diagnostic PSG (n=9), Referred ENT (n=2), CPAP Titration (n=3)

MOS2 (n=7); PSQ 0.32-0.90, PSG AHI 6.4-24/OAHI 2.6-22.8, Age 4-14 years

MOS3 (n=4); PSQ 0.71-0.76, PSG AHI 0.6-6.6/OAHI 0-4.4, Age 5-11 years

MOS4 (n=2); PSQ 0.45-0.86, PSG AHI 26.4-78/OAHI 26.2-78, Age 3-15 years

Conclusions: The SNTC model improved access and prioritisation for children with suspected Obstructive sleep apnoea (OSA).

Paediatric patients who were asymptomatic or no longer required specialist sleep appointments were discharged, improving clinic capacity. Category 2 appointments exceeding 90 days were reduced. Clinician-evaluated McGill scored oximetry (MOS1-4) and high-risk oximetry by automated analysis methods, were used to identify children for priority review by sleep specialist.

Children with suspected OSA received expedited access to specialist care, reducing delays in management and treatment.

Acknowledgments: Queensland Children's Hospital Sleep Medicine Department

Sleep and emotion regulation in elementary school children

A. Schlarb¹, L. Petrasch¹, J. Faber¹

¹Bielefeld University, Faculty of Psychology and Sports Science, Bielefeld, Germany

Introduction: Various aspects of sleep, like sleep disorders, especially insomnia symptoms, nightmares or restricted sleep, are closely associated with daytime impairments like behavior problems. In children and adolescents sleep problems and sleep deprivation are also associated with a decrease in functional emotion-regulating behavior and impaired emotion generation, whereas prolonged sleep enhances better mood and affect. In this study, we investigated various facets of sleep and emotion regulation in elementary school children. We hypothesized that sleep problems, like insomnia symptoms or impaired sleep, are associated with emotional problems and emotion-regulation problems.

Materials and methods: Participants were 62 elementary school children (6-11 years) and their parents. The mean age of the children was 8.71 (± 1.4), with 50.8% being girls. Parents filled in the Children's Sleep Habit Questionnaire (CSHQ-DE) and the Strengths and Difficulties Questionnaire (SDQ-DE), whereas the children completed the Sleep Self Report (SSR-DE). CSHQ-DE and SSR-DE focused on sleep anxiety, bedtime resistance, night-waking, sleep duration, sleep-onset delay, daytime sleepiness, sleep disordered breathing, and parasomnias, whereas the SDQ-DE contained questions regarding conduct problems, hyperactivity inattention, emotional symptoms, peer problems, and pro-social behavior. The emotion-regulation profile was calculated based on recommendations published.

Results: We found that children exceeding the SSR-DE cut-off had significantly more dysregulation symptoms and overall emotional problems. Comparisons of children with healthy scores and children with clinically relevant scores resulted in significant differences regarding the SDQ-DE Total Problem Score, the Subscale Conduct Problems, the Subscale Hyperactivity Inattention and SDQ-DE Dysregulation Profile based on parental ratings. Concerning children's assessments, sleep problems were associated with emotional dysregulation problems, emotional problems, and peer problems. Results regarding nightmares show similar effects.

Conclusions: Results show that parents, clinicians, and teachers should assess sleep problems in children to prevent emotional and peer problems in children. Early or secondary prevention, like school programs or sleep-related therapeutic stories, might help those children cope with sleep difficulties.

Sleep Characteristics, Patterns, and Problem in Children at Respiriology Clinic in Jakarta

M.R. Jasin¹, W. Indawati¹, N. Kaswandani¹, F.A. Neldy¹, D.B. Setyanto¹, B. Supriyatno¹

¹Universitas Indonesia/ Cipto Mangunkusumo Hospital, Pediatric, Jakarta, Indonesia

Introduction: Sleep is essential in child's growth and development. Optimal sleep habit and routines are important to support healthy growing and developing children. Sleep is a multifactorial phenomenon, and sleep problems in children maybe due to interplay of biological, psychological, and social influences from environment. We aim to describe characteristics, patterns, and problems of sleep in children who came to pediatric respirology clinic in a tertiary hospital, Jakarta.

Materials and methods: A cross sectional study was conducted in pediatric respirology clinic at Cipto Mangunkusumo Hospital in June 2025, by asking parents or caretakers of their children's, who came the clinic, sleeping habit and problem.

Results: Data were collected from 100 subjects, 52% were boys, mean age was 7 years old (the youngest was 2 months and oldest was 17 years). Majority was in the clinic for tuberculosis treatment (42%), followed with asthma (14%). Most subjects (29%) had 8 hours of sleep, followed by 9 hours (28%) and 10 hours (23%). Majority (84%) reported of nap times. Thirty-five percent of subjects had bedtime at 9 pm, with rise-time at 6 am. Fifty-two percent of subjects was using gadgets before sleeping, and 73% slept with dim-light or no-light. Seventy-eight percent of subjects was co-sleeping with parents/care-takers in one bed. Most subjects (62%) had become respiratory patients for 1 year or less, and only 37% reported sleeping problems appeared after the diagnosis. Occasional snoring was

reported in 33% subjects, 10% had habitual snoring, and 11% of parents/care-takers witnessed cessation of breathing. Majority (56%) reported of nighttime waking, with 54% of them reported twice or more. Reason for waking was mostly thirsty and asking for drink (27%) and coughing (24%).

Conclusion Most respirology clinic patients have sufficient nighttime sleep

Conclusions: Most respirology clinic patients have sufficient nighttime sleep and co-sleep with parents/care-takers. Signs of sleep disordered breathing are found in 10% patients with habitual snoring and 11% with cessation of breathing. Only 37% reported sleep problems appearing after respiratory diagnosis.

Sleep Health Among Children in Foster Care: Understanding Impacts, Interventions, and Research Gaps

A. Wani^{1,2}, J. Castellanos², J. Mcliegh³, A. Kadiwala¹, A. Mohiuddin^{1,1}, A. Bashar¹

¹UT Southwestern Medical Center, Pediatrics and Family and Community Medicine, Plano, United States, ²UT Southwestern Medical Center, Pediatrics and Family and Community medicine, Plano, United States, ³Childrens' Health, Director, Policy, Advocacy and Research Rees-Jones Center for Foster Care Excellence, Dallas, United States

Introduction: Children in foster care face numerous developmental challenges due to early exposure to trauma, maltreatment, and environmental instability. These adverse childhood experiences (ACEs) significantly impact physical and mental health, with growing evidence indicating sleep health as a particularly vulnerable domain. Despite sleep being critical for healthy development, research on sleep disturbances in foster youth remains limited. Disruptions to the hypothalamic-pituitary-adrenal (HPA) axis, psychological stress, and perceptions of environmental insecurity all contribute to poor sleep outcomes. This abstract reviews the literature on sleep health among children in foster care, evaluates interventions, and identifies areas requiring further investigation.

Materials and methods: This review synthesizes peer-reviewed articles, surveys, and intervention studies exploring sleep disturbances in children and adolescents in foster care. Sources were selected for their relevance to foster care populations, inclusion of sleep-related outcomes (e.g., duration, latency, parasomnias), and exploration of psychological and environmental factors affecting sleep. Interventional studies including behavioral, digital, and pharmacological approaches were included to assess the breadth of strategies currently employed. Research findings were categorized into themes: sleep quality, sleep disorders, trauma impact, and intervention effectiveness.

Results: Sleep Quality and Disorders: Children in foster care exhibit higher rates of poor sleep quality across all five domains of sleep health: duration, efficiency, timing, sleepiness, and quality. Studies show prolonged sleep latency, frequent awakenings, and increased parasomnias such as nightmares and sleep terrors. Foster children often report shorter total sleep duration and increased symptoms of insomnia, with prevalence rates of parasomnias markedly higher than in the general population. For instance, nightmares are reported in over 50% of foster children in some studies.

Impact of Trauma: Exposure to ACEs and instability in caregiver relationships elevate stress responses, often resulting in HPA axis dysregulation and hypervigilance. These biological and psychological changes contribute to difficulty initiating and maintaining sleep. Placement transitions and environmental insecurity further exacerbate sleep disruptions. Trauma-related sleep disturbances are often left unaddressed due to limited caregiver training and systemic oversight.

Interventions: Intervention efforts have focused on behavioral strategies, caregiver education, and digital platforms. Programs like SAFE-T—a trauma-informed telehealth sleep intervention—have demonstrated promising results in reducing night awakenings and internalizing symptoms. Caregiver involvement in consistent bedtime routines was associated with fewer sleep disturbances, even in children with multiple placement histories. While melatonin is commonly used, it has shown mixed results and may correlate with worsened daytime behaviors in foster youth.

Conclusions: Foster care youth are disproportionately affected by sleep disturbances stemming from trauma and instability. These sleep issues contribute to broader mental and physical health disparities. Promising interventions include trauma-informed digital therapies and structured caregiver routines, yet gaps remain in long-term data, objective sleep measurement, and systemic integration of sleep health in foster care practices. Future research should prioritize personalized, trauma-sensitive approaches and policy reforms that recognize sleep health as a vital component of foster care support.

Strengthening caregiver training and standardizing sleep assessments can significantly improve outcomes for this vulnerable population.

Sleep Phenotypes in Infancy and Their Continuity into Toddlerhood

S. Thakur¹, M. Lucchini¹, M. Breda², O. Bruni², N. Barnett¹

¹Nanit Lab, New York City, United States, ²Sapienza University of Rome, Rome, Italy

Introduction: Sleep patterns undergo significant developmental changes during infancy and early childhood, with increasing consolidation and regulation over time. Research has shown that individual differences in sleep duration, night wakings, and sleep-onset behaviors emerge early and persist into toddlerhood, influencing cognitive, emotional, and behavioral outcomes. Prior research in a sample of infants aged 9-13 months utilized cluster analysis (hierarchical Ward's method and k-means clustering) and identified three stable sleep phenotypes—Long Sleepers (LS), Interrupted Sleepers (IS), and Short Sleepers (SS)—based on differences in total sleep time, night wakings, parental nighttime visits, sleep efficiency, bedtime, and wake-up time measured with autovideosomnography. Given the developmental changes in sleep over time, the present study aimed to examine whether similar differences in sleep duration, bedtime, night wakings, sleep efficiency between the sleep phenotypes were observed in the same sample at a one year followup.

Materials and methods: A total of 623 infants aged 9-13 months were recruited from the Nanit customer database in 2023, and three distinct sleep phenotypes were identified. To examine whether these clusters remained consistent over time, a follow-up survey was conducted with the same participants. In total, 110 parents of children aged 22-30 months (27.50±1.0, 52.6% males) participated in the follow-up study. Objective sleep data from Nanit autovideosomnography were collected for 2 weeks (average 11.56 nights per child) measuring total sleep time at night (TST), bedtime (BT), night wakings (NW), nighttime sleep efficiency, and parental nighttime visits. Differences between clusters were analyzed using ANOVA and post-hoc pairwise comparisons.

Results: Auto-videosomnography data showed significant differences in TST ($p=0.001$), with LS sleeping 33.72 minutes (95% CI: 10.08, 56.64) more than SS ($p=0.002$) and IS sleeping 39.48 minutes (95% CI: 10.56, 66.4) more than SS ($p=0.004$). BT differences were also significant ($p=0.007$), with SS having later bedtime by 30 minutes than IS ($p = 0.009$; 95% CI: 5.58, 48.36) and by 27 minutes than LS ($p=0.023$; 95% CI: 3.24, 57.24). However, we did not find significant differences in NW ($p = 0.86$), parental nighttime visits ($p = 0.508$), or nighttime sleep efficiency ($p=0.74$) across clusters.

Conclusions: TST and BT remained significantly different across sleep clusters which aligns to the previous research, with LS having the longest sleep duration and SS the shortest and later bedtimes at follow up. No significant differences in NW, parental nighttime visits, or nighttime sleep efficiency were found across clusters. This suggests that infants with more night wakings at 9-12 months of age do not display the same behavior at 22-24 months, possibly reflecting the increasing consolidation of sleep patterns in toddlerhood. This longitudinal analysis of sleep phenotypes highlights the importance of sleep in infancy and its relationship with sleep health in early childhood.

Sleep problems in infants and children with prenatal alcohol exposure: a systematic review and meta-analysis

E.L. Gale¹, C.A. Hunt²

¹University of St Andrews, School of Medicine, St Andrews, United Kingdom, ²University College London, Anna Freud Institute, London, United Kingdom

Introduction: Sleep disturbances are common in children with fetal alcohol spectrum disorders (FASD) and prenatal alcohol exposure (PAE), worsening behavioural and cognitive deficits. Despite this, no review has systematically assessed the timing or severity of these sleep issues. The aim of this review was to identify sleep problems in children with FASD or PAE.

Materials and methods: A systematic search across seven databases followed PRISMA guidelines. Studies included children aged 3-10 with FASD or PAE and provided quantitative sleep data. Two reviewers independently screened articles. A meta-analysis of subjective sleep outcomes used a random-effects model, with heterogeneity assessed via I^2 .

Results: Fourteen studies met inclusion criteria. Children with FASD or PAE had consistently worse sleep than typically developing peers, including longer sleep onset, shorter duration, more awakenings, lower sleep efficiency, and greater sleep variability. Higher PAE levels were linked to earlier onset and persistence of sleep problems, with more severe issues in early pregnancy exposure. Meta-analysis of seven studies showed high heterogeneity ($I^2=0.91$) with medium to large effect sizes, particularly for night awakenings ($d=1.04$) and sleep duration ($d=0.89$).

Conclusions: Children with FASD/PAE face persistent sleep issues, worsening with heavier or earlier exposure, highlighting the need for early screening and interventions.

Acknowledgments: Completed with the support of the University of St Andrews and University College London. Currently under peer-review at Sleep Medicine Reviews.

Slower maturation of the circadian rest-activity rhythm is associated with weight gain across infancy

M. Petrov¹, C. Whisner², L. Liu²

¹Arizona State University, Edson College of Nursing and Health Innovation, Phoenix, United States,

²Arizona State University, College of Health Solutions, Phoenix, United States

Introduction: Circadian-driven sleep-wake regulation rapidly matures across infancy. Evidence suggests that poor regulation and blunted circadian rhythms are associated with weight gain in childhood. Rapid weight gain (RWG; $> .67$ increase in weight-for-age Z-score) during infancy is a potent early risk factor for childhood obesity, yet the relationship between circadian sleep-wake rhythmicity and weight gain in infancy has rarely been studied. This study examined whether actigraphy-assessed circadian rest-activity rhythmicity (CRA) development is associated with RWG across the first year of life. We hypothesized that blunted CRA maturation would be associated with RWG.

Materials and methods: In an ongoing longitudinal, observational cohort (Snuggle Bug |Acurrucadito study), full-term (≥ 37 wk), singleton infants, born of normal weight (parent-reported: 2.5-4kg) were recruited along with their mothers from the Phoenix, Arizona, USA metropolitan area to participate in six home visits across their first year of life at 3 and 8 weeks, and 3, 6, 9, and 12 months. At each visit, infants were weighed with a Seca scale and wore a Micro Motionlogger (Ambulatory Monitoring, Inc.) around their left ankle for five 24-hr periods post-visit. CRA metrics were derived from actigraphy data in one-minute epochs including mesor, amplitude, goodness-of-fit R^2 , interdaily stability, intradaily variability, and relative amplitude. Demographic information, including whether mother-infant dyads were enrolled in the U.S. Special Supplemental Nutrition Program for Women, Infants, and Children (WIC), a program for qualified caregivers of low-income, was collected. Visit-to-visit changes in CRA metrics and their relationship to the occurrence of RWG status since birth were examined with logistic time-varying effect models adjusting for time-varying birth weight and time-invariant WIC status using the *tvem* package in R. Model A examined each CRA metric by its global sample mean as the exposure. Model B examined the between-person and within-person effects of each CRA metric as exposures in the same model.

Results: Preliminary results from the first 117 participants of a possible 205 are presented. Across infancy, regardless of timepoint, there were consistent, mostly trending, negative associations between lower sample-level mean goodness-of-fit R^2 (Model A coefficient range across time points ≈ -0.58 – -0.29 , Lower CI range: -1.56 – -0.59 , Higher CI range: -0.007 – 0.41), and lower person-centered mean goodness-of-fit R^2 (Model B coefficient range ≈ -0.50 – -0.32 , Lower CI range: -1.93 – -0.64 , Higher CI range: -0.002 – 0.93) and lower visit-to-visit within-person variability in goodness-of-fit R^2 (Model B coefficient range ≈ -0.36 , 95%CI: -0.74 , 0.03) with having experienced RWG. In Model A, statistical significance was reached at three months of age. In Model B, the between-person effect reached significance at eight weeks, three months, and six months of age, but the within-person effect did not reach significance. Similar results were found for amplitude and interdaily stability. No other CRA metrics were trending or significantly associated with RWG status.

Conclusions: Slower maturation of the circadian rest-activity rhythm across infancy is associated with a trend toward increased risk of RWG, suggesting that early differences in circadian rhythm development may play a role in the emergence of obesity risk during infancy.

Acknowledgments: National Institutes of Health | National Heart, Lung, and Blood Institute R01HL147931

Socioeconomic Risk, Parenting, and Sleep: Impacts on Kindergarten Academic and Socioemotional Outcomes

E.K. Saini¹, A. Klutse¹, U. Chimed-Ochir², L. Bai³, K. Trexberg¹, B. Crosby¹, D.M. Teti¹

¹The Pennsylvania State University, University Park, United States, ²University of Maryland -Baltimore County, Baltimore, United States, ³Capital Normal University, Beijing, China

Introduction: The transition to schooling is a pivotal point for children, and adjustment to first-time schooling is predictive of subsequent academic performance (Fitzpatrick et al., 2020). A large literature has identified socioeconomic context, parenting, and children's sleep prior to starting kindergarten as important determinants of school adjustment in socioemotional and academic domains (Barger et al., 2019; Larson et al., 2015; Teti et al., 2022; Raby et al., 2015; Zaslow et al., 2006). However, it is unclear how these determinants work in concert with one another to confer risk or resilience in adverse environments. The current study utilized a multi-informant and multi-method longitudinal design to examine socioeconomic risk, parenting quality, and actigraphic sleep prior to kindergarten as unique and interactive predictors of children's adjustment to kindergarten.

Materials and methods: Data for this investigation came from 225 families who participated in assessments across the kindergarten year in mid-to-late August (pre-K), late September, early-mid November, and April. Observations of parenting at pre-K were scored from video recordings of children's bedtimes, using reliable coders trained on the Emotional Availability Scales (EA) (Biringen et al., 1998). Mothers and fathers EA scores were related ($r = .59, p < .001$) and averaged to create a composite EA score for each parent. Socioeconomic risk (SER) was a composite of family income-to-needs ratio, parental education, and subjective reports on monetary resources.

Children wore AW-64 actiwatchs (Philips Respironics, Inc) for 7 consecutive nights at pre-K, which were used to derive multiple sleep parameters including average sleep minutes (minutes scored asleep from sleep onset to morning wake time). Teachers reported on academic and socioemotional outcomes across the year. Academic achievement was assessed via the Academic Competence Evaluation Scale (DiPerna & Elliot, 2000), Academic Performance Rating Scale (DuPaul et al, 1991), and School Readiness Questionnaire (Bierman et al., 2008). Socioemotional and learning outcomes were reported on the Learning Behavior Scale (McDermott et al., 2002), Student-Teacher Relationship Scale (Pianta, 2001), and the Teacher Observation of Classroom Adaptation- Revised (Werthamer-Larsson et al., 1991).

Results: Multilevel models were fit to examine how SER, parent EA, and child sleep individually and interactively predicted outcomes. Main effects of individual predictors, controlling for the other two, revealed that SER was a robust predictor of poor socioemotional and academic outcomes. Parent EA was predictive of greater prosocial and learning behaviors and better academic outcomes. Greater nighttime sleep minutes predicted better academic competence, performance, and school readiness. Also obtained was a significant interaction between EA and sleep predicting academic performance. Children who had good sleep and emotionally available parents showed the highest levels of performance. By contrast, children with poor sleep and emotionally unavailable parents had the lowest levels of performance. Importantly, simple slopes testing revealed that children with at least one protective factor at pre-K (i.e., greater EA or longer sleep minutes) showed improvements in academic performance across kindergarten.

Conclusions: The present findings suggest that parenting quality as well as child sleep prior to the kindergarten year are important points of entry for interventions aiming to promote children's adjustment to first-time schooling.

Spectral Analysis of EEG Activity in Different Sleep Stages Across the Puberty Period by Fast Fourier Transform

M.-C. Lopes^{1,2}, S. Roizenblatt³, L. Azevedo-Soster², K. Spruyt⁴

¹University of Sao Paulo / Childhood and Adolescence Affective Disorders Program, Department and Institute of Psychiatry - School of Medicine at University of Sao Paulo, Sao Paulo, Brazil, ²Children's Institute-University of Sao Paulo, Sao Paulo, Brazil, ³Federal University of São Paulo, UNIFESP, Sao Paulo, Brazil, ⁴Université de Paris, NeuroDiderot, INSERM, Paris, France

Introduction: EEG total power reduction has been observed in post-pubertal adolescents, and brain maturation during sleep is reflected in EEG changes, which can be analyzed using Fast Fourier Transform (FFT). During adolescence, FFT may reveal increased power in the theta and beta bands, particularly during the pubertal period. This study aimed to analyze sleep EEG spectral changes via FFT in peripubertal and post-pubertal children, focusing on all sleep stages to evaluate potential puberty-related changes.

Materials and methods: Twenty healthy children were divided into two groups based on Tanner stage: early puberty (n=10; 5 girls, mean age: 9.8 ± 1.2 , range 8-12) and late puberty (n=10, 5 girls, mean age: 14.3 ± 0.8 , range 13-17). Participants underwent two consecutive nights of polysomnography, with the first night serving as an adaptation period and a minimum of 7.5 hours of recordings. The EEG was recorded using a 32-channel sleep system with a sampling rate of 256 Hz, including 20 EEG leads, two EOG channels, two EMG channels, and an ECG channel. FFT was applied to the C3-A2 derivation throughout the night in 4-second windows, and using Hanning window function before applying independent component analysis. Spectral power for delta1 (0.5-2.0 Hz), delta2 (2.0-4.0 Hz), theta (4.0-8.0 Hz), alpha (8.0-12.0 Hz), sigma (12.0-16.0 Hz), and beta (16.0-20.0 Hz) was calculated for each sleep stage. The Mann-Whitney U-test was used to compare sleep parameters, with significance set at $p < 0.05$. Spearman's correlation coefficient (r_s) was used to explore correlations between sleep parameters and FFT values, with a significance level of 0.05.

Results: The EEG Power spectral analyses in all sleep stages were significantly lower in Tanner 4/5 than in Tanner 2/3 children, compared to the absolute mean EEG power spectral between the two groups. No differences in EEG power spectral analyses were obtained between boys and girls. Differences in spectral sleep EEG were observed between the two groups (U-test, $p < 0.05$) across all sleep stages. Delta 2 ($p = 0.02$) and theta power ($p = 0.04$) were higher in the early puberty group. Delta power correlated negatively with N1 duration ($r_s = -0.46$, $p < 0.05$) and wake time after sleep onset ($r_s = -0.48$, $p < 0.05$), but positively with sleep efficiency ($r_s = 0.45$, $p < 0.05$) in the early puberty group. Theta power during REM sleep positively correlated with N3 duration ($r_s = 0.45$, $p < 0.05$) in the early puberty group.

Conclusions: Our results suggest that sleep EEG undergoes significant changes during puberty, reflecting brain maturation. We observed a decrease in theta and delta activity during REM sleep in the post-pubertal group, indicating a shift in brain function with puberty. These differences may be influenced by hormonal and environmental factors associated with puberty. REM sleep may serve as a useful biomarker of brain function for future therapeutic strategies.

Acknowledgments: MC Lopes is deeply grateful for the valuable advice from Prof. Carole Marcus. We miss her talent and her mentorship.

Study of Sleep Habits and Nutritional Status in Children in a Tertiary Care Hospital: Cross-Sectional Study

D. Chandranaik¹, G. Sai Chinmayee¹, L. Kamath¹, S.S. Rao¹

¹Kasturba Medical College, Mangalore, Manipal Academy of Higher Education, Manipal, Paediatrics, Mangaluru, India

Introduction: Sleep and nutrition are essential components of children's health and development. Sleep is vital for physiological functions like repair, growth, and memory consolidation, while proper nutrition supports physical and cognitive development. Malnourished children—both undernourished and obese—often experience disruptions in their sleep patterns, which can negatively affect their overall health. This study aimed to explore the relationship between sleep habits and nutritional status in malnourished children, providing valuable insights into how nutritional imbalances impact sleep quality.

Materials and methods: This cross-sectional study was conducted at the Regional Advanced Pediatric Care Centre (RAPCC), Mangalore, India, from March to May 2024. A total of 400 children aged 6 months to 10 years were enrolled through convenience sampling. Inclusion criteria were children visiting the outpatient department (OPD) of RAPCC, while those with acute or known chronic diseases or on medication that could affect sleep were excluded. Sleep habits were assessed using the Children's Sleep Habits Questionnaire (CSHQ), completed by parents with translations available when necessary. Nutritional status was categorized based on BMI into undernourished, normal, and obese groups. Data were analyzed using SPSS version 29, employing descriptive statistics, chi-square tests, and ANOVA.

Results:

The mean age of the cohort was 5.42 years (SD = 2.91), with 50.5% male and 49.5% female participants. Among the 400 children, 58.5% were under 5 years old, and 41.5% were aged 5-10 years. Nutritional assessments revealed that 30% of the children were undernourished, 57% had normal nutritional status, and 13% were obese. Sleep quality, measured by the total CSHQ scores (mean $\pm$ SD), was poorest among obese children (48.29 ± 9.55), followed by undernourished children (45.32 ± 8.81), and was significantly better in children with normal BMI (37.12 ± 7.24) (ANOVA $F = 112.43$, $p < 0.001$). Obese children exhibited significantly higher scores for bedtime resistance (mean = 6.78, $p < 0.001$) and sleep-disordered breathing (mean = 7.45, $p < 0.001$), while undernourished children showed higher sleep anxiety scores (mean = 5.92, $p = 0.002$). Parasomnias were more common in obese (56.7%) and undernourished children (38.3%) compared to their normal-weight peers (23.6%) (chi-square = 345.64, $p < 0.001$). Sleep-disordered breathing was observed in 62.5% of obese children and 33.3% of undernourished children, significantly higher than in normal-weight children (18.4%) (chi-square = 285.42, $p < 0.001$). A negative correlation between BMI and total CSHQ scores ($r = -0.27$, $p < 0.001$) indicated that higher BMI was associated with poorer sleep quality, as reflected by higher CSHQ scores.

Conclusions: Malnourished children, including those who are undernourished and obese, exhibit significantly worse sleep quality compared to their normal-weight counterparts. Common sleep issues in these groups include bedtime resistance, sleep anxiety, and sleep-disordered breathing. These findings emphasize the need for targeted interventions to address sleep disturbances in malnourished children, which could improve their overall health and development. This is particularly important in developing countries like India, where malnutrition remains a significant public health challenge.

Acknowledgments: We sincerely thank the children and their families for participating in this study. We also thank KMC, Department of Pediatrics, Mangalore, for their support.

Sustained Myofunctional Therapy in Pediatric Sleep-Disordered Breathing: Correlates of Adherence and Clinical Outcomes

S. Maity¹, A. Halder², P. Chatterjee³, G. Ghosh⁴, S. Roy⁵, D. Datta⁶, K. Ghosh⁷

¹Institute of Sleep Science, Department of Physiotherapy, Consultant Myofunctional Therapist & Sleep Health, Kolkata, India, ²Institute of Sleep Science, Department of Pulmonary Medicine, Consultant Pulmonologist and Sleep Medicine, CMRI, Kolkata, India, ³Institute of Sleep Science, Department of Pediatric Pulmonary Medicine, Consultant Pediatric Pulmonologist and Sleep Medicine, Apollo Multispeciality Hospital, Kolkata, India, ⁴Institute of Sleep Science, Department of Pediatrics, Consultant Paediatrician and Sleep Medicine, Naryana Superspecialty Hospital, Kolkata, India, ⁵Institute of Sleep Science, Department of Pediatrics, Consultant Paediatrician and Sleep Medicine, Manipal Hospital, Kolkata, India, ⁶Institute of Sleep Science, Department of ENT, Consultant ENT and Sleep Apnoea Surgeon, Manipal Broadway Hospital, Kolkata, India, ⁷Raiganj Government Medical College and Hospital, Department of Physiology, Raiganj, Uttar Dinajpur., India

Introduction: Pediatric sleep-disordered breathing (SDB) poses significant health risks, yet effective non-invasive therapies remain underexplored. This study evaluates the efficacy of myofunctional therapy (OMT) in children with SDB, focusing on clinical outcomes, adherence predictors, and the role of therapy duration.

Materials and methods: Data from 39 pediatric patients (mean age: 8.8 years; 82.1% male) undergoing OMT were analyzed. Variables included demographics (age, sex, BMI), clinical metrics (AHI, DI, SpO₂), therapy details (duration, daily minutes), and outcomes (PSQ scores, sleep quality, medication reduction). Statistical analyses identified correlations, adherence predictors (dropout flag = "N"), and effect sizes (Cohen's d).

Results: Clinical Outcomes:

- PSQ Scores: Mean improvement of -4.36 points ($p < 0.0001$), with progressive gains in longer therapy quartiles (Q4: -7.12 vs. Q1: -2.42).
- Sleep Quality: 94.9% reported improvement, achieving 83% success even in short-term therapy (7–30 days).
- Medication Reduction: 66.7% reduced medication use, strongly correlated with therapy duration ($r = 0.56$, $p < 0.001$).

Adherence and Dropouts:

- Adherent patients (n = 28) received significantly longer therapy (173 vs. 43 days, $p = 0.0022$) and longer daily sessions (18.75 vs. 10.45 minutes, $p < 0.001$).
- Dropouts (n = 11, 28%) were unrelated to demographics (age, sex, BMI) or clinical severity (AHI, DI, SpO₂).

Key Correlations:

- Therapy Duration: Strong negative correlation with PSQ ($r = -0.61$) and positive with medication reduction ($r = 0.56$).
- BMI and AHI: Higher BMI predicted worse apnea severity ($r = 0.64$).
- Sleep Quality: Rapid improvement (83% in Q1) but weak duration dependence ($r = 0.22$, $p = 0.17$).

Intervention Characteristics:

- Optimal outcomes occurred with sustained therapy (>180 days), particularly for ESS improvement (Cohen's $d = -1.78$) and medication reduction.
- Patients exceeding 360 days (Q4) achieved near-maximal benefits.

Conclusions: This study underscores the efficacy of OMT in pediatric SDB, demonstrating significant improvements in sleep quality, daytime sleepiness, and medication reliance. Adherence—driven by therapy duration and daily session consistency—emerged as the critical modulator of success, independent of demographics or baseline severity. Clinically, these findings advocate for:

1. Prolonged Therapy: Recommend durations >180 days, with >360 days for maximal PSQ and medication benefits.
2. Adherence Strategies: Universal support for daily sessions (≥ 19 minutes) and early intervention to mitigate dropouts.
3. BMI Monitoring: Address obesity as a modifiable risk factor for apnea severity.

As the first analysis linking OMT adherence to pediatric SDB outcomes, this work provides actionable insights for optimizing non-invasive therapies. By prioritizing sustained engagement, clinicians can amplify therapeutic benefits, reducing long-term health burdens in pediatric sleep disorders.

Keywords: Pediatric sleep-disordered breathing, myofunctional therapy, adherence, therapy duration, clinical outcomes.

The Association between Sleep and Behavioral Problems in Primary School Children in Shanghai

Y. Liu¹, H. Xu¹, J. Guan¹, S. Yin¹

¹Shanghai Sixth People's hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Otorhinolaryngology, Shanghai, China

Introduction: This study examined the associations between sleep disturbance (SD) and behavioral problems (BP) in primary school children in Shanghai.

Materials and methods: We enrolled 18 316 children in Xuhui district, Shanghai. Baseline assessments and follow-up used the Children's Sleep Habits Questionnaire (CSHQ) to classify SD, and the Conners' Parent Rating Scale (CPRS) to evaluate BP. Cross-sectional associations were analyzed via logistic regression; changes in SD status and their impact on BP remission or new onset were assessed with multilevel regression.

Results: With cross-sectional data, SD was linked to higher odds of any BP, including study problems, conduct problems, impulsivity-hyperactivity, hyperactivity index, psychosomatic complaints, anxiety. Daytime sleepiness correlated most strongly with BP symptoms. During follow-up, compared to children without SD, those with persistent or newly developed SD showed reduced BP remission and increased BP onset. Children whose SD remitted experienced no significant change in BP remission or onset.

Conclusions: In urban primary school children, SD closely related to BP. Early detection and targeted management of SD may help prevent or mitigate childhood behavioral difficulties.

The Clinical Utility of Repeat Pediatric Polysomnographies

N. Stoch¹, L. Barcesat-Stoch², A. Gileles-Hillel³, J. Reiter³

¹Hebrew University Faculty of Medicine, Jerusalem, Israel, ²Hebrew University Faculty of Dental Medicine, Jerusalem, Israel, ³Hadassah Medical Center and Hebrew University Faculty of Medicine, Jerusalem, Israel

Introduction: Pediatric sleep-disordered breathing is common and requires a Polysomnography (PSG) for objective diagnosis. In certain cases, such as trisomy 21, post-Adenotonsillectomy (AT), or part of the routine care of children with neuromuscular disorders (NMD), repeat PSGs are needed for diagnosis or follow-up. However, the real-life utilization and yield of repeat studies are unclear. In this study, we aimed to investigate the use of repeat PSGs and their yield in the general pediatric population and in children with background morbidities.

Materials and methods: A retrospective observational, descriptive, cross-sectional study. Data was collected on all children, 0-18 years old who completed two or more PSGs at the Hadassah Medical Center between 2019 and 2023. Demographic, clinical and PSG data was collected, the indications for the repeated PSG, changes in severity, and time elapsed between tests.

Results: A total of 158 (58 female) children were included, of whom 128 completed 2 PSGs, and 69 children 3 or more, at a mean age of 4.4 ± 4.1 years. Patient characteristics included: 76 children after AT, 34 with central sleep apnea (CSA). Common background diseases included trisomy 21 (n=30), prematurity (n=38) and chronic lung disease (n=17). The indication for repeated PSGs included assessment of OSA after an AT (33%), follow-up studies as requested by the treating physician or the parents (25%), and assessment of the need for oxygen or non-invasive ventilation (NIV, 17%). OSA improved in 74% after an AT, but resolved in only 12% of those that had not had an AT ($p < 0.001$). Severity of diagnosis differed following the repeat study in 63% of children with a history of prematurity, 54% with Trisomy 21, and 38% with NMD ($p < 0.001$). CSA diagnosis remained unchanged after repeat studies in 44%, after a mean of 8 months. A major change, defined as a change from moderate-severe to no or mild OSA and vice versa, was found in 39% of the entire cohort and 53% of children after an AT. Children who underwent their first PSG before the age of 1 showed a major change at 1.88 years (SD 1), whereas children who underwent their first PSG between ages 1-18 showed a major at 5.1 years (SD 4.13).

Conclusions: In this study, repeated PSGs revealed changes in sleep apnea diagnosis in a majority of children after AT, but to a far lesser extent in those with underlying morbidities. The study shows a high yield if the initial study was performed in an infant but suggests delaying repeat studies, for indications other than post AT, in older children. We hope our results will assist clinicians when considering the need and timing of a repeat PSG.

The connection between sleep, substance use, and mental well-being in rural Canadian Youth – Preliminary observations from a community-based youth collaboration

F.-G. Duval^{*1}, K. Fonseca^{*2,3}, R. Robillard^{2,3}, R. Tunks⁴, R. Gagnon⁴, A. Chapman⁴, R. Shams^{4,5}, D. Somppi⁴, T. Halsall³, K. Clouthier⁴, G. Forest¹, M. Porteous^{2,3}, . on behalf of the Canadian Sleep Research Consortium^{2,4}

¹Université du Québec en Outaouais, Département de Psychoéducation et de Psychologie, Gatineau, Canada, ²University of Ottawa, School of Psychology, Ottawa, Canada, ³University of Ottawa Institute for Mental Health Research at the Royal, Ottawa, Canada, ⁴Planet Youth, Lanark County, Canada, ⁵Southeast Public Health, Ottawa, Canada

Introduction: Sleep is essential for healthy development, particularly during adolescence – a period when risk factors for mental health challenges and substance use often emerge. Previous Canadian estimates suggested that 30% of adolescents do not meet national sleep recommendations, and over 60% of illicit substance users are between 15 to 24 years old. Insufficient sleep during adolescence has been linked to low self-esteem, difficulties with emotion regulation, and substance use. Many Canadian adults are using alcohol and cannabis as sleep aids. However, the potential connections between sleep, substance use, and mental well-being remain unclear in adolescents and are especially understudied in rural communities. There is also a need to identify modifiable factors associated with better sleep.

Materials and methods: Planet Youth is an ongoing project implementing the Icelandic prevention model in different communities across the world for upstream community action. As part of the Canadian portion of this project, 705 adolescents ($M_{age}:16.1\pm0.26$); 49.7% boy/man, 43.0% girl/woman, 1.8% non-binary, 0.6% gender fluid/non-conforming, 0.4% trans) completed a survey designed to assess risk and protective factors in key community domains (family, school, peer groups, and leisure/out-of-school time activities) and substance use. ACHIEVE, a local youth advisory committee ensuring youth voices are at the forefront of Planet Youth's initiatives, actively contributed to shaping the scope of secondary data analyses of this survey. A series of mediation analyses were conducted to examine the direct relationship between habitual sleep quantity, self-esteem, and anger, as well as the potential moderating role of cannabis and alcohol use in the past 30 days. Logistic regression was used to identify protective factors linked to sleep quantity at or above recommended values based on Canadian guidelines.

Results: In this rural sample of adolescents, 68% reported sleeping less than 8 hours. Insufficient sleep had direct effects increasing anger ($b=-0.77$, $t=-7.23$, $p<.001$) and decreasing self-esteem ($b=-1.67$, $t=-9.74$, $p<.001$). Additionally, insufficient sleep had significant indirect effects on anger that were mediated by higher alcohol (bootLLCI : $-.08$; $-.01$) and cannabis (bootLLCI : $-.11$; $-.01$) use. Insufficient sleep also had an indirect effect on self-esteem through cannabis (bootLLCI : $-.111$; $-.002$), but not alcohol use. Feeling safer at school and having a daily life filled with things that interest youth were the strongest independent protective factors associated with sufficient sleep duration ($|B|>.20$, $p<.003$).

Conclusions: Insufficient sleep was twice as frequent in this rural adolescent sample compared to national estimates. Insufficient sleep had a double effect where, it directly predicted more anger and poorer self-esteem, and had additional indirect effects whereby it increased alcohol and cannabis use, which in turn further worsened anger and self-esteem. Creating safe, stimulating environments for adolescents – both in and outside of school – may contribute to improving sleep, with positive impacts on substance use and mental well-being.

The effectiveness of transcranial magnetic stimulation on sleep structure and quality of life in children with autism

S. Somsup^{1,2}

¹IVIVA POLYCLINIC, Nakhon Pathom, Thailand, ²Robert Debre Hospital, Neuropediatrics, Paris, France

Introduction: Sleep disorders are common in children with autism spectrum disorder (ASD). Transcranial magnetic stimulation (TMS) could be effect the excitability of neuronal cells that leading to improvements of sleep and quality of life in autistic children. Now a day, studies on clinical mechanisms of TMS in sleep disorders associated with ASD are limited. Therefore, our study aimed to explore the effects of TMS on sleep structure and quality of life in children with ASD.

Materials and methods: The recruitment was directly informed through parents of autistic children in special education school in Nakhon Pathom Province, Thailand. Twenty children with ASD who met the diagnostic criteria of the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, were selected in our protocol. The low-frequency TMS 2Hz, 5Hz and 5Hz respectively and intensity of 3mT, 15mT and 30mT respectively were targeted on the prefrontal and dorsolateral cortex on both sides in children with ASD 2 times per week. The frequency and intensity were adjusted every 2 weeks up to maximum frequency and intensity at 6 weeks of treatment. The Sleep Disturbance Scale for Children (SDSC) was performed before treatment and at 12 weeks of intervention. Independent sample *t*-tests and difference *t*-tests were used for statistical analysis of the data.

Results: Before treatment the total SDSC score in difficulty falling asleep, sleep maintenance, awakening disorders, sleep-wake transition disorders, excessive daytime sleepiness, and nocturnal hyperhidrosis scores were high in all ASD children. After TMS were performed in all ASD children, after 8, 16 and 24 session of TMS Treatment with protocol of intensity and frequency adjustment every 4 weeks, the total SDSC score in difficulty falling asleep, sleep maintenance, sleep-wake transition disorders, and excessive daytime sleepiness scores were significantly decreased at 24 sessions of treatment ($P<0.01$). The difference *t*-test analysis showed that after 24 treatment sessions, the reduction rates of the total SDSC score, difficulty falling asleep, sleep maintenance, awakening disorders, sleep-wake transition disorders, excessive daytime sleepiness, and nocturnal hyperhidrosis dimensions were significantly decreased. ($P<0.01$).

Conclusions: Low-frequency TMS targeting the prefrontal and dorsolateral cortex in children with ASD can effectively improve their sleep status, and significant improvement can be achieved after 12 weeks (24sessions) of treatment. Moreover all of children had improved in quality of life in field of ability to learn and communication. Further study in multicenter and large scale population should be performed to achieve more significant statistic data and could be advocated to apply as a non invasive choice of treatment in clinical practice worldwide to improve quality of sleep and quality of life in autistic children.

Acknowledgments:

I would like to express their sincere gratitude to all of patients and their parents for their participation of this research. I also extend our appreciation to staff of our clinic and special education school in Nakhon Pathom Province, Thailand for providing the necessary facilities and advocacy message to parents of autistic children. Special thanks to my parent for their guidance, encouragement and private fund for this study.

The Mechanism of Ferroptosis in Chronic Intermittent Hypoxia Induced Liver Injury and the Regulation Role of Nrf2

S. Zhuge^{*1}, X. An^{*1}, P. Zhong¹, Y. Xu¹, X. Cai¹

¹The Second Affiliated Hospital and Yuying Children's Hospital of Wenzhou Medical University, Wenzhou, China

Introduction: Obstructive sleep apnea (OSA) is characterized by chronic intermittent hypoxia (CIH), which can induce or exacerbate liver injury. Ferroptosis, marked by iron overload and lipid peroxidation, is closely linked to liver injury, but its mechanistic role in CIH-related liver damage remains unclear. Evidence suggests that the antioxidant regulator Nrf2 may protect against ferroptosis-driven injury, though the mechanisms require further exploration. This study established a CIH-induced liver injury mouse model to investigate the role of ferroptosis in CIH-induced liver injury and the protective effect and molecular mechanism of Nrf2 in ferroptosis mediated CIH-induced liver injury.

Materials and methods: In this study, utilizing a CIH model in 4-week-old male mice, we investigated ferroptosis and the potential involvement of Nrf2 in CIH-related liver injury. Post-modeling, serum ALT/AST activity, hepatic iron, MDA, SOD, GSH, histopathology (HE, Masson, Prussian blue staining), mitochondrial ultrastructure (TEM), and ferroptosis-related molecules (GPX4, SLC7A11, TFR1, ACSL4) mRNA/protein levels were analyzed.

Results: Chronic intermittent hypoxia (CIH) exposure in mice induced liver ferroptosis, evidenced by elevated ALT/AST levels, disrupted hepatic architecture, fibrosis, iron overload, mitochondrial damage (outer membrane rupture, cristae loss), oxidative stress (increased MDA, decreased SOD/GSH), and dysregulated ferroptosis markers (downregulated GPX4/SLC7A11, upregulated TFR1/ACSL4). Interventions with DFO (iron chelator) and Lip-1 (ferroptosis inhibitor) reversed these effects, restoring liver function, reducing iron deposition, mitigating mitochondrial injury, and normalizing oxidative/ferroptosis-related biomarkers. Nrf2 activation via sulforaphane (SFN) further alleviated CIH-induced damage, lowering body/liver weight, reducing fibrosis, and modulating ferroptosis markers (upregulating GPX4/SLC7A11/FSP1, downregulating TFR1/ACSL4), whereas Nrf2 inhibition (brusatol, BRU) exacerbated injury.

Conclusions: Chronic intermittent hypoxia exposure can induce lipid peroxidation and iron ion overload, triggering ferroptosis and leading to liver injury in mice. Activation of the Nrf2 signaling pathway can effectively alleviate chronic intermittent hypoxia-related liver injury by reducing iron ion accumulation and upregulating FSP1 expression to inhibit lipid peroxidation, thereby suppressing the ferroptosis process.

The presence or absence of sleep apnea in a healthy newborn aged 2 days

S. Mitachi¹, R. Murasugi², K. Satoh³, K. Fukui², H. Kawanabe²

¹Tokyo University of Technology, Tokyo, Japan, ²Ohu University, Division of Orthodontics and Dentofacial Orthopedics, Department of Oral Growth and Development, Ohu University School of Dentistry, Kohriyama, Japan, ³Ohu University, Department of Pharmacology of Diseases in the Respiratory Medicine of the Dental School Hospital, Kohriyama, Japan

Introduction:

A study was conducted on 171 healthy newborns aged 2 days using a quartz optical fiber-type sleep apnea sensor for approximately 2 hours and 5 minutes in an unrestrained manner, measuring the possibility of the presence of sleep apnea.

Materials and methods: So far, measurements of overnight sleep (ranging from 5 to 8 hours) have been conducted on individuals aged from 0 years and 2 months to 81 years using a plastic optical fiber type sleep apnea sensor, suggesting a possibility of sleep apnea at around 10%. This time, since the measurement is of a lighter weight newborn just 2 days old, a quartz optical fiber type sleep apnea sensor was used to increase sensitivity. Measurements were taken in an unconstrained manner for approximately 2 hours and 5 minutes on 171 healthy newborns aged 2 days, assessing the possibility of sleep apnea.

Results: In this study involving 177 healthy newborns (2 days old), fortunately, there were no instances of rolling over or standing up, allowing for very smooth measurements. Analysis was possible for 171 cases, while 6 cases were deemed unmeasurable due to too low signal levels. For the 171 measurable cases, an apnea was determined if there was a period of apnea of more than 2 breaths (which varies by individual but measured approximately from 2.1 seconds to 4.1 seconds). As a result, among the 171 newborns, 116 had an RDI (Respiratory Disturbance Index) of <5 , indicating normal, 45 cases were mild at $5 \leq$ and <15 , and 9 were moderate at $15 \leq$ and <30 . This showed that 67.8% were normal, 26.3% were mild, and 5.3% were moderate, indicating that even 2-day-old newborns display a distribution similar to that of infants and adults. Further analysis with more cases is needed to substantiate this conclusion.

Conclusions: Using a quartz optical fiber type sleep apnea sensor, measurements were taken regarding the possibility of sleep apnea in a healthy newborn at two days old, yielding results that indicate a distribution of sleep apnea likelihood consistent with infants and adults aged 2 months to 81 years. Going forward, it will be important to continue monitoring how this result may change or remain constant as these newborns grow into toddlers.

Acknowledgments: We would like to sincerely thank Dr. Ken Anzai from the Obstetrics and Gynecology Department of Hoshi General Hospital, who conducted respiratory measurements during sleep for a 2-day-old newborn for this study. We are also deeply grateful to Dr. Naofumi Hosoya, who provided ongoing advice throughout this research. Finally, We would like to thank Mr. Kazuhiro Kuwahara and Mr. Toshifumi Hosoya from Sumitomo Electric Industries, who provided the GI-type optical fiber sheet.

Thermal Properties of Infant Bedding: An Evaluation of Heat Dissipation Efficiency

A. Tange^{1,2}, K. Shimizu¹, Y. Maeda¹, A. Suga^{1,3}, M. Hayashi²

¹Unicharm Corporation, Global Research & Development, Kanonji, Japan, ²Hiroshima University, Graduate School of Humanities and Social Sciences, Higashihiroshima, Japan, ³Nagoya University, Nagoya, Japan

Introduction: Melatonin secretion increases rapidly during the first year of life, contributing to the development of a circadian sleep-wake rhythm. Therefore, establishing an appropriate sleep environment during infancy is essential. In particular, optimizing the thermal environment is believed to reduce nighttime awakenings and shorten sleep onset latency. In Japan, traditional infant bedding typically consists of firm polyester fiber mattresses and comforters. However, bedding systems incorporating 3D fiber structure mattresses and wearable blankets (sleepers), designed to improve thermal regulation, have recently gained popularity.

This study aimed to evaluate the thermal characteristics of infant bedding systems with high heat dissipation performance.

Materials and methods: Fifteen healthy infants aged 1 to 4 months residing in Japan participated. Three bedding types were tested: Bedding P (a newly developed 3D fiber structure mattress with enhanced surface heat dissipation and a sleeper), Bedding Q (a commercially available 3D fiber

mattress with a waterproof sheet and comforter), and Bedding R (a traditional firm polyester fiber mattress with a waterproof sheet and comforter). Each bedding system was used during approximately one hour of daytime napping in a climate-controlled chamber (25°C, 50% RH).

Measurements included sweat rate, mattress surface and underside temperature and humidity, and skin surface temperature at the groin and ankle.

Results: Results showed that Bedding P had the lowest sweat rate (0.108 mg/cm²/min), significantly lower than Bedding Q (0.264 mg/cm²/min, $p = 0.020$). Mattress surface temperature at the back was significantly higher in Bedding R (36.1°C) compared to P and Q (both 34.8°C, $p < 0.001$), indicating heat accumulation. Underside mattress temperature was higher in P and Q (27.4°C) than R (26.6°C, $p = 0.012$), suggesting better heat dissipation. Absolute humidity beneath the mattress was lower in P and Q (15.3 and 14.2 g/m³) than R (16.2 g/m³, $p < 0.001$). The distal-proximal skin temperature gradient showed no significant differences among groups.

Conclusions: Overall, Bedding P demonstrated superior thermal performance, with lower sweat rate and reduced heat accumulation, indicating a more favorable sleep environment. Bedding Q, despite using the same 3D fiber mattress as P, retained more heat due to the waterproof sheet and comforter. Bedding R, with its high-density polyester fiber, showed the greatest heat retention. For infants who cannot adjust posture or wipe sweat, Bedding P's ability to facilitate heat dissipation may help reduce thermal stress and improve sleep quality.

Acknowledgments: We would like to express our sincere gratitude to Professor Yasunori Oka of the Sleep Medicine Center, Ehime University Hospital, for his valuable advice and guidance throughout the course of this research.

The Role of Simple Hematological Indicators in the Assessment of Obstructive Sleep Apnea Syndrome in School-Age Children

Y. Wang¹, S. Wang², Y. He², X. Xu², M. Lv²

¹Children's hospital of Soochow University, Respiratory medicine, Suzhou, China, ²Children's hospital of Soochow University, Respiratory Medicine, Suzhou, China

Introduction: To explore the correlation between simple hematological indicators, including blood routine, biochemical and their combination indicators, and the severity of obstructive sleep apnea hypopnea syndrome (OSAS) in children, providing a certain basis for screen and follow-up after treatment in outpatient or primary hospitals.

Materials and methods: School-age children who visited the respiratory department of Children's hospital of Soochow University from January 2017 to June 2022 for snoring and/or mouth breathing were enrolled. Polysomnography (PSG) were performed and peripheral venous blood was collected for routine blood tests and biochemical tests, and the values of combined indicators were calculated, including Neutrophil-to-Lymphocyte Ratio (NLR), Platelet-to-Lymphocyte Ratio (PLR), Monocyte-to-Lymphocyte Ratio (MLR), Systemic Immune Inflammation Index (SII), Systemic Immune Response Index (SIRI), Aggregated Inflammation Score Index (AISII), White Blood Cell-to-Mean Platelet Volume Ratio (WMR), and High-Sensitivity C-Reactive Protein-to-Albumin Ratio (HCAR). SPSS 26.0 statistical software was used for analysis to examine the correlation between various hematological indicators and severity of OSAS.

Results: 1. A total of 343 school-age children were included, with 104 cases (30.3%) diagnosed with simple snoring, 155 cases (45.2%) with mild OSAS, and 84 cases (24.5%) with moderate to severe OSAS. There were no statistically significant differences in gender ($\chi^2=0.886$, $P=0.642$), age ($H=3.871$, $P=0.144$), or BMI ($H=4.456$, $P=0.108$) among the three groups.

2. The WBC and NE of the moderate to severe OSAS group were $7.94 (6.73, 8.85) \times 10^9/L$ and $3.17 (2.56, 3.94) \times 10^9/L$, respectively, which were significantly higher than those of the mild OSAS group $7.25 (6.23, 8.28) \times 10^9/L$ and $2.99 (2.41, 3.76) \times 10^9/L$. The MPV, PDW, and hs-CRP of the moderate to severe group were 10.3 (9.6, 10.9) fL, 11.8 (10.5, 13.1)%, and 0.44 (0.17, 1.25) mg/L, respectively, which were significantly higher than those of the simple snoring group 9.9 (9.4, 10.4) fL, 10.8 (9.7, 11.7)%, and 0.22 (0.08, 0.7) mg/L, and the mild OSAS group 10.2 (9.6, 10.9) fL, 11.6 (10.4, 12.9)%, and 0.3 (0.11, 1.05) mg/L. The WMR of the mild OSAS group was 703 (607, 859), lower than that of the simple snoring group 782 (658, 898) and the moderate to severe OSAS group 792 (658, 919). The HCAR of the moderate to severe group was 0.009 (0.003, 0.026), significantly higher than that of the simple snoring group 0.005 (0.002, 0.013), with statistically significant differences ($P < 0.05$).

No statistically significant differences were found among the other groups.

3. WBC, NE, PDW, hs-CRP, WMR, and HCAR were positively correlated with OAH1 ($r=0.189, 0.199, 0.165, 0.247, 0.185, 0.184, P<0.05$). WBC, NE, PDW, hs-CRP, WMR, and HCAR were positively correlated with ODI ($r=0.237, 0.215, 0.162, 0.241, 0.202, 0.203, P<0.05$). WBC, NE, PDW, hs-CRP, WMR, and HCAR were negatively correlated with LSpO2 ($r=-0.209, -0.193, -0.162, -0.181, -0.179, -0.151, P<0.05$).

Conclusions: WBC, NE, PDW, hs-CRP, WMR, and HCAR can be used as auxiliary indicators for assessing the severity of OSAS in school-age children.

Acknowledgments: The authors are grateful to all technicians of the Laboratory, the Children's Hospital of Soochow University, for technical contributions.

The temporal associations between sleep and circadian preference, and mental health among Norwegian adolescents

²University of Bergen, Department of Global Public Health and Primary Care, Bergen, Norway,

³University of Bergen, Department of Psychosocial Science, Bergen, Norway, ⁴Sleep Cycle AB,

Gothenborg, Sweden, ⁵University of Bergen, Department of Clinical Dentistry, Bergen, Norway

Introduction: Eveningness, short sleep, sleep problems and mental health problems are all common amongst adolescents. While research has indicated a bidirectional relationship between sleep and mental health, fewer studies have explored the relationship between circadian preference and mental health. The aim of the present study was to explore the temporal associations between sleep, circadian preference, and mental health in adolescents.

Materials and methods: In 2019, all 1st year high school students in two Norwegian counties were invited to complete a web-based survey assessing sleep, circadian preference, and anxiety and depression (response rate 42.0%). Responders were invited to complete a follow-up survey in 2021 (response rate 42.4%). The analyzed sample comprised 1,456 students born in 2002 who completed both surveys (61.4% girls, mean age 16.4 years at baseline). Instruments included the Munich ChronoType Questionnaire, the Bergen Insomnia Scale, the reduced Morningness-Eveningness Questionnaire, the Generalized Anxiety-Disorder-7 (GAD-7) and the Patient Health Questionnaire-9 (PHQ-9). Two sets of logistic regression analyses were conducted: i) Sleep and circadian preference at baseline (continuous parameters) as independent variables, and anxiety (GAD-7 ≥ 8) and depression (PHQ-9 ≥ 10) at follow-up (dichotomous parameters) as dependent variables, controlling for sex, maternal education and anxiety/depression at baseline, and ii) Anxiety and depression at baseline (dichotomous parameters) as independent variables, and sleep and circadian preference at follow-up (dichotomous parameters) as dependent variables, controlling for sex, maternal education and sleep/circadian preference at baseline.

Results: Baseline school night sleep duration was negatively, and insomnia symptom severity positively, associated with anxiety [OR 0.87 (0.78-0.96) and OR 1.07 (1.04-1.09), respectively] and depression [OR 0.81 (0.73-0.89) and OR 1.07 (1.05-1.09), respectively] at follow-up. Higher morningness scores at baseline predicted lower risk for both anxiety and depression at follow-up [OR 0.96 (0.91-0.99) and OR 0.94 (0.91-0.98), respectively]. Social jetlag and free night sleep duration at baseline were not associated with anxiety and depression at follow-up. The reverse analyses showed that both anxiety and depression at baseline were associated with higher risk for chronic insomnia [OR 1.84 (1.37-2.48) and 1.74 (1.27-2.38) respectively] and lower risk for social jetlag ≥ 2 hours [OR 0.74 (0.55-0.99) and 0.66 (0.48-0.90) respectively] at follow-up. Depression but not anxiety predicted evening preference at follow-up [OR 1.40 (1.01-1.96)]. Neither anxiety nor depression at baseline was associated with sleep duration ≥ 8 hours on school nights or free nights at follow-up.

Conclusions: Overall, these results attest to temporal associations, not only between sleep and mental health but also between circadian preference and mental health, in adolescents. Interestingly, whereas short school night sleep duration at baseline predicted anxiety and depression at follow-up, results did not support the reverse association in that anxiety and depression at baseline did not predict short school night sleep duration at follow-up. When promoting adolescent health, it seems important to target both sleep, circadian preference and mental health in order to reduce the risk of later sleep- and mental health problems.

Toddler Sleep Patterns: Exploring Associations Between Bedtime Consistency and Routines, Parental Involvement and Sleep Outcomes

S. Thakur¹, M. Lucchini¹, S. Berger², M. Ordway³, N. Barnett¹

¹Nanit Lab, New York City, United States, ²City University of New York, New York City, United States,

³Yale School of Nursing, Orange, United States

Introduction: Optimal sleep is essential for physical growth, cognitive and emotional development. Sleep patterns in toddlers are influenced by biological maturation, environmental factors, and parental practices. Regarding the latter, previous research has shown that falling asleep independently and a regular and early bedtime are associated with longer total sleep duration, later wake-up times, and fewer nighttime parental visits. Nonetheless, these behaviors have often been investigated independently. To overcome this limitation, we sought to identify distinct patterns of parent-mediated bedtime practices and explore the relationship between these patterns and explore their implications for toddler sleep health.

Materials and methods: A total of 518 parents of toddlers aged 18-48 months ($M = 26.77 \pm 6.8$ months, 52.31% males) from the user base of the Nanit baby monitor in the United States participated in this study. They completed the Brief Infant Sleep Questionnaire-Revised (BISQ-R). Objective sleep metrics from the Nanit autovideosomnography system were available for 241 participants for two weeks (average 10.78 nights per child). K-modes clustering analysis was used to classify patterns of parental practices based on parental report of bedtime routines, bedtime, bedtime consistency, and methods of having their child fall asleep. Differences in objective sleep metrics of Total Sleep Time (TST), Bedtime Variability (BTV), Wakeup Time (WK), Parental Visits (PV), and Night Awakenings (NW) were examined across the identified profiles.

Results: Three distinct profiles were identified: Early Consistent Sleepers (ES, 45.75%, 25.27 ± 6.04 months), Inconsistent Sleepers (IS, 12.16%, 29.4 ± 7.30 months) and Late Consistent Sleepers (LS, 42.08%, 27.65 ± 7.22 months). ES had the earliest bedtime on average (19.59 ± 0.73). ES and LS had the highest proportion of children with a consistent bedtime (97.46%, 93.50%) and the same bedtime routine for 5 or more nights/week (91.56%, 96.3%) respectively, compared to IS with 20.63% of children with consistent bedtime and 9.5% with 5 or more nights/week of same bedtime routine. Additionally, 82.27% of ES fell asleep independently, compared to 50.79% in IS and 70.18% in LS.

Significant differences in sleep outcomes were observed across the profiles. ES slept on average 39.96 minutes (95% CI: 17.28, 62.7) longer than IS and 35.64 minutes (95% CI: 21.18, 50.4) longer than LS. IS had significantly higher BTV than ES by 9.88 minutes (95% CI: 1.8, 17.94) and ES woke up on average 35.28 minutes (95% CI: 16.92, 53.7) earlier than IS and 23.93 minutes (95% CI: 12.24, 35.64) earlier than LS. There were no significant differences observed in NW and PV across the profiles.

Conclusions: One of the strengths of this study is relying on objective sleep data to measure variability in toddler bedtime. These findings provide valuable insights into parental bedtime practices, including timing, consistency, and routines related to toddler sleep. Results suggest that consistent and earlier bedtimes may support longer sleep duration. Understanding these patterns can help tailor targeted sleep interventions to support healthy sleep habits in young children.

Two Cases of Delayed Hemorrhage Following Coblation Adenoidectomy

S. Qiu¹, J. Zeng¹, J. Zhong¹

¹Southern Medical University, Shenzhen, China

Introduction: Coblation adenoidectomy is widely adopted for pediatric obstructive sleep apnea (OSA) due to its precision and minimal invasiveness. Delayed hemorrhage (>24 hours post-surgery), though rare, poses life-threatening risks.

Materials and methods: Through analysis the clinical data of two pediatric cases of delayed hemorrhage following coblation adenoidectomy and discusses the etiology, treatment, and preventive strategies based on a literature review.

Results: Case 1: A 3-year-4-month-old girl with severe adenoid hypertrophy (IV degree) and OSA (OAHI 1.9/h) underwent coblation adenoidectomy. On postoperative day (POD) 14, she presented with recurrent bleeding unresponsive to nasal packing. Emergency exploration under general anesthesia revealed mucosal erosion with active bleeding at the nasopharynx-posterior choanae junction, managed via plasma coagulation (Smith&Nephew Coblator II; cut:7, coagulation:3). Severe anemia (HGB 53g/L postoperatively) required transfusion. Recovery was uneventful, with no recurrence at 1-month follow-up.

Case 2: A 5-year-10-month-old boy with adenotonsillar hypertrophy (IV degree) and OSA (OAHI 5.4/h) underwent concurrent coblation adenoidectomy and tonsillectomy. On POD 16, he developed pulsatile bleeding at the left posterior choanae margin, resistant to nasal packing. Intraoperative endoscopy identified a bleeding site with pseudomembrane detachment, successfully controlled via plasma coagulation. No recurrence occurred during follow-up.

Conclusions: Delayed hemorrhage after coblation adenoidectomy, though rare, requires heightened vigilance. Early recognition, endoscopic exploration, and targeted hemostasis are vital to prevent complications. Further studies are needed to optimize surgical protocols and risk stratification.

Understanding the impact of growth hormone on ventilatory control stability in children with Prader-Willi syndrome

O.R. Patoglu¹, R.S. Horne¹, D.L. Mann², S. Landry³, M.J. Davey^{1,4}, G.M. Nixon^{1,4}, B.A. Edwards³

¹Monash University, Department of Paediatrics, Level 5, Monash Children's Hospital, Melbourne, Australia, ²The University of Queensland, School of Electrical Engineering and Computer Science, Brisbane, Australia, ³Monash University, School of Psychological Sciences, Melbourne, Australia, ⁴Monash Children's Hospital, Melbourne Children's Sleep Centre, Melbourne, Australia

Introduction: A hallmark feature in children with Prader-Willi syndrome (PWS) is dysfunction in the hypothalamic-pituitary axis, which results in markedly reduced growth hormone (GH) secretion in some children. As such, children with PWS often receive GH replacement therapy early in life. However, administration of GH therapy has been implicated in the development of sleep disorders such as obstructive sleep apnoea (OSA). The mechanisms underlying this development are poorly understood but may be related to the impact that the therapy has on the mechanisms known to cause OSA in children, including unstable ventilatory control. Therefore, our study investigated the impact of GH treatment on ventilatory control stability (i.e. loop gain [LG]) during sleep in children with PWS.

Materials and methods: Polysomnographic data pre- and post-GH commencement in 25 children (aged 2 months to 18 years) were collected, with an average time between studies of 6.4 months. To investigate the stability of the negative feedback loop governing ventilation, we utilised a published method that estimates LG from the ventilation changes following spontaneous sighs during sleep. Data were analysed in RStudio using linear mixed-effects modelling. Covariates that could impact LG including: age, obstructive and central sleep apnoea severity (measured as the obstructive-apnoea hypopnoea index (OAHI) and central apnoea-hypopnoea index (CAHI) respectively) were added using a stepwise, manual forward approach and only those with significant associations were retained in the final model.

Results: Loop gain was not altered by GH administration (0.003, 95% CI: [-0.049, 0.042], p=0.878). Adding age, OAHI and CAHI into the main model did not alter the impact of GH on LG. Older children tended to have a slightly higher LG, with each month of age associated with an estimated increase of 6.5×10^{-4} (95% CI: [1.0×10^{-4} , 1.2×10^{-3}], p=0.032) independent of GH treatment. OAHI and CAHI had positive, but very small associations with LG, where higher OAHI and CAHI were associated with higher LG.

Conclusions: Initiation of GH therapy did not impact LG which suggests GH does not alter ventilatory control. The development of OSA post-GH requires further investigation as it is likely related to other mechanisms, such as hypertrophy of the adenoids and tonsils. The contribution of ventilatory control to sleep-disordered breathing in PWS outside of any impact of GH also warrants further investigation.

Acknowledgments: We wish to thank all the parents and children who participated in this study, the staff of the Melbourne Children's Sleep Centre where the studies were carried out and acknowledge the Prader-Willi Research Foundation of Australia for providing funding for this project.

Validation of a national actigraph in children and adolescents

L.A. Evangelista¹, A.L. Eckeli¹, F.G. Stelzer¹, V.D. Carvalho¹, H.F. Soares²

¹Ribeirão Preto Medical School - University of São Paulo, Neurology, Ribeirão Preto, Brazil, ²Ribeirão Preto Medical School - University of São Paulo, Biomedical Informatics, Ribeirão Preto, Brazil

Introduction: Sleep is a neurophysiological process essential to child and adolescent development, playing a central role in cognitive, behavioral, and emotional functions. Early identification of sleep disorders is key to prevent health impairments, which highlights the need for reliable evaluation methods. While polysomnography (PSG) offers detailed analysis of sleep architecture, actigraphy has emerged as a less invasive, more accessible alternative capable of prolonged sleep monitoring. However, validation of actigraphy in children and adolescents is still lacking.

Objectives: This study aimed to validate the ActTrust2 actigraph and to compare the performance of three algorithms (Actiware, Cole-Kripke, and Sadeh) in estimating sleep parameters in children and adolescents, using PSG as the reference.

Materials and methods: Methods: Thirty-three participants, aged 2 to 16 years, underwent simultaneous PSG and actigraphy recording. Evaluated parameters included total sleep time, sleep latency, wake after sleep onset (WASO) and sleep efficiency. The three algorithms were compared using performance metrics such as accuracy, sensitivity, specificity, positive predictive value and negative predictive value. Data normality was assessed using the Shapiro-Wilk test, normality was assessed using the Shapiro-Wilk test, followed by nonparametric analyses including Friedman, Wilcoxon, and Spearman correlation tests with Bonferroni correction.

Results: Results: The Actiware algorithm showed the best overall performance, with higher accuracy (82.4%), sensitivity (86.6%), lower bias, and strong correlations with PSG for total sleep time, WASO, and sleep efficiency. However, its correlation for sleep latency was weak non-significant. The Cole-Kripke algorithm demonstrated intermediate performance, with balanced sensitivity (76.0%) and specificity (78.6%), and moderate bias. Despite higher bias, lower accuracy (69.5%), and sensitivity (65.6%), the Sadeh algorithm was the only one that did not show a significant difference in sleep latency compared to PSG suggesting better agreement.

Conclusions: Conclusions: The results demonstrate that the ActTrust2 actigraph, when combined with appropriate algorithms, is a valid and reliable tool for assessing sleep in children and adolescents.

Validity and Reliability of a Filipino and Cebuano Version of the BEARS Pediatric Sleep Questionnaire

P.M.C. Bernardo¹, S.D. Monzon¹, M.C.C. Galang¹, R.C. Dela Eva², D.Q. Perez²

¹St. Luke's Medical Center - Global City, Comprehensive Sleep Disorders Center, Taguig City, Philippines, ²St. Luke's Medical Center - Quezon City, Comprehensive Sleep Disorders Center, Quezon City, Philippines

Introduction: Sleep is central to the overall health and development of children, yet sleep-related problems are prevalent affecting a significant portion of the pediatric population. The BEARS questionnaire-offers a comprehensive approach to screening for sleep problems. However, the lack of versions in local and familiar languages like Filipino and Cebuano limits its widespread use. The objective of this study is to translate, cross-culturally adapt, and validate the BEARS pediatric sleep questionnaire into Filipino and Cebuano languages This will enable healthcare professionals to effectively screen for sleep-related issues in Filipino children, allowing for early detection and intervention.

Materials and methods: The study was conducted from November 2023 to February 2024. The translation process involved forward-backward translation techniques carried out by a team of linguistic experts, clinicians, and non-clinicians. Cross-cultural adaptation involved testing the translated questionnaires in a sample of 467 pediatric patients 2 to 18 years old and their parents, legal guardians, or primary caregivers. Face validity was assessed qualitatively, while content validity was measured using the Content Validity Index (CVI). Test-retest reliability was evaluated using Cohen's Kappa (κ).

Results: The content validity assessment by subject matter experts (SME) found the questionnaire items highly relevant with strong consensus on item importance (BEARS-Filipino CVI =1, BEARS-Cebuano CVI 0.78-1). While most questions were deemed clear and comprehensive, some suggestions were made to refine language and structure for better understanding among target respondents. Following SME feedback, pre-final versions of the questionnaires were developed and tested on a sample of participants with face validity assessment revealing minimal difficulties and generally positive feedback. Test-retest reliability showed a range from minimal to perfect level of consistency and agreement (BEARS-Filipino 2-5 years κ = 0.2785 to 1, 6-12 years κ = -0.1 to 0.6796, 13-18 years κ = -0.2 to 0.6429; BEARS-Cebuano 2-5 years κ = 0 to 0.7272, 6-12 years κ = 0 to 1, 13-18 years κ = 0 to 1).

Conclusions: The comprehensive analysis underscores the complex nature of pediatric sleep problems and the challenges in capturing these through standardized questionnaires. The findings of this study suggest that the translated tools can be used in the assessment of pediatric sleep problems in the Philippines, most especially in children age 2 to 12 years old, enhancing our ability to address sleep-related concerns effectively

Acknowledgments: The Research Team extends heartfelt gratitude to all participants who generously dedicated their time and insights to this study. Special appreciation goes to the 101 Health Research Team and subject matter experts for their invaluable feedback and guidance during the validation process. We are also deeply thankful to our colleagues, collaborators, and supportive family members whose assistance and encouragement were instrumental at every stage of the research. Additionally, we express our sincere thanks to Dr. Judith Owens for graciously sharing her questionnaire, which greatly contributed to the success of this study. This study would not come into fruition without the collective support and contributions of everyone involved.

WatchPAT tolerance and validity as a sleep assessment tool in children and adolescents

L.C. Nisbet^{1,2}, E.C. McLeod², R.S. Horne², M.J. Davey^{1,2}, G.M. Nixon^{1,2}

¹Monash Children's Hospital, Melbourne Children's Sleep Centre, Melbourne, Australia, ²Monash University, Department of Paediatrics, Melbourne, Australia

Introduction: The WatchPAT (WP, Itamar Medical) is a home sleep assessment device validated in adults, however few studies have assessed its accuracy in the paediatric population, and none have reported patient tolerance or data quality. Tolerability is a key determinant of success in paediatric sleep investigations. The WP measures peripheral arterial tonometry using a one-size finger probe with an inflatable cushion, designed for use in $\geq 12y$. As accurate calculation of total sleep time (TST) is critical for calculation of obstructive sleep apnoea (OSA) severity, we aimed to firstly assess the validity of sleep/wake recording using the WP in children aged 8- $<12y$ and adolescents aged $\geq 12y$ compared to simultaneous polysomnography (PSG), and secondly report tolerability in this population.

Materials and methods: Prospective study of children aged 8-18 years undergoing diagnostic in-laboratory PSG for suspected OSA, with simultaneous WP-300. TST (minutes), wake after sleep onset (WASO; minutes), rapid eye movement sleep (REM; %), light sleep (N1 and N2; %) and deep sleep (N3; %) from the WP automated study report were compared to PSG sleep scored using standard clinical paediatric criteria. As the WP does not quantify signal loss, good quality data was defined as participants having: PSG-TST $>4h$, WP technically valid sleep time $>4h$, and <40 minutes discrepancy between WP and PSG recording time.

Results: Data were collected in 100 patients. All participants tolerated PSG; WP was aborted in 6 participants (6% of $<12y$, 6% of $\geq 12y$; $p>0.05$) prior to sleep onset, mainly due to discomfort from the finger probe. Good quality WP recording was achieved in 79 participants (79%), which was similar in both age groups (82% $<12y$, 76% $\geq 12y$; $p>0.05$), with median (IQR) age 11.9y (9.9, 13.6), BMI z-score 1.1 (0.1-2.1) and 44% were female. Median PSG-TST was 423.5 (387.5, 456.6) minutes compared to WP-TST 444 (402, 474). Median difference from PSG for WP was +14min for TST, +7.4% for %REM, -6.8% for %light sleep (all $p<0.001$), and +1.4% for %deep sleep ($p>0.05$). Moderate correlation was seen between PSG and WP-calculated TST ($Rho=0.66$, $p<0.001$), with weak correlation for %REM ($Rho=0.13$, $p<0.001$) and %light sleep ($Rho=0.19$, $p<0.001$); %deep sleep and WASO were weakly correlated not statistically significant. A similar pattern was seen in both $<12y$ ($n=40$) and $\geq 12y$ ($n=39$) with the exception of in children $<12y$, WP-TST and PSG-TST were not significantly different ($p>0.05$), however WP overestimated WASO ($p=0.002$).

Conclusions: Approximately 4 out of every 5 children tolerate the WP, with similar tolerance and data quality in those above and below 12 years. Compared to PSG, WP significantly overestimates TST in adolescents, and overestimates WASO in children below 12 years. In both children and adolescents, compared to PSG, WP overestimates REM sleep and underestimates N1+N2 sleep. In both children and adolescents, median percentage of WP N3 sleep does not differ from PSG overall, however the large spread of both over- and under-estimation by WP may be clinically significant. How the overestimation of TST affects WP accuracy in assessment of OSA severity in this population is yet to be determined.

“You cannot sleep good sleep if you are in Nigeria”: Perspectives on adolescent sleep in Nigeria

O. Olorunmoteni¹, A. Fatusi², T. Oyetoke³, F.X. Gómez-Olivé⁴, K. Scheuermaier⁵, S. Nieuwoudt⁶

¹Obafemi Awolowo University and Obafemi Awolowo University Teaching Hospital, Ile-Ife, Nigeria, Paediatrics and Child Health, Ile-Ife, Nigeria, ²Obafemi Awolowo University and Obafemi Awolowo University Teaching Hospital, Ile-Ife, Nigeria, Community Health, Ile-Ife, Nigeria, ³Obafemi Awolowo University Teaching Hospital, Paediatrics, Ile-Ife, Nigeria, ⁴University of Witwatersrand, MRC/Wits Rural Public Health and Health Transitions Research Unit (Agincourt), School of Public Health, Faculty of Health Sciences, Johannesburg, South Africa, ⁵University of Witwatersrand, Brain Function Research Group, School of Physiology, Johannesburg, South Africa, ⁶University of Witwatersrand, School of Public Health, Faculty of Health Sciences, Johannesburg, South Africa

Introduction: The social determinants of sleep health in developed countries have been explored. However, there is limited data on the risk and protective factors for adolescent sleep health in Nigeria, and the perspectives of stakeholders need to be understood. Hence, an exploration of the perspectives of stakeholders like parents, teachers and adolescents is relevant. We aimed to understand the perspectives of adolescents, parents and teachers on the barriers and enablers of adolescents' sleep health in Nigeria.

Materials and methods: We utilised pre-tested topic guides to ask participants about the barriers and enablers of adolescents' sleep in Nigeria. We conducted focus group discussions (FGDs) and in-depth interviews (IDIs). There were 12 FGDs for adolescents and 6 for teachers, while IDIs were held for 18 adolescent-parent pairs. Data was transcribed verbatim and coded inductively. Qualitative data were subject to thematic analysis using NVivo-12 software.

Results: Using the socioecological model for sleep health, we identified themes on the barriers and enablers of adolescent sleep health at multiple levels. The sleep enablers identified at the individual level include a correct understanding of sleep needs by adolescents and their parents and good sleep hygiene practices. At the family level, parental control of bedtime was reported as a sleep enabler while living in a safe and quiet neighbourhood was protective at the neighbourhood level and the school level, early school closing time and lecture-free periods were sleep enablers.

Conversely, the barriers to adolescent sleep health at the individual level include bedtime screen use, stress and mental illness. Parental risk factors include parental work-schedule, poor understanding of sleep needs and poor parent-adolescent relationships. Family-level risk factors include bed-sharing, gender roles and sleeping environment. Neighbourhood risk factors include urban residence and noise at night, while school-level factors include early start time, late closing time, afterschool lessons, homework burden, and academic pressures.

These findings are supported by the following quotes:

“Some of us, when we were younger, our parents always tell us go and sleep... but recently, ... for the past three or four years, there's a specific time we must wake up and if you like don't sleep overnight, it's your problem just wake up the time they want you to wake up” - Adolescent FGD participant.
Sleep is disturbed by the “presence of churches and mosques and clubs, loud music, when there's like a party overnight, and distractions... when your house is built near the road like the streets where cars are passing” - an Adolescent IDI participant.

“Some of them stay in school till 6, 7, even past 7 pm.” -Teacher, FGD participant

Another Adolescent IDI participant said “Sometimes when I have plenty of work at school without free periods, it affects my sleep at night”

Conclusions: Many Nigerian adolescents struggle to achieve good sleep due to various factors that impact their sleep health. Comprehensive interventions are necessary to enhance the sleep health of Nigerian adolescents.

Acknowledgments: We acknowledge the Consortium for Advanced Research and Training in Africa for funding this research.

Pharmacology

Association of Hypnotics with Dementia and Cognitive Function in Insomnia Patients: An Observational and Two-sample Mendelian Randomization study

S. Ai¹, H. Zhang², Z. Zhu², X. Luo¹, S. Guo¹, B. Yu³, Y. Liu¹, H. Feng¹, Y. Liang¹, J. Zhang¹, Z. Li²

¹The Affiliated Brain Hospital, Guangzhou Medical University, Center for Sleep and Circadian Medicine, Guangzhou, China, ²The Affiliated Brain Hospital, Guangzhou Medical University, Department of Nutritional and Metabolic Psychiatry, Guangzhou, China, ³The First Affiliated Hospital of Xinxiang Medical University, Department of Cardiology, Heart Center, Weihui, China

Introduction: Dementia is a global public health problem that imposes a tremendous economic burden on both individuals and society. Existing evidence has shown significant comorbidity between insomnia and dementia in clinically. Hypnotic agents, such as benzodiazepines (BZDs) and Z-drugs, are usually prescribed to improve sleep quality in patients with insomnia or dementia. Previous observational studies have suggested associations between hypnotics use and dementia as well as cognitive function, but the conclusions from these studies have been contradictory. Observational studies are vulnerable to residual confounders and reverse causality, and whether there is a causal association between hypnotics use and dementia risk as well as cognitive function in participants with insomnia is still unclear. Therefore, we aimed to explore the causal association between hypnotics use and dementia as well as cognitive function in participants with insomnia by an observational and Mendelian Randomization (MR) study.

Materials and methods: In the UK Biobank (UKB), a propensity score-matched cohort was constructed for individuals with insomnia. The Cox proportional hazards model was used to estimate the association between hypnotics use and dementia outcomes. In the sensitivity analyses, inverse probability of treatment weighting and shared frailty models were further applied. Linear regression models were further used to evaluate the impact of hypnotics on cognitive function. A two-sample MR analysis was used to investigate the potential causal associations between target genes of hypnotics with dementia and cognitive functions. Co-localization, summary-data-based MR, external cohort validation and protein-protein interaction (PPI) were used for sensitivity analysis to enhance the credibility of the results.

Results: During a median follow-up of 15.5 years, a total of 195 dementia cases were identified in all participants of the matched cohort. Observational analysis provides strong evidence supporting that the hypnotics use (Hazard ratios [HR]: 1.61, 95% Confidence Interval [CI]: 1.19-2.17, $P = 1.79 \times 10^{-3}$), specifically for benzodiazepines (HR: 1.82, 95%CI: 1.23-2.64, $P = 1.52 \times 10^{-3}$) but not for Z-drugs (HR: 1.35, 95%CI: 0.90-2.04, $P = 1.50 \times 10^{-1}$), is associated with an increased risk of dementia and impaired cognitive function, as well as reasoning, reaction time, visual memory, and numeric memory. Drug-target MR analysis suggested a potential causal association between the benzodiazepine target genes and dementia, as well as impaired cognitive function. These associations were largely replicated in the summary-data-based MR and external cohort validation. Protein-protein interaction network revealed that benzodiazepine drug targets, such as GABRG3 and BRD3 interacted with the risk genes of cognitive function. Co-localization analysis provides further evidence supporting the true causal association between GABRG3 in the brain and impaired reasoning ability.

Conclusions: Our results suggest that benzodiazepine use may be causally linked to increased risk of dementia and impaired cognitive function. Both observational and genetic evidence highlight safety concerns related to the adverse effects of benzodiazepines on dementia risk and cognitive function among individuals with insomnia.

Acknowledgments: Dr. Sizhi Ai was supported by the National Natural Science Foundation of China (82471506), the GuangDong Basic and Applied Basic Research Foundation (2025B1515020036, 2024A1515012967), and Guangzhou Science and Technology Plan Project (2024A03J0213).

Becoming sleep-drunk during alcohol withdrawal treatment: narcolepsy-like condition displaying sleep attacks and cataplexy, related to baclofen

L. Ralet¹, J. Newell², D. Neu^{2,3,4}

¹Erasme Academic Hospital Université Libre de Bruxelles, Psychiatry, Brussels, Belgium, ²CHIREC Delta Hospital, Center for the Study of Sleep Disorders, Brussels, Belgium, ³Erasme Academic Hospital Université Libre de Bruxelles, Sleep Laboratory Department of Neurology and Department of Psychiatry, Brussels, Belgium, ⁴Université Libre de Bruxelles, Neurosciences Institute, Brussels, Belgium

Introduction: Baclofen, a GABA-B receptor agonist, is commonly used for hypertonic muscular spasticity and off-label for alcohol use disorder (AUD). Narcolepsy is a hypersomnia disorder, mainly defined by excessive daytime sleepiness (EDS), symptoms related to REM sleep impairments and cataplexy (in type 1 narcolepsy). We report a case of a supposedly drug-induced narcoleptiform condition, involving cataplectic events and sleep attacks, appearing related to baclofen.

Materials and methods: A 40-year-old man, treated for AUD, increased the dosage of baclofen intake to 200 mg per day. Subsequently he developed severe EDS (Epworth Sleepiness Scale - ESS scoring at 17 /24) and experienced transient episodes of muscle atonia and uncontrollable sleep attacks (with reported average durations ranging from 60 seconds up to approximately 5 minutes), appearing to be triggered by intense and/or sudden emotions. These symptoms were distinct from any latent sedation. HLA phenotyping has been carried out alongside extensive blood sample tests. Polysomnography and multiple sleep latency tests (MSLT) have been performed accordingly, after the condition's acute phase.

Results: Clinical symptoms of EDS and signs of cataplexy progressively displayed complete remission upon gradual reduction of baclofen to alternating dosages of respectively 87.5 and 100 mg per day (ESS scoring at 3 /24). HLA class assessment did not reveal any alleles commonly associated with a genetic risk for narcolepsy. Moreover, both polysomnography and MSLTs ruled out narcolepsy and other significant primary sleep disorders. The striking temporal occurrence relations, between high-dose baclofen administration, the sudden symptom onset and its subsequent total remission upon dosage decrease, suggest a possibly causal tie. Causal relation is further suggested by the herewith documented absence of a formerly undiagnosed narcolepsy-cataplexy. The present observations thereupon contrast with prior studies suggesting a potentially beneficial effect of baclofen on cataplexy. The observed clinical signs, could possibly be explained by an inhibition of neuronal orexinergic activity via baclofen-induced enhanced GABA-B receptor stimulation.

Conclusions: Our case report suggests that high-dose baclofen may generate a reversible condition that partially mimics narcolepsy-like signs, such as sleep attacks and cataplexy. Clinicians should be aware of this potential side effect, particularly when using baclofen at higher dosages and especially in an off-label context of an AUD treatment.

Chronic cannabis use and sleep architecture: A cross-sectional study using polysomnography in a clinical sample

R. Velzeboer¹, S. Wei², W. Lai³

¹University of British Columbia, Interdisciplinary Studies, Vancouver, Canada, ²University of British Columbia, Department of Psychology, Vancouver, Canada, ³University of British Columbia, Faculty of Medicine, Vancouver, Canada

Introduction: The utilisation of cannabis as a self-administered remedy for sleep disturbances is increasingly common. The existing body of research on the subject encounters many challenges in delineating effects accurately, due to the multifaceted nature of influencing factors such as individuals' prior history of cannabis consumption, concurrent substance and medication use, and the presence of other medical conditions that are often not adequately controlled for. In addition, polysomnographic evidence remains limited.

Materials and methods: We conducted a retrospective cohort study of 1,449 patients referred to a Canadian sleep clinic between 2022 and 2024 for overnight polysomnography. Chronic cannabis use ($\geq$ once daily for $\geq$ 1 year) was reported by 151 patients (10.4%). Eleven polysomnography outcomes—total sleep time, sleep onset latency, wake after sleep onset, sleep efficiency, REM latency, and N1, N2, N3, and REM sleep (both presence and duration were measured for the latter two, resulting in eleven

measured outcomes)—were modelled with outcome-appropriate regressions adjusted for 28 demographic, lifestyle, comorbidity, medication, and sleep-related covariates. HC3 standard errors and false-discovery-rate correction were applied. Robustness was evaluated via winsorised and trimmed datasets, two minimal-covariate specifications, exclusion of medication and morbidity blocks, and a 1:1 propensity score matched model.

Results: After multiple-correction testing, chronic cannabis use was associated with higher wake after sleep onset ($\beta = 21\%$; 95% CI +6.7% to +37.2%), lower sleep efficiency ($\beta = -3.8\%$; 95% CI -6.6% to -1.0%), and elevated N1 stage sleep ($\beta = +2.8$ percentage points (pp); 95% CI 0.3pp to 5.6pp). Nominally, total sleeping time was lower among individuals using cannabis ($\beta = -3.3\%$; 95% CI -6.3% to 0.3%). Effect directions and magnitudes persisted across sensitivity analyses. Compared to cannabis-naïve patients, individuals using cannabis were more likely to be male (SMD = 0.251), younger (SMD = -0.595), and showed higher rates of nicotine (SMD = 0.866), sedative (SMD = 0.244), antidepressant (SMD = 0.219), antipsychotic (SMD = 0.355), and opioid use (SMD = 0.207), as well as a higher rate of psychiatric disorders (SMD = 0.418).

Conclusions: Among sleep-clinic patients, long-term daily cannabis use was associated with greater nocturnal wakefulness and a slightly larger proportion of light sleep. The demographic and clinical profile of cannabis users in this study align with existing data, supporting ecological validity and generalisability of the findings. Our results highlight the need for better-controlled longitudinal studies examining dose, frequency, and formulation.

Acknowledgments: This study was performed through the Tranq Sleep Care network of clinics.

Dual-Edged Dosing: Dexamphetamine and Lisdexamfetamine Suppress Binge-like Eating but Disrupt Sleep in Female Rats

J. Raymond¹, A. Desai¹, T. Joseph¹, S. Narava¹, A. Armanious¹, M. James^{1,2}

¹Rutgers University, Psychiatry, Piscataway, United States, ²The University of Sydney, Psychology, Camperdown, Australia

Introduction: Binge eating disorder (BED), defined by recurring episodes of fast-paced, excessive food consumption over which individuals perceive a loss of control, is also frequently comorbid with sleep disturbances, particularly insomnia. Lisdexamfetamine, the only FDA-approved medication for BED, reduces the frequency of binge episodes and broadly suppresses appetite. However, its stimulant properties—mediated via the metabolic conversion to dexamphetamine—have raised concerns about sleep disruption, especially when lisdexamfetamine is taken in the evening to target when episodes of binge eating typically occur. Despite clinical subjective reports of iatrogenic sleep disturbances, little to no clinical or preclinical studies have objectively/quantitatively examined the impact of these medications on sleep physiology at efficacious binge-suppressant doses.

Materials and methods: To investigate the sleep-related consequences of lisdexamfetamine and dexamphetamine used to treat BED, adult female Long Evans rats were implanted with wireless telemetry devices capable of continuous polysomnographic (PSG) monitoring of EEG (fronto-parietal), EMG, activity, and temperature. Sleep stages (wake, NREMS, REMS) were scored over 19-hour periods (ZT23–ZT18) following intraperitoneal administration of dexamphetamine hemisulfate (0.1875–1.5 mg/kg) and equivalent doses of lisdexamfetamine mesylate (0.463–3.71 mg/kg) at ZT23. Binge-like eating was assessed separately using an intermittent access model, where animals with ad libitum access to standard chow received twice weekly 30-minute periods of exposure to a highly palatable fat-sugar mixture (8.6 kcal/g; 90% fat, 10% sugar) on non-consecutive days. Dosing for binge-like eating assessment occurred 30 minutes prior to binge access (ZT20–22) to model evening consumption patterns.

Results: Both lisdexamfetamine and dexamphetamine dose-dependently suppressed binge-like eating, but at the lowest effective doses, significant sleep disruptions were also evident. Specifically, both medications dose-dependently delayed sleep and REM sleep onset, increased the proportion of time spent awake, and reduced both NREM and REM sleep during the early light phase (i.e., first 3-6 hours post-administration). Notably, these effects occurred without overt compensatory rebound sleep during the remaining period of the light or dark phases.

Conclusions: These findings provide objective preclinical evidence that these stimulant-based treatments for BED induce substantial sleep impairments even at the lowest effective doses for effects on eating behaviour. This aligns with clinical concerns of subjective iatrogenic sleep disturbances

associated with lisdexamfetamine and its active metabolite, dexamphetamine. Given the bidirectional relationship between sleep loss and dysregulated appetite—including increased craving for calorie-dense foods following sleep loss—these results highlight a critical need for the development of BED treatments that do not interfere with sleep processes, especially in individuals vulnerable to comorbid binge eating and insomnia.

Acknowledgments: This research was supported by the New Jersey Health Foundation (PC144-23) and the National Institute of Drug Abuse (R37061303).

Impact of Benzodiazepine Dose Reduction on Subjective Sleep and Anxiety in Insomnia Patients

²Kyoto University Hospital, Department of Psychiatry, Kyoto, Japan

Introduction: Long-term prescription of benzodiazepine receptor agonists (BZRAs) for insomnia is common in clinical practice, despite the associated risks, such as cognitive impairment, dependence, and withdrawal symptoms. Although reducing or discontinuing BZRA use is recommended, few studies have examined its impact on subjective sleep and anxiety symptoms using validated rating scales after long-term hypnotic use. This study retrospectively investigated the effects of BZRA dose reduction or discontinuation on insomnia severity, subjective sleep quality, anxiety symptoms, and adverse events in patients with long-term hypnotic use.

Materials and methods: We reviewed the medical records of 13 patients with ≥ 12 months of BZRA use who underwent dose reduction or discontinuation between April 2018 and May 2019 at Kyoto University Hospital. Insomnia severity was evaluated using the Japanese version of the Insomnia Severity Index (ISI-J). Secondary outcomes included sleep quality (Pittsburgh Sleep Quality Index Japanese version, PSQI-J) and anxiety symptoms (Generalized Anxiety Disorder-7, GAD-7). BZRA doses were converted to diazepam-equivalents. Concomitant medications (antipsychotics and antidepressants) were converted to chlorpromazine- and imipramine-equivalents, respectively. Assessments were conducted at baseline and 2–4 weeks post-intervention. Adverse events and persistence of dose changes were monitored. This study conformed to the Declaration of Helsinki and was approved by the Ethics Committee of Graduate School of Medicine of Kyoto University (R0545-2).

Results: Diazepam-equivalent doses significantly decreased in both the discontinuation group (mean change: -4.6 ± 0.9 mg, $p < 0.05$) and the reduction group (-6.7 ± 4.9 mg, $p < 0.05$). Mean ISI-J scores showed no significant change: 12.0 ± 3.5 to 10.0 ± 4.0 ($p = 0.07$) in the discontinuation group and 8.2 ± 5.6 to 8.3 ± 6.1 ($p = 0.91$) in the reduction group. PSQI-J and GAD-7 scores also did not change significantly. Most patients in both groups had well-controlled insomnia ($\text{ISI-J} < 14$) at baseline. The incidence of adverse events, including somnolence, fatigue, abnormal dreams, and irritation, did not increase significantly. The maintenance rate of dose reduction/discontinuation was 100% in the discontinuation group and 83.3% in the reduction group over three months.

Conclusions: Dose reduction or discontinuation of BZRA after long-term use did not significantly worsen sleep or anxiety symptoms. Our findings suggest that, with appropriate monitoring and individualized support, particularly in patients with mild baseline insomnia, deprescribing BZRAs can be safe and feasible in clinical practice.

Optimizing timing and dose of melatonin administration: a randomized, double-blind controlled trial in healthy adults

S. Bruno¹, F. Cruz-Sanabria², M. di Galante³, L. Lo Giudice⁴, S. Ceccanti⁴, F. Daddoveri⁵, C. di Pede⁴, P. Frumento⁶, U. Faraguna^{4,2}

¹University of Wisconsin, Department of Psychiatry, Madison, United States, ²IRCSS Fondazione Stella Maris, Department of Developmental Neuroscience, Calambrone, Pisa, Italy, ³Sleepacta srl, Montacchiello, Pisa, Italy, ⁴University of Pisa, Department of Translational Research and of New Surgical and Medical Technology, Pisa, Italy, ⁵University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy, ⁶University of Pisa, Department of Political Science, Pisa, Italy

Introduction: Exogenous melatonin is widely used as a sleep aid, yet its overall effectiveness remains under debate because of inconsistent findings that possibly arise from heterogeneous experimental designs. In our recent meta-analysis, we demonstrated that administering exogenous melatonin mimicking its endogenous circadian rhythm—i.e., 3 hours before the desired bedtime—optimizes its sleep-inducing effects, while increasing the dose to 4 mg appeared to enhance sleep maintenance. This study aimed to replicate those findings in a clinical trial.

Materials and methods: Fourteen healthy adults (aged 22–40 years; 50% female) with no history of sleep disorders participated in this double-blind, randomized controlled trial. They underwent five experimental conditions:

Condition 1: 2 mg melatonin administered 30 minutes before bedtime, placebo 3 hours before bedtime.

Condition 2: Placebo 30 minutes before bedtime, 2 mg melatonin 3 hours before bedtime.

Condition 3: 4 mg melatonin 30 minutes before bedtime, placebo 3 hours before bedtime.

Condition 4: Placebo 30 minutes before bedtime, 4 mg melatonin 3 hours before bedtime.

Condition 5: Placebo 30 minutes and 3 hours before bedtime.

After the recruitment, participants also completed a habituation night without receiving any active substance or placebo. Polysomnography was used to assess sleep parameters. Sleep onset latency (SOL) was selected as the outcome measure for sleep promotion, while wake after sleep onset (WASO) served as the outcome measure for sleep maintenance. The impact of administration timing and dosage was analyzed using random-effects linear regression models.

Results: All melatonin conditions resulted in an approximate 10-minute reduction in SOL compared to placebo. Among the active treatment conditions, earlier time of administration was associated with a further SOL reduction ($\beta = -0.041$, $p = 0.034$). WASO was significantly reduced in Condition 4 ($\beta = -15.77$, $p = 0.049$) and showed a trend in Condition 3 ($\beta = 14.22$, $p = 0.084$). When conditions were grouped by dose, the 4 mg dose produced a significant reduction in WASO compared both to placebo and to the 2 mg dose ($\beta = -15.03$, $p = 0.028$). Adjusting for the time interval between administration and bedtime did not substantially change these results, and timing itself did not significantly predict WASO ($\beta = -0.006$, $p = 0.867$). Notably, compared to placebo, Condition 4 only was associated with a significant increase in N3 stage duration ($\beta = 30.07$, $p = 0.036$) and REM latency ($\beta = 28.47$, $p = 0.047$).

Conclusions: Our findings confirm that administering melatonin to mimic its endogenous, circadian pattern enhances its sleep-promoting efficacy. Specifically, melatonin administration 3 hours before bedtime significantly reduced SOL. Consistent with our meta-analysis, a dose of 4 mg improved sleep maintenance independently of the timing of administration. Moreover, for the first time, we provide evidence that the combination of an earlier administration time and a higher dose induces changes in sleep macroarchitecture suggestive of deeper sleep. Further research is needed to clarify the clinical relevance of these findings for insomnia treatment and to explore whether optimized melatonin administration parameters might lead to sustained changes in sleep microarchitecture.

Psychotropic Drug Induced Sleep Bruxism

S. Gupta¹

¹Rak Dental Care & Implant Centre, Orofacial Pain & Dental Sleep Medicine, Ras Al Khaimah, United Arab Emirates

Introduction: Bruxism, a stereotyped oromandibular movement disorder, is a repetitive jaw muscle activity characterized by clenching or grinding of teeth and / or thrusting of the mandible. Two distinct circadian manifestations of Bruxism are (i) Sleep Bruxism which occurs during sleep and classified under the subgroup of Sleep related Movement Disorders (ii) Awake Bruxism, which occurs during wakefulness. Sleep Bruxism primarily occurs in younger population, more common amongst children as compared to adults. Sleep Bruxism can be comorbid with other sleep disorders like Obstructive Sleep Apnea (OSA), Parasomnias, Restless Leg Syndrome (RLS), Mandibular myoclonus and Rapid Eye Movement disorders. Bruxism can lead to several complications including jaw muscle hypertrophy, tooth wear, fracture or failure of teeth restorations and implants, sensitivity and pain in teeth, muscle or joints, Temporomandibular joint disc displacements, myofascial pain, headaches, insomnias and other sleep disturbances.

Materials and methods: The etiology of Sleep Bruxism is multifactorial which includes biological, physiological, psychosocial, environmental, genetic factors or can be secondary to medication usage. The most recent hypothesis on the etiology of Sleep Bruxism supports the roles of Central and

Autonomic Nervous Systems in the genesis of oromandibular activity during sleep. Moreover, Sleep bruxism may be seen as a centrally mediated condition which may be modulated by medications acting on the neurotransmitters of the Central Nervous System (CNS).

Results: An imbalance between Serotonergic and Dopaminergic pathways may play an important role in the genesis of rhythmic masticatory muscle activity and sleep bruxism. Iatrogenic Sleep Bruxism has been reported following treatment with several Psychotropic medications such as Selective Serotonin Reuptake Inhibitors (SSRIs), Antidepressants, Antipsychotics. A Psychotropic (or psychoactive) drug is a chemical substance that crosses the blood-brain barrier and acts primarily on the CNS where it affects brain function, resulting in alterations in perception, mood, consciousness, cognition and behavior.

Conclusions: One of the side effects of psychotropic drugs is Sleep bruxism. It is postulated that the mesocortical disinhibition provided by SSRIs may lead to dopamine depletion that manifests itself as Sleep Bruxism. Buspirone, an anxiolytic, corrects Bruxism by reducing Serotonergic activity and increasing Dopaminergic Activity. A detailed history, including past and current medications is a must for every patient reporting with a complaint of sleep bruxism.

Rationale and Study Design for the Evaluation of Samelisant (SUVN-G3031) in a Phase-2 Study for the Treatment of Cataplexy in Patients with Narcolepsy

P. Jayarajan¹, V.K. Goyal¹, V. Benade¹, A. Shinde¹, R. Nirogi¹

¹Suven Life Sciences Ltd., Hyderabad, India

Introduction: Samelisant (SUVN-G3031) is a potent and selective histamine 3 receptor inverse agonist, which works by modulating the histamine system, a key part of the brain's sleep-wake regulation. In animal models, Samelisant has shown wake-promoting effects and also modulated neurotransmitters with role in wake promotion and anticataplectic effects.

Materials and methods: Samelisant was evaluated in animal models of narcolepsy like orexin knockout mice and orexin-B SAP lesioned rats. Effects on cataplectic like episodes were measured using Electroencephalography (EEG). Rat brain microdialysis was performed to evaluate the modulation of cortical norepinephrine levels.

Results: Samelisant produced significant reduction in cataplectic like episodes in orexin knockout mice, similarly significant decrease in DREM (direct wake to REM sleep) episodes was observed in orexin-B SAP lesioned rats. Samelisant produced significant increase in cortical norepinephrine levels in rats. Based on the evidence from animal studies, Samelisant will be evaluated in a Phase-2 proof-of-concept study in the USA and Canada to treat cataplexy in patients with narcolepsy. The study will recruit about 129 narcolepsy type 1 (NT1) patients with an established diagnosis of NT1 according to the ICSD-3 TR or DSM-5 TR.

The proposed Phase-2 study is a placebo-controlled, double blind randomized, parallel-group study. After a prescreening period of 4-weeks, eligible patients will enter a 2-week baseline period to assess number of cataplexy attacks. Patients confirmed with continued presence of cataplexy as defined by at least 14 cataplexy attacks in a typical 2-week baseline period will be eligible for the double-blind treatment period. Patients will be treated for eight weeks with the investigational product.

The primary objective of the study will be to evaluate changes in weekly cataplexy rates in NT1 patients. Secondary objectives will be to evaluate the effectiveness of Samelisant on the Clinical Global Impression–Severity score and total Epworth Sleepiness Scale score. Other exploratory measures will be Clinical Global Impression of Change and Patient Global Impression of Change score, with regard to cataplexy, Health-related quality of life 5-dimension, 5-level questionnaire and Narcolepsy Severity Scale score.

Conclusions: Outcomes from animal models of narcolepsy suggest that Samelisant may have anticataplectic effects. The Phase-2 study results will inform the therapeutic utility of Samelisant for the treatment of cataplexy in NT1 patients.

Self-reported sleep changes among medical cannabis users: Associations with symptom targets and use patterns

R. Velzeboer¹, K. Scullion², L. Boulet², H. Buhler², Z. Walsh³, W. Lai⁴

¹University of British Columbia, Department of Interdisciplinary Studies, Vancouver, Canada, ²Interior Health Authority, Research Department, Kelowna, Canada, ³University of British Columbia, Department of Psychology, Vancouver, Canada, ⁴University of British Columbia, Faculty of Medicine, Vancouver, Canada

Introduction: Cannabis is commonly used to manage sleep disturbances, with many users reporting improved sleep quality. However, it remains unclear which types of users experience sleep benefits and the specific aspects of sleep most affected. This study explored self-reported sleep changes among individuals who use cannabis for medical purposes and examined how changes related to use patterns and symptom targets.

Materials and methods: A cross-sectional online survey was conducted in British Columbia, Canada and completed by 614 participants recruited via social media ads; 490 reporting cannabis use for medical reasons were analysed. Most were long-time users (97.6% ≥ 1 year), used cannabis at least daily (88.2%), used within one hour of bedtime (77.1%), preferred smoked or vaporised methods (80.4%), and most commonly reported using cannabis to help sleep (78.8%), reduce/control anxiety (67.7%), or reduce pain (64.7%). Participants were predominantly female (58.5%) and White (87.5%), mean age 44.7 ± 14.7 years, with 80.4% having education below the bachelor's level. Measures included an adapted version of the Pittsburgh Sleep Quality Index to assess perceived changes in sleep since initiating cannabis use, a checklist of 31 symptom targets (covering mental health, pain, and neurological issues), and cannabis usage patterns. Univariable regressions (n=468) examined associations between sleep changes and demographics, symptom motivations, and usage patterns.

Results: Most participants reported improved sleep quality (78.6%), reduced sleep onset latency (75.5%), longer sleep duration (67.6%), and fewer awakenings (55.3%). Among prior sleep aid users (n=249), 65.5% reported reducing their usage since initiating cannabis use. Targeting anxiety (p = 0.002), targeting trauma (p = 0.002), and younger age (p < 0.001) predicted perceptions of reduced sleep onset. Female gender predicted greater perceived improvement in nighttime anxiety (p = 0.002) and sleep quality (p = 0.017), though the latter did not survive multiple-comparison correction. Longer cannabis use duration predicted less perceived improvement in waking during the night (p < 0.001) and ability to fall asleep within 30 minutes (p = 0.008). No clear associations emerged between THC:CBD ratios and sleep outcomes, nor between targeting pain and improved sleep.

Conclusions: Regular cannabis users frequently perceive improvements in their sleep, particularly those targeting anxiety and trauma symptoms. However, some benefits may diminish with longer use. Findings are based on retrospective, cross-sectional self-report; further research integrating diagnostic and subjective assessments is needed to better understand cannabis' impact on sleep across different populations.

Acknowledgments: The authors would like to acknowledge the Kelowna General Hospital Foundation (KGHF) for funding and general support. This study was performed through the Tranq Sleep Care network of clinics.

Psychiatric Disorders Affecting Sleep/Wake

Accurately predicting mood episodes in mood disorder patients using wearable sleep and circadian rhythm features

D. Lim¹, J. Jeong², Y.M. Song³, C.-H. Cho², J.W. Yeom², T. Lee⁴, J.-B. Lee⁴, H.-J. Lee², J.K. Kim¹

¹KAIST, Daejeon, Korea, Republic of, ²Korea University College of Medicine, Seoul, Korea, Republic of, ³Institute for Basic Science, Daejeon, Korea, Republic of, ⁴Sun Moon University, Asan, Korea, Republic of

Introduction: Wearable devices enable passive collection of sleep, heart rate, and step-count data, offering potential for mood episode prediction in mood disorder patients. However, current models often require various data types, limiting real-world application.

Materials and methods: Here, we develop models that predict future episodes using only sleep-wake data, easily gathered through smartphones and wearables when trained on an individual's sleep-wake history and past mood episodes. Using mathematical modeling to longitudinal data from 168 patients

(587 days average clinical follow-up, 267 days wearable data), we derived 36 sleep and circadian rhythm features.

Results: These features enabled accurate next-day predictions for depressive, manic, and hypomanic episodes (AUCs: 0.80, 0.98, 0.95). Notably, daily circadian phase shifts were the most significant predictors: delays linked to depressive episodes, advances to manic episodes.

Conclusions: This prospective observational cohort study shows sleep-wake data, combined with prior mood episode history, can effectively predict mood episodes, enhancing mood disorder management

A comparative study of sleep and suicidality in Major Depressive Disorder and bipolar depression

A. Taru¹, R. Tripathi¹, S. Singh¹

¹All India Institute of Medical Sciences, Gorakhpur, Psychiatry, Gorakhpur, India

Introduction: Both Major Depressive Disorder (MDD) and bipolar disorder (BD) are associated with sleep problems. Presence of sleep disturbances is manifested as more severe physical, mental, and psychological impairment in both the disorders. In BD it is associated with rapid cycling, anxiety, substance use comorbidities and suicide. The aim of the present study was to compare sleep disturbances and suicidality in patients with MDD and BD.

Materials and methods: Adult population of either sex having diagnosis of MDD or BD (irrespective of number of episodes and treatment status) as per DSM-5 were included in the study. Participants of BD having current manic episode, suffering from any other psychiatric disorder or use of any substance in dependent pattern except nicotine were excluded. The participants were evaluated on socio-demographic profile, depression severity, suicidal ideation and sleep problems with the help of Hamilton Depression Rating Scale (HAM-D), Becks scale for suicidal ideation, insomnia severity index (ISI), Epworth sleepiness scale (ESS) and Pittsburgh sleep quality index (PSQI) respectively.

Results: A total of 44 patients (32 males & 12 females) participated in the study (n=22 each, 15 males and seven females in MDD group and 17 males and five females in BD group). The mean age of the unipolar group and bipolar group was 23.7 (7.7) years and 38.1 (12.7) years respectively. Most of the participants in MDD group were unmarried (n=20,90.9%). BD group had more married participants (n=17,77.3%). The mean subjective sleep latency and total sleep time in the MDD and BD group were 102.3 minutes, 343.6 minutes and 98.9 minutes, 337.5 minutes respectively suggesting an average sleep of less than six hours with high sleep latency in both the groups. The mean HAM-D score of MDD and BD group were 18.7 and 17.3 respectively suggesting moderate depression in both groups. The mean score on Beck's suicidal ideation scale were 9.5 and 8.5 in MDD and BD group respectively. The total scores on ISI and PSQI were high in both the groups suggesting significant sleep problems and clinical insomnia of moderate severity as per ISI scores (MDD group: ISI-19(3.4),PSQI-12.6 (3.3); BD group: ISI-15.2 (6.6),PSQI-12.1 (3.9). No significant difference was observed between depressive scores, suicidal intent and total PSQI scores between the two groups. However, significant difference was observed between total ISI scores and subscores between both the groups. No significant correlation was observed between depression and sleep problems and suicidality and sleep problems in the MDD group. However, a significant positive correlation was observed between HAM-D scores and total ISI scores, sleep latency, total PSQI scores in the BD group. A significant positive correlation was also observed between suicidal ideation and total ISI scores, sleep latency, total PSQI scores in the BD group. A significant negative correlation was observed between HAM-D scores and total sleep time and between suicidality and total sleep time in the BD group.

Conclusions: Both the MDD and BD group showed significant sleep problems. However, depressive symptoms and suicidal ideation correlated with sleep problems in BD group only.

Acknowledgments: None

A Long-Lasting Low-Threshold Spiking in Laterodorsal Tegmental Glutamatergic Neurons Regulates Anxiety Hyperarousal

J.B. Jiang¹, W.T. Yang², L. Xu², Z.L. Huang³

¹Fudan University/Institutes of Brain Science, State Key Laboratory of Brain Function and Disorders, Shanghai, China, ²Fudan University/School of Basic Medical Science, Dept. of Pharmacology, Shanghai,

China, ³Fudan University/School of Basic Medical Science/Institutes of Brain Science, Dept. of Pharmacology/State Key Laboratory of Brain Function and Disorders, Shanghai, China

Introduction: Anxiety-associated hyperarousal represents one of the most prevalent emotional sleep disturbances globally. In the context of an increasingly fast-paced and high-stress society, this condition significantly compromises quality of life and poses a substantial public health burden. Although conventional anxiolytic agents can alleviate symptoms to some extent, their clinical utility is often limited by issues of drug tolerance and adverse side effects. The lack of effective, targeted interventions is largely attributable to an incomplete understanding of the underlying neural circuitry. The laterodorsal tegmentum (LDT), a brainstem nucleus implicated in arousal regulation, receives dense projections from multiple anxiety-related regions, suggesting a potential integrative role in mediating anxiety-related hyperarousal states. Utilizing a chronic stress-induced anxiety model, we identified the LDT as a candidate node in this regulatory network. The present study aims to elucidate the functional involvement of the LDT in anxiety-related hyperarousal and to dissect the underlying neurobiological mechanisms.

Materials and methods: This study established a chronic unpredictable mild stress (CUMS) model to induce anxiety in mice, verified through open field and elevated plus maze tests, while monitoring sleep-wake alterations and identifying anxiety-related brain regions. In vitro electrophysiology was used to examine neuronal changes in the laterodorsal tegmentum (LDT), focusing on ion dynamics underlying the long-lasting low-threshold spike (LLTS) in glutamatergic neurons. Optogenetics combined with behavioral assays enabled precise induction of LLTS to assess its effects on anxiety and sleep. Neural circuitry was mapped using retrograde tracing and the Cre-loxP system to trace inputs regulating anxiety hyperarousal. Neuropharmacological approaches evaluated the impact of Cav 3.1 channel inhibitors and anxiolytics on behavior and arousal, while RNA interference of Cav 3.1 further validated its role through behavioral and sleep assessments.

Results: After CUMS, mice showed anxiety-like hyperarousal and a 132% increase in wakefulness, with elevated c-fos in LDT. LDT glutamatergic neurons shifted toward a higher proportion (76%) of long-lasting low-threshold spike (LLTS), while GABAergic and cholinergic neurons remained unchanged. Optogenetic activation of LLTS neurons induced anxiety and wakefulness; general activation of LDT glutamatergic neurons increased only wakefulness. LDT glutamatergic neurons receive diverse upstream inputs, with 16% from the LH. The LH^{GABA}-LDT^{Vglut2} circuit was key in anxiety hyperarousal. LLTS was mediated by T-type calcium channels; pharmacological inhibition of T-type calcium channels and genetic knockdown of Cav3.1 expression in LDT neurons reduced LLTS firing and normalized anxiety hyperarousal.

Conclusions: These findings suggest that Cav3.1 channels are crucial mediators of LDT glutamatergic plasticity in anxiety hyperarousal, offering a potential therapeutic target for treating anxiety hyperarousal and related sleep disorders. Our work offers insights into the neural mechanisms underlying anxiety-related sleep disorders.

Acknowledgments: This study was supported by the Postdoctoral Foundation of China (BX20240074, 2024M760521) and the Natural Science Foundation of Shanghai Science and Technology Commission (24YF2706300).

An AI-Driven Model for Depression Detection Using Sleep Heartbeat and Breathing Signals

D. Lyu¹, X. Chen², Y. Wang², Y. Zhang², A. Krystal³, Y. You⁴, L. Wang⁵, J. Chen⁵, W. Chen⁴, Y. Leng³

¹Shanghai Mental Health Center, Department of Sleep Disorders, Shanghai, China, ²Beijing Five Seasons Medical Technology Co., Ltd, Beijing, China, ³University of California, San Francisco, Department of Psychiatry and Behavioral Sciences, San Francisco, United States, ⁴Sir Run Run Shaw Hospital, Zhejiang University School of Medicine, Department of Psychiatry, Hangzhou, China, ⁵Beijing HuiLongGuan Hospital, Peking University, Sleep Medicine Center, Beijing, China

Introduction:

Autonomic dysfunction, marked by changes in heart rate and breathing patterns, is a core symptom of depression. However, the role of autonomic dysfunction during sleep as a marker for depression is not well understood. This study evaluates the utility of polysomnography (PSG)-derived cardiorespiratory signals for depression detection.

Materials and methods:

We examined clinical polysomnography (PSG) data and electronic health records collected between 2021 and 2025 from Sir Run Run Shaw Hospital (RRS). Depression cases were identified based on the International Classification of Diseases, 10th Revision (ICD-10) diagnosis codes, Hamilton Depression Rating Scale (HAMD) scores of 8 or higher, and/or chief complaints suggestive of depression. Age- and sex-matched controls were selected based on ICD-10 diagnoses or HAMD scores. A foundational model approach was employed: abdominal (ABD) signals and RR intervals (RRI) derived from electrocardiogram signals were first used to pre-train a model to predict other PSG channels. Subsequently, the model was fine-tuned using logistic regression for depression classification. Data from RRS was used for model training and internal validation (randomly split into 90% training and 10% internal testing sets). Model performance was assessed using the area under the receiver operating characteristic curve (AUROC), sensitivity, and specificity.

Results:

The study included 1303 depression cases and 1978 controls. The mean age was 48.9 ± 17.4 years for cases and 48.9 ± 17.3 years for controls, with 66.2% and 66.1% female, respectively. The model achieved an AUROC of 0.761, with an accuracy of 0.706, sensitivity of 0.735, and specificity of 0.674 in the internal validation set.

Conclusions:

Our findings demonstrate that AI-driven analysis of sleep-derived heartbeat and breathing signals can effectively detect depression, with moderate sensitivity and specificity. By leveraging cardiorespiratory signals, this model offers a sleep-based solution for in-home depression screening. This approach paves the way for precision mental health tools that support early identification and intervention for depression in community settings.

Acknowledgments: This study was supported by Shanghai Mental Health Center (2021-YJ12, 2021-QH-05).

An AI Prediction Model for Depression and Anxiety Using Polysomnographic Electroencephalography Signals

W. Wu¹, D. Lyu², C. Ji², J. Zhang², Y. Wang², R. Qian², C. Zhang³, C. Yuan²

¹Shanghai Artificial Intelligence Laboratory, Shanghai, China, ²Shanghai Mental Health Center, Department of Sleep Disorders, Shanghai, China, ³Tsinghua University, Department of Electronic Engineering, Beijing, China

Introduction:

Depression and anxiety are two of the most prevalent mental disorders globally, yet a significant portion of symptomatic cases remain undiagnosed. Sleep disturbances often emerge early in the course of depression and anxiety and are among their most prevalent symptoms, with electroencephalography (EEG) features detectable via polysomnography (PSG). This study aims to determine whether PSG-EEG signals can predict depression and anxiety using an AI model.

Materials and methods:

We analyzed PSG-EEG and clinical records from Shanghai Mental Health Center from 2023 to 2024. Participants were classified as depressed (HAMD ≥ 17) or non-depressed (HAMD < 17) based on the Hamilton Depression Rating Scale, and as anxious (HAMA > 21) or non-anxious (HAMA ≤ 14) based on the Hamilton Anxiety Rating Scale. We designed a token-based machine learning framework, which transforms PSG-EEG signals into symbolic representations. A tokenizer is pretrained via self-supervised learning on miscellaneous EEG data. The tokenizer discretizes continuous brain signals into a sequence of symbolic tokens using a codebook of 512 entries. For each sample, we identified the most informative tokens by computing class-wise frequency differences between groups. Tokens showing statistically significant group differences ($p < 0.05$) were further ranked by Cramér's V to assess their effect size, and the top 20 tokens were selected as features. We then extracted term frequency-inverse document frequency (TF-IDF) representations over these tokens for each subject and trained a support vector machine (SVM) for binary classification. Models were trained and evaluated using an 80/20 train-test split. Model performance was assessed using accuracy, unweighted average recall, macro F1, and weighted F1 for binary classification.

Results:

We analyzed 93 cases (mean age 40.5 years, 66.1% female) and 128 controls (mean age 39.2 years, 72.0% female) for depression, and 69 cases (age 38.7 years, 75.4% female) and 83 controls (mean age

42.9 years, 63.9% female) for anxiety. In the binary classification task predicting depression from controls, our model achieved an accuracy of 0.73, unweighted average recall of 0.72, macro F1 of 0.72, and weighted F1 of 0.73. In the binary classification task predicting anxiety from controls, our model achieved an accuracy of 0.74, unweighted average recall of 0.76, macro F1 of 0.74, and weighted F1 of 0.74. We observed distinct patterns in the frequency distribution of tokens across sleep stages. For instance, one token appeared more frequently during light sleep (N1/N2) but not in deep sleep (N3) or REM. These findings indicate that the model has learned internal representations that correspond meaningfully to different stages of sleep. The frequency distribution of these components may serve as interpretable, stage-sensitive markers reflecting underlying neural or physiological dynamics.

Conclusions:

This study demonstrates that PSG-EEG features can predict depression and anxiety with an interpretable AI model. These findings highlight the utility of sleep physiology in enabling sleep-based depression screening, offering precision mental health risk assessment and intervention in Asian mental health settings.

Acknowledgments: This study was supported by Shanghai Mental Health Center (2021-YJ12, 2021-QH-05).

A PVT^{D2R}-CeA circuit underlies sleep disturbance and negative effects induced by morphine withdrawal

W. Chen¹, G. Zhang¹, T. Yuwen¹, Y. Han¹, J. Shi¹

¹Peking University, Beijing, China

Introduction: Opioid use disorder (OUD) is a chronic, relapsing condition that contributes to a substantial global health burden. Individuals suffering from OUD often experience intense and prolonged withdrawal symptoms, including sleep disturbance and negative emotional states, which significantly increase the risk of relapse. The paraventricular nucleus of thalamus (PVT) plays a crucial role in opioid withdrawal, yet its specific role in the sleep disturbance and negative effects induced by opioid withdrawal remains unclear.

Materials and methods: Firstly, following six days of chronic morphine administration, we monitored sleep architecture and negative affective states of mice during withdrawal, and further assessed the impact of chronic sleep deprivation on these affective states. Secondly, we utilized immunofluorescence staining, in situ hybridization and fiber photometry recording to determine the involvement of PVT and dopamine D2 receptor-expressing neurons in the PVT (PVT^{D2R} neurons) in morphine withdrawal. Finally, using whole-cell patch clamp recordings and chemogenetic approaches, we investigated the role of PVT^{D2R} neurons and their projections to the central amygdala (CeA) in sleep disturbance and negative effects induced by morphine withdrawal.

Results: During the first week of withdrawal, mice exhibited increased wakefulness, which was accompanied by anxiety-like and depression-like behaviors. Notably, chronic sleep deprivation during this withdrawal further aggravated these negative affective states. To investigate the underlying neural mechanisms, the immunofluorescence staining and in situ hybridization study revealed the activation of PVT^{D2R} neurons in the PVT. Consistently, real-time fiber photometry recordings further confirmed the activation of these neurons during withdrawal. Moreover, electrophysiological recordings demonstrated that PVT^{D2R} neurons projecting to the CeA showed a significant reduction in both frequency and amplitude of spontaneous inhibitory post synaptic currents one week after withdrawal. Subsequently, chemogenetic inhibition of either PVT^{D2R} neurons or PVT^{D2R}-CeA projection during withdrawal alleviated sleep disturbance and negative emotional symptoms, while chemogenetic activation of same neurons or projection exacerbated these symptoms.

Conclusions: In conclusion, this study highlights the critical role of PVT^{D2R} neurons and PVT^{D2R}-CeA circuit in mediating sleep disturbance and negative emotional states induced by morphine withdrawal, offering new insights to the mechanisms of OUD and providing potential strategies to prevent relapse.

Association between EEG Power during Sleep and Attention Levels in Patients with Major Depressive Disorder

L. Chen¹, Y. Li¹

¹Department of Sleep Medicine, Shantou University Mental Health Center, Shantou University Medical College, Shantou, China

Introduction: Major depressive disorder (MDD) is associated with cognitive impairment through unclear mechanisms. We examined the relationship between sleep electroencephalogram (EEG) power and attention level in MDD.

Materials and methods: Forty-seven untreated patients with MDD and forty-seven age- and sex-matched controls were included. We examined relative EEG power during non-rapid eye movement (NREM) sleep and rapid eye movement (REM) sleep by fast Fourier transform. The Attention Network Test (ANT) was performed to evaluate attention levels.

Results: Compared to controls, patients with MDD had lower theta power during NREM ($P = 0.018$) and REM ($P = 0.002$) sleep, while higher beta power ($P = 0.050$) during NREM sleep and delta power ($P = 0.018$) during REM sleep. Regarding attention level, patients with MDD had lower levels of accuracy ($P = 0.021$), longer mean reaction time ($P < 0.001$), poorer manifestations of the alerting effect ($P = 0.038$) and worse executive control ($P = 0.048$). Moreover, decreased theta power during NREM sleep was correlated with worsened accuracy ($\beta = 0.329$, $P = 0.040$), decreased theta power during REM sleep was correlated with worsened alerting effect ($\beta = 0.355$, $P = 0.020$), and increased delta power during REM sleep was correlated with longer mean reaction time ($\beta = 0.325$, $P = 0.022$) in patients with MDD. No association between ANT performance and other frequency bands was observed in patients with MDD.

Conclusions: Our findings suggest that patients with MDD manifest impaired selective attention function that is associated with decreased theta power during NREM/REM sleep and increased delta power during REM sleep.

Associations Between REM Sleep and Depressive Symptoms in Pediatric Narcolepsy Type 1

G. Wang¹, J. Worhach¹, H. Sharples¹, B. Zhang¹, K. Maski^{1,2}

¹Boston Children's Hospital, Department of Neurology, Boston, United States, ²Harvard Medical School, Neurology, Boston, United States

Introduction: Children and adolescents with Narcolepsy Type 1 (NT1) have higher rates of depression and more disrupted nighttime sleep than healthy controls (HC) (Abenza-Abidula et al., 2023; American Academy of Sleep Medicine, 2014). In the otherwise healthy adolescents, sleep disruptions, particularly in REM sleep, have been associated with depressive symptoms (Riemann, 2020; Pesonen et al., 2019, Thorpy et al., 2024). However, the relationship between REM disturbances and depressive symptoms in pediatric NT1 is understudied. We hypothesized that shorter REM onset latency, increased total REM duration, and more REM fragmentation would be associated with depressive symptoms in NT1 and HC groups, with stronger associations in the NT1 group.

Materials and methods: 24 NT1 and 25 HC participants, aged 9-20 years old, completed the Children's Depression Inventory (CDI) and underwent an in-lab polysomnogram. We used linear regression controlling for age, gender, and SSRI/SNRI use to determine associations between depressive symptoms and REM sleep onset latency, total REM duration, and median REM bout duration as well as other sleep fragmentation variables such as N3 median bout duration and global transitions index.

Results: NT1 participants had higher CDI T-scores than HC participants indicating higher depressive symptoms ($p < 0.001$). Across groups, shorter REM median bout duration, shorter N3 median bout duration, and increased global transitions index were associated with higher CDI total score (p 's < 0.05). Within groups, increased global transitions index was associated with higher CDI total scores in HC ($p = 0.003$), but we found no significant associations with sleep variables and CDI scores within the NT1 group.

Conclusions: Sleep fragmentation, across sleep and notably affecting REM and N3 sleep, may reflect or contribute to increased depressive symptoms in children and adolescents. Future studies should recruit larger cohorts of children and adolescents with NT1 with varying degrees of mood symptoms to clarify these relationships and guide targeted interventions for depression in this population.

Acknowledgments: This study was supported by a grants to K.M. from the National Institutes of Health grant K23 NS104267.

Associations of Atypical Depressive Features with Sleep disturbances: Evidence from the Cluster Analysis

C.C.W. Cheng¹, Y.C. Sun¹, R. Huang¹, J. Chen¹, N.Y. Chan¹, S.X. Li^{2,3}, J.W.Y. Chan¹, Y.K. Wing^{1,4}, T.M.H. Li¹

¹The Chinese University of Hong Kong, Li Chiu Kong Family Sleep Assessment Unit, Department of Psychiatry, Hong Kong, Hong Kong, SAR of China, ²The University of Hong Kong, Department of Psychology, Hong Kong, Hong Kong, SAR of China, ³The University of Hong Kong, The State Key Laboratory of Brain and Cognitive Sciences, Hong Kong, Hong Kong, SAR of China, ⁴The Chinese University of Hong Kong, Li Ka Shing Institute of Health Sciences, Faculty of Medicine, Hong Kong, Hong Kong, SAR of China

Introduction: Depression remains a leading cause of global disease burden, with atypical Depression (ADep) as a clinically distinct subtype characterized by mood reactivity, hypersomnia, increased appetite, and fatigue. Despite its unique symptomatology, the relationship between ADep and sleep disturbances in Asian populations is underexplored. This study examines associations among atypical depressive features, insomnia, and sleep quality among individuals in Hong Kong.

Materials and methods: We recruited 115 participants (mean age: 53.4 ± 11.0 ; female: $n = 76$, 66.1%) with non-remitted major depressive disorder (MDD) from the local public psychiatric outpatient clinics. They were assessed by the Structured Interview Guide for the Hamilton Depression Rating Scale with Atypical Supplement (SIGH-ADS). Sleep quality and disturbances were measured with Pittsburgh Sleep Quality Index (PSQI), Insomnia Severity Index (ISI), and Epworth Sleepiness Scale (ESS). Unsupervised clustering algorithms, including k-means clustering, hierarchical clustering, and Gaussian mixture model, were applied to define symptom-based clusters. K-means clustering with two clusters was selected based on validity indices.

Results: Two clusters were identified after adjustment for age, sex and education, with cluster 1 ($n = 45$, 39.1%, female: $n = 33$) having significantly higher score on 17-item Hamilton Rating Scale for Depression (HDRS-17) and 8-item atypical neurovegetative symptoms (ANS) (HDRS, Cluster 1 mean score = 19.34 ± 2.73 vs Cluster 2 mean = 11.75 ± 2.72 , $p < 0.01$; ANS, Cluster 1 mean score = 8.24 ± 1.74 vs Cluster 2 mean = 4.50 ± 1.73 , $p < 0.01$, respectively). Cluster 1 showed a higher proportion of clinically significant insomnia ($ISI \geq 15$) and excessive daytime sleepiness ($ESS \geq 14$) (Insomnia, 66.7% vs. 37.1%, OR: 3.57, 95% CI: 1.44, 8.85, $p = 0.01$; EDS, 31.1% vs. 18.6%, OR: 2.93; 95% CI: 1.06, 8.10, $p = 0.04$, respectively) than Cluster 2. Ostensibly, cluster 1 exhibited significantly higher scores on PSQI (Cluster 1 mean score = 14.61 ± 3.15 vs Cluster 2 mean = 12.36 ± 3.15 , $p = 0.01$) and ISI (Cluster 1 mean score = 12.75 ± 3.15 vs Cluster 2 mean = 9.04 ± 4.48 , $p < 0.01$), indicating poorer sleep quality and greater insomnia severity. For the single item from SIGH-ADS, there was no significant difference on the item "hypersomnia" across two clusters, but "difficulty awakening" (Cluster 1 mean = 1.68 ± 0.72 vs Cluster 2 = 0.28 ± 0.72 , $p < 0.01$) was more pronounced in Cluster 1.

Conclusions: This study reveals that there was a cluster having more atypical depressive symptoms (39.1%) among individuals with non-remitted MDD in the psychiatric clinic, with significant associations between atypical depressive features and a series of sleep disturbances characterised by more severe and prevalent insomnia, poor sleep quality, difficulty awakening and excessive daytime sleepiness. Future research should incorporate objective sleep measures, larger and broader samples to validate these results for better subtyping and potential personalised intervention.

Can Wake after nightmare duration (WAN) serve as a Clinical marker of Trauma-related nightmares' impact during sleep?

D. Feingold¹, M. Quiquempoix^{2,1}, M. Remadi³, G. Sipahimalani⁴, D. Gomez-Merino^{2,1}, M. Chennaoui^{2,1}, D. Leger^{5,1}, E. Saguin^{3,1}

¹Université Paris Cité, UMR 7330 VIFASOM (Vigilance Fatigue Sommeil et Santé Publique), Paris, France, ²French Armed Forces Biomedical Research Institute (IRBA), Bretigny-sur-Orge, France, ³Begin Military Teaching Hospital, Psychiatric Department, Saint-Mandé, France, ⁴Percy National Military

Teaching Hospital, Psychiatric Department, Clamart, France, ⁵APHP, Hôtel Dieu, Sleep and Vigilance Center, Paris, France

Introduction: Trauma-related nightmares (TRNs) are vivid and specific sleep phenomena with strong ties to traumatic events, provoking intense distress and abrupt awakenings. Beyond being a PTSD symptom, TRNs can persist independently and vary in replicativity: replicative (REP) closely mirror the trauma, partially replicative (PREP) mix trauma elements with symbolic content, and non-replicative (NREP) retain only thematic traces. Despite their impact, objective markers of TRNs' severity remain scarce. Wake After Nightmare (WAN) duration—the time a patient remains awake after a TRN—may index TRN intensity. This study evaluates WAN as a potential clinical marker of TRN burden during sleep.

Materials and methods: We conducted a prospective, multicentric observational study (SOMMEPT) involving 74 French former military personnel with PTSD (PCL-5 > 44) from a cohort of 131. Sleep was recorded at home over seven nights using the Dreem V2 EEG headband and Empatica E4 wristband. Across the last five nights, 412 TRN-related awakenings were identified. Median WAN duration per patient was calculated, and participants were divided into tertiles (Low, Mid, High WAN). Assessments included standardized clinical questionnaires (PTSD, depression, insomnia, sleep quality), EEG-derived sleep metrics, and TRN replicativity/phenomenological features from the TRNS-FR. Group comparisons used Kruskal-Wallis, Mann-Whitney U, and Fisher's exact tests.

Results: Weekly TRN frequency was 4.40/week across participants. WAN groups showed: Low (n = 24) = 0.97 min (3.03 TRNs/week), Mid (n = 25) = 2.06 min (3.53 TRNs/week), High (n = 25) = 13.40 min (2.63 TRNs/week). Although TRN frequency did not differ significantly, the High WAN group displayed higher BDI scores (p = 0.0499) and a trend toward elevated PTSD re-experiencing symptoms (p = 0.0355). They also had shorter total sleep time (p = 0.0147) and reduced NREM duration (p = 0.0262) compared to the Low WAN group. High WAN patients reported more NREP TRNs (p = 0.0488), vivid sensations (p = 0.0488), realistic imagery (p = 0.0223), tremors (p = 0.0378), and fear of dying (p = 0.0209).

Conclusions: Longer WAN durations may indicate stronger nocturnal TRN burden, with heightened emotional aftereffects, disrupted sleep, and more trauma-specific content. While frequency remained stable, the association between WAN and nightmare replicativity supports its clinical relevance as a simple, objective marker of TRN severity. Further studies should assess its potential for real-time monitoring and personalized follow-up in trauma-exposed populations.

Circadian Motor Asymmetry and Homeostatic Dysregulation in Adults with ADHD: An Actigraphic Study

F. Giudetti¹, N.R. Conca², G. Giupponi², S. Holzer², C. Mattei², V. Natale¹, M. Re¹, L. Tonetti¹, A. Conca²
¹University of Bologna, Department of Psychology, Bologna, Italy, ²General Hospital of Bolzano, Department of Psychiatry, Bolzano, Italy

Introduction: Attention Deficit Hyperactivity Disorder (ADHD) is a neurodevelopmental condition characterized by persistent inattention, motor hyperactivity, and impulsivity, often persisting into adulthood.

Concerning wakefulness, a motor hyperactivity is commonly reported, while reduced sleep efficiency and prolonged sleep onset latency are reported during sleep. Taken together, these dimensions might reflect altered circadian rhythmicity.

As hyperactivity represents one of the core features of ADHD, objective measurement of motor activity could enhance diagnostic precision, and inform follow-up strategies.

Actigraphy—an accelerometer-based wrist-worn device—offers an ecological method to monitor motor activity across 24-hour periods in both wake and sleep states.

Prior studies have suggested a small but reliable phase difference in circadian motor activity between the dominant and non-dominant wrist, interpreted as a potential reflection of asymmetric hemispheric regulation of sleep-wake processes. The left hemisphere, being more sensitive to homeostatic sleep pressure (Process S), may deactivate earlier in the evening, while the right hemisphere may remain

active longer, influenced more by the circadian drive (Process C). This functional asymmetry has been documented in a healthy population. Investigating such asymmetry in adults with ADHD may shed light on altered regulation of circadian and homeostatic mechanisms and potentially serve as an objective biomarker of the disorder.

We investigated:

1. Between-group differences in left wrist motor activity to detect the presence or absence of the post-lunch dip, previously reported as blunted in ADHD;
2. Within-group differences in acrophase (right vs. left wrist) as an index of hemispheric asymmetry;
3. Presence of a circadian phase shift between wrists, particularly in healthy controls.

Materials and methods: We enrolled 21 adults with ADHD (11 females; mean age 39.7 ± 8.9) and 13 healthy controls (7 females; mean age 22.7 ± 1.06). Participants wore Actiwatch AW64 devices on both wrists for seven consecutive days, pressing the event marker to signal bedtime and wake-up. Data were analyzed with the Actiwatch Activity & Sleep Analysis software.

Results: 1. Post-lunch dip: Functional linear modeling (FLM) of left wrist activity showed a reduced post-lunch dip in the ADHD group compared to controls, especially between 14:00 and 16:00. Although the F-statistic did not exceed the maximum critical threshold, pointwise values indicated a subtle but consistent difference

2. Acrophase: ADHD: no significant difference between left (14.85 ± 1.37) and right (14.96 ± 1.25) wrist acrophase ($p = 0.200$). Controls: significant difference between left (15.47 ± 1.26) and right (15.24 ± 1.21) wrist acrophase ($p = 0.043$).

An ANOVA revealed a significant Group $\times$ Side interaction ($F(1,54) = 5.35, p = 0.025$),

3. Circadian pattern: Controls showed a statistically significant difference between wrists, absent in ADHD.

Conclusions: Our findings reveal altered circadian motor patterns in ADHD: absent post-lunch dip, absence of differences in acrophase and absence of differences between wrists in the circadian pattern, potentially caused by a homeostatic dysregulation. Motor asymmetry may serve as a non-invasive biomarker in ADHD. However, small sample size and age differences limit generalizability. Larger, age-matched studies are needed to confirm these results.

Clinical Association Between Current Depressive Symptoms and Odds Ratio Product in US Sleep Centers

A. Defillo¹, M. Grassi^{1,2,3}, S. Dacco^{1,2,3}, J. Martin^{4,5}, V. Guadagni⁶

¹Medibio Limited, Savage, United States, ²Humanitas University, Rozzano, Italy, ³Villa San Benedetto Menni, Albese con Cassan, Italy, ⁴University of California, Department of Medicine, David Geffen School of Medicine, Los Angeles, United States, ⁵VA Greater Los Angeles Healthcare SystemU, Geriatric Research, Education and Clinical Center, California, United States, ⁶University of Calgary, Department of Physiology & Pharmacology, Cumming School of Medicine, Calgary, Canada

Introduction: The Odds Ratio Product (ORP) is a well-established metric for assessing sleep depth and the sleep-wake continuum. Compared to traditional sleep measurements, ORP has demonstrated superior sensitivity in evaluating sleep quality. While several studies have examined ORP variations across sleep stages and their correlations with both objective and subjective sleep parameters in healthy individuals and those with sleep-wake disorders, evidence remains limited regarding its role in psychiatric conditions. Nevertheless, it is plausible to hypothesize that ORP may serve as a novel and sensitive biomarker for identifying sleep characteristics associated with depressive symptoms.

Materials and methods: Methods

We conducted a retrospective analysis of 829 adults whose overnight polysomnography (PSG) recordings and clinical data were collected in two naturalistic, multicentre studies: the Sleep Analysis of Depressive Burden (SADB) study (ClinicalTrials.gov Identifier: NCT04232267) and the Sleep Signal Analysis for Current Major Depressive Episode (SAMDE) study (ClinicalTrials.gov Identifier: NCT05708222). Before PSG, all participants completed a demographic/medical questionnaire and the Patient Health Questionnaire-9 (PHQ-9). PSG recordings were sleep-staged automatically with the

STAGER software, and the ORP was calculated from central EEG derivations via Cerebra Medical's algorithm. Mean and standard-deviation ORP values were extracted for the whole night and for Wake, N1 + N2, N3 and REM periods. Associations between ORP metrics and depressive burden were tested with linear regression for PHQ-9 total score, and with logistic regression for PHQ-9 ≥ 10 , incorporating linear and quadratic ORP terms, and adjusting for age and sex. Fixed- and mixed-effects model structures (random intercepts $\pm$ slopes by clinical centre group) were compared with Akaike Information Criterion (AIC); the best-fitting model for each analysis was refitted with restricted maximum likelihood.

Results:

Fixed-effects models consistently outperformed mixed-effects alternatives (lowest AIC), indicating that centre-to-centre variability did not significantly influence the findings. Mean ORP across the entire night and in light-sleep (N1 + N2) showed a significant quadratic (U-shaped) association with both the PHQ-9 Total Score and PHQ-9 ≥ 10 . Thus, individuals with either elevated (indicative of shallower sleep) or reduced (indicative of deeper sleep) mean ORP values across the night and in deep sleep exhibited higher depression scores compared to those with average ORP values. Instead, the mean ORP in deep sleep (N3) showed a significant and positive linear association with them. The standard deviation of ORP across the entire night showed a linear negative association the PHQ-9 Total Score and PHQ-9 ≥ 10 , while the standard deviation of ORP in deep sleep (N3) showed a significant and positive linear association with only the PHQ-9 Total Score.

Conclusions:

A complex relationship between mean ORP and PHQ-9 scores was found in our study, highlighting a direct correlation in deep sleep and a U-shaped pattern in lighter sleep stages and overall sleep architecture. Our findings demonstrate the potential utility of ORP analysis in clinical sleep settings as a non-invasive marker of depression severity. Since ORP can be readily derived from PSG data, its integration into routine sleep evaluations may improve the detection of clinically relevant depressive symptoms.

Discordance in Physiological and Subjective Stress Measurements: Hair Cortisol, Self-reported Stress Scales and Heart Rate Variability in Healthcare Night-shift Workers

F. Ding¹

¹Fudan Univeristy, Shanghai, China

Introduction: Chronic stress increases risks of multiple diseases. Stress is usually evaluated by subjective psychological scales. Hair cortisol concentration (HCC) and Heart rate variability (HRV) have also been used as stress indicators. However, there is no gold standard to measure stress.

Materials and methods: In-total 74 healthcare workers with regular night-shifts were recruited. HCC was measured by liquid chromatograph/mass spectrometer. Subjective psychological scales were performed, including Perceived Stress Scale-14 (PSS), Depression Anxiety Stress Scales-21, Epworth Sleepiness Scale, Fatigue Assessment Scale and Subjective Happiness Scale. HRV indices (SDNN, RMSSD, HF and LF) were measured from 24h-Holter. All these data were collected both before and after 3-month stress management.

Results: HCC showed positive correlation with PSS ($r = 0.228$, $P = 0.050$) but not with other scales and HRV indices in cross-sectional analysis based on baseline data. Longitudinally, subjective scales showed a significant remission in stress and adverse mood after 3-month intervention. However, HCC was significantly elevated after stress management, and HRV indices, including 24h SDNN, nighttime SDNN, RMSSD, HF and LF/HF, were decreased (all $P < 0.05$). Upon the 3-month intervention, the changes of HCC did not correlate with the changes of scale scores, but correlated with the changes of HRV indices (negatively with 24h and daytime LF/HF and LFnu, and positively with daytime HF).

Conclusions: This study aims to explore the correlation between physiological stress indicators and subjective psychological scales. Subjective and objective measures of stress could exhibit differential

changes upon the same interventions. The combined measurements would be recommended as routines for the clinical practice.

Effect of transcranial direct current stimulation on the sleep electroencephalogram in major depressive disorder: findings of intrinsic multiscale entropy from a randomized controlled study

T. Chen¹, Y. Zhao¹, M. Li¹, Z. Li¹, X. Du¹

¹The Affiliated Guangji Hospital of Soochow University, Suzhou, China

Introduction: Transcranial direct current stimulation (tDCS) is a non-invasive method of brain stimulation used to treat individuals with major depressive disorder (MDD). In this study we determined the differences in sleep electroencephalogram (EEG) complexity between patients with and without MDD.

Materials and methods: Twenty-two healthy controls (HCs) and 37 MDD patients were recruited. The patients were assigned randomly to receive either active tDCS stimulation (n = 19) or sham stimulation (n = 18). To assess sleep structure and EEG complexity, polysomnography was applied to all MDD patients and HCs. Intrinsic multi-scale entropy (iMSE) was utilized to quantify the complexity of EEG signals.

Results: By comparison with PSG data from HCs, the characteristic EEG complexity during rapid eye movement (REM) sleep was validated in MDD patients. More importantly, there was a notable increase in the iMSE of non-REM sleep stage 1(N1) following active tDCS stimulation compared to pre-stimulation, and there was no longer a significant distinction between patients and HCs. There was a marked contrast in complexity between the sham group and HCs both before and after tDCS sham stimulation.

Conclusions: tDCS was shown to nearly restore the sleep N1 EEG complexity in MDD patients to that of HCs. The intervention effect of tDCS stimulation in MDD patients is characterized by iMSE of EEG signals.

Acknowledgments: The contributions of all the participants and all members of study team are greatly acknowledged.

Effects of a Dual Orexin-receptor Antagonist on Sleep Architecture and Opioid Withdrawal Severity during a Buprenorphine Taper

A. Huhn¹, N. Skandan¹, A. Hoadley¹, K. Dunn²

¹Johns Hopkins University School of Medicine, Psychiatry and Behavioral Sciences, Baltimore, United States, ²University of Maryland School of Medicine, Department of Psychiatry, Baltimore, United States

Introduction: Sleep disturbance is a key component of opioid withdrawal that drives negative opioid use disorder (OUD) treatment outcomes, but the relationship between sleep architecture and opioid withdrawal severity during treatment initiation remains poorly understood. This study builds on prior research by examining associations between sleep architecture and opioid withdrawal during administration of suvorexant, a dual-orexin receptor antagonist, versus placebo during an opioid withdrawal paradigm.

Materials and methods: These analyses were conducted on N = 26 participants who completed the 11-day (10 night) parent study. In brief, participants with OUD who were seeking supervised withdrawal treatment were first inducted and maintained on 8/2mg to 16/4mg buprenorphine/naloxone (hereafter buprenorphine) for 3 days, then randomized to 0mg, 20mg, or 40mg suvorexant for the duration of the study. Participants were then tapered off buprenorphine over a 4-day period followed by a 4-day post-taper observation. Each night, participants wore a 3-lead electroencephalography device (Sleep Profiler) to objectively measure sleep architecture. Participants also completed the 16-item Subjective Opiate Withdrawal Scale (SOWS) at 4 timepoints each day.

Linear regression models were used to model the correlation of total rapid eye movement (REM) sleep, REM percent, REM onset latency, total sleep time (TST), and total NREM3 sleep with subjective opioid withdrawal outcomes (assessed via the SOWS). For the linear regression models, each continuous variable was averaged per participant within each phase (stabilization, taper, post-taper), to account for

repeated measures. The effect of suvorexant versus placebo on sleep architecture and subsequent opioid withdrawal symptomatology was modeled with a 2-group comparison, without differentiation of suvorexant dose. Suvorexant moderation was only examined during the taper and post-taper phases, as suvorexant had not yet been administered in the stabilization phase. All analyses were conducted using R version 4.2.3 with statistical significance set at $\alpha = 0.05$.

Results: During the taper, increased total REM sleep and suvorexant were each associated with reduced SOWS (both p 's < 0.05), with a marginally significant interaction between suvorexant and total REM sleep ($p = 0.051$). Similarly, increased REM percent was associated with reduced SOWS (both p 's < 0.05). A significant interaction between total REM percent and suvorexant ($p = 0.013$) indicated that suvorexant attenuated the association between REM percent and withdrawal severity.

In the post-taper phase, the pattern reversed. Increased REM and total sleep time were associated with increased SOWS ($p < 0.05$), and suvorexant mitigated this effect ($p < 0.05$). Suvorexant also had a significant effect on mitigating withdrawal in the post-taper phase after accounting for REM sleep ($p < 0.05$).

Conclusions: Suvorexant may reduce withdrawal severity both directly and by moderating associations between sleep architecture and withdrawal during a buprenorphine taper. REM sleep including rebound REM might be biomarkers of different phases of opioid withdrawal. Improving our mechanistic understanding of the role of the orexin neurotransmitter system during early OUD treatment can lead to medication development and ultimately improved treatment for OUD.

Acknowledgments: We would like to thank the National Institute on Drug Abuse for funding this study UG3DA048734 (Huhn/Dunn)

Efficacy of non-pharmacological approaches to improve sleep in patients with post-traumatic stress disorder: systematic review and meta-analysis

H. Canas-Simião¹, R. Guiomar², L. Santana³, D. Carreiras⁴, J.P. Azenha³, C. Reis⁵, D. Garcia-Borreguero⁶

¹Serviço de Saúde da Região Autónoma da Madeira, Entidade Pública Empresarial da Região Autónoma da Madeira (SESARAM, EPERAM), Psychiatry, Funchal, Portugal, ²University of Coimbra, Faculty of Psychology and Educational Sciences, Center for Research in Neuropsychology and Cognitive and Behavioral Intervention, Coimbra, Portugal, ³Unidade local de Saúde de Lisboa Ocidental, Psychiatry, Lisboa, Portugal, ⁴Lusófona University, HEI-Lab: Digital Human-Environment Interaction Labs, Porto, Portugal, ⁵Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal, ⁶Sleep Research Institute, Madrid, Spain

Introduction: Exposure to violence and adversity during childhood has been identified as a significant risk factor for the later development of both psychiatric conditions and sleep disturbances, with post-traumatic stress disorder (PTSD) frequently emerging as a consequence. While current evidence-based guidelines advocate for trauma-focused psychotherapies (e.g., Imagery Rehearsal Therapy, Cognitive Processing Therapy) as first-line treatments for PTSD, two main challenges persist. First, sleep-related dysfunction, manifesting as maladaptive cognitions about sleep and irregular sleep behavior, is often insufficiently addressed by these therapeutic approaches and frequently remains as a residual symptom post-treatment, impairing quality of life and increasing the risk of relapse. Second, access to psychotherapy is not universally available, underscoring the need to explore alternative interventions. Non-pharmacological strategies, such as physical exercise and mindfulness-based approaches, have shown beneficial effects on both sleep and mental health, and may thus be helpful for individuals with PTSD. Considering the bidirectional relationship between sleep and psychological functioning, we conducted a systematic review and meta-analysis to evaluate the efficacy of non-pharmacological interventions in improving sleep outcomes among individuals diagnosed with PTSD. We included non-psychotherapeutic interventions, trauma-focused psychotherapies, non-trauma-focused psychotherapies, and combined psychotherapies.

Materials and methods: This systematic review and meta-analysis (PROSPERO: CRD42022318904) examined randomized controlled trials (RCTs) investigating the effects of non-pharmacological treatments on sleep in adults diagnosed with PTSD. Studies were included if they were peer-reviewed, published in English, involved adult participants with a PTSD diagnosis, and reported at least one sleep-related outcome. Eligible trials compared non-pharmacological interventions (e.g., psychotherapy, yoga, exercise, acupuncture) with other non-pharmacological treatments, treatment-as-usual, waitlist control,

or no treatment. Standardized mean differences (SMDs) were calculated, and subgroup and meta-regression analyses were conducted to explore potential sources of heterogeneity.

Results: Across 34 studies, with a total pooled sample of 3,688 participants ($n = 2,070$ in experimental groups and $n = 1,618$ in control groups), active treatments significantly improved sleep quality compared to control conditions, with a large overall effect size ($SMD = 0.77$, $p < .001$) and significant heterogeneity ($I^2 = 88.89\%$). The effect remained robust after excluding studies at high risk of bias ($SMD = 0.90$, $p < .0001$). Subgroup and regression analyses revealed no significant effects of participants' age, percentage of male participants, or baseline severity of negative symptoms. No evidence of funnel plot asymmetry was found ($p = 0.107$), suggesting a low risk of publication bias. Additional analyses are ongoing and will be reported as defined in the protocol.

Conclusions: Our findings suggest that non-pharmacological interventions, including psychotherapies and behavioral strategies, are associated with significant improvements in sleep quality among adults with PTSD, with a robust and clinically meaningful effect. These results support the integration of sleep-focused, non-pharmacological approaches into treatment plans for PTSD. Addressing sleep disturbances in PTSD is essential, as persistent sleep problems contribute to symptom maintenance and increased risk of relapse. Targeted sleep interventions may enhance emotional regulation, facilitate fear extinction, and improve overall treatment outcomes. Further analyses are underway to clarify the specific characteristics and mechanisms of the most effective interventions.

Exploratory Study of Sleep-wake Patterns in People with Schizophrenia Residing in the Community

Introduction: Disturbances in circadian and sleep-wake rhythms are frequently observed in individuals with schizophrenia and other psychiatric disorders. However, their lifestyles and sleep patterns, particularly in community-dwelling settings, remain insufficiently explored. This study investigated the sleep-wake rhythms of individuals with schizophrenia living in non-urban communities, and receiving home nursing care, using both subjective and objective measures.

Materials and methods: This study population comprised of nine individuals (aged 28–52 years) who were using home nursing care. Demographic data (age, employment history, smoking history, sports experience, and the presence of chronic constipation) were collected through interviews. Subjective sleep quality was assessed using the Pittsburgh Sleep Quality Index (PSQI). Objective sleep parameters were collected via an actigraphic device consistently worn on the participant's lumbar region for 7 d, excluding bathing time. Sleep variables were determined using SleepSign Act 2 (KISSEI COMTEC Co., Ltd.). Additionally, a chi-square periodogram was used to evaluate the 24-h cycle and note any deviations. Life functioning was evaluated using the World Health Organization Disability Assessment Schedule (WHODAS) 2.0. This study was approved by the Research Ethics Review Committee of Iryo Sosei University (Approval No. 22-04), and written informed consent was obtained from all individuals.

Results: Eight participants (seven males and one female) enrolled in this study. One was excluded because of poor attachment. The mean PSQI score was 8.17 and WHODAS 2.0 score was 22.88. Spearman's rank correlation analysis showed a moderate positive correlation trend ($\rho = 0.673$, $p = 0.067$) between PSQI and WHODAS 2.0 scores, suggesting a potential link between sleep quality and self-reported life function scores. Furthermore, when self-reported total sleep time was compared with the actigraphic measurements, a discrepancy of >1 h was observed in four individuals, indicating a potential misperception of sleep duration. Four participants showed a deviation in the peak of the chi-square periodogram of >30 min from the 24-h (range: -42 to $+48$ min). Actigraphic sleep parameters revealed that most participants showed a decline in sleep quality, characterized by reduced total sleep time, lower sleep efficiency, longer sleep latency, and increased wake time after sleep onset.

Conclusions: These results suggest a meaningful relationship between subjective sleep quality and life functioning among community-dwelling individuals with schizophrenia. Approximately half of the participants also deviated from a standard 24-h activity rhythm, which is consistent with previous findings. These results underscore the importance of promoting better sleep habits to improve lifestyle and mental functioning. Future support strategies should include individualized and comprehensive sleep interventions such as utilizing Cognitive Behavioral Therapy for Insomnia, alongside lifestyle modifications. Continued evaluation incorporating both subjective complaints of the individual and objective data will reinforce these findings.

Exploring Sleep Disturbances Among Trauma-Exposed Psychiatric Populations

E. Davies-Vickers^{1,2}, P.J. Ireland^{2,1}, S. Chu^{1,2}

¹The University of Central Lancashire, Psychology, Preston, United Kingdom, ²Ashworth High Secure Hospital, Ashworth Research Centre, Liverpool, United Kingdom

Introduction: Sleep disturbances are complex, encompassing a range of disruptions to quality, quantity, and timing (Altman, Knauert & Pisani, 2017; Cormier, 1990). A well-established bidirectional relationship exists between poor sleep and mental health issues, with psychological distress increasingly recognised as impacting sleep health (Brindle et al., 2019). Hence, sleep issues are common among those with psychosis, where trauma exposure is prevalent (Kamphuis et al., 2013). However, little research has explored the relationship between life experiences and sleep among this population (Greenwood, 2020). The current study, therefore, explored the nature of sleep disturbances in psychiatric patients at a high-secure forensic mental health hospital in the UK.

Materials and methods: Semi-structured interviews, informed by measures such as the Pittsburgh Sleep Quality Index (Buysse et al., 1989) and the Morning Eveningness Questionnaire (Horne & Östberg, 1976), were conducted with 30 psychiatric inpatients with both active and residual psychosis symptoms. Participants discussed sleep patterns, preferences, and behaviours, as well as past experiences and night-time cognitions. Interviews were recorded and transcribed using Winscribe and thematically analysed using NVivo software.

Results: Five major themes emerged from the data, emphasising sleep behaviours characteristic of this population. Firstly, participants consistently reported evening chronotypes, alongside delayed sleep patterns, highlighting the impact of misaligned circadian rhythms on unhealthy behaviours, such as poor diet and disrupted routines. Secondly, negative night-time cognitions, such as ruminations of past violence and regrets, were common, often causing physical distress and pre-sleep arousal, further driving sleep disturbances. Thirdly, there was a persistent overlap between nightmares and trauma flashbacks, with participants discussing the two interchangeably, emphasising the impact of intrusion symptoms on sleep. Another prevalent theme was a long history of sleep issues, with participants identifying a 'tipping point' where both sleep and psychosis symptoms had significantly worsened. This appeared to be used as a reference point from which current sleep perceptions were measured. Finally, trauma therapies, such as eye-movement desensitisation and reprocessing (EMDR), were praised for improving sleep outcomes by reducing post-trauma nightmares and psychological distress.

Conclusions: Overall, findings highlight the relationship between trauma and sleep in those with psychosis, suggesting that circadian misalignment, negative cognitions, such as rumination, and intrusion symptoms, drive sleep disturbances. These findings emphasise the importance of exploring patient perspectives, recognising trauma as a target for improving sleep outcomes across secure settings.

Acknowledgments: I would like to thank Professor Jane Louise Ireland and Dr. Simon Chu for their continued guidance and support throughout my PhD project. I would also like to acknowledge the support from my colleagues at The University of Central Lancashire and Ashworth Research Centre, as well as the patients themselves at Ashworth Hospital.

From genetic variants to genes: dissecting shared genetic architecture and biological mechanisms linking sleep traits and suicide attempt

Y. Lu¹, Y. Xu¹, Y. Sun², Y. Li³, S. Chang², J. Que⁴, C. Lavebratt⁵, J.J. Liu¹

¹Peking University, School of Nursing, Beijing, China, ²Peking University Sixth Hospital, Beijing, China, ³Karolinska Institutet, Department of Medical Epidemiology and Biostatistics, Stockholm, Sweden, ⁴Xiamen Xianyue Hospital, Xiamen, China, ⁵Karolinska Institutet, Stockholm, Sweden

Introduction: Suicide attempt is a serious public health concern with complex causes involving both environmental and genetic factors. Sleep traits have emerged as promising targets in suicide prevention efforts. Epidemiological studies support associations between sleep traits and increased risk of suicide attempt, independent of psychiatric comorbidities. Moreover, both sleep traits and suicidality are moderately heritable. These lines of evidence suggest a potential shared polygenic architecture underlying both phenotypes. However, the genetic underpinnings linking the two remain not been fully elucidated. This study aimed to systematically identify shared genetic variants, genes, and biological mechanisms between 11 sleep traits and suicide attempt using a comprehensive multi-layered analytic framework.

Materials and methods: We conducted a genome-wide pleiotropic association study using GWAS summary statistics from European-ancestry cohorts, covering 11 sleep traits—7 self-reported (e.g., insomnia, short/long sleep, chronotype) and 4 accelerometer-derived traits—and suicide attempt. We first assessed genome-wide genetic correlations using linkage disequilibrium score regression (LDSC) and overall genetic overlap via genetic analysis incorporating pleiotropy and annotation (GPA). Then, pleiotropic single nucleotide variants (SNVs) were identified using the PLACO method, followed by functional annotation with FUMA and Bayesian colocalization analysis. MAGMA was used to identify pleiotropic genes, which were further evaluated through phenotype enrichment (MGI), GO/KEGG pathway analysis, and cell-type specificity analysis. Drug-gene interactions and druggability of pleiotropic genes were assessed using DGIdb. Finally, bidirectional Mendelian randomization (MR) was performed to examine potential causal relationships.

Results: Six trait pairs exhibited significant genetic correlations, while all 11 showed significant genetic overlap (Bonferroni-corrected $p < 4.54 \times 10^{-3}$). The PLACO analysis identified 2,224 pleiotropic SNVs (1,640 unique), mapped to 50 genomic risk loci, including two novel loci not previously reported. Colocalization analysis further supported shared causal variants at 15 loci (PP.H4 > 0.7). MAGMA identified 44 significant pleiotropic genes (32 unique), enriched in metabolic and neurodevelopmental pathways. Gene set enrichment revealed significant involvement in synaptic structure, immune signaling, and H3K27me3-mediated repression. DGIdb analysis highlighted several pleiotropic genes as druggable targets, notably DRD2 with extensive approved drug interactions. MR analysis indicated a significant protective effect of morning chronotype on suicide attempt (OR = 0.25, $p = 0.003$), and nominally significant risk associations for insomnia, short sleep, daytime napping, and reduced sleep duration.

Conclusions: This multi-layered pleiotropic analysis provides robust evidence of shared genetic mechanisms linking sleep traits and suicide attempt. The identified loci and genes uncover novel biological pathways including synaptic function, immune regulation, and epigenetic repression. Importantly, several candidate genes are druggable, offering promising therapeutic targets for translational research and targeted interventions to reduce suicide risk via modulation of sleep-related pathways.

Acknowledgments: The authors acknowledge the participants and investigators of the included GWAS studies.

From Sleep to Diagnosis: A Novel Nomogram for Identifying Major Depressive Disorder Using Comprehensive Sleep Metrics

B. Zhou¹, Y. Li¹

¹Mental Health Center of Shantou University, Department of Sleep Medicine, Shantou, China

Introduction: Sleep impairment is a one of the most common symptoms of Major depressive disorder (MDD). The stigma of MDD causes patients to conceal their core MDD symptoms, resulting in missed diagnosis. We aimed to develop a predictive model integrating self-report sleep, objective sleep architecture and EEG activity to estimate the probability of MDD in individuals with sleep complaints.

Materials and methods: Ninety-one patients with MDD and ninety-one age and sex-matched controls were included. All subjects were assessed by overnight polysomnography, electroencephalogram (EEG) relative power during sleep, Pittsburgh Sleep Quality Index (PSQI), Flinders Fatigue Scale (FFS) and

Epworth Sleepiness Scale (ESS). The Beck Depression Inventory (BDI) was used to assess depressive symptoms. Predictive factors were identified using random forest analysis and logistic regression. A nomogram was created based on the logistic regression results. Area under the receiver operating characteristic curve (AUC) was used to evaluate the discrimination of the nomogram. Bootstrapping was used for internal validation, and accuracy of the model was evaluated using the Hosmer-Lemeshow test. Decision curve analysis (DCA) of the nomogram was conducted.

Results: The prediction model included total scores for PSQI and FFS, wake after sleep onset, and EEG theta power during rapid eye movement sleep as predictors, and gave an AUC of 0.924 (95% confidence interval: 0.887 - 0.961). The Hosmer-Lemeshow test showed a $\chi^2=4.36$ ($p = 0.823$), and DCA showed a higher net benefit for the nomogram compared to the BDI.

Conclusions: This predictive model provides a reliable tool for identifying MDD in individuals with sleep complaints, which may help to decrease missed diagnosis rate of MDD.

Acknowledgments: The authors thank the sleep technicians and staff of the Department of Sleep Medicine, Shantou University Mental Health Center, for their support with this project. This study was supported by the 2020 Li Ka Shing Foundation Cross-Disciplinary Research Grant [2020LKSFG05B].

Genetic association of depression and antidepressant targets with α -synucleinopathy spectrum disorders

J. Wang^{1,2,3}, C. Yang¹, S. Ai^{1,2}, Y.K. Wing^{3,4}, Y. Liu^{1,2,3}, J. Zhang^{1,2}, Y. Ning^{2,5,6}

¹The Affiliated Brain Hospital, Guangzhou Medical University, Center for Sleep and Circadian Medicine, Guangzhou, Guangdong, China, ²Key Laboratory of Neurogenetics and Channelopathies of Guangdong Province and the Ministry of Education of China, Guangzhou, Guangdong, China, ³The Chinese University of Hong Kong, Li Chiu Kong Family Sleep Assessment Unit, Department of Psychiatry, Hong Kong, China, ⁴The Chinese University of Hong Kong, Li Ka Shing Institute of Health Sciences, Faculty of Medicine, Hong Kong, China, ⁵The Affiliated Brain Hospital, Guangzhou Medical University, Department of Geriatric Psychiatry, Guangzhou, Guangdong, China, ⁶The Affiliated Brain Hospital, Guangzhou Medical University, Department of Neurology, Guangzhou, Guangdong, China

Introduction: Observational studies have suggested the associations between depression, antidepressant use, and α -synucleinopathy spectrum disorders, including rapid eye movement sleep behavior disorder (RBD), Parkinson's disease (PD), dementia with Lewy bodies (DLB), and multiple system atrophy (MSA). However, their genetic associations remains unclear. This Mendelian randomization (MR) study aimed to investigate the genetical associations between depression, antidepressant targets, and α -synucleinopathy spectrum disorders.

Materials and methods: We obtained summary statistics of genetic variants associated with depression and α -synucleinopathy spectrum disorder phenotypes from respective genome-wide association studies (GWAS). Expressive quantitative trait loci (eQTL) for antidepressant target genes were extracted from the eQTLGen Consortium. Antidepressant targets expression in blood with significant associations with α -synucleinopathy spectrum disorder phenotypes were further examined in brain tissues. Sensitivity analyses including stringent linkage disequilibrium (LD) criteria, summary-based Mendelian randomization (SMR), colocalization, and shared genetic architecture analyses were conducted to ensure the robustness of the findings.

Results: No significant effect of depression on overt α -synucleinopathies was confirmed. Conversely, RBD was suggested to be causally associated with depression (OR[95%CI] = 1.04[1.02 to 1.06], $p = 5 \times 10^{-5}$), driven by the 3'-SNCA variant rs3756059. Expression of three target genes—SLC29A4, SIGMAR1, and CYBA—in blood showed associations with PD, MSA, and DLB, respectively. However, these associations were not replicated in brain tissue nor supported by sensitivity analyses. No significant shared genetic architecture or colocalization was identified between depression or antidepressant targets and α -synucleinopathy spectrum disorders.

Conclusions: Our findings do not provide conclusive evidence for a genetic causal relationship between depression or antidepressant target genes and α -synucleinopathy spectrum disorders. Nonetheless, the observed association between RBD and depression, potentially mediated by the rs3756059 variant in the SNCA gene, suggests that depression may serve as a prodromal marker rather than a risk factor for RBD. These insights underscore the importance of considering depression in the early identification and management of individuals at risk for α -synucleinopathies.

How are insomnia and sleepiness complaints influenced by use of tobacco, alcohol, cannabis and screens ?

F. SERRE¹, H. ALIA¹, J. COELHO¹, F. PECUNE¹, E. DE SEVIN¹, S. MORICEAU¹, M. AURIACOMBE¹, P. PHILIP¹

¹University of Bordeaux, SANPSY Lab, Bordeaux, France

Introduction: Addiction is one of the most prevalent psychiatric disorders in the general population. It is characterized by impaired control over substance use and the occurrence of repeated relapses. The co-occurrence of addiction and sleep disorders is highly prevalent and exhibits a bidirectional relationship: while substance use can lead to poorer sleep quality, sleep disorders are also associated with an increased risk of developing substance use and addiction.

Materials and methods: The KANOPEE smartphone application offers interactions with a virtual companion to assess insomnia complaints using the Insomnia Severity Index (ISI), excessive daytime sleepiness (EDS) using the Epworth Sleepiness Scale (ESS), and to screen for problematic use of substances and screens: tobacco (CDS-5), alcohol (CAGE), cannabis (CAGE), and screens (CAGE). Mental health symptoms are evaluated using the PHQ-2 for anxiety and the PHQ-9 for depression. Then, a 7-day prospective sleep diary was used to measure sleep behaviors, including, sleep duration (total sleep time), sleep timing (mid-sleep point, defined as the middle between the sleep time and wake time), and sleep regularity (sleep regularity index, defined as the consistency of being asleep or awake at any two time points 24 hours apart).

These secondary analyses were conducted within the Kanopée cohort. Each participant was categorized into mutually exclusive primary addiction groups based on the substance/screens use identified as most problematic (i.e., scoring positive on the relevant screening tool and indicating the highest severity or complaint when multiple), or into a control group if they reported only non-problematic use(s).

Results: Since April 2020, 14,512 participants (61.7% women; mean age: 49.3 years) have been screened and classified in primary addiction groups as follows: Alcohol: 18.4% (n=2676), Tobacco: 12.0% (n=1739), Screens: 10.0% (n= 1458), Cannabis: 1.7% (n=247), and Control: 57.5% (n=8350). Sleep complaints were frequent, with 48.9 % reporting moderate to severe insomnia, and 42.0 % with reporting moderate to severe EDS.

In multivariate models accounting for socio-demographic characteristics and sleep behaviors, insomnia was significantly more frequent in the tobacco ($\beta=0.64$, $p < .001$), screens ($\beta=0.38$, $p < .001$), and alcohol ($\beta=0.28$, $p = .002$) groups, compared to the control group. EDS was significantly more frequent in the screens group ($\beta=0.55$, $p < .001$), but notably less frequent in the cannabis group ($\beta=-0.96$, $p = .002$) compared to the control group. When psychopathological variables were included in the models, the associations with insomnia were no longer significant, although the direction and significance of associations for EDS remained unchanged.

Conclusions: Sleep complaints and problematic substance/screens use are common among Kanopée users. The link between insomnia and problematic use of tobacco, alcohol, and screens appears to be largely mediated by underlying depression/anxiety symptoms. In contrast, the association between problematic screens use and EDS seems to be independent of psychopathology, insomnia, or total sleep time. Interestingly, the seemingly protective effect of being in the cannabis group for EDS contrasts with existing literature. Future studies should explore the direction and temporality of these relationships.

Impact of Alcohol Dependence on Sleep Patterns: A Polysomnographic Analysis of Detoxified Patients

A. Gaur¹, S. Tikka², P. Kamble¹, M. Taranikanti¹, N. John¹, M. Umesh¹, V. Ganji¹, K. Medala¹

¹All India Institute of Medical Sciences, Bibinagar, Physiology, Hyderabad, India, ²All India Institute of Medical Sciences, Bibinagar, Psychiatry, Hyderabad, India

Introduction: Chronic alcohol use significantly disrupts the circadian rhythm, impairing the central nervous system and biological systems, which often leads to sleep disturbances such as insomnia. These disturbances can complicate the detoxification process and contribute to relapse, underscoring the importance of understanding and addressing sleep issues in alcohol-dependent individuals. The objective of this study was to objectively assess sleep disturbances in alcohol-dependent patients using polysomnography (PSG), a gold standard in sleep assessment, after the detoxification process.

Materials and methods: Twelve alcohol-dependent patients were recruited after obtaining ethics approval. The patients were detoxified and ensured to be free of withdrawal symptoms. Benzodiazepine effects were also accounted for to avoid confounding factors. The sleep parameters were recorded using Polysomnography (SOMNO HD PSG with camera compact wS) , a level 1 recording was done the reporting done.

Results: The mean age and BMI of recruited patients was 41.5 years and 20.7. The average sleep efficiency was 79.32%, which indicates that the patients spent a significant portion of time in bed awake, a common symptom in alcohol-dependent individuals. The mean sleep onset latency was 24.9 minutes, showing a moderate delay in falling asleep.

Stage Distribution:

- **N1:** 15.15% (Light sleep)
- **N2:** 56.3% (Light sleep)
- **N3:** 8.9% (Deep sleep)
- **REM:** 19.4% (Rapid Eye Movement sleep)
- A noticeable finding is reduced N3 (deep) sleep, essential for restorative sleep. This reduction could contribute to physical and psychological exhaustion and may be linked to the increased likelihood of relapse during detoxification.

Conclusions: Alcohol-dependent individuals showed moderate sleep disturbances, characterized by slightly reduced sleep efficiency, delayed sleep onset, and significantly reduced N3 (deep) sleep. These disruptions could contribute to the cognitive and physical impairments commonly observed in alcohol-dependent individuals during the withdrawal process.

Acknowledgments: I would like to acknowledge the psychiatry department for helping in patient recruitment.

Narcolepsy, Depression, and REM Suppressing Antidepressants: Comorbidity & Confound Impacts on Sleep Architecture and Diagnostic Sensitivity

C. Fernandez¹, S. Rusk¹, Y. Nygate¹, N. Watson^{2,1}, J. Herdegen³

¹EnsoData, EnsoData Research, Madison, United States, ²University of Washington School of Medicine, Department of Neurology, Seattle, United States, ³Rush University Medical Center, Rush Sleep Center, Chicago, United States

Introduction:

Systematic reviews and meta-analyses showed a 32%-57% prevalence of Depression or depression symptoms in patients with Narcolepsy disorders. MSLT protocols recommend a drug washout period of ≥14-days for antidepressants and other medications known to confound sleep architecture and REM sleep. Patient noncompliance with washout protocols for REM-suppressing antidepressants (REMS-AD) was found to reduce the incidence of SOREMP observations in MSLTs by ≥89% compared to washout-compliant patients. Prior studies demonstrated potential for improvements in Narcolepsy diagnostic sensitivity and reproducibility by exploiting more comprehensive analysis of full-night polysomnography (PSG) signals, through deep learning-based AI models (ROC-AUC 0.96) and algorithmic approaches. Prior research characterized Narcolepsy-specific microarchitectural sleep EEG abnormalities that manifest in Sleep Latency (SL), REM (Latency (REML), median/minimum duration, density, prevalence), N3 (time/prevalence), hypnodelta characteristics, and separately, Depression-

specific state and trait EEG markers including low Delta Sleep Ratio (DSR), high/oscillatory Gamma, and high/asymmetric Alpha. Few works examine the extent of confounds to Narcolepsy diagnostic parameters from Depression comorbidity with and without the specific influence of REMS-ADs.

Materials and methods:

A nonrandomized, observational, de-identified cohort of N=282 PSGs were collected from subjects that underwent MSLT immediately following the PSG. Excluding subjects without drug-screen and/or medication questionnaire results, the final cohort (N=133) was composed of 59.6% Narcolepsy(+) subjects (N=35 NT1, N=44 NT2), and 40.4% Narcolepsy(-) Clinical Controls (CC) subjects. 47.9% of subjects had a documented Depression diagnosis, 52.1% with verified absence of Depression diagnostic history, and a 49.3% rate of comorbid Depression in Narcolepsy. The sample included N=39 subjects that were Narcolepsy(+)/Depression(+) for comparison to N=40 Narcolepsy(+)/Depression(-) subjects. Among Narcolepsy(+)/Depression(+), N=29 were REMS-AD(+) and N=10 REMS-AD (-). Mean latency, density, and prevalence were calculated for sleep stages (N1, N2, N3, REM, Wake, All-Stages), mean power spectral densities and ratios were calculated (Delta, Theta, Alpha, Beta, Gamma), then evaluated for differences and statistical significance in mean diagnostic parameter values based on two-sided 95% bootstrap median-percentile method Confidence Intervals (R=2,000).

Results:

In NT1, NT2, and CC, Mean REML was shortest in MDD(+)/REM-AD(-) subjects (NT1/NT2: 67mins (54mins, 77mins), CC: 118mins (97mins, 125mins)), the longest in MDD(+)/REM-AD(+) subjects (NT1/NT2: 156mins (115mins, 203mins), CC: 190mins (133mins, 247mins)), with MDD(-) subjects falling between (NT1/NT2: 108mins (93mins, 125mins), CC: 120mins (94mins, 152mins)). In both Narcolepsy and CC, Mean REM density was highest in MDD(+)/REM-AD(-) subjects (NT1/NT2: 111mins (88mins, 128mins), CC: 97mins (91mins, 105mins)), and substantially reduced in MDD(+)/REM-AD(+) subjects (NT1/NT2: 101mins (87mins, 113mins), CC: 82mins (62mins, 104mins)). Mean DSR was lowest in CC MDD(+)/REM-AD(-) subjects (CC: 0.96), and normalized in MDD(+)/REM-AD(+) (CC: 1.45) relative to MDD(-) (CC: 1.28). Mean DSR was lower in Narcolepsy MDD(+)/REM-AD(+) and MDD(+)/REM-AD(-) subjects than MDD(+)/REM-AD(+) and MDD(-) CCs (NT1/NT1: REM-AD(-): 1.19, REM-AD(+): 1.14, MDD(-): 1.39). Mean SOREMPs were lowest for MDD(+)/REM-AD(+) both in Narcolepsy (NT1/NT2: MDD(+)/REM-AD(+): 1.00, MDD(+)/REM-AD(-): 1.71, MDD(-): 1.50) and CCs (CC: MDD(+)/REM-AD(+): 0.21, MDD(+)/REM-AD(-): 0.33, MDD(-): 0.42).

Conclusions:

Comorbid Depression patients with and without REM-ADs showed substantial alterations in key Narcolepsy disorder diagnostic and sleep architecture parameters. Given significant rates of comorbidity, these findings highlight needs to better understand the interactions and impact of Depression on Narcolepsy diagnosis.

Network Controllability of rTMS Targets Predicts Improvement in Depression and Comorbid Sleep Disturbances

J. Wang¹, P. Huang¹, B. Li¹, H. Huang², Y. Zhang¹, J. Liu¹

¹Air Force Medical University, Xi'an, China, ²Xi'an University of Science and Technology, Department of Physical Education, Yanta Campus, Xi'an, China

Introduction: Sleep disturbances, as one of the most prevalent somatic symptoms of depression, manifest as difficulties in falling asleep, sleep maintenance problems, or early awakenings, severely impairing patients' quality of life. Repetitive transcranial magnetic stimulation (rTMS), a non-invasive neuromodulation technique, has demonstrated efficacy in alleviating depressive symptoms in patients with comorbid sleep disturbances. However, significant individual variability exists in treatment response, with some patients showing limited improvement to conventional protocols. Brain network

controllability theory provides a novel framework for understanding neuromodulation mechanisms, yet its application in sleep disturbances and comorbid depression remains unexplored. This study investigates whether the controllability of rTMS target regions can serve as a neuroimaging biomarker for predicting treatment response and examines its potential role in modulating sleep-related neural circuits.

Materials and methods: Totally 64 depression patients with clinically significant sleep disturbances were enrolled. All patients underwent individualized target localization following the Stanford Neuromodulation Therapy protocol, based on resting-state functional MRI (fMRI) and functional connectivity analysis. Clinical assessments (HAMD-17 for depression) and fMRI scans were conducted pre- and post-treatment. We evaluated local neural activity changes using amplitude of low-frequency fluctuations (ALFF) analysis and computed average controllability from functional connectivity matrices to quantify network regulatory capacity. Correlations between controllability and clinical improvement were analyzed.

Results: Firstly, the local neural activity of the core brain regions related to emotion and sleep changed significantly ($p < 0.05$) after treatment, as well as the control characteristics of the switching of the patient's brain network. Secondly, when stratified by treatment response (responders vs. non-responders based on HAMD-17 reduction), responders exhibited significantly lower baseline average controllability at stimulation targets ($p < 0.05$). Finally, pretreatment target controllability showed a significant negative correlation with clinical improvement ($r = -0.4227$, $p = 0.0314$), whereas the strength of targeted functional connections showed no predictive value.

Conclusions: This study pioneers the application of network controllability theory to rTMS treatment for depression with comorbid sleep disturbances. We identify network controllability as a predictive biomarker for dual symptom improvement, suggesting that low-controllability targets may be more susceptible to neuromodulation, thereby inducing beneficial network reorganization that concurrently alleviates depressive symptoms and sleep disturbances. These findings provide novel insights into the neural mechanisms of rTMS effects on sleep-related somatic symptoms and establish a theoretical foundation for developing personalized neuromodulation strategies based on network dynamics.

Neural activation reveals affective processing during sleep and correlates with depression symptoms in humans

X. Lin¹, M. Cho², K.A. Paller¹, E. Schechtman²

¹Northwestern University, Department of Psychology, Evanston, United States, ²University of California Irvine, Neurobiology and Behavior, Irvine, United States

Introduction: While we sleep, neural networks supporting cognition and emotion are activated, driving subsequent behavior. Based on converging evidence showing that depression is linked with abnormal sleep and that affective networks are activated during sleep, we hypothesize that the activity of affective networks during sleep governs mental well-being in health and disease. We propose that maladaptive activation of brain networks supporting emotional processing during sleep is implicated in the etiology and progression of major depressive disorder. Negative biases in emotional processing (e.g., during ruminations) are a hallmark of wake-processing in mood disorders. Excessive ruminations lead to prolonged depression episodes and predict future depressed mood. We suggest that these biases perpetuate during sleep and play a causal role in the progression of depression symptoms.

Materials and methods: We examined the connection between affective processing during sleep and depression symptoms in a cohort of healthy young participants ($N = 52$). We first used EEG to identify neural patterns engaged in processing negative and positive images during wakefulness. Participants ($N = 52$) were fitted with a 64-electrode EEG system. They completed questionnaires, napped in the lab, and were presented with images taken from the International Affective Picture System. Stimuli were split evenly between positively and negatively valenced images. Locking to stimulus onset, we used the EEG data to train time-dependent support vector machine classifiers to label each trial's valence (positive vs. negative), using individual electrodes as features. These patterns were used as templates for analyzing data collected during sleep, essentially yielding individualized indices reflecting the valence of neural affective processing (positive vs. negative) during sleep. These indices were then correlated across participants with mental health indices, including Beck's Depression Inventory 2 (BDI-2) scores.

Results: During wakefulness, classification accuracy between negative and positive images was high throughout the first 2 s of image display ($p < 0.001$, corrected). EEG data therefore reflect affective processing during wakefulness. We applied each participant's wake-based classifiers to their sleep data. For each time point over sleep and each classifier, the models assigned a label (positive or negative). This revealed a ubiquitous, participant-specific pattern of activity that persisted throughout the nap and pre-nap rest, with little differences across sleep stages. The valence assigned by the classifier during this time period correlated with BDI-2 scores, so that more negative valence correlated with higher symptom severity ($r = 0.46$, $p < 0.001$; $p < 0.01$ after cluster correction).

Conclusions: Our results indicate that, during sleep, brain activity patterns expose affective processing and correlate with depression symptoms. These findings provide evidence that spontaneous affective processing during sleep contributes to waking mental well-being, with potential implications for identifying sleep-related biomarkers of affective disorders.

NeuroACT: Skills training for adolescents with neurodevelopmental disorders and symptoms of insomnia

S.J. Støre^{1,2}

¹Karlstad University, Department of Social and Psychological Studies, Karlstad, Sweden, ²Örebro University, School of Behavioural, Social and Legal Sciences, Örebro, Sweden

Introduction:

Adolescents with neurodevelopmental disorders, such as Autism Spectrum Disorder (ASD) and Attention-Deficit/Hyperactivity Disorder (ADHD), often experience significant sleep disturbances, including difficulties with sleep initiation and sleep maintenance (i.e., insomnia). These sleep issues may exacerbate existing challenges related to emotional regulation, stress, and daily functioning. Despite the high prevalence of sleep disorders in this population, few studies directly address both neurodevelopmental challenges and sleep-related problems. This study evaluates the feasibility and preliminary effects of NeuroACT, a skills training program based on Acceptance and Commitment Therapy (ACT) principles, among adolescents with neurodevelopmental disorders and symptoms of insomnia.

Materials and methods:

The study employs a within-group design and is conducted at child and adolescent psychiatry services in Karlstad, Sweden. Participants (current: $n=4$; target: $N=34$) are adolescents aged 13-19 diagnosed with autism and/or ADHD, and symptoms of insomnia, recruited through clinical services. Inclusion criteria include fluency in Swedish, stable medication regimen (if applicable), and informed consent from both participants and guardians for those under 15 years. Exclusion criteria comprise ongoing substance abuse, suicidality, psychosis, intellectual disability, or severe mood disorders. The NeuroACT intervention consists of 12 weekly sessions, each lasting 120 minutes, involving groups of 4–8 participants. Two licensed psychologists, with at least one having formal NeuroACT training, lead the sessions. The training covers key themes such as stress management, emotional regulation, mindfulness, social interactions, and goal setting. Quantitative data are collected using validated measures of insomnia (Insomnia Severity Index), stress (Perceived Stress Scale), psychological distress (Hospital Anxiety and Depression Scale), mindfulness (Five Facet Mindfulness Questionnaire), and overall functioning (Strengths and Difficulties Questionnaire) at pre-, mid-, and post-intervention. Additionally, qualitative feedback is gathered through semi-structured interviews to capture participants' subjective experiences of the skills training.

Results:

The initial results indicate that the intervention is feasible and promising for this patient group in terms of perceived stress (pre $M=38.00$, $SD=14.00$; post $M=27.25$, $SD=6.45$), and mindfulness (pre $M=66.00$, $SD=33.96$; post $M=80.25$, $SD=22.59$). Measures of insomnia (pre $M=9.75$, $SD=4.27$; post $M=10.50$, $SD=3.42$), psychological distress (pre $M=16.75$, $SD=10.97$; post $M=22.33$, $SD=6.03$), and overall

functioning (pre $M=21.67$, $SD=5.03$; post $M=20.00$, $SD=8.19$) have not shown improvements at this stage, highlighting areas for further investigation. Attendance rates are relatively high, and no significant adverse effects have been reported thus far. Preliminary themes from the interviews: (1) Overcoming initial hesitation and vulnerability; (2) Group support and tailored treatment as enablers of change; and (3) Improvements within a complex reality.

Conclusions: Early findings suggest that NeuroACT is a feasible and potentially beneficial intervention for adolescents with neurodevelopmental disorders, particularly in reducing stress and enhancing mindfulness. These results support continued evaluation of Acceptance and Commitment Therapy-based approaches addressing the complex interplay between neurodevelopmental symptoms and sleep problems in youth.

Neurometabolic Alterations in the Anterior Cingulate Gyrus and Putamen: Insights from Adolescents with Insomnia and Depression

S. Lai¹, S. Zhong¹, Y. Wang², Y. Zhang¹, S. Yan¹, P. Chen², D. Huang¹, J. Zhang¹, X. Lu¹, Q. Zhong¹, X. Song¹, S. Liu¹, R. Zhang¹, Y. Wu¹, S. Luo¹, L. Chu¹, Y. Jia¹

¹Department of Psychiatry, First Affiliated Hospital of Jinan University, Guangzhou, China, ²Medical Imaging Center, First Affiliated Hospital of Jinan University, Guangzhou, China

Introduction: Previous research has established that sleep disorders are prevalent among individuals with major depressive disorders (MDD), particularly in adolescents, with an incidence rate surpassing that of low mood. Nonetheless, the effects of sleep disorders on brain function in depressed adolescents remain inadequately understood.

Materials and methods: We recruited 97 right-handed, untreated adolescent patients with MDD, and 68 demographically matched healthy controls (HCs) and underwent the proton magnetic resonance spectroscopy (1H-MRS) scan in the anterior cingulate gyrus (ACC) and putamen. Differential and association analysis was performed to investigate the relationship between sleep quality and the severity of depression and neurometabolism ratios of ACC and putamen in MDD groups.

Results: The study identified 64 patients as Insomnia (IS) group, characterized by an insomnia item score of ≥ 1 on the 24-item Hamilton Depression Rating Scale (HDRS) and a Pittsburgh Sleep Quality Index (PSQI) total score of ≥ 6 , while 33 patients were categorized into the Non-Insomnia (NIS) group. The IS group exhibited significantly lower choline-to-creatine (Cho/Cr) ratios in the right ACC compared to both the NIS and HCs, as well as lower Cho/Cr ratios in the left ACC relative to the HCs. Furthermore, the NIS group showed reduced N-acetylaspartate-to-creatine (NAA/Cr) ratios in the right putamen compared to the IS and HC groups. The 24-item HDRS scores were negatively correlated with Cho/Cr ratios in the bilateral ACC ($r = -0.354$ and $r = -0.246$, respectively; both $p < 0.05$), and insomnia item scores were correlated with Cho/Cr ratios in the right ACC ($r = -0.294$, $p = 0.018$) within the IS group.

Conclusions: A substantial proportion of adolescents with depression experience clinically significant sleep disturbances. The observed brain dysfunction is influenced by the cumulative effects of previous severe mood episodes and sleep disturbances. Therefore, incorporating therapeutic interventions for sleep disorders should be an integral component of antidepressant treatment strategies for depressed adolescents.

Obstructive Sleep Apnea and Psychiatric Co-morbidities: A Territory-Wide Study in Hong Kong

S. Pan¹, B.P. Or¹, T.M. Li¹, R.N. Chan¹, Y.K. Wing¹, J.W. Chan¹

¹The Chinese University of Hong Kong, Li Chiu Kong Family Sleep Assessment Unit, Department of Psychiatry, Faculty of Medicine, Hong Kong, Hong Kong, SAR of China

Introduction: The bidirectional relationship between obstructive sleep apnea (OSA) and psychiatric disorders is increasingly recognized. However, most existing studies rely on convenient clinical samples, focus on symptoms rather than formal psychiatric diagnoses, and are typically limited to adult populations. There is a lack of large-scale, population-based studies examining OSA and its associated psychiatric co-morbidity across the lifespan.

Materials and methods: We conducted a retrospective study using the data from Clinical Data Analysis and Reporting System (CDARS), covering over 90% of health services in Hong Kong. Patients of all ages with at least one psychiatric diagnosis (ICD-9-CM codes 290–319) between 2014 and 2023 were included. Those with missing or implausible data (age < 0 or death before diagnosis date) were excluded. OSA was identified by ICD-9-CM codes 780.51, 780.3, and 780.57. Each OSA patient (OSA group) was matched with a non-OSA psychiatric control (Controls) by sex and age at first psychiatric diagnosis using propensity score matching. An "archive date" was set as the date of the first OSA diagnosis. Psychiatric diagnoses within ± 2 years of the archive date were captured as the psychiatric comorbidity surrounding the diagnosis of OSA. For the Controls, we match the time interval between the archive date to the first psychiatric diagnosis with the OSA group to ensure comparable observation windows. Age at archive date was stratified into child (<18), adult (19–64), and senior (65+) groups. Diagnoses were grouped into anxiety, depression, bipolar disorder, psychosis, dementia, substance-related disorders, insomnia, sexual/gender identity disorders, eating disorders, ADHD/hyperkinetic disorders, autism, and others. Group differences were tested using chi-square, Fisher's exact, or t-tests with False Discovery Rate correction (significance: adjusted $p < 0.05$).

Results: We identified 11400 patients in the OSA group (64.3% male; mean age = 50.3 ± 21.3), of whom 14% were children, 61.5% adults, and 24.5% seniors. Insomnia was significantly more prevalent in the OSA group across all ages (children: 1.6 vs. 0.2%; adults: 2.8 vs. 0.8%; seniors: 5.5 vs. 1.3%). In children, OSA was associated with higher rates of intellectual disability (19.8 vs. 10.6%) and eating disorders (3.6 vs. 0.8%). Among adults and seniors, anxiety (21.3 vs. 17.3%; 17.0 vs. 12.2%) and depression (15.1 vs. 10.0%; 12.9 vs. 8.4%) were more common in the OSA group. Bipolar disorder (2.8 vs. 1.8%) was also significantly higher in adults with OSA. Conversely, co-morbid substance-related disorders and psychosis were significantly lower in the OSA group. Dementia appeared lower in seniors with OSA (21.2 vs. 23.9%), though became insignificant in a sensitivity analysis limited to diagnoses after the archive date (13.0 vs. 11.9%).

Conclusions: This study provides an age-stratified description of psychiatric diagnostic patterns associated with OSA in a real-world psychiatric population. Our findings confirm well-established associations between OSA and mood or sleep disorders. In contrast, substance-related disorders and psychosis were significantly less prevalent in the OSA group, which may reflect underdiagnosis due to help-seeking behaviors, diagnostic overshadowing, or assessment barriers specific to these populations.

Out of Bed, Out of Reach: Sleep Disruption in a Marginalized Patient with Dual Diagnosis

J.P. Azenha¹, H. Canas Simião²

¹Unidade Local de Saúde de Lisboa Ocidental, Lisbon, Portugal, ²Serviço de Saúde da Região Autónoma da Madeira, Entidade Pública Empresarial da Região Autónoma da Madeira (SESARAM, EPERAM), Psiquiatria, Funchal, Portugal

Introduction: In patients with psychiatric comorbidities and chronic alcohol use, nocturnal disturbances may stem from various overlapping phenomena. Diagnostic clarity is often impaired in socioeconomically vulnerable individuals, particularly when poor adherence and limited health literacy interfere with investigation and treatment. We present a diagnostically challenging case of a man with profound sleep disruption in the context of chronic alcohol misuse and complex psychopathology.

Materials and methods: Clinical data were collected through interviews, chart review, and collateral reports. Patient consent was obtained.

Results: A 56-year-old man with alcohol dependence (consuming 15–20 beers/day) and poor social support (unemployed, lives alone, illiterate) presented with auditory hallucinations, depressed mood, irritability and long-standing nocturnal disturbances. He reported vivid, action-filled dreams with themes of pursuit and threat (e.g., helicopters, cemeteries, tanks), often awakening disoriented, out of

bed, or with bedding disarranged. Episodes were accompanied by intense autonomic arousal, fear, and urgent flight responses, sometimes described as “waking up screaming” and “needing to escape” or episodes in which he was awakened by others due to be “jumping in bed”, which he did not recall afterward. These symptoms raised multiple diagnostic possibilities, including RBD, sleep-related panic attacks, PTSD and alcohol-induced hallucinosis. He was started on sertraline 150 mg, olanzapine 15 mg and gabapentin 300mg, which led to improvement in mood and resolution of auditory hallucinations; however, sleep disturbances persisted despite psychiatric stabilization. The patient was admitted to a residential alcohol rehabilitation unit, where he maintained abstinence for three months. Notably, despite the cessation of alcohol use, his sleep disturbances remained unchanged, undermining a purely substance-related etiology. Formal polysomnography was scheduled but not completed due to nonadherence. Blood tests, neuroimaging and ECG were otherwise unremarkable.

Conclusions: This case exemplifies the diagnostic complexity of sleep disturbances in individuals with dual diagnosis. Chronic alcohol use exerts a profound impact on sleep architecture, promoting REM rebound, increasing vulnerability to parasomnias, and exacerbating emotional dysregulation. More broadly, it underscores the challenges of diagnostic clarification in real-world, resource-constrained settings and the imperative to adapt sleep medicine practices to better address the needs of socioeconomically disadvantaged populations. Factors such as limited health literacy, precarious living conditions, and fragmented mental health care systems may significantly compromise the feasibility and effectiveness of gold-standard assessments such as polysomnography.

Physiological dynamics surrounding trauma-related nightmares: Differentiating REP, PREP, and NREP awakenings in patients with PTSD

D. Feingold¹, M. Quiquempoix^{2,1}, M. Remadi³, G. Sipahimalani⁴, D. Gomez-Merino^{2,1}, D. Leger^{5,1}, M. Chennaoui^{2,1}, E. Saguin^{3,1}

¹Université Paris Cité, UMR 7330 VIFASOM (Vigilance Fatigue Sommeil et Santé Publique), Paris, France, ²French Armed Forces Biomedical Research Institute (IRBA), Bretigny-sur-Orge, France, ³Begin Military Teaching Hospital, Psychiatric Department, Saint-Mandé, France, ⁴Percy National Military Teaching Hospital, Psychiatric Department, Clamart, France, ⁵APHP, Hôtel Dieu, Sleep and Vigilance Center, Paris, France

Introduction: Trauma-related nightmares (TRNs) are vivid, distressing nocturnal episodes tied to trauma-specific imagery and high emotional recall. They differ from idiopathic nightmares through their strong trauma anchoring and tendency to cause prolonged awakenings, perpetuating hyperarousal, anticipatory anxiety, and chronic sleep disruption. Clinically, TRNs vary in replicativity: replicative (REP) closely mirror the trauma, partially replicative (PREP) mix symbolic and trauma content, and non-replicative (NREP) retain only thematic traces. While this typology may reflect trauma integration levels, its physiological correlates remain poorly understood. This study examined autonomic dynamics before, during, and after TRN-related awakenings to determine whether they differ by subtype.

Materials and methods: We included 74 French former military personnel with PTSD (PCL-5 > 44) from a cohort of 131. Sleep was recorded at home over seven nights using the Dreem V2 EEG headband and Empatica E4 wristband. Across the final five nights, 412 TRN-related awakenings were identified (mean 2.13/night) and classified as REP (n = 160), PREP (n = 183), or NREP (n = 68) using the TRNS-FR questionnaire. For each event, 17 physiological parameters (electrodermal activity [EDA], heart rate [HR], heart rate variability [HRV], movement) were extracted for three windows: 10 minutes before awakening, 2 minutes after, and 10 minutes after returning to sleep. Group comparisons used Kruskal–Wallis tests.

Results: **Ten minutes before awakenings**, REP TRNs showed the highest sympathetic activation with elevated EDA ($p < 0.001$), greater SCR activity, increased HR, and decreased HRV indices (SDNN, RMSSD, pNN50; all $p < 0.001$), indicating parasympathetic withdrawal. PREP values were intermediate, while NREP displayed the lowest pre-awakening arousal. **Two minutes post-awakening**, REP and PREP remained in heightened sympathetic states: REP showed elevated EDA ($p < 0.001$), blunted HRV (LF, HF, SDNN; all $p < 0.001$), and delayed SCR recovery ($p < 0.01$). NREP showed lower EDA and faster HR/HRV return to baseline. **Ten minutes after falling back asleep**, only REP TRNs retained significant physiological deviation from baseline (EDA $p < 0.001$; HRV suppression $p < 0.001$), while PREP trended toward baseline and NREP was indistinguishable from baseline.

Conclusions: TRN subtypes are associated with distinct autonomic activation profiles during the peri-awakening period. REP TRNs are linked to higher and more persistent sympathetic arousal, particularly elevated EDA and sustained HRV suppression. These findings support the utility of temporal physiological monitoring—especially EDA and HRV—to differentiate TRN subtypes and potentially inform personalized interventions targeting TRN-related autonomic dysregulation in PTSD.

Pre-Infusion EEG Vigilance Dynamics as Predictive Indicators of Ketamine Response in Major Depression: A Placebo-Controlled Study

M. Brunovsky^{1,2}, J. Horacek^{1,2}, V. Andrashko^{1,2}, C.-T. Ip³, M. de Bardeci⁴, G. Kronenberg⁴, L. Hageman Pinborg⁵, S. Olbrich⁴

¹National Institute of Mental Health, Klecany, Czech Republic, ²Charles University, Third Faculty of Medicine, Prague, Czech Republic, ³Centre for Cognitive and Brain Sciences, University of Macau, Taipa, Macao, SAR of China, ⁴Hospital for Psychiatry, Psychotherapy and Psychosomatic; University Zurich, Zurich, Switzerland, ⁵Neurobiology Research Unit, University Hospital Rigshospitalet, Copenhagen, Denmark

Introduction: Ketamine has gained increasing attention as a rapid-acting intervention for treatment-resistant forms of major depressive disorder (MDD). Accumulating evidence suggests that neurophysiological markers derived from EEG-based vigilance regulation may serve as early predictors of antidepressant outcomes.

Materials and methods: A placebo-controlled, single-blind, within-subject trial was conducted involving two patient cohorts diagnosed with MDD (combined n = 48). Each participant received an intravenous ketamine infusion (0.54 mg/kg), with brain arousal fluctuations quantified using the Vigilance Algorithm Leipzig (VIGALL). EEG was recorded at multiple intervals: baseline, infusion onset, midpoint, termination, and 24 hours post-infusion. The primary clinical endpoint was a ≥33% reduction in the Montgomery–Åsberg Depression Rating Scale (MADRS) score after 24 hours. Resting-state EEG data were segmented into 1-second epochs for vigilance stage classification.

Results: Ketamine administration, in contrast to saline placebo (0.9% NaCl), produced a notable increase in stage B1 (reduced vigilance) by the end of the infusion. This alteration showed a significant correlation with serum ketamine concentrations, independent of clinical outcome. However, patients classified as responders—regardless of the intervention—exhibited a marked shift in EEG profile: decreased time in high-vigilance stage A1 and increased time in stages B2/3. Pre-infusion EEG characteristics differed meaningfully between responders and non-responders, with responders displaying a substantially higher baseline proportion of stage A1 (53% vs. 21%). Predictive modeling using logistic regression and leave-one-out cross-validation yielded an area under the ROC curve of 0.7, supporting the prognostic value of initial vigilance stage distribution.

Conclusions: This study supports the utility of EEG-derived vigilance metrics as potential biomarkers for predicting the clinical efficacy of ketamine in depression. Elevated baseline stage A1 may indicate increased likelihood of treatment response, suggesting a stratification approach for optimizing antidepressant interventions based on neurophysiological profiling.

Psychiatric comorbidities associated with obstructive sleep apnea

S. Latif¹, N. Nagy^{2,3}

¹New Giza Medical School, Psychiatry, Cairo, Egypt, ²Ain Shams University, Psychiatry, Cairo, Egypt, ³Ain Shams Medical School, Psychiatry, Cairo, Egypt

Introduction: Over the past 2 decades, sleep researchers have made significant advances in understanding sleep disorders including obstructive sleep apnea (OSA). OSA commonly coexists with

psychiatric disorders encompassing mental health issues like depression, anxiety, bipolar, schizophrenia and others. This study aims to assess the comorbidity of OSA with depression and anxiety disorders among Egyptian patients.

Materials and methods: During the study, we conducted a cross-sectional study involving 92 adults diagnosed with OSA. Those patients were interviewed using a checklist to gather information regarding their chief complaints and other associated symptoms. The psychological status was assessed utilizing the Structured Clinical Interview for DSM-IV Axis I Disorders (SCID I), Beck Anxiety Inventory (BAI), and Beck Depression Inventory (BDI) scoring. The severity of the breathing disorder was classified as mild, moderate, or severe based on the respiratory disturbance index (RDI), which was confirmed through overnight polysomnography. Daytime sleepiness was assessed by the Epworth Sleepiness Scale (ESS).

Results: The sample of patients as a whole shows that witnessed apneas represent the highest percentage (70.7%), followed by fatigue (69.6%), then non-refreshing sleep (67.4%), and snores (63.0%). The least frequent presenting symptom is frequent naps.

The majority of OSA patients have a comorbid psychiatric disorder (65.0%). Among these, depressive disorders are the most prevalent (31.5%), followed by anxiety disorders (23.9%) and psychoses (6.5%). It is worth noting that 38% of OSA patients do not have any psychiatric disorders.

In terms of anxiety disorders, the most common subtype observed is OCD (8.7%), followed by GAD (6.5%), panic (5%), and PTSD (3.3%). As regards depressive disorders, the predominant subtype present is depressive disorder not otherwise specified (11.9%), followed by dysthymic disorder and major depressive disorder (8.7% for each), and then bipolar disorder (depression) at 2.2%.

Conclusions: We conclude the following:

1. OSA patients are likely to present with comorbid depression and/or anxiety disorder(s).
2. Fatigue was found to be the most prevalent presenting symptom in OSA patients with comorbid anxiety compared to those without anxiety.

rTMS Modulation of Sleep-Related Brain Networks in Major Depressive Disorder: Multisite Identification and Therapeutic Validation

Y. Liu¹, J. Liu², B. Li¹, H. Huang³, Y. Zhang⁴

¹The Fourth Military Medical University, School of Biomedical Engineering, Xi'an, China, ²The Fourth Military Medical University, Xi'an, China, ³Xi'an University Of Science And Technology, Xi'an, China, ⁴The fourth military medical university, Xijing Hospital, Xi'an, China

Introduction: Sleep disturbances (SD) represent a core symptom of major depressive disorder (MDD), affecting up to 90% of patients. Critically, SD exhibits a strong bidirectional relationship with MDD and significantly elevates the risk of suicidal behavior. While antidepressant pharmacotherapy can improve SD and subsequently alleviate associated symptoms like suicidal ideation and mood dysregulation, its utility is often limited by prolonged treatment duration and significant side effects. Repetitive transcranial magnetic stimulation (rTMS), an FDA-approved rapid-acting intervention for MDD, offers a promising alternative. However, despite its established antidepressant efficacy, the specific impact of rTMS on the core symptom of SD and the neural mechanisms underlying any potential sleep improvement remain poorly characterized. Crucially, it is unknown whether successful mood modulation via rTMS reliably translates to concurrent SD amelioration, potentially undermining long-term outcomes. Elucidating the core brain regions implicated in MDD-related SD based on multisite datasets and investigating how rTMS modulates these regions is critical.

Materials and methods: Resting-state fMRI data from the REST-meta-MDD Project (988 MDD patients across 16 sites) were analyzed. Neural activity was quantified via mean amplitude of low-frequency fluctuations (mALFF). SD severity was assessed using HAM-D sleep sub-scores (items 4-6). Correlation analyses identified SD-associated brain regions. An independent randomized controlled trial (RCT) cohort received 2-week rTMS with multimodal MRI at baseline/post-intervention. Clinical assessments occurred at baseline, post-treatment, and 6-week follow-up. Paired t-tests evaluated rTMS-induced neural changes. Altered mALFF in identified regions was correlated with sleep improvement to determine rTMS efficacy for SD.

Results: Multicenter analysis revealed that MDD patients with severe sleep disturbances showed increased activation in the putamen, insula, thalamus and supplementary motor area, alongside decreased activation in the subgenual anterior cingulate cortex, posterior cingulate gyrus, precuneus,

superior frontal gyrus and superior temporal gyrus. In the clinical trial, patients receiving active rTMS demonstrated significantly greater improvement in both depressive symptoms and sleep disturbances compared to the sham group. Neuroimaging analysis indicated that rTMS activated multiple regions related to sleep disturbances, including the subgenual anterior cingulate cortex and superior frontal gyrus. Furthermore, rTMS-mediated inhibition of putamen and supplementary motor area activity correlated with sleep improvement.

Conclusions: This study identified the brain activation patterns associated with sleep disturbances in MDD using multisite neuroimaging data. The randomized controlled trial demonstrated that rTMS effectively alleviates both depressive symptoms and sleep disturbances in MDD patients. rTMS modulated key brain regions implicated in sleep pathology, particularly through suppressing overactive areas including the putamen and supplementary motor area. These findings support rTMS as a targeted intervention for MDD-related sleep disturbances and provide neurophysiological insights into its therapeutic mechanisms.

Sleep and Circadian Predictors of Depression Outcomes: A Systematic Review

J.E.A. Cunningham¹, M. McAdam^{1,2}, P.-O. Couture¹, A. Slyepchenko³, D. Huang¹, Z. Hubshman¹, D. Wiens¹, V. Pardo¹, B. Harri¹, S. Najafi¹, C. Glenham⁴, B. Rusak^{1,4}, M. Alda^{1,2,5}, R. Uher^{1,2}, A. Nunes^{1,2,6}
¹Dalhousie University, Department of Psychiatry, Halifax, Canada, ²Nova Scotia Health Authority, Mood Disorders Program, Halifax, Canada, ³Independent Researcher, Hamilton, Canada, ⁴Dalhousie University, Department of Psychology and Neuroscience, Halifax, Canada, ⁵National Institute of Mental Health, Klecany, Czech Republic, ⁶Dalhousie University, Faculty of Computer Science, Halifax, Canada

Introduction:

Major depressive disorder (MDD) is a debilitating psychiatric disorder, affecting 5% of individuals yearly. Only approximately 30% of patients will remit with their first antidepressant treatment, and another 20-30% with a medication switch or augmentation. As further treatment steps are required, response rates decrease substantially. Similarly, bipolar disorders (BD) affect 1-2% of individuals, and patients with bipolar I disorder remain depressed for up to 35% of long-term follow-up. In both disorders, relapse is common. Changes in sleep and circadian (SC) rhythms are also common to both disorders, and are associated with worse outcomes.

There are currently no well-validated biomarkers to predict response to antidepressants in MDD or BD; there are also no clinically applicable models to predict relapse in depression. SC factors represent potential operationalizable predictors of treatment outcomes; to our knowledge, there has been no previous comprehensive review investigating this question. Our study systematically reviews and synthesizes current literature investigating whether SC factors predict response, remission, and relapse in depression.

Materials and methods: Our systematic review followed PRISMA guidelines. Search concepts included *depression* and *sleep or circadian rhythms*. Prognosis/prediction methodology were further selected for using validated search filters. Searches were conducted on January 22, 2025, of Embase, Ovid Medline, PsycINFO, CINAHL, and Cochrane databases. Records were then exported to Covidence. Title/abstract and full-text screening were performed by two authors independently. Included articles were required to be full-text empirical studies of human participants with depressive symptoms in the context of existing diagnoses of MDD or BD. Studies must have investigated SC factors as predictors of depression outcomes.

Results:

28,650 records were initially retrieved, with 7,074 excluded via de-duplication. 20,778 articles were excluded through title/abstract screening, advancing 798 for full-text screening. 513 articles were excluded at this stage, with 285 preliminarily included in our review. Risk of Bias assessment and data synthesis are ongoing and nearing completion. Primary outcomes will include prediction of response, remission, and relapse in depression; we anticipate that these measures may have heterogeneous definitions (e.g., what constitutes 'response' versus 'remission'). Wherever possible, we will standardize these outcomes, or will report study-specific definitions. Similarly, effect measures for our main

outcomes may vary. We will report study-specific measures of effect, and where possible, mathematically convert to standardized effects. For all predictors for which meta-analysis is possible, a random-effects meta-analysis will be carried out.

Conclusions: To our knowledge, there has been no prior comprehensive review characterizing sleep and circadian factors as potential biomarkers of response, remission, or relapse in depression. By summarizing existing literature on this topic, our review can potentially help to identify biomarkers of personalized treatment response in depression. If such biomarkers could be identified, this could help to improve patient functioning and quality of life, and enable more effective depression management strategies.

Thank you to Jackie Phinney, Instruction/Liaison Librarian, Dr. Robin Parker, Evidence Synthesis and Information Services Librarian, and Dr. Natalie Chartrand, Nicole Stinson, Lilith Nosko, and Julia Fraiha Pegado for their assistance with this review.

Sleep and Pharmacotherapy in Treatment-Resistant Late-life Depression: Findings from the OPTIMUM Clinical Trial

M.S. Mak¹, M.A. Gebara¹, E.J. Lenze², D.M. Blumberger³, P.J. Brown⁴, A.J. Flint³, J.F. Karp⁵, H. Lavretsky⁶, J.P. Miller², C.F. Reynolds III¹, S.P. Roose⁴, B.H. Mulsant³, S.T. Stahl¹

¹University of Toronto, Psychiatry, Toronto, Canada, ²University of Pittsburgh, School of Medicine, Pittsburgh, United States, ³Washington University School of Medicine in St. Louis, St. Louis, United States, ⁴Columbia University College of Physicians and Surgeons and the New York State Psychiatric Institute, New York City, United States, ⁵University of Arizona, Department of Psychiatry, College of Medicine, Tucson, United States, ⁶University of California, Los Angeles, Department of Psychiatry and Biobehavioral Sciences, Los Angeles, United States

Introduction: Adults with treatment-resistant late-life depression (TRLDD) have high rates of sleep problems. However, little is known about the occurrence and change in sleep during pharmacotherapy of TRLDD or how sleep affects treatment response. We investigated the bidirectional relationship between sleep and treatment outcomes in the Optimizing Outcomes of Treatment-Resistant Depression in Older Adults (OPTIMUM) study, the largest comparative effectiveness trial of pharmacotherapy for TRLDD to date.

Materials and methods: This analysis examined: (1) occurrence of reduced sleep in 634 participants in the OPTIMUM randomized controlled trial; (2) how their sleep changed during pharmacotherapy; and (3) whether treatment outcomes differed among participants with consistent insufficient sleep [$n = 164$], worsened sleep [$n = 62$], or with improved sleep [$n = 158$]. We used item #4 (scale 0 – 6) from the Montgomery-Asberg Depression Rating Scale (MADRS) to assess insufficient sleep, representing reduced sleep duration or depth compared to usual sleep pattern. Scores >2 indicate a meaningful reduction in duration or sleep depth. Patients who scored >2 on item #4 throughout the trial were classified as having consistent insufficient sleep; patients who reported an increased score (and >2 at trial end) were classified as having worsened sleep; and patients who reported a decreased score (and ≤ 2 at trial end) were classified as having improved sleep. Treatment response was defined as a $> 50\%$ reduction in the total MADRS score (minus item #4) at trial end.

Results: About half (51%, $n = 323$) of participants with TRLDD reported reduced or insufficient sleep before treatment. At trial end, consistent insufficient sleep and worsened sleep were each associated with treatment non-response. Improved sleep was not a significant predictor of treatment response, however participants with consistent sufficient sleep or improved sleep were three times more likely to experience treatment response compared to patients with insufficient sleep and worsened sleep.

Conclusions: Insufficient or reduced sleep are modifiable factors that may improve treatment outcomes in TRLDD. Given that sleep complaints including insomnia are associated with greater risk of depressive relapse and treatment non-response, a tailored treatment plan for those at greatest risk of sleep disturbance with concomitant depression may facilitate better outcomes.

Sleep and PTSD Symptom Severity in Military Personnel: Insights from Multi-Night Ecological Recordings

E. Saguin^{1,2}, D. Feingold², G. Sipahimalani¹, M. Quiquempoix^{2,3}, D. Leger^{2,4}, B. Lahutte^{1,5}, D. Gomez-Merino^{3,2}, M. Chennaoui^{2,3}

¹Begin National Military Teaching Hospital, Psychiatric, Saint-Mandé, France, ²UMR 7330 VIFASOM - Université Paris Cité, Paris, France, ³French Armed Forces Biomedical Research Institute (IRBA), Bretigny-sur-Orge, France, ⁴APHP, Hotel-Dieu, Centre du sommeil et de la vigilance, Paris, France, ⁵Ecole du Val-de-Grâce, Paris, France

Introduction: Sleep disturbances—especially insomnia and trauma-related nightmares—are prominent features of post-traumatic stress disorder (PTSD) in military populations. These nocturnal symptoms are not only persistent but also deeply intertwined with daytime impairment, psychiatric comorbidities, and the chronicity of PTSD. Despite accumulating evidence of altered sleep architecture in PTSD, most existing studies rely on single-night laboratory assessments, which fail to capture the natural variability of sleep. The current study aimed to examine the relationship between PTSD severity and intra-individual fluctuations in sleep using multiple consecutive nights of home-based EEG recordings.

Materials and methods: We conducted a prospective controlled study involving 130 military personnel with diagnosed PTSD and 65 healthy military controls. Participants recorded their sleep at home for five nights using a validated EEG headband device. Key sleep metrics included total sleep time (TST), sleep onset latency (SOL), wake after sleep onset (WASO), sleep efficiency index (SEI), and sleep architecture parameters. PTSD symptoms were assessed using standardized clinical tools, including the PTSD Checklist for DSM-5 (PCL-5). Mixed-effects models were used for between-group comparisons, and sleep-symptom associations were tested using Spearman's rank correlations.

Results: Compared to controls, individuals with PTSD showed significantly longer SOL and WASO, reduced SEI, and diminished N3 and REM sleep durations ($p < 0.001$). Night-to-night variability in SOL and WASO was markedly higher in the PTSD group. Sleep fragmentation—particularly during non-REM sleep—was strongly correlated with overall PTSD severity ($\rho = 0.42$, $p < 0.001$), with the most robust associations found for intrusive and avoidance symptom clusters.

Conclusions: This study emphasizes the clinical value of multi-night, home-based sleep assessment in capturing the instability of sleep in PTSD. The observed links between symptom severity and fragmented, variable sleep suggest that night-to-night instability may be a key modifiable target. Future research should explore whether improving sleep regularity and reducing fragmentation could contribute to better clinical outcomes in PTSD.

Acknowledgments: The authors acknowledge the contributions of all study participants and thank the French Military Health Service for their support.

Sleep and Suicide: The Influence of Sleep Quality on Suicide Risk in Adults

L.F. Baioni Aylon^{1,2}, F. Gustavo Stelzer¹, V. Cunha Cardoso³, A. Luiz Eckeli¹

¹Faculty of Medicine of Ribeirão Preto - University of São Paulo, Department of Neuroscience and Behavioral Science, Division of Neurology, Ribeirão Preto, Brazil, ²Londrina State University, Department of Internal Medicine, Division of Psychiatry, Londrina, Brazil, ³Faculty of Medicine of Ribeirão Preto - University of São Paulo, Department of Pediatrics, Ribeirão Preto, Brazil

Introduction: Suicide is a serious global public health problem, causing between 700,000 and 1 million deaths annually. Identifying modifiable risk factors and developing prevention strategies is essential. Sleep disorders (SD), such as insomnia, nightmares, and poor sleep quality (PSQ), have been highlighted as important risk factors for suicide, as they increase suicidal ideation, planning, and attempts, regardless of the presence of depression. This study aims to evaluate the relationship between sleep quality and suicide risk (SR) using validated instruments.

Materials and methods: Cross-sectional study nested within a birth cohort from Ribeirão Preto, with data collected from 1,775 participants between 2016/2017 on mental health, sleep quality, and sociodemographic information, using the Mini International Neuropsychiatric Interview and the Pittsburgh Sleep Quality Index. For the analyses, 1,702 individuals with complete information on sleep and SR were included; after controlling for major depressive disorder (MDD), the sample comprised 372 participants, and, after adjustment for melancholia, 236 remained. There was not a sufficient

sample for analysis of bipolar disorder. Statistical tests such as Chi-square and logistic regression were applied, with significance defined as $p < 0.05$.

Results: Among participants with good sleep quality (GSQ) (PSQI < 5), 93% did not present SR, compared to 77.5% in the PS group (PSQI > 5). Individuals with PS showed significantly higher percentages of both low (15.1% vs. 5.5%) and high SR (7.3% vs. 1.5%) compared to the group with GSQ ($\chi^2 = 88.86$; $p < 0.001$).

In the PS group, 73.7% of individuals presented with MDD, compared to 50.7% in the GSQ group ($\chi^2 = 20.14$; $p < 0.001$). This represents a 2.7 times greater chance of having MDD among those with PS (OR = 2.72; 95% CI [1.75–4.25]).

After adjustment for current MDD, individuals with PS had 2.4 times greater chance of presenting high SR (OR = 2.38; 95% CI [1.02–5.56]; $p = 0.045$). When adjusted for current melancholia, this risk increased to 3.3 times (OR = 3.3; 95% CI [1.29–8.45]; $p = 0.01$).

Conclusions: The study demonstrated a statistically significant association between PS and increased SR, corroborating previous evidence linking PS to worsening suicidal ideation, planning, and attempts. Critically, this association remained robust and independent after adjustment for MDD, confirming that PS quality may be an autonomous predictor of high SR, not merely a depressive symptom.

These findings highlight that inadequate sleep increases suicidal vulnerability. Thus, we can suggest as possible clinical implications the urgent need to assess and monitor sleep disorders in patients with suicidal behavior, integrating this approach into prevention strategies.

The study has limitations. The lack of sample size for analysis in patients with bipolar disorder indicates the need for future research with this population. Additionally, as this is a cross-sectional study, it is not possible to establish causality, reinforcing the importance of further studies to deepen this relationship.

The study highlights that PS quality is associated with SR, even after controlling for depression and melancholia. We emphasize the importance of healthcare professionals including the assessment and treatment of sleep disorders in suicide prevention strategies.

Sleep Complaints in Children and Adolescents with Major Depressive Disorder: Early Markers of Illness Severity

M.-C. Lopes¹, K. Spruyt², L. Fu-I³

¹University of Sao Paulo / 1. Childhood and Adolescence Affective Disorders Program at Institute 2. Children's Institute, Department of Psychiatry and Institute - School of Medicine at University of Sao Paulo, Sao Paulo, Brazil, ²Université de Paris, NeuroDiderot, INSERM, Paris, France, ³University of Sao Paulo / 1. Childhood and Adolescence Affective Disorders Program, Department of Psychiatry and Institute - School of Medicine at University of Sao Paulo, Sao Paulo, Brazil

Introduction: Affective disorders are among the most prevalent forms of mental illness in youth, and they can impose a substantial and often long-lasting burden on development if left unaddressed. Evidence suggests that sleep disturbances not only increase the risk of developing depression within five years but are also associated with a higher incidence of suicidal behavior in youth. This study aimed to investigate whether children and adolescents with depression and multiple sleep complaints present higher depression severity and how these complaints may impact their global functioning.

Materials and methods: Our sample included 142 children and adolescents with Major Depressive Disorder (MDD) and reporting sleep complaints, according to DSM-IV criteria assessed by Diagnostic Interview for Children and Adolescents (DICA IV). The participants were consecutively referred to an outpatient clinic. Depression severity was measured using the Children's Depression Rating Scale (CDRS), a 16-item clinician-rated scale. Global functioning over the past month was assessed using the Children's Global Assessment Scale (CGAS) for individuals under 18 years old. A one-way ANOVA was used to compare CDRS T-scores and CGAS scores across youth presenting with 1 to 4 different sleep complaints. The significance level was set at 0.05 in this study.

Results: All participants had sleep complaints (mean of age = 11 ± 8.1 ; 55% boys) and 57% were under 12 years old ($n=142$). The severity of disease were obtained by the mean CDRS T-score: 78.7 ± 7.1 ,

indicating clinically significant depressive symptoms. Prevalence of specific sleep complaints: 88.7% had initial insomnia, 54.2% had night awakenings, 34.5% showed early awakening, and 31% exhibited hypersomnia. Youth with three or more sleep complaints had significantly higher depression scores with CDRS T-score: $[F(3,138)=5.7, p=0.001]$, and particularly among adolescent boys: $[3,138]=3.1, p=0.027]$. Having more sleep complaints in depressive youth, these patients did not worsen the overall CGAS score $[F(3, 138)=.96, p=0.41]$.

Conclusions: Sleep complaints in youth with depression are associated with greater severity of depressive symptoms, specially in adolescent boys. Interestingly, this was not reflected in overall global function scores, suggesting that sleep disturbances may serve as early clinical markers of illness severity rather than indicators of broader functional impairment. A comprehensive evaluation of sleep disturbances is crucial in managing depressive episodes in youth. Future studies should clarify the specific role of different types of sleep complaints and their potential link to suicidal risk and treatment outcomes in this population.

Sleep in schizoaffective disorder: a systematic review and meta-analysis

D. Morra¹, G. Ficca¹, G. Barbato¹

¹University of Campania "L. Vanvitelli", Psychology, Caserta, Italy

Introduction: A systematic review and a meta-analysis of sleep studies in schizoaffective disorder were conducted using published articles researched in major databases within the period since inception to June 15, 2025. Sleep parameters of drug-free schizoaffective patients (SZA) were analyzed and, where available, compared with case-control data of healthy controls (HC), drug-free schizophrenics patients (SCZ) and drug-free depressed patients (MDD).

Materials and methods: A total of 9 studies with 67 SZA, 88 SCZ, 79 HC and 131 MDD were included in the meta-analysis. Further 23 studies with 87 SZA, 143 SCZ, 1038 HC and 31 MDD were included in the systematic review. Data were extracted regarding 15 sleep parameters: total sleep time (TST), sleep latency (LAT), wakefulness time during sleep (WAKE), REM time (REMT), REM percentage (%REM), REM latency (REMLT), REM density (REMD), stage 1, 2 and 4 sleep time (ST1, ST2, ST4) and percentage (%ST1, %ST2, %ST4), delta sleep time (DELTAT) and percentage (%DELTA). All the patients were drug-free for a minimum of two weeks in all but one study, where they have been drug-free for two days. A minimum of three studies was required to perform a meta-analysis for each parameter. The primary outcome was the standard mean difference. Data were fitted with a random-effects model. Publication bias assessment was checked by means of Egger's Regression and funnel plot asymmetry.

Results: SZA showed reduced TST ($p<0.001$), increased LAT ($p<0.001$) and WAKE ($p<0.001$) compared to HC. SZA showed reduced REMT ($p=0.006$) and shortened REM latency ($p=0.007$) compared to HC. SZA showed reduced stage ST4 ($p<0.001$) and %ST4 ($p<0.001$) compared to HC. SZA did not differ from HC regarding %REM and DELTAT.

SZA showed increased LAT compared to MDD ($p<0.001$). SZA did not differ from MDD regarding TST, WAKE, REMT, %REM, REML, REMD, ST4, %ST4, DELTAT, %DELTA.

SZA did not differ from SCZ regarding any sleep parameter.

Conclusions: Drug-free SZA sleep does not seem to differ from that of drug-free SCZ and drug-free MDD (except for SLAT in this last comparison). SZA patients show a shorter and more fragmented sleep, with difficulties falling asleep, compared to HC. SZA show a shortened REML and a reduced REMT compared to HC, with slow-wave sleep time deficits like that of SCZ and MDD. Literature regarding sleep in SZA is very limited, therefore meta-analysis could not be performed for some parameters (REMD and %DELTA in SZA vs HC; ST1, %ST1, ST2, %ST2 in SZA vs HC and in SZA vs MDD). Heterogeneity of 40% of meta-analyses in this study was substantially high ($>70\%$). Further studies, preferably involving drug-naïve patients, are needed to clarify whether SZA sleep is more similar to that of SCZ or MDD. Specific attention should be allocated to the investigation of REMD in SZA, for this data could help clarifying the significance of REMD in human sleep and its usefulness as a marker of affective and/or psychotic disorders.

Sleep Profiles in Schizophrenia Inpatients: A Cross-Sectional Study of Clinical and Genetic Associations

K. Gasenko¹, A. Asadullin², V. Gashkarimov³, R. Sultanova⁴, I. Efremov⁵

¹Omsk Psychiatric Hospital, Omsk, Russian Federation, ²RMACPE, Moscow, Russian Federation,

³Republican clinical psychiatric hospital, Ufa, Russian Federation, ⁴Medical clinic Chaika, Moscow, Russian Federation, ⁵Ufa University of Science and Technology, Ufa, Russian Federation

Introduction: Schizophrenia is frequently accompanied by sleep disturbances that persist beyond acute psychotic episodes. Up to 80% of patients report dyssomnia, which correlates with poorer outcomes. While insomnia dominates during psychosis, emerging evidence suggests circadian rhythm disruptions become prominent in non-acute schizophrenia, potentially linked to genetic variations in clock genes. This study hypothesized that sleep disturbance in schizophrenia is clinically heterogeneous, circadian sleep-wake abnormalities are prevalent and associated with polymorphisms in circadian system genes.

Materials and methods: Design and Participants

A cross-sectional study (2021–2023) enrolled 391 inpatients with paranoid schizophrenia (ICD-10: F20.0) from psychiatric hospitals in Omsk and Ufa, Russia. Exclusion criteria included comorbid diagnoses, active psychosis, or recent benzodiazepine use.

Assessments

- **Sleep Quality:** Pittsburgh Sleep Quality Index (PSQI) and Insomnia Severity Index (ISI).
- **Psychopathology:** PANSS (Positive and Negative Syndrome Scale) and Calgary Depression Scale (CDSS).
- **Genetic Analysis:** RT-PCR genotyping of *CLOCK* (rs1801260), *MTNR1A* (rs34532313), and *MTNR1B* (rs10830963).

Statistical Approach

Non-parametric tests, ROC analysis, and two-step cluster analysis (IBM SPSS 27). Propensity Score Matching (PSM) balanced groups with/without sleep disturbances (155 patients each) for therapy heterogeneity.

Results: Prevalence and Characteristics of Sleep Disturbances

Among 391 patients, 58.9% (n=236) exhibited poor sleep quality (PSQI ≥ 5). Strikingly, 48.7% reported subjective sleep dissatisfaction (e.g., prolonged latency, fragmentation) despite normal sleep duration (ISI < 7). This discordance highlighted the inadequacy of duration-based metrics alone for assessing sleep dysfunction in schizophrenia.

Propensity Score Matching (PSM)

To control for confounding effects of therapy, PSM created matched groups (n=155 each) with comparable antipsychotic treatment. Post-matching analysis confirmed no significant differences in treatment profiles ($p > 0.05$), enabling unbiased comparisons.

Cluster Analysis: Three Sleep Phenotypes

Cluster 1 (44.6%): Minimal Sleep Issues – lowest PANSS-Positive scores (15,00 [12,00; 18,00]) and no depression (CDSS: 1,00 [0,00; 3,00]).

Cluster 2 (29.6%): Insomnia Phenotype – highest PANSS-Positive (16,00 [13,00; 20,00]) and CDSS scores (6,00 [3,00; 10,50]), with severe sleep fragmentation and shortened sleep time.

Cluster 3 (25.7%): Circadian Phenotype – delayed sleep onset (latency: 60 ± 22 min) with preserved total sleep duration, interrupted sleep, difficult awakening, and daytime dysfunction. In this group there were practically no patients with depressive symptoms (3,00 [1,00; 5,00]) and P subscale scores (15,00 [12,00; 18,00]) were average for the sample.

Genetic Correlates

- *CLOCK* CC homozygotes had prolonged sleep latency ($p = 0.005$).
- *MTNR1A* CC ($p = 0.043$) and *CLOCK* TT ($p = 0.017$) variants were linked to frequent nocturnal awakenings.

Conclusions:

1. Sleep disturbances in schizophrenia are heterogeneous, with distinct phenotypes: insomnia-dominant (linked to positive symptoms/depression) and circadian-rhythm disruption (genetically driven).
2. The *CLOCK* and *MTNR1A* polymorphisms highlight circadian system dysregulation as a therapeutic target.

3. Clinical Implications:

- Insomnia requires personalised antipsychotic-antidepressant therapy.
- Circadian interventions may benefit 25% of patients.

Acknowledgments: We thank the staff of Solodnikov Psychiatric Hospital (Omsk) and Republican Clinical Psychiatric Hospital (Ufa) for their collaboration. Genetic analyses were supported by the V.M. Bekhterev National Medical Research Center. Special gratitude to the patients who participated in this study.

Sleep regularity, actigraphic rest-activity rhythms and light exposure patterns in patients with bipolar depression and evening chronotype

X. Gao¹, B.P.N. Or¹, S.W.H. Chau¹, N.Y. Chan¹, S.X. Li², Y.K. Wing¹, J.W.Y. Chan¹

¹The Chinese University of Hong Kong, Department of Psychiatry, Hong Kong, Hong Kong, SAR of China, ²The University of Hong Kong, Department of Psychology, Hong Kong, Hong Kong, SAR of China

Introduction: Sleep and circadian rhythm disturbances, which are closely related to light exposure, are closely related to bipolar disorder (BD). Eveningness, fragmented and irregular sleep are common features in BD. A lower Sleep Regularity Index (SRI) score has been reported in euthymic BD patients compared to healthy controls, particularly among those with phase delay. This study focuses on a vulnerable group of patients with bipolar depression and eveningness and we hypothesized that a lower SRI correlates with greater delays in sleep and light exposure.

Materials and methods: This study analysed the baseline data obtained from an ongoing randomized controlled trial (ClinicalTrials.gov ID: NCT05357313) involving patients with non-seasonal bipolar depression and eveningness (defined as a Morningness-Eveningness Questionnaire, MEQ score < 42). The assessments included 1-week prospective sleep diary and actigraphy, and one sample of overnight urinary 6-sulfatoxymelatonin (aMT6s). In addition to basic sleep parameters, non-parametric analyses were applied to both rest-activity rhythm (RAR) and white light (WL) exposure actigraphic data. Key actigraphic metrics included: SRI (range 0-100, higher scores indicating greater regularity), intradaily variability (IV; range ≥ 0 , higher values indicating increased activity-rest fragmentation), and L5/M10 start times (onset of the 5-hour/10-hour periods with minimal/maximal average activity or light exposure). The associations between SRI and the sleep/light metrics were explored by Pearson (r) or Spearman (r_s) correlation, where appropriate.

Results: Thirty-two patients with bipolar depression (mean age = 42.0±11.4 years, female: 84.4%) and evening chronotype (MEQ score mean ± SD = 34.3±8.2) were included in the analysis. The SRI scores ranged from 44.6 to 95.0, with a mean of 71.1±14.7. A lower SRI score correlated with a later rest start time ($r = -0.481$, $p = 0.005$), a later sleep start time ($r = -0.491$, $p = 0.004$), shorter time in bed (TIB; $r = 0.418$, $p = 0.017$), and reduced total sleep time (TST; $r = 0.413$, $p = 0.019$). Regarding light exposure, a lower SRI correlated with a later light exposure L5 start time ($r_s = -0.562$, $p = 0.001$) and a higher IV ($r = -0.475$, $p = 0.006$). No correlation was found between SRI and the creatinine-adjusted urinary aMT6s levels ($r = 0.162$, $p = 0.459$).

Conclusions: In patients with bipolar depression and evening chronotype, a lower sleep regularity, as measured by SRI, correlated significantly with delayed sleep timings, shorter sleep duration, and an increased variability of light exposure. Our study underscores the intricate relationship among sleep regularity, timing, and light exposure. The findings suggest the potential to integrate therapeutic interventions that target improving sleep regularity, aligning sleep timing, and optimizing light exposure patterns to enhance outcomes in patients with bipolar depression and eveningness.

Acknowledgments: This study is supported by the General Research Fund, Research Grants Council, University Grant Committee of Hong Kong (Ref No. 14115021).

Sleep Revolution: The Interplay between Mental Health and Sleep in Untreated Obstructive Sleep Apnea

A. Seiger¹, K. Ludwig², H. Gouveris², M. Tremel³, S. Matthes³, S. Bailly⁴, T. Toncar¹, P. Pourriahi¹, T. Penzel¹

¹Charité – Universitätsmedizin Berlin, Interdisciplinary Center of Sleep Medicine, Berlin, Germany,

²Universitätsmedizin der Johannes Gutenberg-Universität Mainz, HNO-Universitätsklinik, Mainz,

Germany, ³Wissenschaftliches Institut Bethanien für Pneumologie e.V., Institut für Pneumologie an der Universität zu Köln, Solingen, Germany, ⁴Grenoble Alpes University, HP2 Laboratory, INSERM U1300, Grenoble, France

Introduction: Obstructive sleep apnea (OSA) is a highly prevalent sleep disorder, affecting nearly one billion individuals globally, and is associated with substantial cardiovascular and neurocognitive morbidity. In addition to its well-established physiological impacts, growing evidence points to a link between OSA and psychological distress, including symptoms of depression, anxiety, and stress. Despite these associations, the relationship between psychological symptoms and both objective sleep architecture and subjective sleep experience in untreated OSA remains insufficiently understood. This study aims to examine how psychological distress—specifically levels of depression, anxiety, and stress—is associated with objective sleep parameters assessed via polysomnography (PSG) and with subjective sleep quality in individuals with untreated OSA. Additionally, the study will explore whether these associations vary by OSA severity.

Materials and methods:

This exploratory, cross-sectional study includes N = 143 untreated OSA patients (≥18 years) recruited through the Sleep Revolution project (WP8, ISRCTN17539031) across three sleep centers in Germany (Berlin, Mainz, Solingen). Each participant completed a full overnight PSG and a battery of standardized questionnaires assessing psychological distress and subjective sleep parameters. Exclusion criteria included prior OSA treatment, respiratory failure, cardiac instability, and recent substance use disorder.

Key Variables:

- **Objective sleep:** PSG-derived measures (TST, SE, SOL, WASO, REM/NREM stages, arousal index, SpO₂)
- **Subjective sleep:** Insomnia and fatigue scales (ISI, PSQI, ESS, FSS)
- **Mental Health:** DASS-21 subscales for depression, anxiety, and stress

Results: Descriptive and inferential analyses (Pearson/Spearman correlations, multivariable linear regressions) will assess the associations between distress scores and both sleep physiology and perceived sleep quality. Models will be adjusted for age, sex, and BMI. Severity-stratified subgroup analyses (based on OSA severity) will explore potential severity-dependent relationships. Results are currently being analyzed and will be presented at the congress.

Conclusions: By identifying patterns between psychological distress and sleep characteristics in untreated OSA, this study aims to enhance understanding of the mental health implications of sleep-disordered breathing. Findings may inform more personalized diagnostic and therapeutic strategies, integrating mental health support alongside standard OSA treatments.

Acknowledgments: This research is part of the EU-funded Sleep Revolution project (grant agreement no. 965417). We thank all participating patients and collaborating sleep centers.

Stimulant Medications and Sleepiness in ADHD: Insights from a Sleep Deprivation Study

I. Haimov¹, O. Dan¹, S. Eisenstein¹, K. Asraf¹, A. Cohen¹

¹The Max Stern Yezreel Valley College, Psychology, Yezreel Valley, Israel

Introduction: Individuals with attention-deficit hyperactivity disorder (ADHD) often experience heightened levels of sleepiness compared to the general population, particularly under conditions of sleep deprivation. This study investigates the impact of stimulant medications (Methylphenidate and Amphetamine) on the sleepiness curve of young men diagnosed with ADHD, during and following an extended period of sleep deprivation.

Materials and methods: Fifty-nine young men (age 18 – 35) participated in this study. Among them, 39 participants had been diagnosed with ADHD combined type and were regular users of stimulant medications (ADHD group), while 20 served as a control group without ADHD (control group). The ADHD group was further divided into two subgroups: a medicated ADHD group (n = 17), who took

their regular doses of either Methylphenidate (n = 13) or Amphetamine (n = 4) during the experimental session: at 8:00 a.m. and again at midnight (ADHD medicated group), and an unmedicated ADHD group (n = 22), who refrained from medication during the experimental session (ADHD unmedicated group). Participants were required to maintain a regular sleep schedule for five consecutive nights prior to the experimental session, ensuring at least seven hours of sleep per night (from 23:00/24:00 to 7:00/8:00), verified via actigraphy. The experimental session began at 8:00 a.m. and included 25 hours of sleep deprivation, during which participants were kept awake in a controlled environment. During this period, Sleepiness was measured hourly using the Karolinska Sleepiness Scale (KSS).

Results: No significant differences were observed in sleep duration, sleep onset latency, or sleep efficiency between the two ADHD subgroups (the ADHD unmedicated group and the ADHD medicated group) during the pre-experimental period. However, during the sleep deprivation session, the unmedicated ADHD group exhibited significantly higher sleepiness scores compared to the control group, particularly during the post-midnight hours. In contrast, the medicated ADHD group displayed sleepiness scores similar to those of the control group throughout the experimental session.

Conclusions: Stimulant medications, such as Methylphenidate and Amphetamine, effectively mitigate excessive sleepiness experienced by young men diagnosed with ADHD, even under conditions of extended sleep deprivation. These findings have important clinical and theoretical implications. Given the negative effects of sleepiness on cognition and emotional regulation, these results suggest that the beneficial effects of stimulant medications in ADHD may partially stem from their effect on sleepiness.

Systematic Review and Meta-analysis of Nonpharmacologic Interventions for Sleep Disorders in Individuals with Attention-Deficit Hyperactivity Disorder (ADHD)

W.M. Troxel¹, B. Peterson², S. Baxi¹, D. Zhang³, M. Bolshakova³, J. Gomez³, J. Balayan³, J. Myers³, K. Sysawang³, S. Yagyu³, J. Miles³, A. Motala³, D. Tolentino³, S. Hempel³

¹RAND, Social and Economic Wellbeing, Pittsburgh, United States, ²Children's Hospital Los Angeles, Los Angeles, United States, ³University of Southern California, Southern California Evidence Review Center, Los Angeles, United States

Introduction: Sleep disturbances are highly prevalent among both children and adults with ADHD, contributing to increased symptom severity and can negatively affect psychosocial functioning and quality of life for individuals with ADHD and their families.

Materials and methods: We conducted a systematic review of studies evaluating nonpharmacological interventions for sleep and ADHD interventions evaluating the effects on sleep. We searched PubMed, CINAHL, Embase, Web of Science, Scopus, and PsycINFO; and we reference-mined systematic reviews indexed in PubMed, Cochrane Database of Systematic Review (CDSR), Campbell Collaboration, and PROSPERO. We also searched guideline and research repositories, reference-mind reviews, and consulted a technical expert panel. Two independent reviewers screened citations and full text. We used random effects meta-analyses and explored multiple potential effect modifiers. We assessed risk of bias, applicability, and strength of evidence (SoE).

Results: In total, 44 studies met inclusion criteria. This included 32 studies evaluating an intervention that addressed sleep as well as 12 studies reporting on the effect of sleep of an ADHD intervention not explicitly targeting sleep. Nonpharmacological sleep interventions showed positive effects on sleep (SMD 0.47; CI 0.14, 0.80; 15 studies; RR 1.10; CI 0.59, 2.08; 5 studies; moderate SoE) and ADHD symptom scores (SMD 0.61; CI 0.26, 0.95; 11 studies; moderate SoE). We did not detect systematic effects of nonpharmacological ADHD interventions on sleep. No direct comparisons of two competing interventions has been replicated. Identified studies rarely tested the effects of specific nonpharmacological sleep intervention components and the evidence was insufficient. Studies reported on the potential effect modifiers for age, sex, and ADHD presentation but the evidence was insufficient for concrete evidence statements.

Conclusions: Targeted nonpharmacological interventions focusing on sleep have the potential to improve both sleep quality and ADHD symptoms. Addressing ADHD symptoms alone may not lead to improvements in sleep. These findings may inform clinician and patient decisions regarding incorporation of sleep-focused interventions in comprehensive treatment strategies for ADHD.

The Bidirectional Association Between Sleep and Affect: Evidence from the Budapest Sleep, Experiences, and Traits Study

R. Pierson-Bartel¹, P. Przemysław Ujma¹

¹Semmelweis University, Institute of Behavioural Sciences, Budapest, Hungary

Introduction: Sleep and mood are closely linked, but findings more consistently show that sleep predicts next-day mood than vice versa. Prior research often relies on subjective measures and cross-sectional designs, limiting insight into their dynamic, bidirectional relationship. We aimed to examine the bidirectional associations between sleep and daily affect and to identify which trait-level moderators influence these links.

Materials and methods: We analyzed data from the Budapest Sleep, Experiences, and Traits Study (BSETS), a 7-day observational study involving 269 participants and 1,901 nights of data, combining psychological assessments with daily mood and sleep tracking. Participants completed a baseline test battery assessing personality traits and affective dispositions, followed by 7 days of diary-based PANAS mood ratings and sleep monitoring using the Dreem2 portable EEG device. Subjective sleep quality was measured with the Groningen Sleep Quality Scale. Within-person associations were examined using random intercept and random slopes models.

Results: Higher daily positive affect (PA) predicted later bedtime ($p < 0.001$). In the reverse direction, earlier bedtime ($p < 0.001$), earlier wake-up time ($p < 0.001$), shorter sleep latency ($p < 0.01$), and better subjective sleep quality ($p < 0.001$) predicted higher next-day PA. Extraversion, sociability, and depression moderated the association between sleep timing and PA.

Conclusions: Our findings confirm that sleep and mood influence each other bidirectionally. Earlier sleep timing and better subjective (but not objective) sleep quality are associated with improved next-day mood, particularly in individuals high in extraversion and sociability. In contrast, participants with higher depression scores showed weaker sleep–mood links. These findings suggest that targeting sleep timing may be especially effective for mood enhancement in socially engaged individuals, while alternative approaches may be needed for those with elevated depressive traits.

The Impact of Sleep Quality on Prefrontal Hemodynamic Response during Verbal Fluency Task in Depression: An fNIRS Study

Y. Zhang¹, W. Li¹

¹Central South University, Department of Psychiatry, National Clinical Research Center for Mental Disorders, and National Center for Mental Disorders, The Second Xiangya Hospital, Changsha, China

Introduction: Major depressive disorder (MDD) is frequently accompanied by significant sleep disturbances. Sleep quality critically impacts cognitive functions, including verbal fluency, and neurovascular activity. Functional near-infrared spectroscopy (fNIRS) provides a non-invasive method for investigating task-evoked cortical hemodynamic responses. This study aimed to investigate how sleep quality in individuals with MDD influences hemodynamic responses, primarily indexed by changes in oxygenated hemoglobin (HbO) concentration, in target brain regions during a verbal fluency task (VFT).

Materials and methods: This study enrolled 196 patients with MDD fulfilling DSM-5 diagnostic criteria. Participants' sleep status was assessed using Item 4 of the Self-Rating Depression Scale (SDS). Depressive symptoms, anxiety, and anhedonia were evaluated with the SDS, Self-Rating Anxiety Scale (SAS), and Snaith-Hamilton Pleasure Scale (SHAPS) respectively, while ruminative symptoms were measured using the Ruminative Response Scale (RRS). During performance of a standardized Verbal Fluency Task (VFT), participants underwent hemodynamic monitoring via a 48-channel fNIRS system. Statistical analysis was performed using SPSS 26.0. Functional near-infrared spectroscopy (fNIRS) data underwent dedicated preprocessing with NirSpark software. Primary analytical methods employed included the chi-square test, analysis of variance (ANOVA), and Pearson/Spearman correlation analyses.

Results:

1. No significant differences were observed between groups in age, gender, or educational level (all $P > 0.05$).
2. Significant differences were observed between MDD patient groups stratified by sleep problem severity on measures of anhedonia ($F = 4.274$, $p < 0.05$), depression ($F = 32.234$, $p < 0.05$), anxiety ($F = 106.413$, $p < 0.05$), and rumination ($F = 64.367$, $p < 0.05$).
3. During the VFT, MDD patients with severe sleep problems, compared to other groups, demonstrated significantly increased HbO concentration activation in the temporal pole (Brodmann Area 38, BA38) and Broca's area (BA44), alongside significantly reduced HbO concentration activation in the dorsolateral prefrontal cortex (BA46). Furthermore, the dorsolateral prefrontal cortex demonstrated the weakest haemodynamic response intensity during the 60-second task activation period."

Conclusions: This study demonstrates that poorer sleep quality in MDD patients is associated with more severe symptoms of anxiety, depression, anhedonia, and rumination. Furthermore, compromised sleep quality may alter patterns of task-evoked cerebral hemodynamic responses. These findings provide novel evidence supporting the neurophysiological mechanisms underlying the sleep-cognition-emotion interactions in depression. Improving sleep quality represents a promising intervention target for optimizing cognitive function and enhancing the efficacy of neuromodulatory treatments in MDD.

Acknowledgments: This study was supported by the Hunan Provincial Administration of Traditional Chinese Medicine (Grant No. A2023011) and the National Natural Science Foundation of China (Grant No. 82371521). The authors appreciate the effort of all participants who took part in this study.

The Mediating Role of Depressive Symptoms in the Association Between Dysfunctional Sleep Cognition and Insomnia Severity Among Chinese Students

Y. Zhang¹, Y. Wang¹, H. Zongling¹, C. Xiao¹

¹The Forth People's Hospital of Chengdu Mental Health Center of Chengdu, Sleep Medicine Center, Chengdu, China

Introduction: Insomnia is prevalent among students and is often influenced by both cognitive and emotional factors. Dysfunctional beliefs about sleep (DBAS) have been linked to poor sleep outcomes, but the underlying mechanisms remain underexplored in young populations. This study aimed to investigate whether depressive symptoms mediate the relationship between dysfunctional sleep-related cognition and insomnia severity among Chinese students.

Materials and methods: A cross-sectional survey was conducted among 161 student participants (mean age = 16.99 years, 73.2% female). Participants completed the Dysfunctional Beliefs and Attitudes about Sleep Scale (DBAS-16), the Patient Health Questionnaire (PHQ-9), and the Insomnia Severity Index (ISI). Mediation analysis was performed using regression-based methods and Sobel test to examine the indirect effect of DBAS on ISI through PHQ-9 scores.

Results: Dysfunctional beliefs about sleep significantly predicted both depressive symptoms ($\beta = 0.25$, $p < .001$) and insomnia severity ($\beta = 0.21$, $p < .001$). When controlling for depressive symptoms, the direct effect of DBAS on ISI remained significant but reduced ($\beta = 0.11$, $p = .025$). The Sobel test confirmed a significant mediation effect ($Z = 3.73$, $p < .001$).

Conclusions: Depressive symptoms partially mediate the association between sleep-related dysfunctional cognition and insomnia severity in students. Targeting both cognitive distortions and emotional distress may enhance the effectiveness of sleep interventions in this population.

Therapeutic Education Targeting Sleep in Military PTSD: Design and Progress of the EDUSOMMEPT Study

E. Saguin^{1,2}, M. Remadi¹, G. Sipahimalani¹, D. Feingold²

¹Begin National Military Teaching Hospital, Psychiatric, Saint-Mandé, France, ²UMR 7330 VIFASOM - Université Paris Cité, Paris, France

Introduction: Sleep disturbances are highly prevalent in military post-traumatic stress disorder (PTSD), notably insomnia and trauma-related nightmares. Despite their clinical significance and prognostic value, no standardized program in France specifically targets these nocturnal symptoms. Building on preliminary qualitative assessments and prior psychoeducational workshops, we developed a therapeutic patient education (TPE) module addressing sleep-related issues in PTSD, inspired by core principles of cognitive behavioral therapy for insomnia (CBT-I) and adapted to the specific constraints of military populations.

Materials and methods:

The EDUSOMMEPT study aims to evaluate the effectiveness of this therapeutic module on insomnia severity, trauma-related sleep symptoms, quality of life, and sleep physiology, using a multimodal assessment strategy.

This ongoing, prospective, multicenter study (National Military Teaching Hospital Begin and Percy) involves 50 active or former military personnel diagnosed with PTSD (PCL-5 > 38). The TPE module integrates cognitive-behavioral principles, psychoeducation, and relaxation techniques. Outcomes are assessed pre- and post-intervention (1 and 6 months) using validated instruments, including the Insomnia Severity Index (ISI), WHOQOL-BREF, PCL-5, BDI, PSQI, and the TRNS-FR—recently validated in our team (*Military Medicine*, 2024). Sleep is also monitored via actigraphy and home EEG (Zmax®).

Results: Initial feedback reveals high patient adherence and perceived relevance. To illustrate the program's clinical utility, we propose to present individual patient cases, showing pre/post intervention changes in subjective and objective sleep parameters.

Conclusions: EDUSOMMEPT is the first structured TPE program in France designed to address sleep disturbances in PTSD. It offers a promising model for personalized, scalable interventions in trauma-exposed populations.

Acknowledgments: We thank the French Military Health Support for their service.

Trauma-related nightmares: From nosography to physiology, bridging Mind-Body dynamics in sleep

D. Feingold¹, J.-B. Roseau², C. Verdonk^{3,1,4}, A. Richards^{5,6}, M. Chennaoui^{3,1}, D. LÉGER^{1,7}, E. Saguin^{8,1}

¹Université Paris Cité, UMR 7330 VIFASOM (Vigilance Fatigue Sommeil et Santé Publique), Paris, France, ²Clermont-Tonnerre Military Teaching Hospital, Pneumology and Sleep Medicine Department, Brest, France, ³French Armed Forces Biomedical Research Institute (IRBA), Bretigny-sur-Orge, France, ⁴Laureate Institute for Brain Research, Tulsa, United States, ⁵VA Health Care System, San Francisco, United States, ⁶University of California, Department of Psychiatry and Behavioral Sciences and UCSF Weill Institute for Neurosciences, San Francisco, United States, ⁷APHP, Hôtel Dieu, Sleep and Vigilance Center, Paris, France, ⁸Begin Military Teaching Hospital, Psychiatric Department, Saint-Mandé, France

Introduction: Trauma-related nightmares (TRNs) are vivid, specific sleep phenomena tightly anchored to traumatic experiences and occurring during both REM and non-REM sleep. Unlike idiopathic nightmares, TRNs display a repetitive structure and can precede or persist long after PTSD remission. They are typically classified as replicative, partially replicative, or non-replicative, reflecting different

levels of symbolic transformation. TRNs exemplify mind–body dynamics in sleep through strong autonomic activation and distressing, often abrupt awakenings.

Materials and methods: We synthesized current evidence across nosography, physiology, and clinical management to build an integrative, mind–body model of TRNs. We organized findings from clinical observations and ecologically valid home-based recordings—combining subjective reports with wearable physiological measures (e.g., heart rate, electrodermal activity)—into five blocks: trauma-linked triggers, pre-TRN sleep conditions, sleep-stage mechanisms, TRN-associated awakenings, and post-TRN consequences, leading to treatment implications.

Results: TRNs are triggered by internal/external cues (environmental factors, psychiatric stress, sleep disorders) and converge with sleep instability (arousal, fragmentation, REM/NREM instability) before awakening. They arise from either REM (more symbolic, often late-night) or NREM sleep (more realistic content, higher sympathetic arousal and skin conductance). Awakenings involve panic, hypervigilance, and emotional distress—especially after NREM TRNs—and contribute to chronic sleep fragmentation and daytime impairment. Long-term consequences span psychiatric, cognitive, sleep, and somatic domains, creating a self-reinforcing cycle linking trauma exposure, nocturnal arousal, and health deterioration. Management options supported in this framework include sleep-focused interventions (CBT-I; CPAP for OSA), imagery-based therapies (IRT, ERRT, EMDR, TPE), and pharmacological agents (prazosin, propranolol), within tailored, multimodal care.

Conclusions: TRNs represent a distinct, systemic condition that necessitates personalized, multimodal strategies. Integrating environmental modulation and physiological monitoring with behavioral and pharmacologic treatments is a promising path to disrupt the TRN cycle and reduce their mental and physical health burden.

Trauma-related nightmares: how to stop losing sleep over subjective complaints!

E. Saguin^{1,2}, D. Feingold²

¹Bégyn National Military Teaching Hospital, Psychiatric, Saint-Mandé, France, ²UMR 7330 VIFASOM - Université Paris Cité, Paris, France

Introduction: Trauma-related nightmares (TRNs) are a core symptom of post-traumatic stress disorder (PTSD), characterized by trauma-specific imagery, vivid recall, and sudden arousals. They often cause severe sleep fragmentation and extended awakenings, perpetuating hyperarousal and anxiety. While validated questionnaires such as the Trauma-Related Nightmare Survey – French Version (TRNS-FR) quantify frequency, intensity, and distress, they cannot capture the physiological dynamics of TRNs. Ecological momentary assessment (EMA) enables real-time symptom tracking, while neurophysiological recordings may detect brain and autonomic activity surrounding TRNs. This study explores current methods for bridging subjective reports and objective markers of TRNs.

Materials and methods: We conducted a literature review on psychometric assessments, EMA, and polysomnographic or wearable-based physiological monitoring of TRNs. We also present original findings from our team using TRNS-FR in French-speaking military PTSD patients, combined with home-based sleep recordings. Participants wore a push-button EEG headband (Dreem V2) and an EDA wristband (Empatica E4) over seven consecutive nights to signal TRNs. Sleep stage scoring, electrodermal activity (EDA), and fragmentation indices were computed to examine temporal relationships between nightmare events and autonomic activation. All events were reviewed by a psychiatrist and certified sleep physician to confirm TRN-related awakenings.

Results:

Existing literature confirms that TRN frequency and distress can be reliably measured subjectively, but variability limits objective event capture. Our recordings showed that 65.5% of TRN-related awakenings occurred during NREM sleep, challenging the predominance of REM-related TRNs. EDA analyses revealed significantly higher autonomic reactivity preceding NREM TRNs, with greater EDA

peak frequency than during REM awakenings. These findings support integrating psychometric data with physiological monitoring to address discrepancies between reported symptoms and objective markers.

Conclusions: Current TRN assessment methods face limitations, with persistent gaps between subjective complaints and objective measures. Combining validated questionnaires, EMA, and wearable-based physiological recordings improves TRN characterization and may help refine diagnoses and interventions. Our findings highlight the need to integrate brain and autonomic data into TRN evaluation to better capture instability beyond REM sleep and support advanced analytic methods for PTSD populations.

Acknowledgments: We thank the French Military Health Service and the French Defense Innovation Agency (AID, 50%), as well as Université Paris Cité (50%), for supporting the doctoral research presented in this poster through the European Harpocrates project.

Umbrella Review of Pharmacological and Behavioural Sleep Interventions in ADHD Across the Lifespan

A. Dey^{1,2}, A. Lee³, H. Xie³, M. Mak^{1,4}, D. Almagor^{1,5}, M. Katzman^{6,7}, T.L. Do⁵, A. Khullar⁸

¹University of Toronto, Psychiatry, Toronto, Canada, ²North York General Hospital, Psychiatry, Toronto, Canada, ³University of Toronto, Medicine, Toronto, Canada, ⁴Centre for Addiction and Mental Health, Psychiatry, Toronto, Canada, ⁵Possibilities Clinic, Toronto, Canada, ⁶Northern Ontario School of Medicine, Psychiatry, Thunder Bay, Canada, ⁷START Clinic, Toronto, Canada, ⁸University of Alberta, Psychiatry, Toronto, Canada

Introduction: Sleep disturbances are highly prevalent in individuals with attention-deficit/hyperactivity disorder (ADHD) and can exacerbate core symptoms and impair quality of life, yet evidence-based guidance on effective sleep interventions across the lifespan remains limited and fragmented. This umbrella review synthesizes findings from systematic reviews of pharmacological and behavioural sleep interventions for individuals with attention-deficit/hyperactivity disorder (ADHD) across the lifespan.

Materials and methods: Following PRISMA guidelines, 1243 studies published up until November 9th, 2024 were identified across five databases. (Embase: 817, MEDLINE: 183, PubMed: 164, Web of Science: 69, Scopus: 10). After exclusions (909 at title/abstract review; 52/67 full-text assessments), 15 systematic reviews were included. Methodological quality was assessed using AMSTAR 2.

Results: Melatonin demonstrated the strongest evidence, particularly when combined with sleep hygiene strategies, improving sleep onset latency (21-27 minutes) and total sleep time (TST) (20-23 minutes) in paediatric ADHD populations. Clonidine showed subjective improvements in sleep latency and evening restlessness with mild side effects (e.g. sedation/fatigue) reported in 31%. Guanfacine was associated with high somnolence rates (up to 73%) and worsening of several sleep parameters. Zolpidem offered minimal objective benefits with frequent mild side effects, while L-theanine improved sleep efficiency but not latency or TST. Behavioural interventions, including CBT for insomnia (CBTi), showed preliminary promise but were limited by methodological heterogeneity and inadequate bias reporting.

Conclusions: Melatonin shows the strongest evidence for managing ADHD-related sleep disturbances in children. Other pharmacological and behavioural interventions show promise but require further evaluation. Notably, dual-orexin receptor antagonists (DORAs) and CBTi, which have robust evidence for treating insomnia in the general population, are relatively underexplored among those with ADHD despite their potential to address circadian dysregulation and comorbid insomnia. Significant research gaps also persist in adult ADHD populations, who are underrepresented in the ADHD and sleep literature despite comprising most new diagnoses. Future studies should adopt standardized methodologies and objective sleep assessments while prioritizing high-quality trials of DORAs and ADHD-specific adaptations of CBT-I to expand evidence-based treatment options across the lifespan and not just in paediatric populations.

Uncovering hidden depression: the critical role of depression screening in sleep disorders at U.S. sleep centers

A. Defillo¹, S. Dacco^{1,2,3}, M. Grassi^{1,2,3}

¹Medibio Limited, Savage, United States, ²Humanitas University, Rozzano, Italy, ³Villa San Benedetto Menni, Albese con Cassan, Italy

Introduction: Depression and sleep disorders are strongly linked, with sleep centers (SCs) reporting depressive symptoms in up to 63% of patients and depression diagnoses in 22%. Despite this, routine depression screening is not standard in SCs. This study aimed to identify patients meeting criteria for a current major depressive episode (cMDE) among those self-reporting clinically significant depressive symptoms (CSDS) in U.S. SCs.

Materials and methods: This retrospective sub-analysis of an ongoing multicenter trial included 147 adults (22-75 years) referred for sleep disorder evaluation. Participants underwent psychiatric assessments using the Mini-International Neuropsychiatric Interview and Patient Health Questionnaire-9 (PHQ-9), with CSDS defined as PHQ-9 ≥ 10 . Descriptive statistics were compared between patients with/without a confirmed cMDE using non-parametric tests. Additional Mann-Whitney U tests assessed sleep characteristics by cMDE, major depressive disorder (MDD), and bipolar disorder (BD) (statistical significance, $p < 0.05$).

Results: Of 147 patients, 57 (38.8%) had a PHQ-9 score ≥ 10 . Among them, 23 (40.3%) were diagnosed with cMDE: 17 (29.8%) met cMDD criteria, and 6 (10.5%) had BD, type I. A significantly lower cMDE prevalence was observed in patients without CSDS. Sleep characteristics showed no significant differences except for a lower N3 percentage in cMDE. BD, type I was associated with higher obstructive sleep apnea comorbidity compared to cMDD.

Conclusions: Our findings suggest major depression prevalence in SCs is five times higher than in the general population, highlighting the need for routine depression screening and psychiatric confirmation. This also aids in identifying comorbidities and fostering tailored interventions to improve outcomes.

REM Behavior Disorders

Altered Interhemispheric Excitability in Patients with REM Sleep Behavior Disorder: An Exploratory TMS Study

¹Oasi Research Institute-IRCCS, Clinical Neurophysiology Research Unit and Sleep Research Center, Troina, Italy, ²University of Catania, Department of Surgery and Medical-Surgical Specialties, Catania, Italy, ³Oasi Research Institute-IRCCS, Troina, Italy, ⁴University of Catania, Catania, Italy, ⁵Vita-Salute San Raffaele University, Milan, Italy, ⁶San Raffaele Scientific Institute, Milan, Italy, ⁷University of Verona, Verona, Italy, ⁸University of Cagliari, Cagliari, Italy, ⁹University of Sassari, Sassari, Italy, ¹⁰Ludwig-Maximilians University, Munich, Germany

Introduction: REM Sleep Behavior Disorder (RBD) is characterized by the loss of normal muscle atonia during REM sleep, leading individuals to act out their dreams, often violently. RBD is a well-recognized predictor of neurodegenerative diseases, particularly alpha-synucleinopathies such as Parkinson's disease and Lewy body dementia. Understanding the brain changes that occur in RBD, even years before the onset of an overt alpha-synucleinopathy, is crucial for early diagnosis and potential therapeutic interventions. Transcranial Magnetic Stimulation (TMS) is a non-invasive brain stimulation technique offering a translational window into the brain's electrocortical activity, allowing to detect subtle, even preclinical, alterations in intracortical and intercortical excitability. Previous TMS studies in RBD revealed specific changes supporting the theory of a "retrograde neurodegeneration" spreading from the brainstem upwards to the cortex. However, a key aspect of brain connectivity, i.e., the GABA-mediated interaction between the two hemispheres, largely through by the corpus callosum, had not yet been explored to TMS in this patient group, which is the aim of this exploratory study.

Materials and methods: 10 right-handed individuals with RBD (70.0 years, IQR 65.0-76.0; 6 males) and 10 healthy individuals (65.5 years, IQR 59.0-69.5; 5 males) underwent screening for cognitive function to the Montreal Cognitive Assessment, quantification of depressive symptoms through the Geriatric Depression Scale (short form), and excessive daytime sleepiness to the Epworth Sleepiness Scale. To assess transcallosal functioning, both latency and duration of the ipsilateral silent period (iSP) was

assessed by stimulating the left primary motor cortex at an intensity of 130% of each participant's resting motor threshold (rMT). Motor responses were recorded from the First Dorsal Interosseous muscle from the same side as the stimulation, during active contraction.

Results: Patients and controls were well-matched for sex, age, and years of education. There was no significant difference between the groups for cognitive performance, depressive symptoms, and daytime sleepiness. Similarly, they did not differ for the rMT and iSP latency; conversely, the iSP duration was significantly shorter in patients than in controls (15.0 ms, IQR 13.0-23.5 vs. 27.0 ms, IQR 26.0-28.5; $p < 0.001$). Moreover, a significant positive correlation between the iSP duration and cognitive scores was found; namely, a more pronounced reduction in interhemispheric inhibition was associated with poorer cognitive performance ($r = 0.5349$; $p < 0.05$), although overall cognitive scores remained within the normal limit.

Conclusions: These findings provide the first evidence of interhemispheric disinhibition to TMS in individuals with RBD at risk for alpha-synucleinopathies. This might potentially contribute to the abnormal motor behavior experienced by these patients during REM sleep and support the involvement of GABA-mediated interhemispheric circuits in the pathophysiology of RBD, even when overt motor and/or cognitive symptoms are still not evident. This also aligns with recent imaging studies identifying both structural and functional changes in the corpus callosum of RBD patients. Future studies on larger samples will help to confirm the role of interhemispheric disinhibition to TMS as a potential biomarker for RBD and its progression, ultimately contributing to a better understanding of RBD pathophysiology and improving assessment strategies and therapeutic options.

Acknowledgments: None.

Artificial Intelligence in REM Sleep Behavior Disorder: A Systematic Review of Machine and Deep Learning Methods

Introduction: Rapid Eye Movement (REM) sleep behavior disorder (RBD) is increasingly recognized as a prodromal stage of alpha-synucleinopathies, including Parkinson's disease and dementia with Lewy bodies. Machine learning (ML) and deep learning (DL) hold promise for improving RBD diagnosis, predicting phenoconversion, and enabling large-scale population screening. However, the quality and transparency of ML/DL research in RBD has not been systematically assessed. This systematic review aims to evaluate the reporting quality of ML/DL studies in RBD using the APPRAISE-AI tool.

Materials and methods: PubMed and Web of Science were searched up to April 30, 2025, for studies applying ML/DL where RBD was either the primary outcome or a key input feature. Studies were included if they focused on RBD, confirmed diagnosis using video-polysomnography, and employed ML/DL models. Two reviewers independently screened studies, with disagreements resolved by a third. Reporting quality was assessed using the APPRAISE-AI tool, which scores 24 items across six domains: clinical relevance, data quality, methodological conduct, robustness of results, reporting quality, and reproducibility.

Results: A total of 75 studies met the inclusion criteria. Most studies included cohorts of 20–100 iRBD participants and control groups. Regarding aim, 73.3% focused on RBD detection, 16% on phenoconversion prediction, and a minority on disease subtyping. Most studies relied on traditional ML

approaches while DL models were used in 12% of studies. APPRAISE-AI scoring revealed that 80% of studies demonstrated moderate reporting quality (40–59 points), and 20% had high reporting quality (60–79 points). Key deficiencies included low average scores for transparency (23.3%), hyperparameter tuning (17.1%), bias assessment (26.9%), and error analysis (0.7%). Data leakage was identified in 32% of studies, typically through inappropriate feature selection or overlap of subjects in training and test sets.

Conclusions: ML/DL applications in RBD research are expanding and show encouraging progress. To enable robust development and clinical translation of AI tools, future studies must adopt open science practices, report model development in detail, and avoid critical errors such as data leakage. Clinical journals, in collaboration with sleep and ML societies, should implement stricter reporting standards for evaluation of ML.

A Sleep-Stage-Independent Framework for Automatic Detection of REM Sleep Behavior Disorder Using Single-Channel EEG

G.S. Giarrusso¹, I. Rechichi¹, U. Mosca¹, A. Cicolin^{2,3}, G. Olmo¹

¹Politecnico di Torino, Control and Computer Engineering, Turin, Italy, ²Centre for Sleep Medicine, Molinette University Hospital, Turin, Italy, ³Department of Neuroscience “Rita Levi Montalcini”, University of Turin, Turin, Italy

Introduction:

Rapid Eye Movement (REM) Sleep Behavior Disorder (RBD) is a parasomnia characterized by the loss of the physiological REM sleep muscle atonia. In its idiopathic form, it can be considered a prodromal neurodegenerative stage, thus serving as an early marker of neurodegenerative disorders such as Parkinson’s Disease. State-of-the-art diagnostic criteria for RBD are visual-based and require manual scoring of polysomnography (PSG), a labor-intensive and time-consuming process. Various Machine Learning (ML) approaches, based on the automated analysis of PSG-derived signals, have been proposed to support RBD diagnosis. However, they significantly rely on sleep staging and hand-engineered features to characterize N3 and REM phases. This work presents an ML-based, stage-agnostic framework for the automatic detection of RBD individuals through single-channel EEG sleep data, facilitating minimally-invasive sleep investigations while improving diagnostic robustness and scalability.

Materials and methods: PSG scored recordings from 58 patients (6.91 ± 1.19 hours), encompassing 26 Healthy-Control (15 males, 36.8 ± 17.6 years) and 32 RBD (27 males, 62.2 ± 6.4 years), were included. Single-channel EEG data (C3-A2, or C4-A1) were selected to extract features further used to characterize sleep. Specifically, in two approaches: (1) first only NREM segments were considered to assess the impact of N1 and N2 inclusion on RBD classification, compared to N3 alone, (2) then, all sleep was taken as a whole, stage-independent segment, to evaluate the robustness of the approach, which constitutes the main novelty of the current study. Features were extracted separately on the two EEG segments in an epoch-wise fashion; multi-domain features (time, frequency, time-frequency, and nonlinear) were extracted, taking into account key attributes found in topic-related studies. Supervised ML models (Support Vector Machine, K-Nearest Neighbors, Random Forest, Logistic Regression, and XGBoost) were employed to automatically detect RBD subjects by focusing on the top-10 most important features (p -value < 0.001). They retained clinically relevant information, hence highlighting the high interpretability of the proposed framework.

Results: In the NREM-based classification approach, the Logistic Regression emerged as the best model, correctly classifying 84.4% of RBD subjects. The classifier exhibited an 81% Accuracy, 76.9% Specificity, 83.1% F1 score, and 0.91 AUC. On average, all tested models yielded moderately high accuracy, with an average AUC value of 0.86 ± 0.03 on a Leave-One-Subject-Out validation approach. In the stage-independent classification, the XGBoost was the best classifier, with a 86.2% Accuracy,

90.6% Sensitivity, 87.9% F1 score, and 0.91 AUC. The stage-independent approach proved good predictive performance, with an average AUC value of 0.89 ± 0.02 across all models, and valuable overall balance, also compared to previous studies on the same database.

Conclusions: The proposed analysis framework revealed effective diagnostic support capabilities, with moderately high automatic detection performance of RBD subjects. The promising results of the stage-independent analysis point to scalable and accessible RBD screening studies, with clinical implications also in decision-making applications for early identification of neurodegenerative states.

Association Between Iron Metabolism Biomarkers and REM Sleep Behavior Disorder: A Mendelian Randomization Study

G. Zhang¹, Y. Liu¹, W. Wang¹, A. Liu¹, Y. Peng¹

¹The Affiliated Brain Hospital of Guangzhou Medical University, Center for Sleep and Circadian Medicine, Guangzhou, China

Introduction: REM sleep behavior disorder (RBD) is a parasomnia characterized by loss of muscle atonia during REM sleep, often preceding neurodegenerative diseases such as Parkinson's disease. Emerging evidence suggests that iron metabolism may play a role in neurodegenerative processes, but its association with RBD remains unclear. This study investigates the causal relationship between iron metabolism biomarkers and RBD using Mendelian randomization (MR).

Materials and methods: We performed a two-sample MR analysis to evaluate the effects of genetically predicted iron metabolism biomarkers, including ferritin, iron, total iron-binding capacity (TIBC), and transferrin saturation (TSAT), on RBD risk. Genetic instruments were obtained from genome-wide association studies (GWAS) of iron metabolism traits, and summary-level RBD data were sourced from a large publicly available GWAS. Several MR methods were applied, including inverse variance weighted (IVW), MR-Egger, weighted median, weighted mode, and simple mode, to ensure robust findings. Sensitivity analyses, including Cochran's Q test, MR-Egger intercept, and leave-one-out analysis, were conducted to assess pleiotropy and heterogeneity.

Results: Our MR analysis demonstrated that genetically predicted higher ferritin levels were associated with a lower risk of RBD (IVW: $\beta = -0.15$, SE = 0.25, $p = 0.57$; MR-Egger: $\beta = -1.22$, SE = 0.46, $p = 0.01$; Weighted median: $\beta = -0.47$, SE = 0.29, $p = 0.11$). For serum iron levels, the IVW method showed a negative association with RBD risk ($\beta = -0.03$, SE = 0.14, $p = 0.83$), while the MR-Egger method suggested a stronger negative effect ($\beta = -0.48$, SE = 0.30, $p = 0.12$). TIBC exhibited a weak positive association with RBD (IVW: $\beta = 0.07$, SE = 0.12, $p = 0.55$; MR-Egger: $\beta = 0.16$, SE = 0.28, $p = 0.57$). For TSAT, no clear association with RBD was observed (IVW: $\beta = -0.02$, SE = 0.08, $p = 0.79$; MR-Egger: $\beta = -0.18$, SE = 0.14, $p = 0.21$). Sensitivity analyses indicated no substantial heterogeneity (Cochran's Q test: $p > 0.05$ for all exposures) and no significant horizontal pleiotropy (MR-Egger intercept $p > 0.05$).

Conclusions: Our findings suggest a potential protective role of ferritin in RBD, with a stronger effect observed in MR-Egger analysis. While other iron metabolism markers, including iron, TIBC, and TSAT, did not show strong causal evidence, the direction of effect estimates warrants further investigation. Future studies are needed to explore the underlying mechanisms linking iron metabolism to RBD and its progression to neurodegenerative diseases.

Automated analysis of home video for screening REM sleep behaviour disorder

Introduction: Isolated REM sleep behavior disorder (iRBD), a prodromal syndrome of alpha-synucleinopathy neurodegeneration is characterized by vivid and often action-packed dream enactment behaviors (DEBs) during REM sleep. Early detection of iRBD benefits in preventing the progress of neurodegeneration, and sleep-related injuries caused by DEBs. With the availability of ambulatory home-PSG measurement, emerging studies have supported the validity of screening and diagnosing varieties of sleep disorders, including iRBD, at home setting. In corroborating a diagnosis of iRBD, the use of video-polysomnogram (vPSG) will help to document sleep related movement during REM sleep. However, the detailed manual analysis of vPSG recording is time-consuming and labor-intensive. There has been increasing number of studies exploring the automated video analysis method in distinguishing iRBD from healthy controls, albeit most of them were conducted in laboratory settings. Here we aimed to explore the automated video analysis for screening RBD at the home setting.

Materials and methods: This study included 35 patients with iRBD and 35 non-RBD controls, with the diagnoses confirmed (or excluded) by prior in-laboratory vPSG monitoring, respectively. All subjects underwent home vPSG (Nox A1s) with time-synchronized infrared-night-vision video recording (XIAOMI C700/TP-Link C212). Sleep-wake stages were scored by certified polysomnographic technologists. For the automated video analyses, pixel-value differences between adjacent 2-seconds-frames were calculated to quantify the intensity of movements from REM sleep videos, generating a temporal motion signal. Motion signals were compared with manually score movements results (based on criteria proposed by Frauscher B, 2009). Then, following features of motion signal were compared between iRBD and controls: movement counts (counts of motion signal larger than 1.2/1.4/1.6/1.8 times median of motion signal's peaks [baseline, indicating a "static status" of sleep]) per minute, movement duration percentage (duration of motion signal larger than 1.2/1.4/1.6/1.8 times baseline), and averaged normalized intensity.

Results: We firstly compared motion signals versus manually scored movements during REM sleep. A total of 95 major jerk/movements (e.g., whole body jerk, gross body movement, raising the arm, isolated elevation of one leg) were manually identified from five iRBD patients (66.4 ± 7.4 years, 80.0% male), while the motion signal threshold of 1.2/1.4/1.6/1.8 times baseline identified these movements with sensitivities of 100.0/96.3/91.3/87.9% and specificities of 35.63/83.21/92.31/95.67%, respectively. Then, we compared the motion signals between iRBD patients (67.9 ± 6.6 years, 71.4% male) and controls (66.7 ± 6.8 years, 31.4% male), whose results showed that iRBD group exhibited significantly higher values than controls in movement counts (e.g., 1.6 times: median [IQR]: 2.03 [1.25-3.33] vs 0.23 [0.13-0.50] per minute, $P < 0.001$), movement duration percentage (e.g., 1.4 times: 8.7% [6.1-13.1%] vs 1.2% [0.7-3.7%], $P < 0.001$), and averaged normalized intensity (1.61 [1.45-1.96] vs 1.25 [1.16-1.47], $P < 0.001$).

Conclusions: This study suggested that automated video analysis method would be able to identify epochs with possible behavioral events and differentiate iRBD patients from controls. The findings may highlight the feasibility of using ambulatory home-PSG measurement with infrared-night-vision camera to screen RBD at home settings.

Introduction: Isolated REM sleep behavior disorder (iRBD) is a parasomnia characterized by abnormal movements during REM sleep and is strongly associated with the development of synucleinopathies. As a prodromal condition, iRBD provides a unique window for investigating early neurodegenerative processes preceding Parkinson's disease (PD) and dementia with Lewy bodies (DLB). While disruptions in brain structural connectivity have been well-documented in PD and DLB, their presence during prodromal phases such as iRBD remains unexplored. In this study, we used the largest international multicenter neuroimaging dataset of polysomnography-confirmed iRBD participants to characterize the presence of white matter alterations and their impact on brain architecture. We evaluated global and local efficiency in iRBD, which are key metrics for detecting network disruptions in pathology. Additionally, we explored how other network properties influence local efficiency. We hypothesized that participants with iRBD would show reduced global efficiency, alongside decreased local efficiency in regions implicated in PD or DLB, compared to controls.

Materials and methods: We analyzed Diffusion-Weighted Imaging data from 198 polysomnography-confirmed iRBD patients and 174 controls across seven cohorts. Structural connectivity maps were generated using advanced tractography and connectivity pipelines to reconstruct the white matter architecture between 448 cortical and 14 subcortical regions. Global and local efficiency metrics were calculated to quantify network efficiency and compared between iRBD and control groups, with FDR correction applied for multiple comparisons. W-scores were used to control for age and sex, and ComBat was applied to regress out scanner effects. Additionally, we investigated the association between changes in local efficiency and global efficiency, and other local network features, namely clustering coefficient (interconnectedness of a region's neighbors), connection strength, and degree (number of connections per region).

Results: Structural connectivity in iRBD patients showed significant disruptions compared to controls, with reduced global and local network efficiency. Local efficiency was decreased in 18 cortical and 3 subcortical regions, including the left putamen and bilateral thalamus, and increased in 9 cortical regions, many of which are associated with PD or DLB. Decreased global efficiency was associated with decreased local efficiency in the left putamen, bilateral thalamus, and left lateral orbitofrontal gyrus, as well as increased local efficiency in the left inferior and superior parietal cortices, left insula, and right orbitofrontal cortex. Additionally, local efficiency was positively correlated with clustering coefficient ($r=0.98$, $p\text{-value}_{\text{spin-FDR}} = .001$) and negatively correlated with connection strength ($r=-0.63$, $p\text{-value}_{\text{spin-FDR}} = .001$) and degree ($r=-0.66$, $p\text{-value}_{\text{spin-FDR}} = .001$).

Conclusions: This study reveals global and local efficiency changes in iRBD, aligned with what is observed in PD and DLB. Our results indicate that both decreased local efficiency in subcortical regions and increased local efficiency in specific cortical regions are associated with decreased global efficiency. Additionally, higher-efficiency regions in iRBD have more clustered neighboring regions, and are defined by weaker and fewer connections, potentially reflecting greater tissue damage. Overall, these findings highlight networks reorganization in iRBD, offering insights into white matter alterations preceding DLB and PD, and the mechanisms driving the progression towards these diseases.

Causal Associations Between Tea Consumption and REM Sleep Behavior Disorder: A Mendelian Randomization Study

S. Zhang¹, G. Cui¹, W. Zhang¹

¹The Affiliated Hospital of Xuzhou Medical University, Xuzhou, China

Introduction: Previous studies have shown that tea consumption may have a protective effect against neurodegenerative diseases. However, the exact causal relationship between tea consumption and the precursor stages of certain neurodegenerative diseases, namely REM sleep behavior disorder (RBD), remains unclear. To evaluate the causal association between tea consumption and RBD, we employed a Mendelian randomization study.

Materials and methods: We identified genetic instrumental variables that are significantly associated with tea consumption through genome-wide association studies (GWAS) in European populations. Bidirectional two-sample Mendelian randomization was utilized to determine the causal relationship between tea consumption and RBD, while sensitivity analyses were further employed to evaluate the robustness of the results. The multivariate Mendelian randomization method was used to assess the influence of relevant confounding factors on the results.

Results: In the MR analysis using the inverse variance weighting method, a significant causal relationship between tea consumption and RBD was observed (OR=0.046, 95% CI 0.004- 0.563, $p=0.016$). The consistency of findings across maximum likelihood, MR PRESSO, and multivariate MR after adjusting for potential confounding further supports this causal association. Sensitivity analyses revealed no evidence of heterogeneity or pleiotropy.

Conclusions: The findings of our study demonstrate a robust causal association between tea consumption and RBD, indicating that tea consumption may serve as a protective factor against the development of RBD.

Acknowledgments: The datasets were derived from sources in the public domain: GWAS (<https://gwas.mrcieu.ac.uk>).

Circadian dysregulation in probable isolated REM sleep behaviour disorder: actigraphy insights from the Tasmanian ISLAND Sleep Study

S. Bramich¹, A. Lam¹, A.E. King², A. Noyce³, S.L. Naismith^{4,1}, L. Pérez-Carbonell⁵, J.C. Vickers², J. Alty^{2,6}
¹University of Tasmania, Wicking Dementia Research and Education Centre, Hobart, Australia, ²University of Sydney, Brain and Mind Centre, Sydney, Australia, ³Queen Mary University of London, Wolfson Institute of Population Health, London, United Kingdom, ⁴University of Sydney, Charles Perkins Centre, Sydney, Australia, ⁵Guy's and St Thomas' NHS Foundation Trust, Sleep Disorders Centre, London, United Kingdom, ⁶Royal Hobart Hospital, Department of Neurology, Hobart, Australia

Introduction: Circadian rhythm disruption is increasingly implicated in the prodromal stages of alpha-synuclein-related diseases, such as Parkinson's disease and dementia with Lewy Bodies. Isolated REM sleep behaviour disorder (iRBD) is one of the earliest symptoms of these diseases, often occurring 10 years or more before a clinical diagnosis. There is an urgent need to develop new methods of detecting iRBD and associated circadian changes early in the disease process. Wearable devices offer a non-invasive, easily accessible means to capture these changes. This study examined whether actigraphy-derived measures of sleep and circadian rhythms could distinguish individuals with 'probable' iRBD (pRBD) from controls.

Materials and methods: 263 participants aged 50+ years from the Tasmanian ISLAND (Island Study Linking Ageing and Neurodegenerative Disease) Sleep Study completed the REM Sleep Behaviour Disorder Single-Question Screen to determine pRBD, and underwent wrist-worn actigraphy to assess sleep (total sleep time, wake after sleep onset, and number of overnight awakenings) and circadian metrics (sleep regularity, interdaily stability, intradaily variability, and timing and magnitude of daily activity). Cosinor analysis was performed to model circadian rhythms by fitting a cosine function to the activity data

Results: 122 participants with pRBD (mean (SD) age 68 (7.4) years; 62% male) and 161 controls (mean (SD) age 69 (7.5) years; 61% male) wore an actigraphy watch for two weeks and completed a sleep diary each day. General sleep metrics, including total sleep time, number of awakenings overnight, and moderate or vigorous activity during the sleep period did not differ between those with pRBD and controls. In contrast, circadian metrics revealed significant group differences. Individuals with pRBD showed decreased sleep regularity ($p < 0.01$), reduced interdaily stability ($p < 0.001$), increased intradaily variability ($p < 0.01$), altered timing of the least active 5 hours of the day ($p < 0.01$), and altered magnitude of activity during the most active 10 hours of the day ($p < 0.01$). Cosinor analysis further confirmed significant differences in circadian rhythm characteristics between the two groups, in both mesor (rhythm-adjusted mean activity; $p < 0.01$) and amplitude (half the difference between peak and nadir of the fitted cosine wave; $p < 0.001$).

Conclusions: In this community-based cohort, actigraphy metrics found significant circadian variation in those with pRBD compared to controls. This study highlights the utility of actigraphy-derived circadian metrics in detecting circadian dysregulation; a feature that has been strongly associated with the development and progression of neurodegenerative disease. These findings suggest that wearable

device data could be used more widely in the community to assist in identifying and monitoring those at-risk for alpha-synuclein-related diseases.

Clinical, Physiological, and Behavioral Characteristics of iRBD Patients With Ambulatory Dream Enactment Behaviors

S.M. Kim¹, T.-G. Noh¹, S.J. Han², C. Schenck³, K.-Y. Jung¹

¹Seoul National University, Seoul, Korea, Republic of, ²Wonkwang University Sanbon Hospital, Wonkwang University School of Medicine, Gimpo, Korea, Republic of, ³Minnesota Regional Sleep Disorders Center, and Department of Psychiatry, Hennepin County Medical Center and University of Minnesota Medical School, Minneapolis, United States

Introduction: Isolated rapid eye movement (REM) sleep behavior disorder (iRBD) is characterized by dream enactment behaviors (DEBs) during REM sleep, accompanied by REM sleep without atonia (RWA). While most patients exhibit DEBs confined to the bed, a minority engage in ambulatory behaviors. This study aimed to investigate the clinical, physiological, and behavioral characteristics of patients exhibiting such ambulatory behaviors.

Materials and methods: This retrospective study reviewed the electronic medical records (EMRs) of 361 patients with video-polysomnography (v-PSG)-confirmed iRBD (mean age: 71.29 years; 213 males). Patients were classified as RBD-walkers if they or their witnesses reported at least one DEB episode involving ambulation, specifically exiting the room through a door; all others were categorized as non-walkers. Group comparisons of demographics, clinical assessments, and PSG metrics between RBD-walkers and non-walkers were conducted using Mann-Whitney U test and Fisher's exact test. Dream contents and related behaviors, obtained through structured sleep interviews, were qualitatively analyzed through thematic analysis.

Results: Among the 361 patients, 23 (6.4%) were classified as RBD-walkers. Clinically, RBD-walkers were more frequently female (60.4% vs. 39.1%, $p = 0.051$) and showed higher scores on Factor 1 of the RBDQ-KR (13.68 vs. 10.74, $p = 0.012$). They were more frequently prescribed a combination of clonazepam and melatonin (60.9% vs. 20.4%, adjusted residual = +4.46), and received higher doses of clonazepam (0.67 mg vs. 0.45 mg, $p = 0.006$).

Behaviorally, RBD-walkers exhibited more complex motor behaviors involving interaction with the sleep environment, such as opening doors (60.9% vs. 0.0%) or performing household tasks (17.4% vs. 0.0%). In contrast, non-walkers more often displayed vigorous bed-bound behaviors, including falling out of bed (43.5% vs. 21.7%). Among RBD-walkers, females more commonly engaged in chores, such as laundry or organizing clothes, than males (17.4% vs. 0.0%), whereas males more frequently exhibited aggressive behaviors, such as punching or kicking (88.9% vs. 42.9%) and weapon use (33.3% vs. 7.1%). Polysomnographic findings showed that RBD-walkers tended to have higher sleep efficiency (84.41% vs. 78.00%, $p = 0.054$) and reduced wake after sleep onset (55.03 min vs. 78.83 min, $p = 0.054$), along with significantly greater proportions of both deep (N3; 13.23% vs. 6.62%, $p = 0.006$) and REM sleep (23.42% vs. 20.69%, $p = 0.046$). Notably, EMG amplitude during REM sleep was higher in RBD-walkers compared to non-walkers (5.56 μV vs. 3.71 μV , $p = 0.031$), observed in both RWA epochs (10.64 μV vs. 8.04 μV , $p = 0.012$) and non-RWA epochs (3.46 μV vs. 2.68 μV , $p = 0.091$).

Conclusions: This study demonstrates that RBD-walkers represent a distinct clinical and neurophysiological phenotype within the iRBD spectrum. Their complex, environmentally interactive behaviors, elevated treatment requirements, and heightened baseline EMG activity during REM sleep suggest involvement of multifactorial mechanisms beyond simple motor disinhibition. These observations highlight the need for further research into the neural correlates and potential prognostic significance of this subgroup.

Cognitive and motor wobbling in isolated RBD: A multicentric study by the International RBD Study Group (IRBDSG)

Introduction: Patients with iRBD often develop motor and non-motor signs and symptoms before phenoconversion to overt alpha-synucleinopathy. These may fluctuate (wobble) for a long time, making the exact time of the clinical diagnosis of phenoconversion difficult. Although such patients may be called prodromal PD, prodromal DLB or prodromal MSA, they do not yet fulfil diagnostic criteria for any overt synucleinopathy or other neurodegenerative disorder.

Aim of this study was to define and characterize clinically fluctuating transition phases from isolated RBD (iRBD) to possible overt alpha-synucleinopathy.

Materials and methods: IRBDSG centers included patients with over a 3-year follow-up period, who underwent ≥ 3 assessments at intervals ≥ 6 months apart. A wobble event was defined as an improvement at least once in at least one of the following: MDS-UPDRS III (≥ 4 points); MoCA (≥ 4 points) or MMSE (≥ 3 points) or MCI reverting to normal; orthostatic hypotension reverting to normal. PD, DLB or MSA criteria could not be fulfilled at any timepoint.

Results: 87 iRBD wobblers (17.2% female) from 15 centres (Europe, Canada, USA, Australia, Hong Kong, South Korea) were included. Mean age at iRBD diagnosis was 65.3 ± 7.2 y, with a time from diagnosis to first wobble event of 4.9 ± 4.3 y. At baseline the MDS-UPDRS-III was 3.7 ± 3.6 and MoCA 23.7 ± 3.2 . At baseline, 26.1% presented with MCI, 13.0% OH, 55.6% a cardiovascular disease, 29.6% a psychiatric disorder, and 12.0% diabetes mellitus. 50.0% of the patients were taking symptomatic treatment for RBD. 41 patients (48%) were classified as pure cognitive (C) wobblers, 22 (25%) as pure motor (M) wobblers, 19 (22%) as both cognitive and motor (C+M) wobblers. Age at RBD diagnosis, sex, time from diagnosis to first wobble event, presence of MCI, OH, comorbidities, and use of RBD symptomatic treatment did not differ among groups. At baseline, the MDS-UPDRS-III score was higher in the M wobblers and in the C+M wobblers, compared to the C wobblers. The MoCA score was lower in the C wobblers and in the C+M wobblers, compared to the M wobblers.

Conclusions: In iRBD, cognitive and motor symptoms can wobble over time, making the clinical diagnosis of phenoconversion difficult. Wobbling is a yet unreported phenomenon in iRBD and presents important clinical and research implications: if these measures are selected as outcomes in neuroprotective trials, wobbling could be misinterpreted as treatment efficacy. Further observations of wobblers are necessary to determine their final outcomes.

Data-Driven Subtyping of REM Sleep Behavior Disorder Using Sleep-Stage-Independent EEG and Unsupervised Learning

M. Carenzo¹, I. Rechichi¹, G.S. Giarrusso¹, U. Mosca¹, A. Cicolin^{2,3}, G. Olmo¹

¹Politecnico di Torino, Control and Computer Engineering, Torino, Italy, ²Centre for Sleep Medicine, Torino, Italy, ³University of Turin, Neuroscience "Rita Levi Montalcini", Torino, Italy

Introduction:

Rapid Eye Movement (REM) Sleep Behavior Disorder (RBD) is a parasomnia characterized by the loss of physiological muscle atonia during REM sleep, often leading to dream-enactment behaviors. In its idiopathic form, RBD is widely recognized as a prodromal marker of alpha-synucleinopathies; longitudinal studies revealed a conversion rate of up to 73.5–96% within 12–14 years from the

diagnosis. Despite its clinical and prognostic relevance, RBD heterogeneity and intra-group disease progression remain underexplored. This work proposes an unsupervised learning framework based on sleep-stage-independent, single-channel EEG sleep data with the aim of identifying subgroups within the RBD population, potentially reflecting different stages or trajectories of disease evolution.

Materials and methods:

Polysomnographic (PSG) recordings of 32 patients diagnosed with RBD (27 males, 62.2 ± 6.4 years) were included in the analysis. A single EEG channel was selected from each recording; the whole sleep segment was employed in the analysis, without sleep stage distinction, to allow for a comprehensive view of sleep-related dynamics. The analysis pipeline is as follows. First, a comprehensive set of features was extracted, capturing overnight brain activity and signal morphology over time, frequency, and nonlinear domains. Second, features were standardized and Principal Component Analysis (PCA) was employed to reduce dimensionality and retain only the most informative variables for the analysis. Then, multiple unsupervised learning algorithms (K-means, Agglomerative, and Spectral Clustering) were applied to the reduced feature space, to identify patient subgroups. Finally, the REM Atonia Index (RAI) was extracted from the EMG signal during REM sleep and used as clinical reference for disease severity.

Results: The clustering analysis revealed two distinct subgroups across all applied algorithms, with K-means showing the highest internal validity (Silhouette score: 0.4), indicating moderate performance on real-world data. The PCA dimensions contributing to cluster separation primarily reflected differences in EEG signal complexity and spectral content, suggesting varying patterns of brain activity during sleep. Specifically, one cluster included subjects with higher EEG frequencies, lower signal regularity and lower values of RAI (0.1347 ± 0.208), while the other showed opposite trends, shifting towards lower EEG frequencies, higher regularity, and increasing values of RAI (0.246 ± 0.275). These findings suggest that the identified subgroups differ not only in electrophysiological features, but also in a clinical marker of severity. Although no single parameter is deemed responsible for cluster separation, the results support the presence of underlying neurophysiological and clinical heterogeneity within the explored RBD population.

Conclusions: This study demonstrates the feasibility of using unsupervised learning on sleep-stage-independent, single-channel EEG data to explore heterogeneity in RBD and identify latent subgroups. The clustering results support the presence of different trajectories in RBD and highlight varying electrophysiological profiles, potentially corresponding to different disease stages. These insights could contribute to the development of early diagnostic support tools and personalized interventions in the context of neurodegenerative disease prevention and management, offering a non-invasive, data-driven approach for stratifying patients and monitoring disease progression.

Acknowledgments: This work is supported by the PNRR EU NextGenerationEU project MUR-M4C2 1.5 (Italy).

Diagnosing idiopathic REM sleep behavior disorder, Parkinson's Disease with or without RBD using single-lead electrocardiogram of polysomnography

W. Lee¹, H.J. Lee², J. Park³, J.H. Han⁴, K.M. Kim⁵

¹Yongin Severance Hospital, Yonsei University College of Medicine, Department of Neurology, Yongin-si, Korea, Republic of, ²Chung-Ang University Gwangmyeong Hospital, Department of Neurology, Gwangmyeong-si, Korea, Republic of, ³Konyang University, Department of Medical Artificial Intelligence, Daejeon, Korea, Republic of, ⁴Konyang University, Department of Medical Engineering, Daejeon, Korea, Republic of, ⁵Severance Hospital, Yonsei University College of Medicine, Department of Neurology, Seoul, Korea, Republic of

Introduction: Rapid eye movement (REM) sleep behavior disorder (RBD) is recognized as a prodromal stage of alpha-synucleinopathies. Among individuals with Parkinson's disease (PD), the presence of RBD is associated with a more severe clinical phenotype and extensive cerebral pathology compared to those without RBD. This study aimed to differentiate idiopathic RBD (iRBD), PD with RBD (PDRBD), and PD without RBD (PDnoRBD) using heart rate variability (HRV) features derived from single-lead electrocardiogram (ECG) recordings during polysomnography (PSG).

Materials and methods: We retrospectively analyzed subjects who underwent both PSG and dopamine transporter positron emission tomography (PET) between January 2010 and December 2021. The study cohort comprised 4 individuals with iRBD, 9 with PDRBD, 8 with PDnoRBD, 9 clinical controls (NotRBD), and 15 healthy controls (HC). HRV features were extracted from PSG-derived ECG data, and group classification was performed using machine learning algorithms.

Results: Demographic variables and obstructive sleep apnea severity did not differ significantly across the groups, except for the HC group. Machine learning models effectively distinguished between iRBD, PDRBD, and PDnoRBD based on ECG-derived HRV metrics.

Conclusions: This study highlights the potential of single-lead ECG signals as a non-invasive tool to classify RBD and PD subtypes. These findings support the utility of autonomic biomarkers in differentiating neurodegenerative phenotypes and provide a basis for future prospective studies to predict phenoconversion from iRBD to overt synucleinopathy.

Diagnostic Cutoffs for REM Sleep Without Atonia in Isolated REM Sleep Behavior Disorder from a Korean Population

T.-G. Noh¹, J.K. Hong², I.-Y. Youn², K.-Y. Jung³

¹Seoul National University, Interdisciplinary Program in Neuroscience, College of Natural Sciences, Seoul, Korea, Republic of, ²Seoul National University Bundang Hospital, Department of Psychiatry, Seongnam, Korea, Republic of, ³Seoul National University Hospital, Department of Neurology, Seoul, Korea, Republic of

Introduction: Isolated REM sleep behavior disorder (iRBD), characterized by REM sleep without atonia (RWA), is a prodromal stage of alpha-synucleinopathies. Although diagnostic cutoffs for RWA are established in Western populations, ethnic variations necessitate confirmation of these criteria in Asian cohorts. Previous Korean studies were limited by small sample sizes, manual scoring methods, and inconsistent quantification standards. Using advanced automated algorithms, this study aimed to establish reliable diagnostic cutoffs for RWA quantification for Koreans.

Materials and methods: Baseline polysomnograms were analyzed from 95 iRBD patients (aged 66.2 ± 7.4 years; 63.2% male) diagnosed at Seoul National University Hospital, free from secondary causes, neurological disorders, or severe obstructive sleep apnea. Controls consisted of 24 matched individuals (16 with restless leg syndrome, 8 healthy subjects), and an external validation cohort comprised 95 matched elderly Koreans without RBD. Single-night PSG included EEG, EOG, ECG, respiratory monitoring, mentalis (MT), and bilateral flexor digitorum superficialis (FDS) EMG recordings. MT electrodes were attached to all participants, whereas FDS electrodes were attached to all controls and 42 patients with iRBD. Automated RWA quantification utilized the validated in-laboratory algorithm (AURA), demonstrating high reliability compared to human scoring (PABAK: 0.736–0.945). RWA was assessed using SINBAR criteria, AASM criteria, cumulative RWA percentage (CRWA%), and REM atonia index (RAI). Diagnostic performance was assessed using receiver operating characteristic analyses, with bootstrap methods (1,000 iterations) for 95% confidence intervals (CI), determining cutoffs internally and validating externally.

Results:

Optimal and specificity=1 cutoffs for the MT channel included CRWA% (5.62% and 5.62%, AUC: 0.94 [0.91–0.98]), Tonic SINBAR (0.55% and 2.83%, AUC: 0.86 [0.80–0.91]), Phasic SINBAR (14.32% and 19.89%, AUC: 0.87 [0.79–0.93]), Any SINBAR (17.47% and 20.02%, AUC: 0.92 [0.87–0.96]), Phasic AASM (4.48% and 15.07%, AUC: 0.82 [0.73–0.91]), Any AASM (7.55% and 16.00%, AUC: 0.92 [0.87–0.97]), and RAI (0.90 and 0.78, AUC: 0.92 [0.85–0.96]).

For the FDS channels, cutoffs were CRWA% (4.50% and 13.16%, AUC: 0.90 [0.82–0.97]), Phasic SINBAR (18.72% and 33.22%, AUC: 0.86 [0.76–0.95]), Any SINBAR (23.92% and 34.95%, AUC: 0.91 [0.83–0.97]), Phasic AASM (8.84% and 27.75%, AUC: 0.84 [0.74–0.94]), and Any AASM (10.00% and 29.38%, AUC: 0.90 [0.82–0.96]).

For the combined MT+FDS channels were: CRWA% (9.21% and 16.40%, AUC: 0.97 [0.94–1.00]), Phasic SINBAR (28.30% and 34.91%, AUC: 0.92 [0.85–0.97]), Any SINBAR (MT) + Phasic SINBAR (FDS)

(36.24% and 36.24%, AUC: 0.97 [0.92–0.99]), Phasic AASM (9.80% and 26.67%, AUC: 0.88 [0.79–0.96]), and Any AASM (MT) + Phasic AASM (FDS) (13.86% and 27.52%, AUC: 0.97 [0.94–1.00]).

When the optimal and specificity=1 cutoffs for the MT channel were applied to the external validation cohort, both specificity and sensitivity fell within the CIs observed in the internal cohort, indicating no significant differences in performance.

Conclusions: Our findings showed that RWA diagnostic cutoffs in Koreans, especially for Phasic and Any RWA, were largely consistent with those reported in Western populations. Notably, the lower tonic RWA observed in our study may help explain the lower phenoconversion rate reported in Korean cohorts compared to Western populations.

Distinct gut microbial, brain gene expression and clinical progression profiles in REM sleep behavior disorder biotypes

S. Tang¹, Y. Yang¹, Y. Wang², Y. Liu³, J. Wang³, L. Zhou¹, S. Gong¹, J.W. Chan¹, B. Huang¹, Y.K. Wing¹
¹Li Chiu Kong Family Sleep Assessment Unit, Department of Psychiatry, The Chinese University of Hong Kong, Shatin, Hong Kong, SAR of China, ²Brain and Mind Institute, The Chinese University of Hong Kong, Shatin, Hong Kong, SAR of China, ³Center for Sleep and Circadian Medicine, The Affiliated Brain Hospital, Guangzhou Medical University, Guangzhou, China

Introduction: Idiopathic REM sleep behavior disorder (iRBD) is a well-established prodromal stage of α -synucleinopathies. However, individuals with iRBD demonstrate considerable heterogeneity in clinical symptoms, disease progression, and neurodegenerative trajectories. Our previous work identified two distinct brain-clinical biotypes of iRBD: Biotype 1 (characterized by brain atrophy) and Biotype 2 (characterized by structural brain reserve) with unique neuroanatomical patterns, connectivity, and clinical profiles, while underlying mechanisms driving these divergent biotypes remain unclear. Given the growing evidence implicating the gut-brain axis in neurodegeneration, this study investigated whether these biotypes exhibit differential gut microbiome profiles. We further explored gene expression profiles associated with structural brain changes and clinical trajectories in each biotype.

Materials and methods: T1-weighted MRI and clinical assessments were obtained from 86 Biotype 1 and 86 Biotype 2 iRBD patients, along with 126 controls. Fecal samples were collected from a subset of these subjects, including 42 Biotype 1 and 50 Biotype 2 patients, and 75 controls. Shotgun metagenomic sequencing was performed on these samples to analyze gut microbial profiles, which were then compared between each iRBD biotype and controls. Gene set enrichment analysis (GSEA) was performed to examine transcriptomic pathways associated with neuroanatomical alterations in each biotype. A two-year clinical follow-up evaluated motor and cognitive decline among the two biotypes and controls.

Results: Biotype 1 displayed a severe dysbiosis pattern relative to controls, whereas Biotype 2 showed a microbiome profile more akin to controls after adjusting age and sex. Specifically, Biotype 1 demonstrated elevated abundances of proinflammatory species, including *Collinsella aerofaciens*, *Bacteroides fragilis*, *Eggerthella lenta*, and *Ruthenibacterium lactatiformans*, alongside reduced levels of short-chain fatty acid (SCFA)-producing bacteria, such as *Phocaeicola vulgatus* and *Faecalicatena fissicatena*. Multivariate analyses revealed significant associations between brain atrophy pattern in Biotype 1 and the presence of microbial species such as *Ruthenibacterium lactatiformans*, *Eggerthella lenta*, *Akkermansia muciniphila*, *Hungatella hathewayi* and *Bacteroides fragilis*. GSEA showed that brain atrophy in Biotype 1 was uniquely associated with pathways such as *Alzheimer's disease*, *vesicle-mediated transport in synapse*, *intracellular protein transport*, and *positive regulation of monoatomic ion transport*, converging on neuroinflammation and apoptotic processes. Increased brain structure in Biotype 2 was associated with pathways such as *regulation of postsynaptic neurotransmitter receptor activity* and *enzyme-linked receptor protein signaling pathway*, suggesting adaptive or potentially neuroprotective mechanisms. Longitudinally, Biotype 1 exhibited significantly more rapid progression of motor and cognitive decline compared to Biotype 2 and controls.

Conclusions: The two distinct brain-clinical biotypes identified in iRBD also exhibited divergent profiles in gut microbiota composition, brain gene expression, and clinical progression. These findings also highlight the gut-brain axis with integration of neuroimaging features as a critical contributor to disease

progression and suggest that microbiome-targeted interventions may hold promise as personalized and precision therapeutic strategies in prodromal neurodegenerative stage.

Introduction: Idiopathic REM sleep behavior disorder (iRBD), a prodromal stage of α -synucleinopathies, exhibits gut dysbiosis characterized by enriched pro-inflammatory bacteria and depleted short-chain fatty acids (SCFA)-producing bacteria. Previous studies have shown that microbiome is shaped by shared environment, with cohabiting spouses exhibiting strong similarities. However, whether iRBD-related microbiome dysbiosis exists in iRBD spouses (RS), and how lifestyle and clinical factors affect their gut microbiome remain unclear. This study aims to characterize clinical, lifestyle and gut microbial features in RS, and explore the underlying host-microbiome interplays.

Materials and methods: This cross-sectional study included 58 video-polysomnography-confirmed iRBD patients (69.5 $\pm$ 6.6 years, 87.9% male), 58 RS (66.1 $\pm$ 6.8 years, 12.1% male) and 58 unrelated controls (UC, 66.0 $\pm$ 6.9 years, 13.8% male). UC were 1) age- and sex-matched with RS; 2) not cohabiting with or genetically related to iRBD couples; and 3) had spouses free of RBD or neurodegeneration. Participants underwent clinical assessments, questionnaires, and fecal shotgun metagenomic sequencing. Dietary information was collected using a 20-item questionnaire. Data were analyzed using SPSS 29.0 and R 4.4.2.

Results: Compared to UC, RS trended toward a higher prevalence of possible RBD (defined as RBDQ-HK total score > 18: 8.9% vs. 1.8%, $p=0.098$). RS also exhibited higher prevalence of depression and upper gastrointestinal (GI) disorders. Additionally, the occurrence of injuries in iRBD patients was positively associated with depression in their spouses ($p=0.029$). In contrast, lower GI symptoms—as reflected by Rome-IV diagnosed constipation, bowel movement frequency, and SCOPA-AUT subscores—appeared to be milder in RS versus UC ($p=0.050$, $p=0.088$, $p=0.014$, respectively).

Regarding lifestyle, RS had significantly lower dietary diversity and higher consumption of salty snacks and animal fat than UC. Further analyses within iRBD couples showed positive correlations between patients and their cohabiting spouses in education level, consumption of most food groups (16/20, 80%), cognitive function, and upper GI symptoms.

Metagenomic analyses revealed comparable gut microbial composition between RS and UC, with no significant differences in alpha or beta diversity, or any individual taxa. However, compared to iRBD patients, RS showed significantly reduced observed species, as well as microbial dissimilarity after adjusting for age, sex and constipation. Nine species and five genera differed significantly between RS and iRBD patients, with RS displaying higher abundances of SCFA-producing genera *Agathobaculum*, *Faecalibacterium* and *Roseburia*. Host-microbiome interaction analyses showed that longer constipation duration was negatively correlated with all these SCFA-producing genera, while constipation was associated with reduced *Faecalibacterium* abundance. Additionally, higher consumption of unhealthful plant-based foods, including refined grains and bakery products, was negatively correlated with *Agathobaculum* abundance.

Conclusions: iRBD spouses exhibit higher prevalence of depression and upper gastrointestinal symptoms, alongside lower constipation rates and dietary diversity. Despite shared environmental and lifestyle factors, iRBD spouses did not display RBD-like gut dysbiosis; instead, their microbiota featured a possible enrichment of SCFA-producing bacteria, suggesting a "healthier gut" phenotype. Lifestyle factors, particularly fewer bowel disorders (e.g., constipation), are likely associated with these health-promoting bacteria.

Evaluation of cardiac autonomic modulation via deceleration capacity during polysomnography in isolated REM sleep behavior disorder and Parkinsonian syndromes

E. Ruppert^{1,2}, C. Gross¹, M. Habibi¹, K. Kesper³, A. Bauer⁴, T. Penzel⁵, D. Vadasz¹, V. Ries¹, E. Sittig¹, U. KOEHLER³, A. Janzen¹, W. Oertel¹

Introduction: Isolated REM sleep behavior disorder (iRBD) is considered a prodromal stage of alpha-synucleinopathies (aSYN), such as Parkinson's disease (PD) and multiple system atrophy (MSA). These neurodegenerative diseases present both motor and non-motor symptoms, including autonomic dysfunction, which can precede or accompany motor signs. Cardiac autonomic disturbances show syndrome-specific patterns and are also observed in iRBD. However, early clinical differentiation between iRBD converting to PD or MSA remains challenging due to overlapping motor features. Heart rate variability (HRV) offers a non-invasive assessment of cardiac autonomic function, with deceleration capacity (DC) emerging as a sensitive parasympathetic marker. This study investigates HRV and DC profiles in iRBD, PD, and MSA to explore their potential for early diagnosis and potential differential classification of aSYN.

Materials and methods: In this retrospective study, we analyzed full-night polysomnography recordings from 105 healthy controls (HC), 61 iRBD patients, 50 PD patients, and 28 MSA patients. HRV parameters were assessed across all groups, including DC as a marker of parasympathetic function, SDNN (Standard Deviation of NN intervals) reflecting overall HRV, and SDANN (Standard Deviation of the Average NN intervals) representing long-term heart period variability over consecutive 5-minute segments. HRV parameters were analyzed for each sleep stage (NREM stages 1-3, REM sleep), total sleep time, and total recording time.

Results: During the total recording time, HC showed the highest mean DC values (7.35 ms $\pm$ 0.52), followed by PD (7.26 ms $\pm$ 2.8) and iRBD (7.22 ms $\pm$ 1.97). During NREM1 sleep, PD patients showed the highest mean DC values (8.29 ms $\pm$ 3.37), followed by HC (8.13 ms $\pm$ 3.23) and iRBD (7.86 ms $\pm$ 2.51). MSA patients had significantly lower values during total recording time and NREM1 sleep (mean 5.21ms $\pm$ 2.07; 5.73 ms $\pm$ 2.91) compared to all other groups. During total sleep time, mean SDNN was significantly lower in MSA (53.39 ms $\pm$ 30.64) compared to HC (68.12 ms $\pm$ 27.98) and iRBD (67.14 ms $\pm$ 22.44), but not to PD (64.05 ms $\pm$ 1.97). These SDNN differences remained significant for NREM1, NREM2, and REM sleep, but not during NREM3. Mean SDANN was significantly lower in HC (50.68 ms $\pm$ 17.54) compared to iRBD (58.83 ms $\pm$ 15.27) and PD (67.33 ms $\pm$ 31.91) during the total recording time, but not MSA (54.68 ms $\pm$ 16.40). Regarding sleep stages, SDANN was significantly lower in HC compared to MSA in NREM1 and REM sleep, and compared to iRBD during NREM1.

Conclusions: DC may help differentiate MSA from PD and iRBD, complementing other more established HRV markers such as SDNN and SDANN. Reduced DC in MSA reflects pronounced cardiac parasympathetic dysfunction. Considering the impact of autonomic impairment on quality of life and mortality, comprehensive autonomic testing should be included in the diagnostic workup. Larger prospective studies and longitudinal follow-ups of iRBD patients are needed to validate these findings, identify prodromal markers predicting conversion to PD or MSA, and further characterize the progression of cardiac autonomic dysfunction over the diseases' courses.

Introduction: Isolated REM sleep behavior disorder (iRBD) is the early manifestation most strongly associated with the development of synucleinopathies, with over 90% of patients eventually converting to dementia with Lewy bodies (DLB) or Parkinson's disease (PD). This makes iRBD a valuable window for early intervention and the evaluation of new neuroprotective therapies. However, there remains a lack of validated, objective, and quantitative biomarkers able to predict disease progression in iRBD, notably in distinguishing progression to DLB versus PD. This study aimed to evaluate the potential of extracellular free water (FW), a diffusion MRI-based proxy of neuroinflammation, as a prognostic biomarker in one of the largest polysomnography-confirmed iRBD neuroimaging cohorts to date.

Materials and methods: Diffusion-weighted imaging scans from 438 participants (261 iRBD patients and 177 controls) were included. Of these, 230 patients were followed longitudinally, for a median of 8.4 years, during which 64 (28%) converted to a neurodegenerative disease and 166 (72%) remained disease-free. FW fractions were computed with the FreeWater Flow pipeline and extracted from the left and right Nucleus Basalis of Meynert (NBM), and posterior substantia nigra (SN). Gray matter volume estimates were also extracted from the NBM regions. FW levels were compared between groups and correlated with motor and cognitive measures. Cox regression models were used to assess the relationship between FW fractions and the likelihood of conversion to PD, DLB, or remaining disease-free. Phenoconversion outcomes were also investigated with multinomial regressions including both FW and NBM volume as covariates.

Results: No significant differences were observed in FW levels between iRBD patients and controls in either the NBM or posterior SN overall. However, stratification by phenoconversion status revealed that iRBD converters showed increased FW values in the left and right NBM and left posterior SN compared to non-converters. Higher FW in the NBM was significantly associated with an increased risk of developing DLB. While NBM volume also predicted phenoconversion to DLB, only FW in the NBM remained a significant predictor when both metrics were included in the same model.

Conclusions: Free water measurement in the SN and the NBM has the potential of predicting the development of a synucleinopathy. Notably, FW in the NBM was specifically associated with the phenoconversion to DLB, but not to PD. Our findings also highlight the greater sensitivity and specificity of FW compared with volumetric measures.

Introduction: Cognitive impairments in dementia with Lewy bodies (LBD) and Parkinson's disease (PD) are associated with cholinergic dysfunctions and volumetric reductions within the nucleus basalis of Meynert (NBM). These patients also experience severe sleep-wake dysfunction whose mechanisms relate to dysfunctions within the suprachiasmatic nucleus (SCN). Tractography allows characterizing changes in white matter (WM) tracts, including those departing from the NBM and SCN. Increased free water (FW) within these tracts has been reported in PD. However, the presence of such changes in prodromal stages, such as in isolated REM sleep behavior disorder (iRBD), remains unknown. Here, we examined the presence of FW changes in the NBM and SCN pathways in a large multicenter cohort of polysomnography-confirmed iRBD individuals and controls.

Materials and methods: A total of 621 diffusion-weighted MRI scans (275 iRBD patients and 300 controls) were processed using Tractoflow-ABS followed by bundle-specific tractography using BST-flow. Selected bundles were extracted from 9 bilateral regions, namely the lateral and medial NBM, amygdala, retino-suprachiasmatic-hypothalamic nuclei, and corpus callosum-forceps (minor and major). Statistical differences in the bundles' FW values between iRBD and control groups were tested using binomial GLM models controlling for age, age squared, sex, site, diffusion-measure (DM), age and sex interaction (FDR correction).

Results: Increased FW in the NBM pathway was found in iRBD compared to controls. This increase was observed specifically within the left lateral projections from the NBM, notably the fibers projecting to the left amygdala. An increase in FW in SCN was also observed between iRBD vs controls suggesting that white matter microstructure alterations in iRBD may involve both cholinergic and neuroendocrine circuitry. Taking account of the NBM volume, FW changes in NBM pathways seem strongly associated with PD phenoconversion

Conclusions: These findings demonstrate that NBM and SCN pathways already display changes in iRBD, potentially indicating new early biomarkers of progression in synucleinopathies such as PD and LBD

Glymphatic defect in isolated REM sleep behavior disorder is associated with phenoconversion to Parkinson's disease

V. Ayral¹, A. Pastor-Bernier², V. Daneault², C. Tremblay², M. Filiatrault¹, C. Haddad¹, J.-F. Gagnon², R.B. Postuma², P. Dusek³, S. Marecek³, Z. Varga³, J. Klein⁴, M. Hu⁴, S. Lehericy⁵, I. Arnulf⁵, M. Vidailhet⁵, J.-C. Corvol⁵, S. Rahaye¹

¹University of Montreal, Montreal, Canada, ²Center of Advanced Research in Sleep Medicine, Montreal, Canada, ³Charles University, Prague, Czech Republic, ⁴University of Oxford, Oxford, United Kingdom, ⁵Sorbonne Université, Paris, France

Introduction: Isolated rapid eye movement (REM) sleep behavior disorder (iRBD) is characterized by the loss of muscle atonia and abnormal, often violent, movements and vocalizations during REM sleep. It is the strongest prodromal marker for progression to synucleinopathies such as dementia with Lewy

bodies (DLB) and Parkinson's disease (PD). iRBD individuals already show brain changes consistent with manifest synucleinopathies, but their mechanisms remain poorly understood. Identifying brain biomarkers that predict disease progression and distinguish future phenoconversion trajectories remains a critical challenge. The glymphatic system is involved in the brain clearance of waste products and its defect has been associated with a higher likelihood of pathological burden and neurodegeneration. MRI-based diffusion tensor imaging along the perivascular space (DTI-ALPS) has been proposed as a noninvasive proxy of glymphatic function. This study aimed to determine whether iRBD patients exhibit a reduced DTI-ALPS index compared to healthy controls, and whether a lower DTI-ALPS index is associated with an increased risk of phenoconversion to PD or DLB.

Materials and methods: We analyzed diffusion-weighted brain MRI data from a large international multicentric cohort of 250 polysomnography-confirmed iRBD individuals (mean age 66.5 ± 6.8 years; 87% men) and 178 healthy controls (65.7 ± 6.8 years; 81% men), recruited across five international centers. Using advanced tractography pipeline (TractoFlow Atlas-Based Segmentation) to calculate the FA map from the ICBM_DTI-81 atlas, we created cubic binary masks (5mm) on bilateral associative and projection fibers at the level of the lateral ventricle. These masks were then aligned to the standard space of each participant using ANTs, followed by quality control. The masks were then multiplied by each directional diffusivity map (x,y,z) obtained from the Tractoflow (FA RGB) results in the subject space. Left and right DTI-ALPS indices were extracted, harmonized for scanner effects, and compared between groups. Cox regression models assessed the relationship between glymphatic index and the likelihood of conversion to PD, DLB or remaining disease-free.

Results: We found a significantly reduced left DTI-ALPS index in iRBD individuals compared to controls (mean difference = -0.034, 95% CI: -0.067 to -0.001; $P = 0.043$). Among the 224 iRBD individuals followed longitudinally (6.1 years, ± 3.5 years), 65 phenoconverted to a synucleinopathy. iRBD converters exhibited lower left DTI-ALPS index compared to non-converters (mean difference = -0.050, 95% CI: -0.098 to -0.003; $P = 0.038$). There was no significant difference between groups for the right DTI-ALPS index. Lower left DTI-ALPS index was associated with increased conversion risk to PD over time (hazard ratio = 2.43, 95% CI: 1.13 to 5.25; $P = 0.012$). Other diffusion metrics inside periventricular masks, namely fractional anisotropy, diffusivity metrics and free water, did not differ between groups.

Conclusions: iRBD patients exhibit reduced DTI-ALPS index, suggesting altered glymphatic function. This reduction was associated with future phenoconversion to PD, supporting the DTI-ALPS index as a potential prognostic MRI biomarker of progression in prodromal synucleinopathies.

Gut microbiota in major depressive disorders with rapid eye movement behavior disorder: tracing a subtype of depression with underlying neurodegeneration

Introduction: REM sleep behavior disorder (RBD) is a parasomnia associated with α -synucleinopathy. RBD features are more common in major depressive disorder (MDD). While initially postulated as an antidepressant-induced phenomenon, emerging evidence suggests that MDD comorbid with RBD (MDD+RBD) represents underlying neurodegeneration. The gut-brain axis is increasingly recognized in both depression and neurodegeneration, with PD-like gut dysbiosis observed in idiopathic RBD (iRBD). This study aims to characterize gut microbiome in MDD+RBD to explore its potential as a distinct depressive subtype with neurodegenerative features for etiological understanding and intervention.

Materials and methods: This case-control study included four groups: patients with MDD+RBD, age- and sex-matched MDD without RBD (MDD-only), healthy control (HC), and iRBD without a psychiatric disease. RBD diagnosis was confirmed by video-polysomnography. MDD+RBD was defined as MDD onset preceding the appearance of RBD. Fecal samples were analyzed using metagenomic sequencing.

Results: A total of 420 participants were included: 124 HC, 80 MDD-only, 82 MDD+RBD and 134 iRBD. The mean age and sex distribution were comparable among HC (65.7 ± 7.0 years, 61.3% male), MDD-only (65.6 ± 6.5 years, 50.0% male), and MDD+RBD (66.3 ± 5.6 years, 62.2% male). However, iRBD group was slightly older (67.9 ± 6.1 years) and had a higher proportion of males (78.4%) compared to the HC group.

1. **Psychiatric and gastrointestinal features:** The psychiatric profiles of MDD-only and MDD+RBD were largely comparable. Regarding gastrointestinal features, lower Bristol stool scale scores (BSS, harder stool) were observed in iRBD and MDD+RBD, compared to MDD-only and HC (3.3 ± 1.2 vs 3.2 ± 1.5 vs 4.2 ± 1.3 vs 4.1 ± 1.1 , $q < 0.001$).
2. **Neurodegenerative biomarkers:** The total likelihood ratio for prodromal PD (excluding RBD) was higher in MDD+RBD than iRBD, MDD-only and HC (1.78 ± 1.11 vs 1.38 ± 0.97 vs 0.74 ± 0.70 vs 0.44 ± 0.55 , p -value < 0.001).
3. **Microbial profiles:** After adjusting for age, sex and BSS, MDD+RBD exhibited a distinct microbial composition compared to both HC ($R^2 = 0.012$, q -value = 0.003) and MDD-only ($R^2 = 0.011$, q -value = 0.013), while its microbiota composition was similar to that of iRBD ($R^2 = 0.0052$, q -value = 0.26). In contrast, MDD-only was similar to HC in terms of microbial clustering. Taxonomic analysis, adjusting for age, sex and BSS, revealed that MDD+RBD displayed a gut dysbiosis with both PD-associated species (e.g., enriched *Akkermansia muciniphila*, *Ruthenibacterium lactatiformans*, and depleted SCFA-producer *Faecalibacterium prausnitzii*) and depression-related (e.g., enriched *Eggerthella lenta* and decreased *Coprococcus eutactus*) alterations. Random Forest model showed that microbial species and GI features could effectively differentiate MDD+RBD from MDD-only (AUC = 0.78).

Conclusions: MDD+RBD exhibited a gut dysbiosis similar to that of iRBD, whereas MDD-only subjects resembled more closely to HC, suggesting that MDD+RBD is likely a variant of depression with underlying neurodegeneration. In addition, the gut microbiome might serve as a promising biomarker for early neurodegenerative risk stratification in psychiatric populations. Our findings offer novel insights into microbiota-gut-brain axis, highlighting its role in the intersection of depression and neurodegeneration.

Introduction: Accumulating evidence indicates that habitual diet, including plant-based dietary patterns, are associated with the risk of developing neurodegenerative alpha-synucleinopathy. However, the role of dietary pattern and its correlation with gut microbiome at prodromal alpha-synucleinopathy, i.e., among patients with isolated REM sleep behavior disorder (iRBD), are largely unclear. This study aims to evaluate the associations of dietary patterns with iRBD and their interactions with gut microbial dysbiosis. Additionally, the effect of dietary factors on neurodegenerative progression in patients with iRBD was further examined.

Materials and methods: A total of 287 iRBD patients (66.9 ± 7.1 years, 74.6% males) and 208 controls (66.6 ± 7.3 years, 68.3% males) were involved in the study. Plant-based diet indices (overall plant-based diet index, oPDI; healthful plant-based diet index, hPDI; and unhealthful plant-based diet index, uPDI) were derived from food frequency questionnaire based on 20 food groups. The shotgun metagenomic sequencing for microbiome was performed in 452 subjects (261 iRBD vs. 195 controls) for further diet-microbiome analyses. After a median of 4.1 years, 45 (15.7%) iRBD patients converted to alpha-synucleinopathies. The impact of habitual diet on neurodegenerative outcomes were analysed using Cox proportional hazards models.

Results: Multivariable logistic regression models showed that subjects in the highest quartile of hPDI experienced 52% lower odds of iRBD (OR [95% CI]: 0.48 [0.29, 0.80], $P = 0.005$) compared to the lowest quartile, whereas that of uPDI would increase the odds of iRBD by 73% (1.73 [1.03, 2.91], $P = 0.04$). In terms of individual food groups, iRBD patients had lower intake of whole grains and were prone to consume more refined grains. Notably, the association of uPDI with iRBD was significantly more pronounced in subjects with depression (OR [95% CI]: 1.93 [1.26, 2.95], $P = 0.002$) and those who were physically inactive ($P = 0.01$). Gut metagenomic analysis revealed that habitual diet was linked to the variations in microbial composition and changes in individual microbes among iRBD patients. Further mediation analyses suggested that 39.1% ($P = 0.006$) of the effects of uPDI on iRBD were mediated by iRBD-enriched microbial species *Ruthenibacterium lactatiformans*. During follow-up, iRBD with higher baseline coffee drinking had a decreased risk of converting to alpha-synucleinopathy (Multivariate-adjusted HR [95% CI] = 0.22 [0.06, 0.74], $P = 0.01$), especially parkinsonism-first conversion (0.11 [0.02, 0.66], $P = 0.02$), whereas increased whole grain consumption was associated with lower risk of dementia (0.06 [0.004, 0.87], $P = 0.04$).

Conclusions: Patients with iRBD consumed more unhealthful plant-based diet and a decreased intake of healthful plant-based foods, such as whole grains. The habitual diet in iRBD is closely associated with gut microbiome dysbiosis with predictive value for neurodegenerative progression. The findings suggest that diet, gut microbiome, and their interplay might hold potential value for future interventions in alpha-synucleinopathy neurodegenerative diseases.

Introduction: REM Sleep Behavior Disorder (RBD), a parasomnia characterized by dream enactment and loss of muscle atonia during REM sleep, is one of the most specific prodromal markers of neurodegenerative synucleinopathies, including Parkinson's disease. Individuals with RBD often exhibit signs of autonomic dysfunction—including altered heart rate variability, abnormal respiratory patterns, and impaired blood pressure regulation—even in the absence of overt neurodegenerative disease. Despite its clinical significance, RBD remains underdiagnosed due to the reliance on resource-intensive video polysomnography (vPSG) for confirmation. Physiological signals such as respiration and heartbeat can now be collected continuously across multiple nights using wearable or nearable home-based devices, enabling scalable and non-invasive route for RBD screening. In this study, we developed and validated a novel artificial intelligence (AI) model for detecting vPSG-confirmed RBD based on such accessible nocturnal biosignals.

Materials and methods: This multi-center study comprised 1,323 nights of in-clinic PSG recordings, including 447 vPSG-confirmed RBD cases (72.9% male, mean age 66.3 ± 9.1 years) and age- and sex-matched controls (1:2 ratio, screened to exclude Parkinsonism and RBD). Data were sourced from six clinical centers: Chinese University of Hong Kong, Ruijin Hospital, Second Affiliated Hospital of Soochow University, Sir Run Run Shaw Hospital, Shanghai Sixth People's Hospital, and Inner Mongolia Mental Health Center. The dataset was split into training (70%), validation (15%), and testing (15%) subsets. Respiratory and cardiac signals were extracted from each night of PSG, focusing on features that are potentially measurable in non-laboratory environments. Our Transformer-based foundational model was pre-trained on 44,451 PSG recordings using heartbeat and abdominal-respiration signals. The model learned high-dimensional representations by predicting EEG spectrograms and oxygen desaturation events. It was then fine-tuned for RBD diagnosis using a multilayer perceptron. External validation was performed on an independent dataset from the Affiliated Brain Hospital of Guangzhou Medical University (39 cases, 41 controls).

Results: On the internal testing dataset, the model achieved an accuracy of 86.4%, recall of 80.0%, precision of 78.8%, specificity of 89.6%, and an area under the receiver operating characteristic curve (AUROC) of 0.921. On the external validation dataset, accuracy was 76.3%, with a recall of 84.6%, precision of 71.7%, specificity of 68.3%, and AUROC of 0.872. While there was a moderate decline in overall accuracy and specificity (68.3%) on the external cohort, the model maintained high sensitivity and strong discriminative performance, suggesting robustness in identifying true RBD cases across clinical populations using only respiration and heartbeat-derived features.

Conclusions: Our findings demonstrate the potential of nocturnal respiration and heartbeat signals as digital biomarkers for RBD detection. Their compatibility with wearable and nearable devices makes them well-suited for multi-night, home-based screening applications. The AI-based framework performed consistently across multiple clinical centers, highlighting its applicability as a non-invasive, scalable tool for RBD screening. Further research should assess its utility in home settings and longitudinal value for predicting neurodegenerative disease progression.

Integrated gut microbiome and metabolome analysis in isolated REM sleep behavior disorder

China, ⁶The Chinese University of Hong Kong, Faculty of Medicine, Li Ka Shing Institute of Health Sciences, Hong Kong, Hong Kong, SAR of China

Introduction: Isolated REM sleep behavior disorder (iRBD) is considered as the most specific prodromal marker of alpha-synucleinopathies, including Parkinson's disease (PD). Emerging evidences suggest similar gut microbiota dysbiosis between iRBD and PD. Fecal metabolomics provide a functional readout of microbial activity, and several key metabolites may play crucial roles in the pathophysiology of PD, including substrates of choline metabolism, amino acids (glutamate and tyrosine), bile acids and long chain saturated fatty acids. However, to date, fecal metabolomics of iRBD has not been thoroughly investigated. This study aims to explore the alterations in fecal microbiome and metabolome in patients with iRBD, along with their possible interactions.

Materials and methods: This is a cross sectional study, including 224 video-polysomnography confirmed iRBD (68.2 ± 7.3 years old, male 73.2 %) and 127 healthy controls (65.7 ± 7.5 years old, male 62.2 %). Fresh stool samples were collected from both groups. Gut microbiota was analyzed using shotgun metagenomic sequencing. Untargeted fecal metabolomics were performed using liquid chromatography–mass spectrometry.

Results: Fecal metabolomics analysis identified 296 metabolites distributed across 37 metabolic pathways. After adjusting for age and gender, 57 differential metabolites were identified (false discovery rate [FDR] < 0.1). Majority of the differential metabolites (N = 45) were more abundant in the iRBD group, including elevated fatty acids (Oleic acid, Myristic acid, traumatic acid) and lipid peroxidation products (15,16-DiHODE, 12(13)-DiHOME, 16-hydroxyhexadecanoic acid), suggesting the potential presence of an inflammatory state and oxidative stress in the gut of iRBD patients. Elevated levels were also observed for amines such as phenylethanolamine, anandamide (AEA), L-histidinol, as well as lithocholic acid, indole and its derivative 2-oxindole. For the metabolites which were decreased in iRBD, Leucine has the most significant depletion, which may indicate disrupted branched-chain amino acid (BCAA) catabolism in iRBD patients.

For the metagenomics, a total of 21 differential microbial species were found between iRBD and controls (false discovery rate [FDR] < 0.1 after adjusted age and gender). For example, the abundances of *Anaeromassili bacillus* sp An250, *Christensenellaceae* bacterium NSJ 63 and *Lachnospiraceae* bacterium NSJ 29 were increased, while *Clostridium fessum* and *Faecalibacterium prausnitzii* were depleted in the iRBD group. We then examined the correlations between differential metabolites and microbial species in both groups. Of note, iRBD-enriched species *Christensenellaceae* bacterium NSJ 63 was widely associated with fecal metabolites indole, leucine, lysophosphatidylglycerol (lysoPG) and lithocholic acid, while these associations were not found in the control group, suggesting that the pathogenesis of iRBD may be closely linked to gut microbiota-mediated metabolic reprogramming.

Conclusions: The gut metabolome, including BCAA degradation, bile acid biosynthesis, phospholipid biosynthesis and tryptophan metabolism, is altered in iRBD, providing important biological insights into the gut-brain pathophysiology of alpha-synucleinopathies. Gut microbiota imbalance may be a driving factor underlying the gut metabolic alterations. These findings support a role for microbial metabolites as potential targets for the development of new biomarkers and therapies in iRBD.

Investigating Cognitive Performance in Isolated REM sleep Behavior Disorder Patients with Digital-based Cognitive Tests

T.C. Lam^{1,2}, Z. He^{1,2}, J. Ni^{1,2}, Y. Ye^{1,2}, S. Tang^{1,2}, Y. Yang^{1,2}, S. Gong^{1,2}, N. Li^{1,2}, J.WY. Chan^{1,2}, B. Huang^{1,2,3}, Y.K. Wing^{1,2,3}

¹The Chinese University of Hong Kong, Department of Psychiatry, Faculty of Medicine, Shatin, Hong Kong, SAR of China, ²The Chinese University of Hong Kong, Li Chiu Kong Family Sleep Assessment Unit, Department of Psychiatry, Faculty of Medicine, Shatin, Hong Kong, SAR of China, ³The Chinese University of Hong Kong, Li Ka Shing Institute of Health Sciences, Faculty of Medicine, Shatin, Hong Kong, SAR of China

Introduction: Isolated rapid eye movement sleep behavior disorder (iRBD) is a well-recognized prodromal syndrome for a-synucleinopathy including Parkinson's disease (PD), associated with

progressive motor dysfunction and cognitive decline. Emerging evidence has indicated that digital measurements provide a sensitive and reliable means to characterize cognitive dysfunctions in PD. This study aims to assess the cognitive performance of iRBD patients with different levels of prodromal Parkinson's disease (pPD) risk using digital-based cognitive tests.

Materials and methods: A total of 354 subjects were enrolled in this study, including 160 controls (mean age 65.8 years, 48.8% males) and 194 video-polysomnography confirmed iRBD patients (68.5 years, 71.6% males). Probability of pPD was calculated according to the 2019 criteria of International Parkinson and Movement Disorder Society 2019 criteria (MDS). Patients with iRBD were stratified into low-to-moderate pPD risk (probability < 0.8, N = 66) and high pPD risk (probability $\geq$ 0.8, N = 128) groups. Cognitive data were collected via the self-developed mobile app SmartBrainApp™, which includes psychomotor vigilance task (PVT), clock setting test, color trails test (CTT), symbol digital modalities test (SDMT), 1-back and 2-back memory tasks, and color vision task. One marker from each task was analyzed to explore group differences using ANCOVA with age as covariate variable and Spearman's correlation was used to examine the relationship between the pPD risk scores and task performance.

Results: Those iRBD patients with high pPD risk showed significantly longer reaction time in SDMT when compared to controls (3.24 vs 2.47, $p < 0.001$) and low-to-moderate risk iRBD patients (3.24 vs 2.61, $p = 0.014$). In addition, the PVT overall reaction time ($p = 0.004$), CTT completion time ($p < 0.001$), and color vision incorrect counts ($p < 0.001$) were higher, while 1-back task d prime ($p < 0.001$) and 2-back task d prime ($p < 0.001$) were lower in high pPD risk iRBD when compared to the controls. No significant differences were found between low-to-moderate risk iRBD and control groups.

In iRBD patients, Spearman's correlation analysis showed weak positive correlations between pPD risk scores and SDMT reaction time ($r = 0.307$, $p < 0.001$). Weaker correlations were observed in CTT completion time ($r = 0.194$, $p = 0.007$), PVT overall reaction time ($r = 0.158$, $p = 0.028$), color vision incorrect counts ($r = 0.156$, $p = 0.03$). Mild negative correlation was also found in correct counts of clock setup test ($r = -0.154$, $p = 0.033$) and 1 back task d prime ($r = -0.25$, $p < 0.001$).

Conclusions: Digital cognitive assessment unveils impairment in working memory, color vision, attention, and executive function among iRBD patients with high pPD risk, whereas those with low-to-moderate pPD risk exhibit no significant deficits. CTT and SDMT are the digital cognitive markers most associated with pPD risk in patients with iRBD. These findings underscore the potential utility of digital biomarkers in stratifying prodromal PD risk and tracking neurodegenerative progression.

Long-term Follow-up of Olfactory Function in isolated REM-Sleep Behaviour Disorder

M. Aktan Süzgün¹, A. Ibrahim¹, M.V. Anselmi Innaco¹, E. Holzknecht¹, E. Brandauer¹, M. Cesari¹, B. Högl¹, A. Stefani¹

¹Medical University of Innsbruck, Department of Neurology, Innsbruck, Austria

Introduction: The presence of hyposmia in isolated REM sleep behaviour disorder (iRBD) is known as a biomarker of short-term phenoconversion to overt alpha-synucleinopathy, in particular Parkinson's disease (PD). Yet, research about the longitudinal changes in olfactory function over time in iRBD is scarce. One cohort study reported a stable course of olfactory function in iRBD (Iranzo A et al. 2013), although these findings have not been replicated so far. This study aimed at investigating long-term changes in olfactory function in patients with iRBD.

Materials and methods: This long-term observational cohort study was conducted at the Centre for Sleep Medicine, Department of Neurology, Medical University Innsbruck, from 2006 to 2025. Patients with iRBD were consecutively included after polysomnography-based diagnosis and were followed up regularly. Follow-ups included clinical assessment to detect phenoconversion, and biomarker assessment including the Sniffin' Stick 16-item identification test. Olfaction scores were categorized into normosmia, hyposmia or anosmia according to age- and sex-based cut-offs. Olfactory function changes over time were compared among those with iRBD at the last follow-up versus those who phenoconverted during the follow-up time.

Results: A total of 88 patients (90.9% men) with ≥ 2 follow-ups were included. After a mean of 54.2 ± 46.4 months of follow-up, 15 patients phenoconverted (10 to PD, 4 to DLB and 1 to multisystem atrophy)[SA1]. The mean age at baseline was 65.1 ± 10.0 years[SA2]. The baseline olfaction score was

12 (3-16) in those with iRBD at follow-up (hyposmia/anosmia 45.0%), and 9 (5-16) (hyposmia/anosmia 60.0%) in phenoconverters, *p* ns. At follow-up, the median olfaction score was 11 (0-16) in the whole cohort, 12 (0-6) in iRBD (hyposmia/anosmia 51.0%) and 8 (4-14) in phenoconverters (hyposmia/anosmia 87.0%), *p*=0.020 for olfaction score and *p*=0.010 for olfactory dysfunction. The increase in hyposmia/anosmia over time was significant only in phenoconverters (*p*=0.046). The percentage of patients who normal olfaction over time was significantly lower in phenoconverters compared to patients with iRBD at last follow-up (13.0% versus 36.9%, *p*=0.032). Eight (9.1%) patients, all with iRBD at the last follow-up, presented an improvement in olfactory function over time [first score: 10.5 (5.0-11.0), last score: 13.0 (12.0-16.0), *p*=0.005].

[SA1]These must be DLB... Please remind me to check this with you during one of our meetings. In the meanwhile, keep them as DLB for the submission

[SA2]Not needed as you report FU time

Conclusions: The high percentage of olfactory dysfunction in phenoconverters in our cohort confirms hyposmia/anosmia as a marker of phenoconversion in iRBD. In contrast to previous studies, we found a worsening in olfactory dysfunction over time in phenoconverters, suggesting that longitudinal monitoring of olfactory function in patients with iRBD could improve the prediction of phenoconversion risk.

Introduction: Idiopathic rapid eye movement sleep behavior disorder (iRBD) is the strongest prodromal markers of α -synucleinopathy, including Parkinson's disease (PD), dementia with Lewy bodies, and multiple system atrophy. PD patients demonstrated altered impulsivity, usually attributed to dopaminergic agonists. Our previous study observed a complex construct of altered impulsivity in iRBD and early PD patients, manifested as decreased risk taking and increased reflection impulsivity. While corticostriatal circuits have been implicated in decisional impulsivity in healthy individuals, their precise role underlying decisional impulsivity across early α -synucleinopathy remains unclear. This study aims to investigate the neural correlates associated with the altered decisional impulsivity in early α -synucleinopathy.

Materials and methods: This was a case-control study conducted among controls, iRBD, and PD patients. Early PD patients were diagnosed with United Kingdom PD Brain Bank criteria with motor symptoms onset within five years. Participants underwent clinical assessments and 3T MRI scanning, including structural, resting-state, and task-based fMRI. Decisional impulsivity was measured using the Balloon Analogue Risk Task (BART) for risk taking and beads task for reflection impulsivity. Regions of interest (ROIs) were selected along corticostriatal circuits. Seed-based functional connectivity (FC) was computed with subcortical ROIs serving as seeds.

Results: A total of 97 patients, including 25 controls (mean age=67.7, male 57.7%), 40 iRBD patients (mean age=70.6, male 72.5%), and 32 PD patients (mean age=69.7, male 89.7%) were recruited. PD and iRBD patients exhibited elevated reflection impulsivity compared to controls, as evidenced by fewer extracted beads (PD vs. iRBD vs. controls: 3.6 ± 2.4 vs. 3.7 ± 2.1 vs. 4.9 ± 2.6 , *P*=0.03).

Meanwhile, risk taking level on the BART was comparable among groups. fMRI analyses revealed augmented neural activities in both ventral and dorsal striatum in iRBD patients during risky decision-making in the BART. Regarding the reflection impulsivity, PD and iRBD patients exhibited enhanced BOLD activations in mPFC during "beads-drawing" phase compared to controls, whereas iRBD patients

showed additional involvement of right ACC/OFC and left parietal lobe during the same phase ($P_{FWE} < 0.05$, TFCE). Further ROI analyses corroborated the findings and additionally revealed increased engagement in bilateral ventral striatum (VS) in PD patients (PD vs. control: right NAc: $0.07[-0.41, 0.70]$ vs. $-0.59[-1.55, -0.26]$, $P=0.002$; left NAc: $0.35[-0.21, 1.16]$ vs. $-1.13[-2.06, 0.05]$, $P=0.03$), whereas enhanced activation in right VS in iRBD patients (iRBD vs. controls: $-0.06[-0.66, 0.44]$ vs. $-0.59[-1.55, -0.26]$, $P=0.002$). Seed-based FC analyses revealed attenuated connectivity in PD patients between right NAc and multiple regions including the bilateral frontal and parietal cortex, striatum, thalamus, and cerebellum. Additionally, iRBD patients displayed decreased FC between the pallidum and both the putamen and OFC. ($P_{FWE} < 0.05$).

Conclusions: Alterations of decisional impulsivity, especially the reflection impulsivity, have already occurred in early α -synucleinopathies. Neuroimaging analyses revealed both the disrupted connectivity which potentially impaired reward networks and the recruitment of corticostriatal circuits contributing to decisional impulsivity deficits. Notably, altered decisional impulsivity in iRBD might reflect compensatory mechanisms following striatal dopamine neurons denervation, suggesting its potential utility as a phenoconversion marker.

Neurodegeneration and Sleep Instability: A CAP-Based Comparison in RBD Patients

E. Ay¹, M. Aksu¹

¹Acibadem Mehmet Ali Aydinlar University, Department of Neurology, Istanbul, Turkey

Introduction: REM Sleep Behavior Disorder (RBD) involves dream enactment and loss of REM muscle atonia. Idiopathic RBD (iRBD) often precedes α -synucleinopathies such as Parkinson's Disease (PD), Dementia with Lewy Bodies (DLB), and Multiple System Atrophy (MSA). Identifying early physiological changes in these patients is critical for intervention and monitoring. The Cyclic Alternating Pattern (CAP), a measure of sleep instability, and the Epworth Sleepiness Scale (ESS), a subjective measure of daytime sleepiness, may reflect early neurodegenerative changes. We conducted a pilot investigation to assess whether these markers differ between RBD patients with and without neurodegeneration.

Materials and methods: This cross-sectional case-control study included 8 patients recruited from a tertiary sleep and movement disorders clinic. All patients had PSG-confirmed RBD, with 4 classified as iRBD (no evidence of neurodegenerative disease after ≥ 12 months of follow-up) and 4 as nRBD (clinical diagnosis of PD, DLB, or MSA).

All participants were 18 years or older and underwent diagnostic overnight PSG demonstrating REM sleep without atonia (RSWA) and/or dream enactment behavior. The ESS was completed within one month of the PSG. Patients were excluded if they were taking medications that could significantly alter sleep architecture (e.g., sedatives, antidepressants) or had comorbid sleep disorders such as obstructive sleep apnea with an apnea-hypopnea index (AHI) ≥ 15 .

Sleep recordings were manually scored in accordance with AASM criteria. Sleep macrostructure parameters included total sleep time (TST), wake after sleep onset (WASO), and sleep efficiency. CAP was scored visually and included CAP rate (percentage of NREM sleep containing CAP sequences), average CAP duration, and the distribution of phase A subtypes (A1, A2, A3). REM-related arousals and total nocturnal arousals were also recorded.

Descriptive statistics were used to compare groups. Given the small sample size, inferential statistical testing was interpreted with caution. Exploratory correlations between ESS scores and PSG features were examined.

Results:

The nRBD group demonstrated a higher CAP rate ($47.8\% \pm 9.1$) compared to the iRBD group ($36.2\% \pm 7.6$, $p < 0.001$). A2 and A3 subtypes were significantly more prevalent in the nRBD group ($p = 0.002$ and $p = 0.009$, respectively), while A1 subtype was lower. REM sleep in nRBD was more fragmented, with increased arousals (12.4 ± 4.1 vs. 7.9 ± 3.6 , $p < 0.001$), and macrostructure was also impaired, with greater WASO and lower sleep efficiency.

Conclusions: Our findings suggest that patients with RBD and neurodegenerative disease exhibit marked sleep instability, particularly reflected in CAP metrics and REM fragmentation. Subjective daytime sleepiness, as measured by ESS, also trended higher in the nRBD group and correlated with CAP-related disruptions, suggesting that these may serve as early physiological signals of underlying neurodegeneration. CAP analysis and ESS may serve as accessible and non-invasive markers to help identify RBD patients at elevated risk of neurodegeneration. Further validation in larger cohorts is needed to confirm these preliminary findings and refine their diagnostic utility.

Neurodegenerative quantification of the putamen in REM sleep behaviour disorder and its impact on brain connectivity architecture

Introduction: Isolated REM sleep behaviour disorder (iRBD) is characterized by a loss of sleep atonia during REM sleep. It's considered a prodromal stage of synucleinopathies, with ~90% of individuals with iRBD developing Parkinson's disease (PD) or dementia with Lewy body (DLB) within 15 years. Synucleinopathies are characterized by a loss of dopaminergic neurons projecting to the putamen, responsible for movement coordination. Dopamine-binding tomography methods fail to measure dopaminergic loss in around 30% of iRBD patients.

MRI is particularly sensitive to brain changes in iRBD, with previous studies identifying atrophy in the putamen.

However, it remains unknown whether this atrophy follows a topographical pattern reflective of dopamine depletion and associated with the organization of structural connectivity networks. Our objective was to investigate using T1- and diffusion-weighted imaging how atrophy affects the morphology of the putamen in iRBD and its impact on architectural organization of brain connectivity.

Materials and methods:

This study includes 198 iRBD participants confirmed by video-polysomnography followed longitudinally and 121 age- and sex-matched healthy controls. All underwent T1- and diffusion-weighted brain MRI in 6 sites as part of an international multi-center initiative. T1 scans were processed using deformation-based morphometry in CAT12 to measure the extent of non-linear deformation required to fit a subject's brain to the template, yielding a map of local tissue deformation for each participant. The putamen was segmented on these maps and divided into segments along the medial-lateral, anterior-posterior, and ventro-dorsal axes to examine the spatial pattern of atrophy.

Diffusion-weighted MRI scans were processed to reconstruct via tractography each participant's structural connectivity matrix. Connectivity strength measured between every pair of regions (463 regions). BrainSpace was used to reduce the dimensionality of these matrices and derive the most significant connectivity gradients for each participant. Gradient expressions were compared between groups to identify whether the putamen was abnormally weighted in each gradient.

Linear mixed models were used on the deformation values to assess a group*segment effect in the putamen and linear regressions to assess a group effect on the putamen's weight on each connectivity gradient.

Time-to-event analyses were done to assess whether deformation in the putamen predicted phenoconversion to PD or DLB using Cox regression.

Results: There was a significant group*segment interaction effect, indicating that iRBD patients had more atrophy in the left hemisphere and that this atrophy followed a medial-lateral gradient. The lateral part showed significantly more atrophied; this atrophy significantly predicted phenoconversion into PD compared to any other progression phenotype. In iRBD patients and controls, 3 gradients of connectivity were identified. Gradient analysis revealed that the putamen's connectivity was impaired on the first gradient of connectivity (explaining the most variance), while it was preserved on the other gradients. This indicates that the putamen becomes disconnected in iRBD but not entirely segregated.

Conclusions: In iRBD, the putamen shows tissue deformation in the lateral segment and gradient-specific alterations in the brain's connectivity architecture.

Lateral tissue deformation in putamen predicts PD in iRBD.

Neuroprotective Effect of Melatonin in Isolated Rapid Eye Movement Sleep Behavior Disorder

Y. Liu^{1,2}, J. Wang^{1,2}, B. Huang², Y. Yang², L. Zhou², N. Li², S. Gong², H. Feng^{1,2}, J. Zhang^{1,2}, V.C. Mok³, Y.K. Wing^{2,4}

¹Guangzhou Medical University, Center for Sleep and Circadian Medicine, Guangzhou, China, ²The Chinese University of Hong Kong, Department of Psychiatry, Hong Kong, Hong Kong, SAR of China, ³The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong, Hong Kong, SAR of China, ⁴The Chinese University of Hong Kong, Li Ka Shing Institute of Health Sciences, Hong Kong, Hong Kong, SAR of China

Introduction: Over 90% of the patients with isolated rapid eye movement (REM) sleep behavior disorder (iRBD) will have a phenoconversion into a subtype of neurodegenerative diseases including Parkinson's disease and dementia over time. It remains unclear whether melatonin, a known hormone and one of the first-line symptomatic treatments of RBD, yields neuroprotective effect in iRBD.

Materials and methods: This study was conducted based on a longitudinal cohort of iRBD patients with naturalistic clinical follow-up of prescription, repeated neuropsychological assessments, and reevaluation on status of phenoconversion. To compare the potential neuroprotective effect of melatonin in iRBD, we first dichotomized the subjects into 'with melatonin' and 'without melatonin' by duration of melatonin use (e.g. 'with melatonin' was defined by using melatonin for at least one year and exceeding half of the follow-up duration). Generalized linear mixed models and Cox proportional regression models were fitted to compare the longitudinal change of neurodegenerative biomarkers, and the risk of conversion to neurodegenerative diseases between two conditions, respectively. Second, melatonin was treated as a time-varying covariate in the time-dependent survival analysis to investigate its effect by handling its varied dosage across the follow-up duration. Besides, the least optimal dosage of melatonin was also estimated for its neuroprotective effect.

Results: A total of 194 iRBD patients were included (66.2 ± 7.3 years, 72.2% male), with a mean follow-up duration of 5.5 years. Comparing with iRBD patients without melatonin (66.2 ± 7.9 years, 72.4% male), those with melatonin (66.2 ± 6.7 years, 71.9% male) showed a lower risk of phenoconversion (adjusted HR [95%CI] = 0.49[0.27, 0.87]), particularly for DLB (0.30[0.11, 0.82]). When considering the time-varying dosages of melatonin during follow-up, the neuroprotective effect of melatonin held (aHR [95%CI] = 0.91[0.84, 0.98]) with a least optimal dosage estimated at 7.25mg. At biomarkers level, iRBD patients with melatonin showed a slower decline of severity of RBD symptoms (group*time interaction, β [95%CI] = 0.94 [0.13, 1.74]) and cognitive performance (0.007 [0.001, 0.01]), and a slower deterioration in color vision (-0.020 [-0.022, -0.018]), visuospatial and attention (-0.018 [-0.033, -0.002]), and motor coordination function (-0.016 [-0.027, -0.006]).

Conclusions: Clinical prescription of melatonin for iRBD symptom management might also have a neuroprotective effect to delay the phenoconversion risk with a dose-response manner. Future research, especially randomized controlled trials and animal studies, is warranted to corroborate efficacy and mechanisms.

Pathological α -synuclein in surplus biopsies and surgical resections of peripheral organs in idiopathic REM sleep behaviour disorder

G. Mayà¹, A. Iranzo¹, J.A. Guerrero², M. Serradell¹, S. Charif³, V. Santiago³, J. Santamaria¹, C. Gaig¹, I. Aldecoa²

¹Hospital Clínic de Barcelona, Spain, Sleep Center, Neurology department, Barcelona, Spain, ²Hospital Clínic de Barcelona, Spain, Pathology department, Barcelona, Spain, ³Universitat de Barcelona, Neurological Tissue Bank of the Biobank-FCRB/IDIBAPS, Barcelona, Spain

Introduction: α -Synuclein deposits (AS) have been found in transversal studies in peripheral organs in patients with idiopathic REM sleep behavior disorder (IRBD) with high specificity and variable sensitivity. When available, surplus biopsies or surgical resections previously obtained for the clinical practise could be leveraged for this detection avoiding side effects.

Materials and methods: unicentric case-control study with 161 blocks from 49 IRBD subjects and matched controls obtained from the pathology service biorepository between 1998-2023.

Immunohistochemistry studies were performed with two antibodies against phosphorylated and oligomeric AS (p-AS and o-AS) in the peripheral autonomic nervous tissue and evaluated positive or negative.

Results: 161 blocks from 49 IRBD patients were assessed. IRBD patients mean age at the time of block acquisition was 70.6 ± 8 years, and 89.4% were male. Samples were obtained in different clinical stages: presymptomatic RBD (n=34), symptomatic RBD stage before the diagnostic polysomnogram (n=38), polysomnography-proven IRBD (n=74), and Parkinson disease or Dementia with Lewy bodies (PD/DLB, n=15). Blocks were obtained from the gastrointestinal tract (49.7%), the genitourinary tract (35.4%), and the skin (14.9%). The p-AS and o-AS had a sensitivity of 6.8% and 11.2% respectively, and 99.4% specificity both, although their correlation was small (ϕ 0.23, $p < 0.001$). A trend of higher AS positivity with clinical progression of sinucleinopathy was found from 5.9% in the earliest presymptomatic RBD stage to 20% in PD/DLB. Unspecific background limited the evaluation of half of p-AS blocks. Eighteen percent of IRBD patients had a positive block with p-AS, and 28.6% with o-AS, compared to 0.8% with p-AS, and 0.8% with o-AS in controls (all $p < 0.001$); 30.6% of IRBD subjects had ≥ 1 positive block with any antibody (p-AS and/or o-AS) versus 1.6% of controls ($p < 0.001$).

Conclusions: The use of heterogeneous previous acquired surplus peripheral tissue blocks to identify AS deposits in IRBD has a low sensitivity but a high specificity. AS pathology can be present in the PANS even years antedating RBD symptoms and probably spreads throughout the PANS with disease progression. In selected cases that RT-QulC for misfolded AS detection is not available, AS immunohistochemistry studies using previous peripheral samples could be considered.

Prevalence of idiopathic REM sleep behaviour disorder in the Spanish community

G. Mayà Casalprim¹, M. Qi Ye², E. Senar², M.F. Poblete², C. Gaig¹, L. Molina³, S. Casablanças², A. Iranzo¹

¹Hospital Clínic de Barcelona, Spain, Sleep Center, Neurology department, Barcelona, Spain, ²CAPSBE Consorci d'Atenció Primària de Salut Barcelona Esquerra, CAP Casanova, Barcelona, Spain, ³Hospital Clínic de Barcelona, Spain, Alzheimer and Other Cognitive Disorders Unit, Neurology Department, Barcelona, Spain

Introduction: Idiopathic REM sleep behavior disorder (iRBD) is a parasomnia with a typical age of onset over 50 years-old characterized by enacting dreams and the loss of REM sleep muscular atonia.

Diagnosing iRBD in the general population is challenging because it requires a video-polysomnography (PSG), a costly test that involves overnight monitoring in a sleep laboratory. Only two IRBD prevalence studies in the general population, both in South Korea, performed a PSG in all the subjects assessed. Kang et al. (2013) found in subjects of >60 years-old a prevalence of 1.15% [IC 95% 0.31-2.92], and Lee et al., (2023) in subjects between 50-80 years-old, of 1.4% [IC 95% 1-1.8]. In addition, five studies have evaluated the prevalence of iRBD using a two-step strategy, first using a questionnaire for RBD

and offering to perform a PSG only in those who tested positive, including: China in >70 years-old (2000), Spain in >60 years-old (2017), Switzerland in 35-75 years-old (2018), Japan in >65-years-old (2020) and Italy in 40-99 years-old (2021), with estimated prevalences ranging from 0.29% [IC 95% 0.06-0.85] in China, to 1.18% IC 95% 0.45-1.37], in Italy. The aim of our study was to study the prevalence and clinical characteristics of iRBD in a representative Caucasian sample from the elderly community of Barcelona, Spain, attending primary care centres.

Materials and methods: This study has been conducted in the primary care center CAP Casanova (Barcelona, Spain), which provides health care for a population of 35.165 inhabitants. Four general practitioners (MQ, ES, MFP, SC) responsible for a panel of approximately 7.000 patients participated in the study. Included subjects were consecutive individuals aged 60 years or older who underwent routine visits with the general practitioners between 7th February 2023 and 29th August 2024. Patients with the diagnoses of IRBD, Parkinson's disease, dementia with Lewy bodies, multiple system atrophy, mild cognitive impairment, Alzheimer's disease or any other neurodegenerative condition were excluded.

Included subjects underwent a two-stage study:

1) A validated screening single question for IRBD diagnosis (RBD1Q) followed by, in those who endorsed positive questionnaire

2) A visit in our sleep center for a clinical assessment by a neurologist offering a PSG.

Results: Of 332 individuals (62% women, mean age 71.8 ± 7.9 years, range 60-93), 33 (9.9%) endorsed positively the RBD1Q. All 33 were visited by a sleep neurologist, and 20 of these 33 accepted a v-PSG. V-PSG ruled out RBD in 16 subjects who had obstructive sleep apnea ($n = 10$), periodic limb movements of sleep ($n = 4$) and normal sleep ($n = 2$). IRBD was diagnosed in four individuals without motor or cognitive complaints, giving an estimated prevalence of 1.20% (95% CI = 0.03-2.37). They were three men and one woman between 64 and 76 years of age, with an interval between estimated RBD onset and V-PSG of 7.5 years (range 0.5-10 years). IRBD patients had constipation ($n=3$), hyposmia ($n=2$), apathy ($n=1$), and depression ($n=1$).

Conclusions: The prevalence of iRBD is 1.2% in the elderly community of Barcelona, similar than in other studies in the Caucasian and Asiatic elderly community.

Progression of prodromal markers of alpha-synucleinopathy neurodegeneration in the first-degree relatives of patients with REM sleep behavior disorder: a 7-year prospective study

Introduction: Idiopathic REM sleep behavior disorder (iRBD) is the most specific prodromal phase of alpha-synucleinopathies, including Parkinson's disease (PD) and dementia with Lewy bodies (DLB). Emerging evidence suggests a familial predisposition of iRBD, highlighted by the familial aggregation of RBD-spectrum features (e.g., dream enactment behaviors) and prodromal markers of alpha-synucleinopathies (e.g., motor dysfunction) in the first-degree relatives (FDRs) of iRBD patients. Building on these cross-sectional observations, this longitudinal 7-year follow-up study aims to further evaluate the progression of neurodegeneration markers and subsequent clinical neurodegenerative

development in the FDRs of patients with iRBD compared to the FDRs of controls, in the established Hong Kong family cohort.

Materials and methods: This prospective matched cohort study included 156 FDRs of patients with iRBD and 130 FDRs of controls as the referent individuals. Comprehensive clinical assessments were conducted, including interviews on sleep patterns and disorders, neuropsychiatric examinations, motor tests using the Unified Parkinson's Disease Rating Scale part III (UPDRS-III), and a series of questionnaires at baseline and follow-up. Additionally, 69 FDRs of iRBD patients and 40 control FDRs underwent video-polysomnographic assessments (v-PSG) at both time points. Linear and generalized linear mixed model analyses were employed to study the longitudinal changes.

Results: The mean follow-up duration for FDRs of iRBD patients and control individuals were 6.6 years and 6.8 years, respectively ($P = 0.28$). Baseline age (54.6 ± 9.0 vs. 55.3 ± 7.2 years, $P = 0.46$) and sex distribution (48.7% vs. 44.6% males, $P = 0.49$) were comparable between the two FDR groups. FDRs of iRBD patients consistently exhibited trends of increased RBD features at both baseline and follow-up, including self-reported dream enactment behaviors and electromyographic activity of chin mentalis evaluated by v-PSG. Over the observation period, six FDRs of iRBD (Cumulative incidence 4.0%) and one FDR of controls (Cumulative incidence 0.8%) were newly diagnosed with iRBD (group effect, $P < 0.001$; group*time effect, $P < 0.001$). Other prodromal markers, such as motor function assessed by UPDRS-III total score and sub-score for bradykinesia, showed greater impairment in FDRs of iRBD patients (group effects, $P = 0.02$ and $P = 0.01$), while gait instability demonstrated a significant group*time interaction effect ($P = 0.01$). However, global cognitive function did not differ significantly between the two groups. During the follow-up, two FDRs of iRBD patients were clinically diagnosed with PD (Cumulative incidence 1.3%), whereas no FDRs of control were diagnosed with PD. None of the FDRs in either group was diagnosed with dementia.

Conclusions: These findings further confirm the familial aggregation of RBD features and alpha-synucleinopathy neurodegeneration markers among FDRs of iRBD patients. Upon 7-year prospective follow-up, FDRs of iRBD patients exhibited higher incidences of RBD features (including iRBD diagnosis), progression of neurodegenerative features and clinical diagnosis of incident PD, highlighting FDRs of iRBD as high-risk populations for future neuroprotective interventions.

Quantitative FP-CIT PET Analysis of Dopaminergic Degeneration in idiopathic RBD and Early Parkinson's Disease

H.R. Park¹, J. Youn¹, S.H. Moon², E.Y. Joo¹

¹Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Neurology, Seoul, Korea, Republic of, ²Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Nuclear Medicine, Seoul, Korea, Republic of

Introduction: Idiopathic REM sleep behavior disorder (iRBD) is regarded as a prodromal stage of alpha synucleinopathies such as Parkinson's disease (PD). This study aimed to identify changes in dopaminergic changes in patients with iRBD using FP-CIT PET.

Materials and methods: FP-CIT PET scans from 33 healthy controls, 77 iRBD patients, and 194 early PD patients were analyzed. Standardized uptake value ratios (SUVRs) were measured in 19 predefined brain regions, including detailed subregions of the striatum, caudate nucleus, and putamen. Asymmetry indices and anterior-posterior (A-P) gradients in the putamen were calculated. These quantitative markers were correlated with clinical parameters and also compared with expert visual interpretations.

Results: SUVRs exhibited a stepwise reduction (Normal > iRBD > early PD) in most regions, particularly in the striatum. Asymmetry indices were elevated only in early PD, while A-P gradients differed significantly across all groups. A-P gradient was significantly associated with depression scores, whereas asymmetry index correlated with UPDRS motor scores. Visual interpretation yielded positive findings in 100% of early PD and 54.5% of iRBD cases.

Conclusions: iRBD patients show intermediate dopaminergic degeneration between healthy controls and PD, with early involvement of the posterior putamen. Quantitative analysis may enhance early detection beyond visual assessment and provide novel insights into the pathophysiology of RBD and its progression to PD.

RBD and other sleep alterations in anti-CASPR2 encephalitis

A. Montini^{1,2}, M. Guasp³, M. Serradell¹, E. Martinez³, G. Mayà¹, R. Ruiz³, F. Provini^{2,4}, C. Gaig¹, A. Iranzo¹

¹Hospital Clínic Barcelona, Universitat de Barcelona, Sleep Unit, Barcelona, Spain, ²University of Bologna, Department of Biomedical and Neuromotor Sciences (DIBINEM), Bologna, Italy, ³Hospital Clínic Barcelona, Universitat de Barcelona, Neuroimmunology, Barcelona, Spain, ⁴IRCCS Istituto delle Scienze Neurologiche di Bologna, Hospital Bellaria, Bologna, Italy

Introduction: Sleep disturbances, including RBD, are frequently observed in autoimmune encephalitis. Although V-PSG studies have been conducted in patients with Contactin-Associated Protein-Like 2 (CASPR2) antibody disease, RBD has not been previously reported. This study aimed to assess the presence of RBD and other sleep disturbances in patients with CASPR2-antibody disease using V-PSG and clinical evaluation.

Materials and methods: Patients diagnosed with CASPR2-antibody disease underwent clinical interviews, sleep questionnaires (PSQI, ESS, ISI), neuropsychological assessment, brain MRI, lumbar puncture and V-PSG following immunotherapy during a follow-up visit.

Results: Four male patients, with a median age of 67.75 years and a disease duration of 4.89 years, were included in the study. One patient was diagnosed with limbic encephalitis, while the other three had Morvan-like syndrome. Median questionnaire scores were: PSQI 5, ESS 4.5, and ISI 4.5. Two patients reported insomnia, with one also experiencing excessive daytime sleepiness. Bed partners observed dream-enactment behaviors (DEB) in two patients and sleep-talking in another. V-PSG revealed RBD with simple major episodes in the two patients displaying DEB. The remaining two patients showed increased tonic EMG activity in the chin during REM sleep, consistent with REM sleep without atonia (RWA). Two patients demonstrated executive function impairments. In all patients, brain MRI ruled out structural lesions, and CSF RT-QuIC for alpha-synuclein was negative.

Conclusions: RBD and RWA are common features in CASPR2-antibody disease and may be associated with autoimmune mechanisms, as structural brain lesions and synucleinopathy have been excluded, suggesting an autoimmune origin for these sleep disorders.

REM Density as a diagnostic indicator in patients with Dream-Enactment Behaviors: Insights into α -Synucleinopathy

M. Yu¹, B. Huang², S. Chau², C.C. Tsang², Y.K. Wing²

¹The Chinese University of Hong Kong, Psychiatry, Ma On Shan, Hong Kong, SAR of China, ²The Chinese University of Hong Kong, Ma On Shan, Hong Kong, SAR of China

Introduction: Recurrent dream-enactment behaviors (DEB) and rapid eye movement (REM) sleep without atonia (RSWA) are two key diagnostic features of REM sleep behavior disorder (RBD), recognized as a prodrome of α -synucleinopathy¹. Increasing evidence suggests that prodromal features of RBD, in the form of isolated DEB, may exist, including those familial ones.²

REM density is defined as the number of REM events per minute during REM sleep, which serves as an important indicator of the intensity and quality of REM sleep, crucial for cognitive function, emotional regulation³ and memory consolidation⁴. Prior studies indicate that changes in REM density may correlate with the severity of dream enactment behaviors, highlighting a connection between the physiological characteristics of REM sleep and the clinical manifestations of the disorder. However, the exact relationship between isolated DEB among those prodromal RBD subjects and REM density is unknown. Furthermore, it is important to investigate how mood states may impact on REM density and DEB in view of close relationship between RBD and mental health.

Materials and methods: We recruited twenty-one subjects who reported dream-enactment behavior but without sufficient REM sleep without atonia (isolated DEB or prodromal RBD) and fourteen age and gender-matched controls. All participants underwent clinical assessment and video-polysomnography.

Results: Age and sex were comparable between the isolated DEB and control groups (Isolated DEB vs. Control: mean age: 58.1 $\pm$ 4.0 versus mean age: 58.9 $\pm$ 4.5, $p=0.60$, Male: 76% vs. 64% $p=0.45$). The

isolated DEB group exhibited had higher scores on the RBD Questionnaire-Hong Kong (RBDQ) (29.4 ± 16.5 vs. 11.1 ± 11.8 , $p=0.001$), Beck Depression Inventory (BDI) (9.1 ± 8.2 vs. 2.8 ± 6.2 , $p=0.038$) and Hospital Anxiety and Depression Scale (HADS) (16.0 ± 9.8 vs. 7.7 ± 6.0 , $p=0.021$) compared to control. Additionally, the isolated DEB group demonstrated significantly higher REM density than the control group (27.8 versus 16.3, $p=0.015$). Notably, 38% of the subjects in the Isolated DEB group were taking antidepressants, compared to 14.3% in Control group. After adjusting for antidepressant use, the REM density in the isolated DEB group remained significantly higher than that of the control group (GLM model, $p=0.014$). The levels of RSWA did not differ significantly between the groups (9.0 ± 7.0 versus 5.3 ± 3.1 , $p=0.073$).

Conclusions: Higher REM density is seen in high risk population with isolated DEB. Further study with larger sample size will be needed to investigate whether REM density may emerge as a reliable and easily accessible marker to enhance diagnostic accuracy of DEB among those with subsyndromal RWSA.

Acknowledgments: We would like to thank our study subjects and research staffs. This study was supported by Research Grants council of Hong Kong (GRF Ref no: 14107520, GRF Ref no: 14116121 & CRF Ref no: C4044-21GF).

Remote unsupervised tests of isolated REM sleep behaviour disorder in the community: results from the Tasmanian ISLAND Sleep Study

S. Bramich¹, A. Noyce², A.E. King¹, E. Roccati¹, S.L. Naismith³, K. Barnham⁴, L.C. Beauchamp⁵, J.C. Vickers¹, J. Alty^{1,6}

¹University of Tasmania, Wicking Dementia Research and Education Centre, Hobart, Australia, ²Queen Mary University of London, Wolfson Institute of Population Health, London, United Kingdom,

³University of Sydney, Charles Perkins Centre, Sydney, Australia, ⁴The Florey Institute of Neuroscience and Mental Health, Melbourne, Australia, ⁵Harvard Medical School, Brigham and Women's Hospital, Boston, United States, ⁶Royal Hobart Hospital, Department of Neurology, Hobart, Australia

Introduction: Isolated rapid eye movement (REM) sleep behaviour disorder (iRBD) may occur at least 10 years before a clinical diagnosis of an α -synucleinopathy, specifically dementia with Lewy bodies (DLB), Parkinson's disease (PD) and multiple system atrophy (MSA). Better understanding is needed around whether people with iRBD experience subtle, disease-specific symptoms and whether these changes can be detected in the community using remote (online and postal) assessment tools. Such tools could aid early detection and monitoring for people at risk of α -synucleinopathy. Here we aim to investigate remote tests of subjective and objective features of α -synucleinopathy in 'probable' iRBD (pRBD). We hypothesise that α -synuclein-related symptoms and signs will be more frequent in pRBD compared to healthy controls.

Materials and methods: 2,351 participants aged 50+ years from the Tasmanian ISLAND (Island Study Linking Ageing and Neurodegenerative Disease) Sleep Study completed the REM Sleep Behaviour Disorder Single-Question Screen to determine pRBD. They also completed several online subjective health and sleep questionnaires, along with unsupervised objective assessments of hand movement, cognition and olfaction. All questionnaires and assessments were completed online, apart from olfactory testing which was completed via post.

Results: People with pRBD ($n = 235$; mean (SD) age 63 (7.6) years; 53% female) reported more α -synuclein-related features than controls, especially for autonomic dysfunction, pain, sleep disturbance, and PD features (all $p < 0.001$). Specifically, they reported more slurred or softer speech, shaking in their lips, hands, arms and/or legs, difficulty with their feet getting stuck to the floor when walking or turning, trouble with balance, and more falls in the last year (all $p < 0.001$). People with pRBD also show objective impairments with greater olfactory dysfunction and slower non-dominant hand movements compared to controls.

Conclusions: This study highlights that people with pRBD exhibit a range of α -synuclein-related symptoms and signs, that can be detected using remote assessment tools. Remote monitoring of these features with a combined set of easily accessible, low-cost, online tools, along with remote olfactory testing may aid in identifying people in the community who are at high risk for developing an α -synucleinopathy. Early diagnosis of these diseases is vital for improving symptomology as well as recruiting those at-risk into clinical trials to explore potentially disease modifying treatments into the future.

Acknowledgments: The authors would like to acknowledge the support of the Wicking Dementia Research and Education Centre at the University of Tasmania, along with the Royal Hobart Hospital Research Foundation and the Clifford Craig Foundation. We also thank Professor Kevin Barnham and Dr Leah Beauchamp for the provision of olfactory test kits.

Resting-State fMRI Functional Connectivity Reveals Dual Network Disruption in REM Sleep Behavior Disorder: Diagnostic Insights from Multi-Metric Analysis

Y.-S. Choo¹, E.Y. Joo¹

¹Sungkyunkwan University School of Medicine/Samsung Medical Center, Department of Neurology, Seoul, Korea, Republic of

Introduction: Idiopathic REM sleep behavior disorder (iRBD) is a prodromal phase of alpha-synucleinopathies such as Parkinson's disease. Functional changes may precede structural degeneration, making resting-state functional MRI (rs-fMRI) a valuable tool for early detection. This study aimed to investigate functional network changes in iRBD across multiple rs-fMRI metrics and evaluate their diagnostic and predictive utility using machine learning.

Materials and methods: We analyzed rs-fMRI data from 132 polysomnography-confirmed iRBD patients and 44 age- and sex-matched healthy controls. The brain was parcellated using the Shen 268-node atlas. Four rs-fMRI metrics—ALFF, fALFF, ReHo, and seed-based functional connectivity (FC)—were computed. Group comparisons were performed using ANCOVA controlling for age and sex. FC was corrected using family-wise error (FWE), and other metrics were thresholded at uncorrected $p < 0.01$. Classification performance was tested using machine learning models including SVM, XGB and MLP.

Results: FC showed the most robust and interpretable group differences. iRBD patients exhibited decreased FC in frontostriatal and default mode networks, and increased FC in cerebellar and motor circuits, suggesting early degeneration and compensatory reorganization. ALFF, fALFF, and ReHo showed scattered, inconsistent changes. SVM using FC features achieved the highest classification accuracy (87%), supporting the feasibility of prediction using rs-fMRI.

Conclusions: FC-based rs-fMRI revealed dual patterns in iRBD, with cognitive network disruption and motor network enhancement. These findings highlight FC as a sensitive marker of early pathological and adaptive changes. In combination with machine learning, FC-based rs-fMRI holds promise as a diagnostic and prognostic tool to stratify iRBD patients and track progression toward neurodegeneration.

Severe dream-enactment behaviors in isolated REM sleep behavior disorder: temporal clustering with sleep continuity and increased forearm EMG activity

Y. Sumi^{1,2}, B. Högl², Q. Tang², M. Aktan Süzgün², M. Cesari², Y. Inoue^{3,4}, A. Stefani²

¹Shiga University of Medical Science, Psychiatry, Otsu, Japan, ²Medical University of Innsbruck, Neurology, Innsbruck, Austria, ³Tokyo Medical University, Somnology, Tokyo, Japan, ⁴Yoyogi Sleep Disorder Center, Tokyo, Japan

Introduction: REM sleep behavior disorder (RBD) is characterized by dream-enactment behaviors (DEBs), which can lead to injury to the patient and/or bed partner. While polysomnographic features of RBD have been widely studied, little is known about the temporal patterns and physiological correlates of DEBs.

Materials and methods: We analyzed video-polysomnography data from 27 patients with isolated RBD (mean age 66.4 ± 7.5 years; 2 women) at the Center for Sleep Medicine, Department of Neurology, Medical University of Innsbruck, Austria. Motor events were scored based on visual video analysis according to the 2022 International RBD Study Group guidelines, classifying events as mild, moderate, or severe. Severe events were defined as forceful or violent movements with potential to cause severe injury, e.g., kicking or punching. Motor event occurrence and duration were recorded at 1-second resolution.

We performed two analyses:

(1) To investigate when severe motor events occurred, we quantified their cumulative duration across

30-minute bins across the whole night and analyzed their timing within each REM sleep period as both absolute elapsed time from REM sleep period onset and normalized relative time.

(2) To identify factors associated with severe motor events, we compared REM sleep periods with and without severe motor events regarding prior NREM sleep duration (measured from the end of the prior REM period to REM onset, or from sleep onset to first REM). We also compared REM sleep without atonia (RWA) indices assessed by the SINBAR method. REM periods were compared using a linear mixed model accounting for within-subject clustering. The study was approved by the ethics committee, and written informed consent was obtained.

Results: We analyzed 88 REM sleep periods including 3,331 motor events, of which 28 were severe, with a total severe event duration of 934 seconds. Severe motor events showed a prominent clustering between 24:00 and 4:00, accounting for 70% of their total duration. Within REM sleep periods, 70% of severe event duration occurred after 20 minutes from REM sleep period onset, and 80% occurred after 50% of each REM sleep period had elapsed.

Severe motor events occurred in 18 REM sleep periods. REM sleep periods with severe motor events were preceded by longer total NREM sleep (median 84.0 [IQR 73.9–115.0] min), particularly longer N2 sleep (median 62.0 [IQR 56.9–73.5] min). Among RWA indices, the flexor digitorum superficialis (FDS) phasic index was higher in REM sleep periods with severe motor events (median 51.1 [IQR 36.3–59.2] %).

Conclusions: This study identified three key findings regarding severe motor events in isolated RBD: (1) severe events tended to occur after a certain elapsed time within each REM sleep period; (2) their occurrence was associated with prolonged NREM sleep prior to REM onset; and (3) their occurrence was associated with increased FDS phasic activity. Severe dream-enactment behaviors may occur under conditions of sustained sleep continuity and defective REM atonia in the arms.

Sex-Specific Challenges in REM Sleep Behaviour Disorder Identification: Insights from Clinical Data, Screening Questionnaires, and REM Sleep Without Atonia

A. Ibrahim¹, M. Serradell², M. Cesari¹, C. Gaig², E. Holzknecht¹, P. Marrero², E. Brandauer¹, L. Pérez-Carbonell², M. Bergmann¹, A. Fernández-Arcos², N. Matos², J. Santamaria², B. Högl¹, A. Iranzo², A. Stefani¹

Introduction: Identifying REM sleep behavior disorder (RBD) is crucial due to the risk of injuries and the fact that its isolated form (iRBD) is an early alpha-synucleinopathy. Current validated RBD questionnaires assume uniform symptoms and clinical presentation in women and men despite existing literature on sex differences. Furthermore only few studies investigated sex differences in REM sleep without atonia (RWA). We aim To investigate sex differences in RBD identification by evaluating clinical data, three validated RBD screening questionnaires, and RWA measures.

Materials and methods: In this bicentric prospective study, 300 subjects referring to a sleep center for the first-time (159 men, 141 women) completed the RBD Screening Questionnaire (RBDSQ), RBD Single-Question Screen (RBD-1Q), and Innsbruck RBD Inventory (RBD-I) before a sleep expert interview and underwent 8-hour video polysomnography (v-PSG) to confirm or exclude RBD diagnosis. Clinical data, questionnaires, and RWA measures were compared between sexes.

Results: In the whole cohort, more women than men exceeded the cut-off for at least one RBD questionnaire (74.5% vs. 63.5%, $p=0.046$). In women, only exceeding the RBD-I cut-off was significantly associated with RBD diagnosis (log odds ratio (LOR) 1.812, $p=0.023$). In men, exceeding the cut-off for all questionnaires was associated with RBD (RBDSQ: LOR 3.076, $p=0.003$; RBD-1Q: LOR 2.837, $p<0.001$; RBD-I: LOR 3.076, $p=0.003$). The RBDSQ performed poorly in women compared to men (AUC 0.48 vs. 0.82, $p=0.001$). Among RBD patients ($n=30$; women:12, men:18), women were less likely to have bed partners (50% vs. 100%, $p=0.002$) and report abnormal sleep behaviors (58.3% vs. 100%, $p=0.006$). Expert suspicion of RBD was lower in women (50% vs. 83.3%, $p=0.102$). Exceeding cut-offs for chin-phasic, FDS, and SINBAR RWA-indices was associated with RBD diagnosis in both sexes ($p<0.005$); of note, exceeding chin tonic index cut-off was associated with RBD in women only ($p<0.001$).

Conclusions: Sex-related variability exists in RBD screening questionnaires, likely due to differences in RBD phenotype and related awareness affecting referrals. In our cohort, RWA measures better

identified RBD in women than questionnaires . These findings emphasize the need for sex-specific approaches for RBD screening and diagnosis.

Sleep Deprivation Accelerates α -Synuclein Pathology via Per2-Mediated Lysosomal Dysfunction in Mice with REM Sleep Behavior Disorder

L. Zhang¹, T. Luo¹, P. Zhang¹, Y. Liu¹, M. Chen¹, W. Wang¹, J. Zhang¹

¹The Affiliated Brain Hospital, Guangzhou Medical University, Center for Sleep and Circadian Medicine, Guangzhou, China

Introduction: Rapid eye movement sleep behavior disorder (RBD) is a well-recognized prodromal manifestation of α -synucleinopathies such as Parkinson's disease (PD). Sleep deprivation has been shown to disrupt circadian gene expression and aggravate dopaminergic neurodegeneration, while autophagy-lysosomal dysfunction represents one of the core mechanisms driving α -synuclein accumulation in PD. However, whether sleep deprivation accelerates α -synuclein pathology by disturbing circadian regulation and lysosomal homeostasis during the RBD stage remains unclear.

Materials and methods: An RBD mouse model was generated by bilaterally injecting α -synuclein preformed fibrils (PFFs) into the sublateralodorsal tegmental nucleus (SLD) of 8-week-old mice. Successful modeling was confirmed at 12-week-old by polysomnographic recordings, which verified RBD phenotypes. At 20 weeks, the mice were subjected to a 7-day sleep deprivation protocol. To investigate the molecular consequences of sleep deprivation in RBD mouse, we first performed RNA sequencing of the substantia nigra, which revealed enrichment of circadian rhythm and autophagy-lysosomal pathways. These findings were further validated by multi-timepoint quantitative real-time PCR experiments (RT-qPCR) assessing circadian gene dynamics. In parallel, α -synuclein pathology, lysosomal function, and PD-like behavioral impairments were evaluated using Western blotting, immunostaining, and motor function tests.

Results: Sleep-deprived RBD mice exhibited exacerbated α -synuclein aggregation, increased loss of tyrosine hydroxylase (TH) positive neurons in the substantia nigra, and earlier onset of PD-like motor impairments. Multi-timepoint RT-qPCR revealed suppressed Per2 expression and dampened circadian rhythmicity, accompanied by marked lysosomal dysfunction as confirmed via Western blotting. Concurrently, we demonstrated that Per1/2 knockout mice also exhibited significant lysosomal impairment and a reduction in TH-positive dopaminergic neurons in the substantia nigra, implicating the involvement of core circadian genes in lysosomal homeostasis. To specifically determine the role of Per2, we performed AAV-mediated knockdown of Per2 in the substantia nigra of RBD mice, which reproduced the lysosomal dysfunction and α -synuclein accumulation observed following sleep deprivation. Conversely, Per2 overexpression in the substantia nigra mitigated these pathological changes and delayed disease progression.

Conclusions: These findings identify Per2-mediated lysosomal dysfunction as a critical mechanism by which sleep deprivation promotes the transition from RBD to α -synucleinopathy, providing novel insight into the circadian regulation of prodromal PD progression.

The Chinese University of Hong Kong, Shatin, Hong Kong, China, ⁷Li Ka Shing Institute of Health Sciences, Faculty of Medicine, The Chinese University of Hong Kong, Shatin, Hong Kong, China

Introduction: Idiopathic REM sleep behavior disorder (iRBD) is the strongest prodromal marker for Parkinson's disease (PD), which is characterized by dopaminergic neuron loss in substantia nigra. Meanwhile, iRBD is manifested as dream-enactment behaviors (DEB) and REM sleep without atonia (RSWA). Recent evidence found that individuals with DEBs and subthreshold RSWA (isolated DEB) level will similarly predispose to an increased risk of neurodegeneration. This finding suggested that individuals with isolated DEB might indicate early neurodegeneration. However, it is unknown whether dopamine dysfunction could be detected at this stage. Thus, this study aims to investigate the potential dopaminergic dysfunction in individuals with isolated DEB.

Materials and methods: Sixteen subjects with isolated DEB and fifteen age and gender-matched controls without DEB underwent clinical assessment, video-polysomnography, and striatal PET scans using F18-FDG and F18-DOPA tracers. Likelihood ratio (LR) of prodromal PD was calculated as a proxy measure of individual's risk of prodromal PD based on Movement Disorder Society research criteria (2019). Dopaminergic functions were assessed using the standardized uptake value (SUVmean) ratio of striatal regions to cerebellum, the putamen-to-caudate SUVmean ratio, and 18F-DOPA influx constant Ki (K value).

Results: The age and gender were comparable between groups (subjects with isolated DEB vs. controls: mean age = 58.6 vs. 59.0 years, $P = 0.8$, male gender proportion: 81.3% vs. 66.7%, $P = 0.4$). Isolated DEB group had a significantly higher LR of prodromal PD (RBD item excluded, median: 0.16 vs 0.01, $P < 0.001$) compared to controls. As for the PET parameters, no significant differences were observed in any striatal parameters between groups, including the putamen-to-cerebellar SUVmean ratios (subjects with isolated DEB vs. controls: 18F-DOPA: 2.69 ± 0.17 vs. 2.70 ± 0.22 , $P = 0.88$; 18F-FDG: 1.36 ± 0.10 vs. 1.33 ± 0.09 , $P = 0.32$), caudate-to-cerebellar SUVmean ratios (18F-DOPA: 2.13 ± 0.19 vs. 2.12 ± 0.19 , $P = 0.89$; 18F-FDG: 1.13 ± 0.10 vs. 1.08 ± 0.11 , $P = 0.16$), putamen-to-caudate SUVmean ratios (18F-DOPA: 1.26 ± 0.06 vs. 1.28 ± 0.06 , $P = 0.48$; 18F-FDG: 1.22 ± 0.08 vs. 1.23 ± 0.09 , $P = 0.69$), and K values (10^{-3}) (L_putamen: 8.68 ± 0.67 vs. 8.87 ± 0.81 , $P = 0.49$; R_putamen: 8.93 ± 0.80 vs. 8.93 ± 0.95 , $P = 0.66$; L_caude: 6.99 ± 0.65 vs. 6.95 ± 0.83 , $P = 0.88$; R_caude: 7.07 ± 0.83 vs. 7.11 ± 0.73 , $P = 0.89$). Within the isolated DEB group, correlation analyses showed that mean 18F-FDG uptake ratio in caudate was negatively associated with total chin electromyography percentage of RSWA after adjustment for confounders, albeit with marginal significance ($r = -0.53$, $P = 0.06$).

Conclusions: Despite an elevated risk of prodromal PD in individuals with isolated DEB, dopaminergic function measured by PET imaging appeared to remain intact, suggesting dopaminergic dysfunction may not be detectable at this early phase. This potential time window of seemingly preserved dopaminergic function provides an opportunity for early neuroprotection. Further longitudinal studies with larger sample size are warranted to elucidate the relationship between dopaminergic dysfunctions and clinical manifestations at the early stage of prodromal PD.

Acknowledgments: We would like to thank our study subjects and research staffs. This study was supported by Research Grants Council of Hong Kong (No.14107520).

[¹⁸F]FDG-PET as staging biomarker in the prodromal to overt neuronal alpha-synucleinopathy continuum

Introduction: Rapid eye movement (REM) sleep behaviour disorder (RBD) is a parasomnia characterized by dream-like behaviours that emerge during REM sleep, resulting from the loss of physiological muscle atonia. Isolated/idiopathic RBD (iRBD) represent a prodromal stage of alpha-synucleinopathy, with the vast majority of individuals eventually developing parkinsonism and/or dementia over time. Whereas [^{18}F]FDG-PET is currently considered an established biomarker of neurodegeneration in alpha-synucleinopathies, its role as a staging biomarker remains unexplored.

Materials and methods: We enrolled 41 controls (age 70 ± 8.6 , 36.5% males); 86 iRBD (age 71 ± 7 , 75.5% males), representing the prodromal alpha-synucleinopathy stage, and 85 patients with either Parkinson's disease (PD, $n=40$, age 72 ± 7.4 , 57.5% males) or Dementia with Lewy Bodies (DLB, $n=45$, age 76 ± 5.8 , 64.4% males), representing the overt alpha-synucleinopathy stage (age 74 ± 6.8 , 61% males). All subjects underwent baseline [^{18}F]FDG-PET and comprehensive clinical examination. Prodromal patients were followed over time (months 23 ± 21) to assess possible phenoconversion, based on the emergence of parkinsonism and/or dementia. Phenoconverted patients (cRBD, $n=30$; age 73 ± 6.8 , 76.6% males), were further divided according to the phenoconversion outcome into cRBD-PD ($n=14$, age 72 ± 8.3 , 64.2% males) or cRBD-DLB ($n=16$, age 74 ± 5 , 87.5% males). Patients that did not phenoconvert at the last available follow-up (months 30 ± 25) were labelled non-converters RBD (ncRBD, $n=56$; age 70 ± 6.9 , 75% males).

We computed spatial covariance analysis on the [^{18}F]FDG-PET data of overt PD (deriving the OvertPD-Related Pattern -RP), and overt DLB (deriving the OvertDLB-RP) patients separately, as well as overt stages combined (i.e. PD and DLB), deriving the Overt Alpha-synucleinopathy-RP. These [^{18}F]FDG-PET disease-related patterns were applied to our study groups, as follows. First, assuming our groups represent progressive neurodegeneration stages, we evaluated whether baseline Overt Alpha-synucleinopathy-RP could stage the alpha-synucleinopathy continuum at two levels of granularity: I) controls, prodromal and overt stage (3-levels); II) controls, ncRBD, cRBD, and overt stage (4-levels). Then, we investigated mainly-motor (controls, ncRBD, cRBD-PD, and overt PD) and mainly-cognitive (controls, ncRBD, cRBD-DLB, and overt DLB) clinical trajectories by applying the overPD-RP and the overDLB-RP respectively.

Results: Visually, the Overt Alpha-synucleinopathy-RP showed relative hypometabolism in occipital cortices and posterior cingulate cortices, precuneus and lateral prefrontal areas, with relative hypermetabolism in hippocampal and parahippocampal regions, brainstem, cerebellum and anterior cingulate cortex. A progressive and statistically significant increase of this pattern's expression was found across the clinical spectrum (both 3-levels and the 4-levels model, $p < 0.0001$).

Expression of the OvertPD-RP and the OvertDLB-RP also significantly increased across stages in the mainly-motor and mainly-cognitive trajectories, respectively ($p < 0.0001$).

Random Forest analyses across the 3-levels and 4-levels models, as well as clinical trajectories models, showed moderate-to-good Negative Predictive Values (NPVs) for all study groups (70-89%), with highest reliability in preventing misclassification within healthy controls and overt alpha-synucleinopathy groups. NPVs for the prodromal group were comparatively lower, reflecting greater classification uncertainty in this transitional stage, but remained within an acceptable range for multiclass prediction.

Conclusions: This study encompassing alpha-synucleinopathy-continuum suggests a potential role of [^{18}F]FDG-PET imaging as a biomarker for staging neurodegeneration across the continuum from prodromal to overt alpha-synucleinopathy.

Toward Scalable Detection of REM Sleep Behavior Disorder: A Lightweight Machine Learning Approach Using Overnight Heart Rate Variability

U. Mosca¹, I. Rechichi¹, G.S. Giarrusso¹, A. Cicolin^{2,3}, G. Olmo¹

¹Politecnico di Torino, Control and Computer Engineering Department, Turin, Italy, ²Molinette University Hospital, Centre for Sleep Medicine, Turin, Italy, ³University of Turin, Department of Neuroscience "Rita Levi Montalcini", Turin, Italy

Introduction: Early diagnosis of neurodegenerative diseases (NDs) such as Parkinson's Disease (PD), Alzheimer's Disease (AD), Multiple System Atrophy (MSA), and Dementia with Lewy Bodies (DLB) is crucial, as it might enable timely interventions that can significantly improve patient outcomes. REM

Sleep Behavior Disorder (RBD) is a parasomnia that entails the loss of physiological muscle atonia during REM sleep, and has emerged as a reliable prodromal marker for several of these conditions. The diagnostic gold-standard for RBD is video-polysomnography (PSG), a comprehensive but invasive, resource-intensive, and costly procedure. Given the growing prevalence of NDs in aging populations, there is an urgent need for scalable, non-invasive, and cost-effective screening tools. Heart rate variability (HRV), derived solely from RR interval time series, reflects autonomic nervous system functioning and has shown promising in distinguishing individuals with neurodegenerative conditions from healthy controls. This study investigates the feasibility of employing Machine Learning (ML) models to classify healthy versus RBD subjects based solely on HRV features.

Materials and methods: We utilized four PSG datasets (three public and one private) comprising recordings from healthy individuals, subjects with RBD, and individuals with obstructive sleep apnea syndrome (OSAS), this latter included to evaluate model robustness against confounding factors. HRV features were extracted using two parallel approaches: first including all detected R-peaks in the recording (All); and then excluding R-peaks corresponding to wake epochs, as identified by hypnograms (Sleep). Multiple experimental configurations were tested by combining four feature selection algorithms with six different ML classifiers. Model performance was evaluated on various dataset combinations to assess generalizability and robustness.

Results: Model performance was assessed using the F1 score, as it balances precision and recall and guarantees robustness despite class imbalance. The best model achieved a 92.31% F1 score using the (All) approach on a single-dataset configuration, indicative of optimal performance. With increasing dataset complexity, performance slightly declined, reaching a F1 score of 86.93% (5.38 percentage point decrease relative to the best-case performance). Nevertheless, the obtained performance remained moderately high, thus reflecting the robustness of the proposed approach. Interestingly, approach (All), that included the whole recording, consistently outperformed (Sleep), with an average improvement of 1.43 percentage points. Including OSAS subjects in the analysis, used as a confounding-factor population, impaired classification performance. Indeed, the transition from a healthy/RBD to a non-RBD/RBD classification witnessed a moderate decrease on the average F1 score, reflecting the diagnostic challenges posed by comorbid sleep disorders.

Conclusions: This study demonstrates the potential of HRV-based ML models for non-invasive RBD screening. Given that HRV data can be collected using simple wearable devices, such as smartwatches, this outcome supports the implementation of large-scale, low-cost screening programs targeting at-risk populations (particularly individuals over 60 years of age). These findings pave the way for accessible early detection tools, thereby supporting timely therapeutic intervention in the prodromal phases of neurodegenerative diseases.

Acknowledgments: This work has been partially funded by Fondazione Compagnia di San Paolo under PoC Instrument Initiative, Project "RBD automatic detection through HRV".

Introduction: Clinical trials in REM sleep behavior disorder (RBD) are anticipated in the near future, in which interventions to delay the onset or prevent the development of Parkinson's disease, dementia

with Lewy bodies and multiple system atrophy will be tested. The Prodromal Synucleinopathy Rating Scale (PSRS) was developed by the NAPS Consortium investigators to capture the breadth and evolution of clinical burden in those with RBD.

Materials and methods: Ratings on the PSRS range from no symptoms/signs (score of 0) to more severe symptoms/signs (max score of 2-4 depending on the domain) based on clinical judgement for the cognitive (COG), neuropsychiatric (NP), motor-axial (MAX), motor-appendicular (MAP), autonomic (AUT), sleep (SLP), and sensory (SEN) domains. For the cross-sectional analyses, PSRS ratings were analyzed on participants (pts) at the baseline visit conducted 8/22-12/24. Spearman correlations were generated between the ratings for each domain, and the total sum score (SUM), with several measures that reflect similar constructs. For the longitudinal analyses, Wilcoxon signed-rank test compared the difference in PSRS SUM and its domains between visits 1 (V1) and 2 (V2) collected 8/22-12/24.

Results: In cross-sectional analyses, data from 365 pts (80% male, mean age 66 ± 10 yrs) were analyzed. The following correlations were determined: COG and Montreal Cognitive Assessment score ($r = -0.40$) and Clinical Dementia Rating Sum of Boxes score ($r = 0.78$, $p < 0.0001$ for each); NP and modified Neuropsychiatric Inventory ($r = 0.40$, $p < 0.0001$); MAX and MAP and the MDS-UPDRS Motor score ($r = 0.78$, 0.67 , respectively, $p < 0.0001$ for each); AUT and Scales for Outcomes in Parkinson's Disease-Autonomic Dysfunction ($r = 0.37$, $p < 0.0001$); SLP and Epworth Sleepiness Scale ($r = 0.19$, $p = 0.0004$); and SEN and Brief Smell Identification Test ($r = -0.64$, $p < 0.0001$) and FM100 color vision, ($r = 0.11$, $p = 0.04$). The PSRS SUM was correlated with Functional Assessment Scale ($r = 0.48$), Schwab and England Activities of Daily Living ($r = -0.60$), and Clinician Global Impression Severity ($r = 0.72$, $p < 0.0001$ for each). In longitudinal analyses, data from 205 pts (81% male, mean age 66 ± 9 yrs) were analyzed. The median (IQR) duration between V1 and V2 was 12 (11-12) months. From V1 to V2, the score increased for COG ($p < 0.0001$), NP ($p < 0.0001$), MAX ($p < 0.0001$), MAP ($p < 0.0001$), AUT ($p < 0.0001$) and SLP ($p = 0.0123$) but not for SEN. Comparing V1 to V2, the frequency of an increased/stable/decreased score for each domain were COG: 36%/52%/12%, NP: 38%/46%/16%, MAX: 37%/54%/9%, MAP: 40%/47%/13%, AUT: 44%/37%/19%, SLP: 18%/55%/27%, and SEN: 19%/64%/17%. The SUM increased (mean 7.5 ± 4.4 to 9.0 ± 4.7 , $p < 0.0001$) and the frequency of an increased/stable/decreased SUM score were 61%/12%/27%.

Conclusions: In this large cohort of individuals with RBD, moderate to strong correlations exist between the PSRS domain and SUM score ratings and many other measures of clinical burden. Additionally, mildly increasing but variable clinical burden can be demonstrated on the PSRS over one year. Although additional longitudinal work is needed in larger and more diverse samples, the current results demonstrate preliminary validity for the PSRS as a useful outcome of synucleinopathy clinical burden for future disease-modifying therapies in those with RBD.

Introduction: Isolated REM sleep behavior disorder (iRBD) is a prodromal stage of synucleinopathies, with over 90% of individuals eventually developing either dementia with Lewy bodies (DLB) or Parkinson's disease (PD). Current brain biomarkers do not accurately predict which individuals with iRBD will develop one or the other of these conditions. This study aims to identify a brain tissue deformation signature, detectable via MRI, that could predict the clinical evolution of individuals with iRBD.

Materials and methods: T1-weighted brain MRI scans from 48 individuals with video-polysomnography-confirmed iRBD from the Montreal iRBD cohort were analyzed using a deformation-based morphometry approach to generate individual brain tissue deformation maps. All 48 participants underwent detailed clinical assessments covering 27 clinical variables spanning motor, non-motor, cognitive, autonomic, neuropsychiatric, and sleep domains. Using a partial least squares regression approach, we identified an anatomo-clinical signature that maximized covariance between brain and clinical changes. This brain map signature was then applied to a database assembled by our lab, comprising 1,404 MRI scans from individuals with iRBD or a related synucleinopathy, to extract a per-subject expression score. These signature expression scores were harmonized and used in logistic and Cox regressions to test whether the score predicted the development of DLB in iRBD, as opposed to other progression trajectories. Signature expressions were also compared across iRBD, DLB, PD groups to assess whether higher expression was associated with DLB. Finally, signature expression was also associated with other markers of disease conversion, including increased free water content and glymphatic system impairment.

Results: Partial least squares regression revealed a significant latent variable explaining 28% of the covariance between tissue deformation and clinical variables in iRBD ($p = 0.006$). Cox regression showed that only the deformation score was significantly associated with the risk of developing DLB rather than PD (HR = 2.14, $p = 0.0016$), suggesting that a higher score roughly doubles the risk of DLB. ANOVA across groups also showed a significant group effect on signature expression ($F(2, 700) = 36.8$, $p < 0.0001$), with DLB patients having significantly higher scores than PD patients (diff = -32.2, $p < 0.0001$) and iRBD individuals (diff = -23.0, $p < 0.0001$). Individuals with iRBD also had higher scores than PD patients (diff = 9.2, $p < 0.0001$). Age- and sex-adjusted partial correlations revealed significant associations between signature expression and other biomarkers, including increased free water in the nucleus basalis of Meynert ($r = 0.15$, $p = 0.02$), and reduced glymphatic function ($r = -0.22$, $p < 0.001$).

Conclusions: This study highlights an anatomical signature based on tissue deformation measurable via MRI, capable of predicting DLB development in individuals with iRBD. This biomarker, easily derived from a standard T1-weighted sequence, could support patient stratification in clinical trials, optimize patient care, and enable the integration of risk-reduction strategies.

Restless Legs Syndrome (RLS)

Actigraphy-Derived Sleep Patterns Distinguish Restless Legs Syndrome from Insomnia and Sleep Apnea

A. Kilty¹, J. Winkelman^{1,2}

¹Massachusetts General Hospital, Sleep Disorders Clinical Research Program, Department of Psychiatry, Boston, United States, ²Harvard Medical School, Boston, United States

Introduction: Restless Legs Syndrome (RLS) is a neurological disorder characterized by an uncontrollable urge to move while resting and relief by movement. Symptoms are pronounced in the evening and first half of the night, often abating late in the sleep period. Actigraphy provides an objective measure which can be employed for multiple nights to assess sleep. We hypothesized that those with RLS have a delayed sleep pattern, with more time awake early in the night and greater sleep toward morning, and that this pattern would be distinct from those with either insomnia or obstructive sleep apnea (OSA).

Materials and methods: Actigraphic recordings of sleep were obtained from the Multi-Ethnic Study of Atherosclerosis (MESA), an ongoing cohort study, initiated in 1999, with enrollment of 6,814 participants between 2000-2002. 2,237 MESA participants wore an Actiwatch Spectrum wrist sleep

actigraphy device (Philips Respironics) 24-hours per day over 8 days to determine sleep duration and quality.

Actigraphic recordings were scored in epoch-by-epoch increments for 2,159 participants by a technician at the Boston Sleep Reading Center. After excluding 88 night-shift workers and 11 with missing data, 2,060 participants remained: 98 with physician-diagnosed RLS, 1,962 without RLS. Groups with RLS and self-reported physician diagnosis of insomnia and OSA were identified. To control for confounders of age, sex, insomnia and OSA, we employed 1:3 propensity score matching, yielding groups with near-identical insomnia prevalence (RLS=22.4%, non-RLS=20.7%) and OSA prevalence (RLS=25.5%, non-RLS=26.9%). The RLS group was 66.3% female with a mean age of 69.6 years, and the non-RLS group was 65.0% female with a mean age of 69.8 years.

We used unpaired t-tests to compare the average sleep time in the first four hours (9PM-1AM) and last four hours (5AM-9AM) of the sleep period between groups.

Results: Participants with RLS slept significantly less in the first four hours of the night compared to those without RLS (144.9 vs. 155.9 minutes, $p=0.02$). Conversely, those with RLS slept significantly more in the last four hours of the night (140.4 vs. 129.3 minutes, $p=0.03$).

While participants with insomnia slept less in the first four hours of the night (144.8 vs. 153.7 minutes, $p=0.03$), they did not sleep significantly more in the last four hours (133.1 vs. 129.5 minutes, $p=NS$). Participants with OSA did not sleep significantly less in the first four hours of the night (151.2 vs. 151.7, $p=NS$), though they did sleep significantly more in the last four hours (133.4 vs. 126.3, $p=0.05$).

Conclusions: This novel analysis identified a distinct pattern of actigraphy-derived sleep in RLS, characterized by delayed sleep onset and increased early morning sleep. This pattern was not shared by those with insomnia or OSA. Actigraphy-based sleep assessment could contribute as an objective diagnostic tool for RLS and may facilitate earlier identification of the disorder and improved patient outcomes.

Association between clinical severity and secondary restless legs syndrome in rheumatoid arthritis - a pilot study

K. Avramov¹, S. Terziyska², I. Yakov², T. Georgiev¹, A. Draganova¹, K. Terziyski¹

¹Medical University - Plovdiv, Pathophysiology, Plovdiv, Bulgaria, ²MHAT "Trimontsium", Plovdiv, Bulgaria

Introduction: Restless legs syndrome (RLS) is a common comorbidity in patients with rheumatological diseases. Prevalence data indicate that RLS occurs more than three times as frequently in individuals with rheumatoid arthritis (RA) compared to the general population. This pilot study explores the clinical and biochemical characteristics of RLS in a cohort of RA patients.

Materials and methods: We enrolled 32 female patients with RA from a single clinic. Patients with conditions (other than RA) or medications known to cause secondary RLS were excluded. Patients completed the Epworth Sleepiness Scale, the Pittsburgh Sleep Quality Index (PSQI) and Restless Legs Syndrome Severity Scale. RA disease activity was assessed using the Disease Activity Score 28 – CRP (DAS28-CRP). Complete blood count (CBC), basic biochemical parameters for inflammation, and serum iron levels were also measured. Statistical analysis employed independent samples Mann-Whitney test and Spearman's rho bivariate correlation in SPSS v.26.0.

Results: Based on clinical interviews and sleep-focused histories, 12 patients (37.5%) met the International Classification of Sleep Disorders (ICSD) criteria for RLS (RLS+ group), while 20 did not (RLS- group). The RLS+ group reported significantly longer sleep onset latency on PSQI item 2 (48.75 min vs. 27.75 min, $p < 0.01$), though total sleep duration did not differ significantly (6.17 h vs. 6.5 h). There were no significant differences in age (61.3 vs. 59.9 years) or body mass index (26.4 vs. 24.9). The neutrophil-to-lymphocyte ratio (2.1 vs. 2.32), C-reactive protein (2.8 mg/dL vs. 4.8 mg/dL), rheumatoid factor (11.45 vs. 10.4), and erythrocyte sedimentation rate (34.10 mm/hr vs. 34.45 mm/hr) were not significantly different between groups. However, the RLS+ group had significantly higher disease activity (DAS28-CRP: 4.88 vs. 3.79; $p < 0.01$) and lower serum iron levels (13.56 $\mu\text{mol/L}$ vs.

18.73 $\mu\text{mol/L}$; $p = 0.026$). Moderate negative correlations were observed between serum iron levels and both sleep latency ($r = -0.461$, $p < 0.01$) and DAS28-CRP ($r = -0.411$, $p < 0.01$).

Conclusions: RA patients with comorbid RLS experience longer sleep onset latency and lower serum iron levels compared to those without RLS. While traditional inflammatory markers such as CRP, ESR, and NLR do not differ significantly between groups, disease activity assessed by DAS28-CRP is notably higher in RLS+ patients. These findings suggest a potential interplay between iron metabolism, disease activity, and the pathophysiology of RLS in RA.

Acknowledgments: This work has been funded by a research grant by the Medical University of Plovdiv.

Calcitonin gene-related peptide monoclonal antibodies improve symptoms of restless legs syndrome in patients with migraine

M. Kashiwagi¹, S. Kobayashi¹, S. Suzuki¹, H. Hujita¹, M. Shioda¹, R. Hida¹, K. Hirata¹, K. Suzuki¹

¹Dokkyo Medical University, Tochigi, Japan

Introduction: The effects of calcitonin gene-related peptide monoclonal antibodies (CGRP mAb) on restless legs syndrome (RLS) are unclear.

Materials and methods: We retrospectively investigated 15 patients with migraine and concomitant RLS (age, 49.1 ± 5.8 years) who were administered CGRP monoclonal antibodies. The number of migraine days per month (MMD) was obtained from headache diaries. Headache disability was assessed using the Migraine Disability Assessment (MIDAS). The severity of RLS was assessed using the International RLS Group Rating Scale (IRLS). Central sensitization was assessed using the Central Sensitization Inventory (CSI).

Results: After 1, 2, and 3 months, the percentage of patients with a 50% or greater improvement in MMD was 53.3%, 66.6%, and 60.0%, respectively. From baseline to 3 months, there was a significant decrease in the MIDAS score (25.1 ± 23.2 vs. 19.7 ± 22.8 , $p=0.005$) and CSI score (36.3 ± 12.9 vs. 29.1 ± 12.3 , $p=0.001$). The IRLS score significantly decreased from baseline to 1 month (-8.8 ± 2.1 points) and 3 months (-11.6 ± 2.3 points) significantly after CGRP monoclonal antibody treatment.

Conclusions: In our study, CGRP monoclonal antibody treatment significantly reduced RLS symptoms, central sensitization, and headache-related disability in patients with comorbid migraine and RLS.

Chronic Health Risk in Restless Legs Syndrome and its Association with Exercise

K. Cederberg¹, G. Camillo Ricciardiello Mejia¹, E. Leary², C. Kushida¹, E. Mignot¹

¹Stanford University, Psychiatry & Behavioral Sciences, Palo Alto, United States, ²Consultant, San Francisco, United States

Introduction: Restless legs syndrome (RLS) disrupts sleep and is associated with increased risk of cardiovascular disease, hypertension, stroke, depression and anxiety, and overall poorer health. Exercise represents one of the most promising non-pharmacological approaches for managing RLS and is a potent modifier of health and disease outcomes. However, there is limited knowledge regarding the influence of exercise on the risk of comorbid conditions commonly associated with RLS.

Materials and methods: Patients ($N=23,937$) seen at the Stanford Sleep Disorders Clinic completed the Alliance Sleep Questionnaire (ASQ) as a standard of care. The ASQ is a comprehensive questionnaire designed to collect standardized subjective sleep and sleep disorder data, including current sleep symptoms, sleep habits and schedule, medical history, and social/behavioral habits (e.g., exercise).

Results: Univariate logistic regression controlling for age, sex, BMI, race, ethnicity, and other sleep problems (e.g., sleep-related breathing, insomnia, daytime sleepiness) identified people with RLS had higher risk of hypertension, cardiovascular problems, atrial fibrillation, cardiac surgeries, GI problems, GERD, IBS, gallstones, liver disease, cholecystectomy, neurological problems, peripheral neuropathy, iron deficiency, anemia, urinary/kidney problems, chronic kidney disease, chronic pain/fatigue, frequent headaches/migraines, fibromyalgia, anxiety, and depression than people without RLS. Multivariate forward stepwise regression identified people with RLS ($n=1,559$ [7.3%]) had significantly higher risk of cardiovascular problems, GI problems, cholecystectomy, urinary/kidney problems, neurological problems, fibromyalgia, chronic pain/fatigue, peripheral neuropathy, and psychiatric diagnoses than

people without RLS (n=19,926). RLS had higher BMI and insomnia symptoms, were more likely to be Hispanic and male, and were significantly less likely to exercise than people without RLS. Multivariate regression demonstrated that people with RLS who exercise (n=1,009 [74.2%]) had lower risk of chronic heart failure, neurological problems, peripheral neuropathy, and depression; had lower BMI, better functional outcomes of sleep, and were more likely to be more educated, younger, and male than people with RLS who do not exercise (n=351).

Univariate logistic regression controlling for age, BMI, RLS severity, and other sleep problems demonstrated women with RLS (n=854[54.1%]) had higher risk of GI problems, IBS, gallstones, and cholecystectomy; iron deficiency, pain/fatigue problems, frequent headaches/migraines, fibromyalgia, chronic fatigue syndrome, anxiety, and depression than men with RLS (n=723). Multivariate regression demonstrated that women with RLS had higher risk of frequent headaches/migraines, fibromyalgia, chronic pain/fatigue problems, metabolic problems, cholecystectomy, and anxiety and were less likely to engage in regular exercise than men with RLS. Multivariate regression demonstrated that women with RLS who exercise (507[70%]) had lower risk of depression and peripheral neuropathy, were less likely to have a pacemaker, and had a lower BMI and higher education level than women with RLS who do not exercise. Men with RLS who exercise (n=495 [79%]) had lower risk of autoimmune disease, type 2 diabetes, and chronic heart failure, lower BMI, better functional outcomes of sleep, and higher daytime sleepiness than men with RLS who do not exercise (n=129).

Conclusions: Exercise is associated with less risk of some chronic health conditions in adults with RLS with differential effects in men and women. Future research should evaluate causality among these relationships to understand the effect of exercise.

Clinical Characteristics, Polysomnography, and Iron Metabolism in Restless Legs Syndrome Patients with Obstructive Sleep Apnea: A Comparative and Cluster Analysis Study

Y. Hou¹, F. Han¹

¹Peking university People's Hospital, Division of Sleep Medicine, Beijing, China

Introduction: Restless Legs Syndrome (RLS) often coexists with obstructive sleep apnea (OSA), worsening symptoms through complex mechanisms. This study investigates the prevalence, clinical features, and phenotypic subtypes of RLS-OSA to improve diagnosis and treatment.

Materials and methods: A multicenter observational study enrolled 1,134 patients with RLS from 23 Chinese sleep labs from January 2020 to December 2024. RLS was diagnosed using the 2014 RLSSG criteria; OSA was confirmed via polysomnography (AHI ≥ 5 with symptoms). Patients were classified into RLS-OSA and RLS-only groups. Clinical characteristics, PSG parameters, and iron metabolism markers were analyzed. To identify distinct subgroups among patients with comorbid RLS and OSA, a K-means clustering analysis was conducted using R. Categorical variables were one-hot encoded and combined with standardized numerical variables (mean = 0, standard deviation = 1) to ensure equal weighting. The optimal number of clusters was determined using the Elbow Method and Silhouette Score. The K-means algorithm was then applied with the identified number of clusters to minimize within-cluster variance. Post-clustering differences in demographic, PSG, and laboratory test variables were evaluated using the t-test or the Mann-Whitney U test for continuous variables and the Chi-square tests or Fisher's exact test for categorical variables.

Results: OSA was present in 69.2% (n=785) of patients with RLS. The RLS-OSA group exhibited higher age, BMI, age at onset, and male proportion, with reduced insomnia (all $p < 0.01$). PSG revealed shorter total sleep time, lower sleep efficiency, increased wake time after sleep onset, and altered sleep stages (less N3, more N1; all $p < 0.01$). Hemoglobin and ferritin levels were elevated ($p < 0.001$). Two RLS-OSA phenotypes emerged: Cluster 1 ("Mild Early-Onset") with younger age, earlier onset, better sleep quality, and relatively normal iron status, and Cluster 2 ("Severe Late-Onset") with older age, later onset, poorer sleep quality, and iron dysregulation (all $p < 0.05$).

Conclusions: OSA is common in RLS, with distinct clinical and sleep-related differences. Two distinct phenotypes of RLS-OSA were identified, highlighting its heterogeneity. These findings underscore the need for tailored diagnostic and therapeutic approaches to improve symptom management and patient outcomes.

Acknowledgments: This study was supported by the National Natural Science Foundation of China (NSFC) (No. 82400114 and No. 32441101).

Clinical feature and alpha-synuclein level of restless legs syndrome with leucine-rich repeat kinase 2 encoding gene mutation

X. Guo¹, J. Ma¹

¹Shanghai Jiao Tong University Medical School Affiliated Ruijin Hospital, Neurology and Institute of Neurology, Shanghai, China

Introduction: Restless leg syndrome (RLS) has been reported associated with Parkinson's Disease (PD). However, it remained largely unknown of the mechanism underlying this association between RLS and PD.

Materials and methods: 199 idiopathic RLS and 114 PD were diagnosed and recruited by neurologists from Ruijin Hospital affiliated to Shanghai Jiao Tong University. And 273 health controls were recruited from community. Eight LRRK2 pathogenic variants were sequenced. Clinical data was collected including symptoms, comorbidities, family history, and iron level. ELISA was used to measure plasma level of α -synuclein.

Results: The G2385R variant was found significantly higher in PD group after Bonferroni correction ($p=0.018$). Taking all LRRK2 mutations as one risk covariant, further logistic regression analysis showed a marginal association of LRRK2 with RLS ($OR=1.847$, $95\%CI:1.022-3.337$, $p=0.042$) after adjusting age and gender. In terms of clinical feature, it was found that RLS-LRRK2 carriers usually reported a positive family history of neurological or psychiatric disorders (48.3% vs 27.6%) ($p=0.026$) and a higher foot involvement of sensory symptoms (33.3% vs 14.0%) ($p=0.042$). Plasma α -synuclein level in RLS ($p=0.021$) and PD ($p=0.018$) was both significantly increased compared to non-manifesting carriers.

Conclusions: Our study showed that LRRK2 mutation was associated with Chinese PD patients but only showed a possible trend of association with RLS. Positive neurological or psychiatric family history and foot discomfort in RLS were important features of indication of LRRK2 mutation in RLS. Plasma α -syn was increased in LRRK2-RLS as well as LRRK2-PD, indicating a possible association of RLS with PD in LRRK2 carriers.

Acknowledgments: This work was supported by STI2030-Major Projects (2022ZD0211600) and The Tung Foundation of Shanghai Jiao Tong University. These funds contributed to the design of the study, data collection, and writing the manuscript.

Clinical influence of restless legs syndrome in migraine patients: a 12-year single-center longitudinal study

K. Suzuki¹, S. Suzuki¹, H. Fujita¹, K. Kato¹, M. Hamaguchi¹, K. Hirata¹

¹Dokkyo Medical University, Department of Neurology, Mibu, Japan

Introduction: A number of studies have shown a significant association between migraine and restless legs syndrome (RLS). However, few studies have investigated RLS in patients with migraine over the long term.

Materials and methods: We conducted a single-center, 12-year longitudinal study of migraine patients to assess the presence of RLS at baseline and after 7 and 12 years, and to evaluate its association with clinical factors. Headache-related disability was assessed using the Migraine Disability Assessment Scale (MIDAS). Sleep quality, daytime sleepiness and depressive symptoms were assessed using the Pittsburgh Sleep Quality Index (PSQI), the Epworth Sleepiness Scale (ESS) and the Beck Depression Inventory-II (BDI-II), respectively.

Results: Of the 262 patients included at baseline, 101 were available after 7 years and 74 after 12 years; RLS prevalence was 13.7%, 20.8%, and 24.3% at baseline, after 7 and 12 years, respectively; this rate increased significantly from baseline to 12 years. RLS severity scores were not significantly different between the three time points. Analysis of covariance adjusted for age and sex showed that MIDAS, BDI-II, PSQI and ESS scores were significantly higher in migraine patients with RLS than in those without RLS at all time points. MIDAS, BDI-II, PSQI and ESS scores were significantly higher in the persistent RLS group, defined as being positive for RLS at the last evaluation in addition to the first and/or second evaluation, than in the RLS-naïve group, defined as having no RLS at any of the three time points.

Conclusions: This 12-year longitudinal study demonstrated a significant impact of RLS on the burden of migraine.

Comparison of Restless Leg Syndrome Characteristics and Treatment Responses Between Male and Female Patients

M. Nitesnoppakul^{1,2}, N. Chirakalwasan^{1,2}

¹Chulalongkorn University, Division of Pulmonary and Critical Care Medicine, Department of Medicine, Bangkok, Thailand, ²King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Excellence Center for Sleep Disorders, Bangkok, Thailand

Introduction: Restless legs syndrome (RLS), also known as Willis-Ekbom disease, affects sleep quality and overall quality of life worldwide. Understanding the demographic and clinical characteristics of RLS, particularly potential gender differences, is essential for effective diagnosis and management.

Objectives: To examine the demographic and clinical features of RLS, including iron status, polysomnographic parameters, treatment practices, and responses, with a comparison between male and female patients.

Materials and methods: We retrospectively analyzed inpatient and outpatient records, identifying RLS cases using ICD-10 codes. Patients aged 18 years and older diagnosed with RLS based on the 2014 IRLSSG criteria and with at least 12 months of follow-up were included.

Results: A total of 29 patients were included, with a female-to-male ratio of 1.42. The mean age was 64.61 ± 17.58 years for females and 62.57 ± 18.91 years for males ($p=0.767$). Body mass index, comorbidities, and the presence of sleep disorders such as obstructive sleep apnea and insomnia did not differ significantly between genders. Although males showed a trend toward a higher apnea-hypopnea index compared to females ($37.8 [3.25, 17.3]$ vs. $10.1 [10.9, 45]$ events/hour, $p=0.075$), females had significantly lower total sleep time and sleep efficiency (328.75 ± 61.42 vs. 425.75 ± 41.73 minutes, $p=0.040$; $74.17 \pm 9.71\%$ vs. $92.1 \pm 3.86\%$, $p=0.014$, respectively). Combined therapy was prescribed more frequently as the initial treatment in females compared to males (62.5% vs. 20% , $p=0.034$). However, treatment response and final medication dosages were similar across genders. Compared to males, females had significantly lower hemoglobin, serum iron, and transferrin saturation (12.65 ± 1.41 vs. 14.12 ± 1.73 g/dL, $p=0.018$; 71 ± 23.03 vs. 98.44 ± 30.38 mcg/dL, $p=0.029$; $24.43 \pm 8.29\%$ vs. $37.35 \pm 15.67\%$, $p=0.032$, respectively). However, the severity of iron deficiency warranting treatment and ferritin levels did not differ significantly between genders.

Conclusions: Sex-related differences in RLS were observed in sleep parameters, iron status, and initial treatment approaches. Female patients exhibited more pronounced clinical impact, as evidenced by reduced total sleep time and sleep efficiency, possibly contributing to the higher use of combination therapy. Despite lower iron status in females, the deficiency was generally not severe enough to require treatment. These findings underscore the importance of gender-specific considerations in the evaluation and management of RLS.

Complete Resolution of Restless Legs Syndrome Symptoms After CPAP Treatment in a Patient with Moderate Obstructive Sleep Apnea: A Case Report

G. Marques¹, L. Bernardi¹, J. Bacelete¹, D. Mata¹, P. Deise¹, P. Starling¹

¹Military Police Hospital of Minas Gerais State, Sleep Clinic, Belo Horizonte, Brazil

Introduction: Restless Legs Syndrome (RLS), or Willis-Ekbom Disease, is a sensorimotor disorder characterized by an uncontrollable urge to move the legs, particularly during rest or inactivity. While comorbid with various sleep disorders, its relationship with Obstructive Sleep Apnea (OSA) remains underexplored. We present a case in which a patient with long-standing RLS symptoms experienced complete remission following Continuous Positive Airway Pressure (CPAP) therapy for moderate OSA.

Materials and methods: This is a single-patient case report based on a retrospective review of electronic medical records from a multidisciplinary sleep medicine outpatient clinic. Clinical history, standardized questionnaires (International Restless Legs Syndrome Study Group Rating Scale and Epworth Sleepiness Scale), polysomnographic data, and CPAP device adherence reports were reviewed and analyzed across multiple follow-up visits between 2023 and 2024.

Results: A 59-year-old male with a history of chronic insomnia reported nightly symptoms consistent with Restless Legs Syndrome (RLS) for over 20 years—described as deep burning pain and an urge to

move the lower limbs during nocturnal awakenings and prolonged sitting. Two polysomnographies (2015 and 2024) confirmed moderate Obstructive Sleep Apnea (OSA), with apnea-hypopnea indices of 24.1/h and 26.4/h, and oxygen saturation below 90% for 5.3% of total sleep time, reaching a minimum of 74%. Relevant comorbidities included bruxism, obesity (BMI: 30.9), systemic hypertension, and gastroesophageal reflux disease, with regular use of metoprolol and olmesartan. He discontinued long-term zolpidem use in late 2023 due to concerns about cognitive side effects. No antidepressants, neuroleptics, antihistamines, or other medications known to worsen RLS were in use.

Baseline laboratory workup showed normal renal, hepatic, thyroid, and hematologic function. Vitamin D (34.1 ng/mL) and B12 (397 pg/mL) levels were within normal limits. Iron metabolism markers were also normal or elevated: serum iron 91 µg/dL, transferrin saturation index (TSI) 30%, and ferritin 404.1 ng/mL—ruling out iron deficiency as a contributing factor to RLS symptoms.

RLS severity was assessed using the International Restless Legs Syndrome Study Group (IRLSSG) Rating Scale, with an initial score of 18 in February 2024 (moderate severity). CPAP therapy was initiated in March 2024. From March to May, usage data from the AirSense 10 AutoSet device showed ≥4 hours of use on 35 out of 41 nights (85% adherence), with a mean daily usage of 5 hours and 5 minutes. By April 2024, the IRLSSG score dropped to 0, indicating full remission of RLS symptoms. The patient reported complete resolution of leg discomfort and urge to move, particularly during evening rest and upon nocturnal awakenings, that used to occur daily for over two decades. Additional subjective improvements were reported in sleep quality, fatigue, mood, and cognition. Epworth Sleepiness Scale score improved from 11 to 4. No pharmacological treatment for RLS was initiated.

Conclusions: This case highlights a potential link between untreated OSA and secondary RLS symptoms. CPAP therapy not only improved respiratory parameters but also resulted in complete resolution of longstanding RLS symptoms. These findings support the consideration of sleep-disordered breathing as a reversible cause of RLS in select patients and underscore the importance of integrated management in sleep medicine.

Efficacy and safety of tonic motor activation (TOMAC) for restless legs syndrome as adjunctive treatment and monotherapy: preliminary results of an individual participant data systematic review and meta-analysis

E.G. Karroum¹, C.G. Bachmann², A. Bronstone³, L. Morrison⁴

¹Department of Neurology, University of Virginia School of Medicine, Charlottesville, Virginia, United States, ²Institute of Cognitive Science, Osnabrück University, Osnabrück, Germany, ³AB Medical Communications, Inc., Los Altos Hills, California, United States, ⁴Biostatistical Consulting Inc., Lexington, Massachusetts, United States

Introduction: Tonic motor activation (TOMAC) is a wearable therapeutic device that transmits bilateral high-frequency electrical stimulation to the peroneal nerve to treat symptoms of restless legs syndrome (RLS) and improve sleep. A recently published meta-analysis of TOMAC used aggregate data. In this meta-analysis, we conducted the first individual participant data meta-analysis of TOMAC, which enabled evaluation of TOMAC as adjunctive treatment and monotherapy.

Materials and methods: The protocol and analysis plan were prespecified and registered on PROSPERO (CRD420251005571). The systematic literature search was conducted with Covidence using Web of Science, Scopus, and PubMed from inception to March 31, 2025, to identify randomized clinical trials (RCTs) that evaluated TOMAC (high-frequency peroneal nerve stimulation) for treatment of RLS. Two independent reviewers performed literature search with discrepancies adjudicated by a third reviewer. Study authors provided individual participant data (IPD) for each of the RCTs, which was used for all meta-analysis. The primary endpoint for reducing RLS symptoms was change from baseline (CFB) in IRLS (International RLS Study Group Rating Scale) total score, and the primary endpoint for improving sleep was CFB in MOS-II score (Medical Outcomes Study Sleep Scale). Treatment arm (TOMAC vs. sham control) was the independent variable and primary analyses adjusted for baseline value of the relevant endpoint. Patients who received TOMAC were categorized as adjunctive if taking prescription medication for RLS and as monotherapy if not. Heterogeneity across studies was assessed with Tau statistic based on restricted maximum-likelihood method and conducting a Wald chi-square test and calculating the I² statistic. Pooled analyses were conducted except in the case of substantial heterogeneity, when a random study effect was used. For additional

subgroup analysis, baseline RLS severity (based on IRLS total score) was treated as a categorical variable and age of RLS onset was treated as a continuous variable.

Results: We identified 3 RCTs with a total of 252 RLS patients: 183 with adjunctive RLS medication (92 TOMAC, 91 sham); and 69 with no adjunctive RLS medication ("monotherapy"; 35 TOMAC, 34 sham). Relative to sham, TOMAC treatment significantly reduced IRLS score both as monotherapy (mean difference [MD]: -3.80, 95% confidence interval [CI]: -6.39 to -1.21, $p=0.0047$) and as adjunctive therapy (MD: -3.39, 95% CI: -5.09 to -1.70, $p=0.0001$). Compared to sham, TOMAC treatment also significantly reduced MOS-II score both as monotherapy (MD: -9.65 points, 95% CI: -17.92 to -1.38, $p=0.0236$) and as adjunctive therapy (MD: -8.23 points (95% CI: -12.88 to -3.59, $p=0.0006$). There was no evidence of heterogeneity between study results for any endpoints ($I^2=0$ and Cochran's Q-statistic chi-square P value > 0.50 for all). Additional subgroup analysis across all patients found no difference in IRLS MD based on baseline RLS severity (interaction $p=0.7889$) or age of RLS onset (interaction $p=0.7959$). There were no serious or severe device-related adverse events in any participant.

Conclusions: TOMAC is safe and efficacious at reducing RLS symptoms and improving sleep both as monotherapy and as an adjunctive therapy to prescriptive medication.

Acknowledgments: We thank the authors of the original publications for providing individual participant data.

Evaluating the Efficacy and Safety of Tonic Motor Activation in Restless Legs Syndrome: A Systematic Review with Meta-Analysis

J.V. Pereira Gonzalez¹, L. Falcão¹, J. Tekchandani², G. Nunes¹, K. Ogasawara¹, A. Donato¹, A. Oliveira¹, C. Fingergut¹, C. Salles¹

¹Escola Bahiana de Medicina e Saude Publica, Medicine, Salvador, Brazil, ²Noctrix Health, Inc., Pleasanton, United States

Introduction: Restless Legs Syndrome (RLS) is a neurological condition marked by an overwhelming urge to move the legs, often disrupting sleep and significantly affecting the health and quality of life of approximately 3% of adults. Current treatments primarily include iron supplementation, dopaminergic agonists and opioids. However, these options are frequently associated with substantial side effects, such as impulse control disorders and dependency. Tonic Motor Activation (TOMAC) has emerged as a promising non-pharmacological intervention, utilizing non-invasive peroneal nerve stimulation to alleviate RLS symptoms while minimizing adverse effects. Growing evidence supports the efficacy and safety of TOMAC, particularly in individuals who have not achieved sufficient relief with conventional therapies. This systematic review aims to assess the efficacy of TOMAC in managing RLS symptoms.

Materials and methods: The PRISMA protocol was used to guide the conduct of this systematic review and meta-analysis. The inclusion criteria encompassed studies involving participants aged 18 years or older with a confirmed diagnosis of RLS, as defined by the International Restless Legs Syndrome Study Group (IRLS) criteria. The intervention of interest was TOMAC for the treatment of RLS. Only randomized clinical trials were considered eligible for inclusion. Statistical analyses were performed using RevMan 5.1.7, and heterogeneity among studies was assessed using the I^2 statistic.

Results: Four Randomized Clinical Trials were located from searching seven databases and 3,193 studies, encompassing 152 participants in the TOMAC group and 163 in the control group, with follow-up durations ranging from 2 to 24 weeks. The mean age ranged from 55.7 to 57.6 years, and 60% of the participants were female. There was a significant reduction in the IRLS rating scale scores among patients treated with TOMAC compared to the control group (MD: -4.11 [-5.49, -2.73]; CI: 95%; $I^2=47\%$, $p<0.0001$). Subgroup analyses revealed a greater mean change in IRLS scores for medication-naïve patients (MD: -4.56 [-5.45, -3.68]; CI: 95%; $I^2=0\%$, $p<0.0001$) and for medication-refractory patients (MD: -3.88 [-4.63, -3.14]; CI: 95%; $I^2=0\%$, $p<0.0001$). In a separate analysis, the Clinical Global Impression-Improvement (CGI-I) responder rate demonstrated an odds ratio (OR) of 7.76 (95% CI: [4.33, 13.90], $I^2=55\%$, $p<0.0001$), favoring TOMAC. Similarly, the Patient Global Impression-Improvement (PGI-I) analysis for medication-refractory patients revealed an OR of 1.10 (95% CI: [0.63, 1.92], $I^2=0\%$, $p=0.7283$). Adverse events reported across all studies were rare, mild, and self-resolving, underscoring the safety of TOMAC.

Conclusions: According to the data from the present meta-analysis, TOMAC is an effective treatment for Restless Legs Syndrome (RLS). Significant reductions in symptoms were observed, as evidenced by improvements in the IRLS rating scale, as well as in CGI-I and PGI-I scores. Subgroup analyses further

demonstrated the efficacy of TOMAC in both medication-naïve and medication-refractory patients. Moreover, the intervention was shown to be safe, with only rare, mild, and self-limiting adverse effects reported. These results highlight TOMAC's potential as a valuable non-pharmacological therapy for RLS, while emphasizing the need for additional robust clinical trials to strengthen and validate these outcomes.

I would like thank **Doctor Salles**. Her guidance was invaluable. I am also deeply thankful to Mr. Tekchandani. His contributions were fundamental.

Genetic Architecture of Restless Legs Syndrome in the Chinese Population and Its Transethnic Correlation with Europeans

W. Zhu¹, C. Zhao², F. Han³

¹Peking university people's Hospital, Peking, China, ²Technical University of Munich, Munich, Germany,

³Peking university People's Hospital, Peking, China

Introduction: Restless legs syndrome (RLS) is a common neurological sensorimotor disorder with a strong genetic component. However, most genetic studies to date have focused on European populations. Here, we conducted a genome-wide association study (GWAS) in a large Chinese cohort and performed cross-ethnic genetic correlation analysis to investigate the shared and distinct genetic architecture of RLS.

Materials and methods: We enrolled 1,493 RLS patients (including 1,226 with primary RLS) and 6,662 ancestry-matched controls from multiple centers across China. GWAS was conducted after stringent quality control and imputation using the 1000 Genomes East Asian reference panel. Transethnic LD score regression (LDSC) was applied to estimate SNP-based heritability and genetic correlation between Chinese and European RLS cohorts. We further conducted functional annotation of lead SNPs and prioritized candidate genes based on chromatin interactions and biological relevance.

Results: A total of **8 genome-wide significant loci** were identified, including **5 novel loci** and **10 RLS susceptibility genes**. Functional interpretation revealed that these loci are significantly enriched in previously published European RLS GWAS results, involved in neural development pathways, overlapped with parapyramidal nucleus-specific gene sets, and overrepresented in BTB/POZ regulatory domains. The SNP-based heritability of RLS in the Chinese population was estimated to be 0.39 ± 0.11 , supporting a substantial heritable component. Cross-ethnic genetic effect correlation ($\rho_{ge} = 0.511$, $P = 0.015$) and genetic impact correlation ($\rho_{gi} = 0.56 \pm 0.19$, $P = 0.002$) were both statistically significant, indicating a moderate degree of shared genetic architecture but also the presence of **population-specific signals**. The most significant associations in the Chinese cohort mapped to **BTBD9** and **GLO1**, both of which are located on chromosome 6 and have been strongly implicated in RLS pathogenesis. Although the **MEIS1** locus did not reach genome-wide significance in our Chinese data, chromatin interaction analysis revealed a physical link between a suggestive SNP (rs10865361) and the MEIS1 promoter, indicating potential long-range regulatory relevance. In addition, 8 of 42 FUMA-annotated genes showed significant enrichment ($P_{adj} = 1.34 \times 10^{-6}$), further supporting their biological involvement.

Conclusions: Our study reveals that RLS in the Chinese population has a higher SNP-based heritability compared to Europeans and shares moderately correlated genetic structure. The identification of BTBD9 and GLO1 as top loci reinforces their central role in RLS etiology, while chromatin interaction findings at MEIS1 suggest long-range regulatory mechanisms. These findings highlight both shared and distinct genetic features across populations and emphasize the value of transethnic GWAS combined with functional annotation in uncovering the biology of complex neurological disorders.

Acknowledgments: This study was supported by the National Natural Science Foundation of China (NSFC) (No. 82400114).

Identification and Prediction of Phenotypic Subtypes of Restless Legs Syndrome

S. Hwang¹, S.Y. Bang², K.-Y. Jung^{2,3}

¹Ewha Womans University Mokdong Hospital, Department of Neurology, Seoul, Korea, Republic of, ²Seoul National University Hospital, Department of Neurology, Seoul, Korea, Republic of, ³Seoul National University College of Medicine, Department of Neurology, Seoul, Korea, Republic of

Introduction: Patients with restless legs syndrome (RLS) presents prominent heterogeneity. For instance, age correlates significantly with symptom severity in early-onset RLS, whereas ferritin levels are associated with severity in late-onset cases. This study aimed to identify phenotypic subgroups of RLS based on a wide range of features and to develop a predictive model for subgroup classification.

Materials and methods: We screened 537 patients diagnosed with RLS who visited Seoul National University Hospital between 2014 and 2024. Patients with secondary RLS were excluded. Demographic, clinical characteristics, laboratory findings, comorbidities, and sleep-related questionnaires were collected. K-means clustering was applied to identify phenotypic subgroups, and statistical tests were used to compare characteristics across clusters. A decision tree-based algorithm was employed to predict phenotypic subgroups.

Results: A total of 360 patients (63.6% females) were included in the analysis. Onset age was 47.7 ± 17.1 years. Cluster analysis revealed three distinct phenotypes. Cluster 1: Late-onset patients with a stable or fluctuating disease course. Cluster 2: Patients with the most severe RLS symptoms and frequent augmentation, showing a fluctuating or refractory disease course. Cluster 3: Early-onset patients with prominent daytime sleepiness, showing an intermittent or stable disease course. A prediction model using a random forest algorithm based on initial characteristics achieved a macro AUC of 0.895 in classifying patients into phenotypic subgroups.

Conclusions: Three distinct phenotypes of RLS were identified through unsupervised cluster analysis. Tailored management strategies should be considered based on individual phenotypic characteristics. Future studies are warranted to validate these subgroups in independent cohorts and to explore their implications for personalized treatment strategies.

Influence of cerebral ischemic stroke on characteristics and laterality of periodic limb movements during sleep (PLMS)

S. Hackethal^{1,2}, S. Duss^{3,4}, S. Miano^{1,2}, L. Nobili^{5,6}, C. Bassetti^{3,4}, R. Ferri⁷, M. Manconi^{1,2}

¹Neurocenter of the Southern Switzerland, EOC, Regional Hospital of Lugano, Sleep Medicine Unit, Lugano, Switzerland, ²Università Della Svizzera Italiana, Faculty of Biomedical Sciences, Lugano, Switzerland, ³Bern University Hospital (Inselspital) and University of Bern, Department of Neurology, Bern, Switzerland, ⁴Bern University Hospital (Inselspital) and University of Bern, Interdisciplinary Sleep-Wake-Epilepsy Centre, BernSe, Switzerland, ⁵IRCCS Istituto Giannina Gaslini, Child Neuropsychiatry Unit, Genoa, Italy, ⁶University of Genoa, Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Child and Maternal Health (DINO GMI), Genoa, Italy, ⁷Oasi Institute for Research on Mental Retardation and Brain Aging (IRCCS), Sleep Research Centre, Department of Neurology IC, Troina, Italy

Introduction: Periodic limb movements during sleep (PLMS) are repetitive leg jerks occurring in series with an interval between 10 and 90 seconds. The neuronal network and the pathogenesis of PLMS are still unknown. Some evidence suggests that PLMS are the motor expression of a disinhibition of spinal circuits due to a reduced supraspinal control. Single case reports and case series describe the presence of PLMS contralateral to brain lesions at the level of the brainstem, basal ganglia and cortex. The idea behind the present analysis was to use ischemic stroke as a lesion model to investigate the impact of presumed cortical disinhibition on the occurrence, pattern and laterality of PLMS.

Materials and methods: Here we present a secondary analysis of data from the prospective multicenter study (Sleep- Disordered Breathing in Transient Ischemia Attack [TIA]/ Ischemic Stroke and Continuous Positive Airway Pressure [CPAP] Treatment Efficacy; SAS-CARE; NCT01097967). Participants underwent a clinical examination, cerebral MRI, nocturnal polysomnography (PSG) during the acute (1–8 days after stroke) phase and/or 3 months after stroke. We selected 25 patients who showed a clear mono-lateral ischemic stroke in a single vascular either cortical or subcortical territory and had good-quality PSG recordings in the acute and chronic phase. Leg movements (LM) were scored according to the WASM criteria (2016) and respiratory related leg movements excluded from the analysis. Other than reporting descriptive statistics, we constructed regression models to investigate confounding factors impacting the asymmetry of the motor-phenomenon.

Results: The 25 included patients (7 women, 18 men) had a mean age of 62 (8.4) years, median BMI of 26.3 [24.4|29.4] and mostly showed cortical ischemic lesions in the territory of the middle cerebral artery (MCA, n=21 (84%)). Median NIHSS at admission was 4 [1.5|5.5]. Overall PLMS burden was very low (1.24[0.79|3.79]/h) with asymmetry in 18/25 patients and strictly unilateral PLMs in 8 cases (4 ipsilateral and 4 contralateral to the stroke side). PLMS showed low overall periodicity (periodicity index (PI) 0.34 [0.18|0.58]) and no difference in PI between relative sides. The same distribution of LM, PLM and PI was seen in the chronic state with however a slight tendency towards higher values in the chronic vs. the acute state. Regression analysis revealed a significant impact of age ($\beta=0.23$, $p=0.01$), vessel other than MCA ($\beta=-7.30$, $p=0.0001$), stroke volume ($\beta=0.198$, $p=0.03$) and total PLMSI ($\beta=0.85$, $p=0.013$) on PLMSI delta (contralateral minus ipsilateral).

Conclusions: In the current analysis we did not find a clear difference between general and periodic leg movement activity in the limbs ipsilateral or contralateral to ischemic cortical or subcortical stroke, neither in the acute nor the chronic phase. However, having an MCA stroke, larger stroke volume, more PLMS activity and being older seemed to increase asymmetry with bias towards the side contralateral to the stroke. Further analyses therefore need to focus on patients with clear pyramidal tract involvement to more adequately address the question of whether spinal disinhibition due to a lesion of the pyramidal tract can lead to asymmetric motor activity during sleep.

Neurological approaches to restless legs syndrome: a systematic review of non-pharmacological interventions

J.V. Pereira Gonzalez¹, C. Fingergut¹, L. Falcão¹, A. Oliveira¹, G. Garrido¹, L. Lopes¹, M. Meira e Cruz¹, C. Salles¹

¹Escola Bahiana de Medicina e Saude Publica, Medicine, Salvador, Brazil

Introduction: Restless Legs Syndrome (RLS) is a neurological disorder affecting approximately 3% of adults, significantly impairing health and quality of life. The standard treatment for RLS is pharmacological, but it often leads to significant side effects. Non-pharmacological neurological interventions, such as neuromodulation, neurostimulation, and neuroactivation, are emerging as promising alternatives. This systematic review aims to evaluate the efficacy of these interventions in treating RLS.

Materials and methods: This review was guided by the PRISMA protocol. The search utilized the terms 'Restless Legs Syndrome,' 'Neuromodulation,' 'Neurostimulation,' and 'Neuroactivation.' Inclusion criteria included studies evaluating the efficacy of neurological interventions in treating RLS.

Results: A total of 3489 studies were identified, of which 21 were included. The total sample comprised 1008 participants, with a mean age ranging from 45.7 to 63.0 years. Chahine et al. (2011) observed that Deep Brain Stimulation (DBS) reduced IRLSSG scores from 23.0 to 13.8 ($p=0.037$). Klepitskaya et al. (2018) reported improvements in IRLSSG scores from 24 to 12. Evidente et al. (2021) found a reduction from 15.8 to 8.5 ($p=0.007$) with DBS. Lei et al. (2022) and Yuan et al. (2022) reported improvements in RLS scores from 22 to 10 and from 23 to 11, respectively. Zeng et al. (2020) showed that Transcutaneous Spinal Cord Stimulation reduced IRLS scores from 27.2 to 15.0 ($p<0.05$) and improved sleep, with a reduction in PSQI from 14.9 to 10.3 ($p<0.05$). Lin et al. (2015) reported that Repetitive Transcranial Magnetic Stimulation (rTMS) reduced IRLSS scores from 23.86 to 11.21 ($p<0.05$). Altunrende et al. (2014) found a reduction from 29.6 to 12.7 ($p<0.001$) with rTMS. Feng et al. (2024) observed reductions from 25.3 to 13.4, and Liu et al. (2015) from 26.1 to 14.2. Abedi et al. (2021) showed that Transcutaneous Electrical Nerve Stimulation (TENS) reduced IRLS scores from 23.36 to 12.5 ($p<0.05$). Augustina et al. (2020) reported a reduction in IRLS scores from 32.27 to 11.87 ($p<0.0001$) in pregnant women. Şanlı et al. (2024) found improvements in IRLS scores from 28 to 18 and PSQI from 12 to 7 with the combined use of pramipexole and TENS. Bogan et al. (2023) reported a reduction in IRLS scores from 31.9 to 24.6 ($p<0.01$) with Tonic Motor Activation (TOMAC). Roy et al. (2023) found a reduction of 11.3 points in IRLS ($p=0.0001$) after 24 weeks. Buchfuhrer et al. (2021) reported improvements in IRLS scores from 30 to 18 ($p<0.001$). Hartley et al. (2022) observed a reduction in IRLS scores from 31.9 to 24.6 ($p=0.0003$) with Vagus Nerve Stimulation (tvNS), and confirmed these results in 2023, showing a reduction from 30.7 to 22.1 ($p<0.01$) after 24 weeks.

Conclusions: Non-pharmacological neurological interventions show significant promise as alternatives for treating RLS. These findings support the need for further randomized controlled trials to confirm and expand upon these results.

Acknowledgments: I would like thank Doctor Salles. Her guidance was invaluable. I am also deeply thankful to Mr. Tekchandani. His contributions were fundamental.

PAP Adherence in RLS Patients with OSA

S. Li¹, B. Li¹, M. Wang¹, X. Dong¹, F. Han¹, L. Xu¹

¹Peking University People's Hospital, Division of Sleep Medicine, Beijing, China

Introduction: Obstructive sleep apnea (OSA) commonly coexists with restless leg syndrome (RLS). Emerging evidence suggests that positive airway pressure (PAP) treatment for coexisting OSA may also reduce RLS symptom. However, often contributes to secondary insomnia, causing difficulties with sleep initiation and maintenance, which may compromise PAP adherence. The combined impact of RLS and OSA on PAP adherence is underexplored. Our study aimed to evaluate PAP therapy adherence and identify key determinants of adherence in patients with coexisting RLS and OSA.

Materials and methods: This retrospective cohort study analyzed clinical data from patients diagnosed with RLS who reported snoring and underwent overnight polysomnography (PSG), between Jan 2022 and July 2024, at the Division of Sleep Medicine in the Peking University People's Hospital. The study assessed clinical characteristics, PAP adherence, and factors influencing adherence. Adherent patient was defined as device use for ≥ 4 hours per night on $\geq 70\%$ of nights. Patients with coexisting RLS and OSA were followed up 1year after PAP initiation via semi-structured telephone interviews and questionnaires. Objective PAP data were obtained from device memory cards mailed by patients.

Results: A total of 114 patients were diagnosed with RLS. Of these, 84 (73.68%) had coexisting OSA. Among these, 70 patients initiated PAP therapy and continued treatment at hospital. Of these, 37 acquired a PAP, device. and 25 provided objective PAP usage data. PAP adherence declined progressively over time with adherent patients of 76% at 1week, 36% at 1month, 20% at 3 months, 16% at 6 months, and 12% at one year. Influencing factors included subjective symptom improvement, device tolerance, and socioeconomic burden.

Conclusions: PAP adherence is low and declines over time in patients with coexisting RLS and OSA. Targeted interventions addressing symptom relief, device tolerability and socioeconomic factors may improve adherence and outcomes in this population.

Acknowledgments: This work was supported by the National Natural Science Foundation of China (82470092); as well as grants from the Capital Medical Science and Technology Innovation Achievement Transformation Promotion Project(YC202301JS0025).

Role of cytokines in RLS: insights into IL6 and iron in the etiology of RLS

S. Beatriz Ranciaro Fagundes¹, D. João Leite Fagundes²

¹Santa Casa, São Paulo, Brazil, ²Governo Estado de São Paulo, São Paulo, Brazil

Introduction: Introduction:

Restless Legs Syndrome (RLS) is a sensorimotor disorder that affects 5% to 15% of the world population and 6.40% of the Brazilian population, affecting sleep and daily activities. The etiology of RLS is unclear, but several studies point to iron deficiency. On the other hand, studies point to IL-6 deficiency. We analyzed 35 amateur athletes with and without RLS. Iron levels were measured: IL-6 before the marathon (42 km), which we call baseline, after the race and 72 hours after the race.

Key words: iron, IL6, hepcidine, RLS, Restless Legs Syndrome

Objectives

This work attempts to trace iron and IL6 mechanism in RLS.

Materials and methods: Materials and Methods:

The group consisted of 35 drug-free amateur runners (M = 41.57 years, SD = 6.24) who completed the race within 5 hours. The researchers (SBRF and DJLF) applied a questionnaire using The International RLS Study Group (IRLSG) diagnostic criteria. RLS severity was assessed using the "IRLSG severity questionnaire". How long she/he has RLS, how long they had been running, and whether they had RLS before they started running. Blood was collected at baseline, post-marathon, and 72 hours later.

Results: Results:

12.96% of athletes met the criteria for SPI. Iron levels were: RLS group: basal: 97.12; post: 109.63; 72h: 86.71. Non-SPI group: basal: 94.68; post: 105; 72h: 82.14. IL-6 levels: SPI group basal: 16.46; post: 43.93; 72h: 52.95. Non-SPI group: basal: 28.24; post: 109.76; 72h: 0.15.

Conclusions: The results of changes in the secretion pattern of IL-6 in runners with RLS may be essential for understanding RLS, as they may be associated with changes in metabolism and inflammatory mechanisms, in addition to being essential for sleep.

Cytokines, specifically IL-6, induce hepcidin, and hepcidin regulates iron. After a strenuous effort, such as a marathon, IL-6 kicks in to restore balance in the body. Our data show that IL-6 continues to increase after strenuous efforts, such as a marathon, in the RLS group. There is no significant difference in iron levels between the RLS group and the non-RSL group. Could the mechanism of RLS be between IL-6 and iron? Further studies are needed to confirm trends.

Acknowledgments: Acknowledgements:

The authors gratefully acknowledge the athletes for their patience as well Gianni M.S. dos Santos for help with statistic analysis.

Severe, refractory restless legs syndrome responding to hyperbaric oxygen therapy: a case report

G. Cotta¹, S. Luu¹, D.ECY Chan¹, J. Di Michiel¹, K. Lowe², B.J Yee^{1,3,4}

¹Woolcock Institute of Medical Research, Macquarie Park, Australia, ²Barker Street Specialists, Randwick, Australia, ³Royal Prince Alfred Hospital, Respiratory and Sleep Department, Camperdown, Australia, ⁴University of Sydney, Camperdown, Australia

Introduction: We present the case of a 73-year-old woman with severe, refractory restless legs syndrome (RLS). She experienced progressively worsening symptoms over more than 20 years, resulting in significantly impaired sleep and daytime dysfunction. This is on a background of mild obstructive sleep apnoea and sleep-maintenance insomnia. Her symptoms of RLS remained debilitating despite multiple pharmacological and non-pharmacological interventions trialled including iron replacement therapy, gabapentinoids, opioids, antidepressants, and cognitive behavioural therapy. At the time of hyperbaric oxygen therapy (HBOT) initiation, she was taking buprenorphine patch 5 mcg/h weekly, amitriptyline 25 mg nocte, agomelatine 25 mg daily, gabapentin 600 mg daily, and zopiclone 7.5 mg nocte.

Materials and methods: Emerging research suggests that peripheral tissue hypoxia may play a role in RLS pathophysiology. A study demonstrated a strong association between reduced leg oxygenation and symptom severity in untreated patients with RLS. Based on this, HBOT was trialled as a novel therapeutic approach. In February 2025, the patient commenced a HBOT protocol consisting of 30 sessions, each lasting 50 minutes and uptitrated to 1.9 atmospheres absolute, delivered 3–4 times per week. No concurrent changes were made to her medication regimen during the HBOT course.

Results: The patient reported symptomatic improvement within two weeks of initiating HBOT. Upon completion of the initial 30-session protocol, she reported marked improvements in subjective sleep quality, mood, and both the frequency and severity of RLS symptoms. Her International Restless Legs Scale score decreased from 21 (severe) to 2 (mild). The treatment was well tolerated, with no reported adverse effects. Given the durability of symptom control between sessions, the patient has continued on HBOT indefinitely with a plan to de-escalate the frequency of sessions. In parallel, the patient began a supervised taper of gabapentin, reducing the dose by 100 mg every three weeks. She is currently stable on gabapentin 400 mg daily, without recurrence of significant symptoms.

Conclusions: This case highlights the potential for HBOT to serve as a novel adjunctive therapy for patients with refractory RLS, particularly when conventional treatment options have been exhausted. If further validated, HBOT may offer a promising avenue for improving quality of life in this challenging patient population.

Acknowledgments: We acknowledge the patient who has provided consent for the abstract.

Tonic motor activation therapy in patients with painful versus painless restless legs: An interim 180-day results from the THRIVE study

E.G. Karroum¹, J. Ojile², M. Buchfuhrer³, H. Singh⁴, A. Roy⁵, R. Bogan⁶, R. Thomas⁷, J. Charlesworth⁸

¹Department of Neurology, University of Virginia School of Medicine, Charlottesville, United States, ²Clayton Sleep Institute, St. Louis, United States, ³Stanford University School of Medicine, Stanford, United States, ⁴Sleep Physicians, San Ramon, United States, ⁵Ohio Sleep Medicine Institute, Dublin, United States, ⁶Bogan Sleep Consultants, Columbia, United States, ⁷Beth Israel Deaconess Medical Center, Boston, United States, ⁸Noctrix Health, Inc., Pleasanton, United States

Introduction: Painful and painless restless legs syndrome (RLS) phenotypes have been characterized in several studies. Compared to painless RLS, painful RLS is a more severe clinical form. However, there is scarcity of data evaluating treatments for painful and painless RLS. Bilateral high-frequency peroneal nerve stimulation or tonic motor activation (TOMAC) is a new non-invasive and non-pharmacological treatment cleared for patients with medication-refractory RLS based on its efficacy and safety profile in several recent clinical trials. The current study compared TOMAC effectiveness in patients with painful and painless RLS using real-world interim results from the THRIVE study.

Materials and methods: The THRIVE study, an ongoing multi-center, prospective, post-market, observational study was used to extract interim 180-day data for analysis. The THRIVE study evaluates long-term effectiveness and safety of the NTX100 TOMAC system (Nidra; Noctrix Health, Inc.) in adults with RLS. Painful RLS was classified based on participants answering 'Yes' to both of the following baseline consecutive questions: "Do you have unpleasant or uncomfortable feelings associated with the urge to move your legs?" and "Are these unpleasant or uncomfortable feelings painful?" Baseline assessments were conducted prior to the initiation of TOMAC treatment, with interim outcomes evaluated at Day 180 relative to baseline. Data collected at baseline included age, sex, family history of RLS, age of RLS onset, current RLS medications, augmentation severity rating scale, International RLS Severity Scale (IRLS) score, diagnosis of neuropathy, and the titrated stimulation intensity of TOMAC. The primary endpoint was the change in IRLS score at 180 days. Secondary endpoints at 180 days included the Clinical Global Impression-Improvement (CGI-I) score and the CGI-I responder rate (defined as the proportion of patients with a CGI-I response of "Very Much Improved" or "Much Improved"). Changes in RLS medications at 180 days were also assessed.

Results: A total of 73 adult patients with medication-refractory, moderate-to-severe RLS—36 with painful RLS and 37 with painless RLS—completed 180-day follow-up. These individuals constituted the intent-to-treat population, with data imputed for those who withdrew from the study. At baseline, patients with painful RLS had significantly more severe symptoms compared to those with painless RLS, as indicated by higher mean IRLS scores (27.7 ± 5.6 vs. 23.9 ± 5.4 ; $P = 0.005$), and were more often treated with dopaminergic agents (66.7% vs. 43.2%; $P = 0.044$). Other baseline characteristics were comparable between the two groups. After 180 days, there was no significant difference in the mean change in IRLS scores between painful and painless RLS patients (-8.7 ± 6.6 vs. -7.8 ± 7.7 ; $P = 0.589$). Similarly, mean CGI-I scores (2.5 ± 1.2 vs. 2.4 ± 1.3 ; $P = 0.817$), CGI-I responder rates (66.7% vs. 51.4%; $P = 0.184$), and changes in RLS medications were not significantly different between groups.

Conclusions: Patients with painful RLS exhibited more severe symptoms and higher dopaminergic use at baseline, consistent with painful RLS being a more severe phenotype. However, after 180 days of TOMAC therapy, both painful and painless RLS groups demonstrated similar improvements, suggesting that TOMAC is similarly effective across both RLS phenotypes.

Acknowledgments: We thank the THRIVE study team.

RevRound 2

Identification of circulating inflammatory proteins as mediators of sleep apnea on aging and validation of inflammation-drug targets using prioritization profiling

J. Wang¹

¹Sun yat-sen university, School of public health, Guangzhou, China

Introduction: Background Sleep apnea (SA) may accelerate aging via inflammation, but its mechanisms and therapeutic targets remain poorly understood. We aimed to explore the causal links between SA, inflammatory proteins, and aging, and prioritize drug targets for SA and healthy aging. We searched PubMed using the search terms "sleep apnea", "inflammation", "aging", "mediation" on March 20, 2024 and identified 14 studies on the associations of SA and aging, showing that SA was associated with several aging indicators (Table S1). However, these studies might be limited by residual confounding

and potential reverse causality, and evidence from randomization clinical trial (RCT) is scarce. Only one RCT reported that adherence to continuous positive airway pressure (CPAP) for 12 months in SA patients slowed epigenetic aging, yet this study examined a single aging marker and involved a short follow-up period.

Materials and methods: Methods We examined the association of SA with aging using data from the Guangzhou biobank cohort study (GBCS) and assessed causality with summary-level statistics from genetic studies involving over 350,000 European participants. We first identified inflammatory proteins mediating the association between SA and aging indicators (leukocyte telomere length (LTL), bioage acceleration (BA) and phenoage acceleration (PA)) using mediation Mendelian randomization (MR), colocalization analysis, and pathway enrichment analysis. Second, we systematically assessed the causal role of these inflammatory proteins on SA and aging outcomes using phenome-wide MR and colocalization analysis, and prioritized drug targets by integrating genetic findings with clinical trial evidence.

Results: Results Of 30,055 participants from the Guangzhou Biobank Cohort Study, with a median follow-up of 11.2 years, 17,487 were assessed for SA, 9,872 for BA, and 2,350 for relative telomere length (RTL). SA was associated with increased PA ($\beta=0.94$, 95% confidence interval (CI) 0.60, 1.28) and higher risk of mortality (Hazard ratio (HR)=1.18, 95%CI 1.07, 1.31), but not with RTL. MR supported the causal association between SA and PA ($\beta=0.82$, 95%CI 0.29, 1.34) and identified HGF and IL-8 as mediators, explaining 17.4% and 15.0% of the variance, respectively. Enrichment analyses showed shared pathways related to cell chemotaxis and cytokine signaling. Drug prioritization profiling in 381 protein-disease pairs identified five inflammatory proteins as promising drug targets for aging, including FGF-5, CCL19, MIP-1 alpha, SLAMF1, and CCL13.

Conclusions: Conclusions This is the first study comprehensively assessing the causal roles of 106 inflammatory proteins as potential mediators of SA on aging and prioritizing inflammation-related drug targets for addressing SA and aging. Phenome-wide Mendelian randomization (MR) analyses support a causal effect of SA on aging acceleration, with HGF and IL-8 mediating a substantial proportion of the effect. Moreover, we identified six promising drug targets for aging deceleration, including two candidates for drug-repurposing (CCL19 and MIP-1 alpha) and three novel protein-aging pairs (FGF-5, SLAMF1 and CCL13) that warrant further investigation.

Acknowledgments: The authors thank the investigators from the GBCS (Guangzhou biobank cohort study) and all the original GWAS used in the present study.

Effect of Sleep Disordered Breathing on Pregnancy Outcomes in Women Undergoing In Vitro Fertilization: A Systematic Review and Meta-Analysis

S. Vinod Kutty¹, R. Gupta², M. Asif¹

¹All India Institute of Medical Sciences, Mangalagiri, General Medicine, Mangalagiri, India, ²All India Institute of Medical Sciences, Rishikesh, Psychiatry, Rishikesh, India

Introduction: Studies suggest that OSA impairs female fertility in patients with polycystic ovary syndrome, suggesting an adverse effect on in vitro fertilization cycle stimulation characteristics and clinical outcomes. Frequent snoring has been found to have an association with a decreased number of available oocytes and an increased risk of pregnancy loss following IVF. Further research is required to understand the potential influence of obstructive sleep apnea (OSA) on infertility and pregnancy outcomes.

Materials and methods: Details of the review are included in the PROSPERO registration CRD420251035788

<https://www.crd.york.ac.uk/PROSPERO/recorddashboard>

Results: Research in progress

Conclusions: There is a potential role for the management of obstructive sleep apnea to improve outcomes in patients undergoing IVF

Sleep Breathing Disorders

A buccal mucosal reflectance oximeter accurately measures arterial oxyhemoglobin saturation and pulse rate

G. Vogel¹, C. Snow², M. Pun², S. Magnison-Benoit², T. Tripp², A. Clarke², B. Hansen², L. Transfiguracion³, G. Di Simone¹, M.-L. Lai¹, J. Rawling², S. Roy², S. Adatia⁴, E. Mosca¹, J. Remmers¹, M. Poulin²

¹ProSomnus Sleep Technologies, Pleasanton, United States, ²University of Calgary, Calgary, Canada,

³Alberta Health Services, Calgary, Canada, ⁴Symmetry Dental, Calgary, Canada

Introduction: Pulse oximeter devices (SpO₂) suitable for multi-night monitoring of arterial oxyhemoglobin saturation (SaO₂) are not readily available despite a need to monitor SaO₂ decreases in patients with sleep apnea and pulmonary diseases during sleep. The objective of the current study was to assess the SpO₂ and pulse rate accuracy of a buccal mucosal oximeter embedded into a custom-fitted overlay of the upper teeth by comparison to a gold standard (CO-oximeter SaO₂ and 3-lead electrocardiogram [ECG] heart rate).

Materials and methods: Twelve healthy participants (four females) aged 30.7±6.7 (22-39) years underwent a progressive stepwise desaturation protocol consisting of six 7-minute stages of decreasing levels of end-tidal oxygen (P_{ET}O₂; 90.1, 63.8, 53.0, 46.4, 41.6, and 37.9 Torr) to achieve a range of SaO₂ from approximately 97-70% during semi-recumbent, non-motion conditions. P_{ET}O₂ and P_{ET}CO₂ were controlled by a dynamic end-tidal forcing function system. Arterial blood was drawn and analyzed using a Radiometer ABL800 CO-oximeter in the last three minutes of each stage. SpO₂ and pulse rate values from the buccal mucosal oximeter were compared with CO-oximeter values of SaO₂ and ECG heart rate, respectively.

Results: SaO₂ values were evenly distributed over the range of 97-67%. Analysis of 325 CO-oximeter SaO₂/buccal mucosal oximeter SpO₂ data pairs yielded: r = 0.95; bias = 0.72; and accuracy root-mean-square (A_{RMS}) = 2.94%. Analysis of 346 ECG heart rate/buccal mucosal oximeter pulse rate data pairs yielded: r = 0.99, bias = 0.30; and A_{RMS} = 2.08 bpm.

Conclusions: The buccal mucosal oximeter accurately measured SpO₂ and pulse rate, as shown by good agreement with a gold standard, over a wide range of arterial hypoxemia. Such clinically acceptable accuracy indicates that this novel reflectance oximeter may prove useful in the management of patients with sleep-induced hypoxemia by providing multi-night monitoring of SaO₂. Additionally, the intraoral placement of the oximeter might overcome some limitations of other pulse oximeters, as the buccal mucosa is highly vascularized, temperature regulated, protected from ambient light, and appears to lack melanin.

Acceptability and results of home sleep apnoea testing in older adults with mild cognitive impairment and dementia and cognitively unimpaired older adults: Towards a multi-centre study of sleep apnoea prevalence in memory clinics

V. Gabb^{1,2,3}, H. Li^{4,5}, A. Kendrick⁶, J. Blackman^{1,2,3}, H. Morrison^{2,1}, N. Turner¹, E. Coulthard^{1,2,3}

¹University of Bristol, Bristol, United Kingdom, ²North Bristol NHS Trust, Bristol, United Kingdom,

³NIHR Bristol Biomedical Research Centre, Bristol, United Kingdom, ⁴King's College London, London, United Kingdom, ⁵King's College Hospital, London, United Kingdom, ⁶University of the West of England, Bristol, United Kingdom

Introduction: Good sleep is key to brain health. Yet, sleep is rarely objectively assessed in cognitive disorders clinics. Sleep apnoea (SA) is a common sleep-breathing disorder with significant impacts on cardiovascular health and cognition, effectively treated using established (e.g., continuous positive airway pressure, CPAP) and emerging techniques (e.g., implant devices, weight loss medications). SA is associated with increased dementia risk and may be a modifiable dementia risk factor. To build towards interventional studies, we examined the prevalence of sleep apnoea and barriers and facilitators to sleep apnoea assessment in a cohort of older people with and without dementia.

Materials and methods: 40 participants (10 with mild cognitive impairment, 10 with dementia and 20 age-matched controls) were enrolled in a longitudinal cohort study of sleep and cognition. All participants were asked to complete questionnaires on SA risk (STOP-BANG) and daytime sleepiness

(Epworth Sleepiness Scale, ESS). Participants without an existing diagnosis of SA were asked to complete two consecutive nights of overnight pulse oximetry (Nonin 3150 WristOx2). Oxygen desaturation index (ODI) was calculated based on number of desaturation episodes ($\geq 3\%$ for > 10 seconds) per hour.

Results: Most participants asked ($N=33/37$, 83%) provided at least one night of analysable overnight pulse oximetry data of > 4 hours. Three participants had an existing diagnosis of SA and were receiving CPAP treatment prior to study enrolment. One participant was unable to tolerate the device due to uncomfortable sensations on the finger and three participants declined SA testing. Referrals to the sleep clinic for likely SA were indicated for 21 participants: 10 had mild ODI ($\geq 5 < 15$), 3 had moderate ODI ($> 15 \leq 30$), 3 had severe ODI (≥ 30), and 5 had normal ODI (< 5) but high pulse rise index. 17/21 (81%) participants agreed to referrals. Barriers to SA testing among older adults included concerns around receiving additional diagnoses, potentially stopping driving, not wanting to use CPAP, and the distance required to travel for appointments. An $ODI \geq 5$ was not associated with excessive daytime sleepiness indicated by $ESS \geq 10$ [$p = 0.722$, sensitivity = 33%, specificity = 73%] but was marginally associated with STOP-BANG scores ≥ 3 [$p = 0.047$, sensitivity = 89%, specificity = 47%].

Conclusions: SA may be a reversible contributor to cardiovascular morbidity, poor sleep quality, and cognitive disorders including dementia. However, SA is often undiagnosed in older adults. Existing screening questionnaires may be suboptimal to accurately screen for SA in this population. To establish prevalence of SA in a memory clinic population and which symptoms most strongly predict SA prevalence, the Sleep Apnoea and Memory (SAM) study will invite all patients attending several sleep clinics across England to undergo SA screening using the WatchPAT home sleep apnoea test and complete detailed SA symptom screening.

Acknowledgments: We would like to thank our participants, their relatives, and our lived experience experts. We would also like to thank the North Bristol NHS Trust Respiratory Physiology department and our funders (BRACE, Bristol & Weston Hospitals Charity, David Telling Charitable Trust, Alzheimer's Research UK, and philanthropic donors S Scobie and A Graham).

Acceptance, Compliance and Efficacy of Mandibular Advancement Splint Therapy in Atrial Fibrillation Patients

A. Mohammadi^{1,2}, J. Colpani³, C.-H. Lee⁴, P. Cistulli^{1,2}

¹University of Sydney, Charles Perkins Centre, Sydney, Australia, ²Royal North Shore Hospital, Respiratory and Sleep Medicine, Sydney, Australia, ³National University of Singapore, Department of Endodontics, Operative Dentistry and Prosthodontics, Faculty of Dentistry, Singapore, Singapore, ⁴National University Heart Centre, Singapore, Singapore

Introduction: Clinical guidelines recommend that the management of atrial fibrillation (AF) should include assessment and treatment for obstructive sleep apnoea (OSA) (1-3). However, acceptance and compliance with CPAP therapy is often low (4). Alternative therapy is needed.

This is a pilot study of Mandibular Advancement Splint (MAS) treatment of OSA in AF patients in Australia and Singapore. Primary outcomes were patient acceptance, compliance, and MAS efficacy. Secondary outcomes included AF burden, MAS patient-centred evaluation, side effects, quality of life, and change in ambulatory blood pressure. In addition, the feasibility of tools for the assessment of AF recurrence was assessed.

Materials and methods: Patients with AF and OSA were treated with MAS over 6 months. Polysomnography (PSG) was performed at baseline and 6 months. Patient acceptance was defined as the proportion of patients who continued using the MAS after an initial one-week lead-in period. Compliance was defined as ≥ 4 hours of MAS usage on $\geq 70\%$ of nights, based on the inbuilt compliance recorder (DentiTrac, Braebon). MAS efficacy was assessed via change in Apnea Hypopnea Index between baseline and six months. Feasibility of tools for the assessment of AF recurrence was evaluated by numerous methods for AF detection.

Results: A total of 33 patients (16 in Australia, 17 in Singapore) were recruited, and all participants have completed the study. Interim data from 12 patients (all in Australia, 75% male, mean age 65.5 ± 10.2 years, and BMI 29.6 ± 4.8 kg/m²) have been analysed. Ten out of 12 patients continued using the MAS after one week, giving an acceptance rate of 83.3%. The pre-determined compliance threshold at 3 and 6 months was met by 80% of the study participants. Of the 10 patients who continued to use the MAS

at 6 months, 60% met the liberal criteria for MAS response, and 40% met the strict criteria for MAS response. A daily at-home ECG device (AliveCor Kardia) showed the best performance in detecting AF recurrence (in 58% of patients).

Conclusions: Interim results from this pilot study suggest that treatment of OSA using MAS therapy in AF patients is feasible. A high level of acceptance, compliance and efficacy was observed. Analysis of the remaining data is underway, including a comparison of Australian and Singaporean groups.

Accuracy of a buccal mucosal reflectance oximeter in measuring and reporting oxygen desaturation index in individuals with obstructive sleep apnea: A pilot study

E. Mosca¹, L. Liptak¹, M.-L. Lai¹, G. Di Simone¹, W. Weisshaar¹, C. Holland¹, S. Adatia², J. Remmers¹

¹ProSomnus Sleep Technologies, Pleasanton, United States, ²Symmetry Dental, Calgary, Canada

Introduction: Pulse oximeter devices (SpO₂) suitable for multi-night monitoring of arterial oxyhemoglobin saturation (SaO₂) are not readily available despite a need to monitor SaO₂ decreases in patients with sleep apnea during sleep. ProSomnus Sleep Technologies (Pleasanton, CA) previously developed a buccal mucosal pulse oximeter embedded into a custom-fitted overlay of the upper teeth. The oximeter has previously been validated against the gold standard, i.e., arterial samples analyzed using CO-oximetry, in a controlled desaturation study in healthy, awake volunteers.

The objective of the current pilot study was to assess the accuracy of the oxygen desaturation index (ODI) of the buccal mucosal oximeter in individuals with obstructive sleep apnea (OSA) during sleep by comparing the ODI from the buccal mucosal oximeter to that from a reference oximeter (WristOx 3150, Nonin Medical Inc., Plymouth, MN).

Materials and methods: Eight volunteers previously diagnosed with moderate or severe obstructive sleep apnea wore the buccal mucosal and reference oximeters overnight in the home for two nights of sleep. Volunteers wore only the upper dental overlay of the buccal mucosal oximeter for the first night (untreated). A lower arch of a mandibular advancement device was added for the second night of sleep to provide mandibular protrusion in the range of 30-70% (treated). Data from the buccal mucosal oximeter were compared to the data from the reference oximeter.

Results: Sixteen nights of data were collected from the eight participants. Linear regression showed good concordance between the buccal mucosal oximeter and reference oximeter ($r = 0.94$; $p < .000001$). Bland-Altman analysis showed a bias of 1.9 and upper and lower 95% limits of agreement of 11.0 and -7.2, respectively. With the upper dental overlay only (untreated), the mean ODI was 26.3 ± 12.9 for the buccal mucosal oximeter and 28.1 ± 13.2 for the reference oximeter ($p = 0.2656$), indicating no significant difference between the two ODIs. When the upper dental overlay was used in conjunction with the lower arch of a mandibular advancement device, the mean ODI was 13.4 ± 8.7 for the buccal mucosal oximeter and 15.4 ± 10.6 for the reference oximeter ($p = 0.4609$), indicating no significant difference between the two ODIs. The difference between the untreated and treated position was significant for both the Nonin oximeter and buccal mucosal oximeter ($p < 0.05$ for both).

Conclusions: The results of this pilot study indicate that a reflectance oximeter embedded in a dental overlay can report an accurate oxygen desaturation index in individuals with obstructive sleep apnea both when used on its own and when used in conjunction with a mandibular advancement device, demonstrating that this technology has the potential to objectively quantify the efficacy of mandibular advancement device therapy. Further research is needed to validate these results in a larger population against a gold standard.

Acknowledgments: The authors thank Dr. Trevor Day (Mount Royal University, Calgary, Alberta, Canada) for loaning Nonin WristOx devices for the project.

A comparative study of a finger-worn One Sleep Test (NightOwl)[™] with in-lab polysomnography for the diagnosis of obstructive sleep apnea

S. Mittal¹, T.K. Boppana¹, P. Tiwari¹, D.S. Chandran², T.M. Suri¹, V. Hadda¹, K. Madan¹, A. Mohan¹

¹All India Institute of Medical Sciences, Pulmonary, Critical care and Sleep Medicine, Delhi, India, ²All India Institute of Medical Sciences, Physiology, Delhi, India

Introduction: Overnight in-lab technician attended polysomnography (PSG) is the gold standard method for the diagnosis of obstructive sleep apnea (OSA). However, long waiting period results in the delay in diagnosis and therapy leading to significant morbidity. For the diagnosis of sleep apnea, newer portable device One Sleep Test™ (OST) is available which is based upon peripheral arterial tonometry rather than conventional flow sensor-based technology. This device has not been well studied in Indian subjects. Aim of the study was to assess the correlation of apnea hypopnea index (AHI) measured using OST and in-lab polysomnography and to estimate the sensitivity and specificity of OST for the diagnosis of obstructive sleep apnea.

Materials and methods: We prospectively evaluated the diagnostic performance of a finger-worn portable sleep study device, the One Sleep Test™, which is a combination of oximetry, actigraphy and peripheral arterial tonometry. Patients with suspected OSA underwent simultaneous in-lab level 1 diagnostic polysomnography and OST testing. The results from both modalities were compared. The PSG scorer was blinded to the result of the OST study.

Results: Thirty-eight patients (25 males and 13 females) were studied and had a mean (SD) age of 40.89 (12.4) years. The mean (SD) body mass index of study subjects was 29.49 (5.17) kg/m². Thirty-one out of 38 patients were found to have OSA (AHI ≥ 5) while 27 had moderate to severe OSA by polysomnography (AHI ≥ 15). The mean (SD) OST sleep efficiency was 83.18% (9.77), whereas the mean (SD) PSG sleep efficiency was 75.46% (17.06). There was a good correlation ($r=0.85$, $p<0.001$) between the median (IQR) OST AHI of 13 (3-45.75) events/hour and the median (IQR) PSG AHI of 20.3 ± 10.87 events/hr.

For the diagnosis of OSA (AHI ≥ 5), the sensitivity as well as specificity of OST were 87.09% and 85.7% respectively. The sensitivity and specificity of OST for the diagnosis of moderate-severe OSA (AHI ≥ 15) were 66.67% and 100% respectively.

Conclusions: OST is a useful portable diagnostic device for the diagnosis of obstructive sleep apnea.

Acknowledgments: The authors would like to thank Mr Aakash Singh for his help with data management.

A Cross-Sectional Study on Sleep-Related Breathing Disorders and School Performance Among School Children in Mindanao, Philippines

G. Urbi¹

¹Southern Philippines Medical Center, Dental medicine, Davao City, Philippines

Introduction: Sleep-Related Breathing Disorders (SRBDs) in children, such as obstructive sleep apnea (OSA), are associated with behavioral, cognitive, and emotional impairments that may hinder academic performance. In low-resource, linguistically diverse regions like Mindanao, the lack of validated screening tools limits early identification and intervention.

Materials and methods: Method: A two-phase design was employed. Phase I involved forward-backward translation and expert validation of the PSQ-SRBD into Bisaya, followed by psychometric testing ($n = 128$) and test-retest reliability ($n = 69$). In Phase II, a cross-sectional study screened 2,320 children (aged 8–14) across Mindanao using parent-reported questionnaires (Bisaya, English, or Filipino versions). Logistic regression identified predictors of SRBD risk and academic outcomes.

Results: Result: The Bisaya PSQ-SRBD demonstrated strong psychometric properties, with high internal consistency (Cronbach's $\alpha = 0.77$) and excellent test-retest reliability (ICC = 0.904), confirming its suitability for use in multicultural, community-based settings. Of the 2,320 schoolchildren screened, 8.7% were identified as high risk for SRBD. Multivariate logistic regression revealed that older age (11–14 years), residence in the Caraga region, lower parental education, presence of comorbid conditions, insufficient sleep duration, and engagement in modular or online learning modalities significantly increased the likelihood of SRBD ($p < .05$). Importantly, SRBD risk was strongly associated with decreased academic performance across all major subjects—Filipino, English, Mathematics, and Science ($p < .001$). Moreover, even after controlling for SRBD status, both household smoking exposure and socioeconomic disadvantage (e.g., low income, low parental education) emerged as robust independent predictors of poor school outcomes. These findings highlight the multifactorial nature of academic underperformance, with SRBD acting as both a direct and indirect contributor.

Originality: This is the first study to validate the PSQ-SRBD in Bisaya and apply it to a large-scale

Conclusions: Conclusion: SRBD significantly impairs school performance, especially among older children, those in socioeconomically disadvantaged regions, and those with poor sleep hygiene. Regional and socioeconomic disparities further intensify academic vulnerability.

Adenotonsillectomy/Adenoidectomy Can Reduce Central Apnea Events in Children with Sleep-Disordered Breathing: A Single-Center 7 Years Prospective Cohort Study Analysis

D. Li¹, J. Xiao¹, G. Yin¹

¹Beijing Tsinghua Changgung Hospital, School of Clinical Medicine, Tsinghua University, Otorhinolaryngology-Head and Neck Surgery, Beijing, China

Introduction: To analyze the effects of adenotonsillectomy (T&A) or adenoidectomy (AT) on central sleep apnea (CSA) in children with adenotonsillar hypertrophy or adenoidal hypertrophy.

Materials and methods: In this prospective cohort study, children with central apnea index (CAI) ≥ 1 event/h who underwent T&A or AT due to adenotonsillar hypertrophy or adenoidal hypertrophy from June 2017 to November 2024 were included.

Results: A total of 2047 children underwent T&A/AT and full-night preoperative PSG with CAI ≥ 1 . 258 children successfully underwent PSG follow-up and were evaluated for surgical efficacy. Compared with the baseline data, CAI was significantly reduced after surgery ($P < 0.001$). The postoperative CAI in 132 (51.16%) children was significantly improved ($\geq 50\%$). Children with significant CSA improvement had significant higher preoperative CAI, OAH1, AHI, HI, ODI, N1 stage percentage and arousal index ($P < 0.05$). Moreover, improvement of CSA was positively correlated with children's age and reduction of arousal index while severe obese children exhibited limited CAI reduction.

Conclusions: The incidence of CSA was noticeable in children with adenotonsillar hypertrophy or adenoidal hypertrophy. T&A/AT can effectively improve CSA among these children. Children with higher preoperative CAI and OAH1 were more likely to obtain greater improvement in CSA.

Adherence-Driven Outcomes of Orofacial Myofunctional Therapy Combined with CPAP in Severe Obstructive Sleep Apnea: A Retrospective Cohort Study

S. Maity¹, A. Halder², D. Datta³

¹Institute of Sleep Science, Department of Physiotherapy, Consultant Myofunctional Therapist & Sleep Health, Kolkata, India, ²Institute of Sleep Science, Department of Sleep Medicine, Consultant Pulmonologist and Sleep Medicine, CMRI, Kolkata, India, ³Institute of Sleep Science, Department of ENT, Consultant ENT and Sleep Apnoea Surgeon, Manipal Broadway Hospital, Kolkata, India

Introduction: Obstructive sleep apnea (OSA), a disorder with significant morbidity, requires effective interventions. This study evaluates the clinical impact of Orofacial Myofunctional Therapy (OMT) combined with CPAP on daytime sleepiness and treatment adherence in severe OSA.

Materials and methods: A retrospective analysis of 197 adults (mean age: 54.4 years; 70% male) with severe OSA (mean AHI: 40.3) assessed ESS scores, medication use, sleep-related quality of life (QoL), and adherence. Statistical analyses included paired t-tests, ANOVA, and chi-square tests.

Results: OMT+CPAP yielded a clinically significant ESS reduction of 8.1 points (pre: 12.69 vs. post: 4.59; $p < 0.001$). High adherence (daily 15–20-minute sessions over ~133 days) correlated with optimal outcomes:

- 92.4% medication reduction ($p < 0.001$),
- 100% QoL improvement,
- 9.1% dropout rate.

Low adherence led to minimal benefits (7.5% medication reduction, 61.2% QoL improvement) and universal dropout (100%). Overall, 84.3% reported improved sleep quality. Statistical significance was confirmed for ESS improvements (paired t-test) and adherence-driven differences (ANOVA, $p < 0.001$). Limitations included data inconsistencies in QoL metrics and a 59.9% overall dropout rate.

Conclusions: OMT+CPAP significantly reduces daytime sleepiness in severe OSA, particularly with high adherence. The strong adherence-outcome relationship underscores the need for patient engagement strategies. While results are promising, data quality issues and attrition highlight the necessity for robust prospective studies.

These findings advocate for integrating OMT into OSA management protocols, emphasizing adherence monitoring through telemedicine. Future research should validate these results in controlled trials with long-term follow-up.

Keywords: Sleep-disordered breathing, myofunctional therapy, adherence, therapy duration, clinical outcomes.

Airflow Dynamics Effects of Velum Collapse Patterns in Obstructive Sleep Apnea: A Computational Fluid Dynamics Study

Y.-F. Chen¹, E.-Y. Huang², P.-H. Liu³

¹Kaohsiung Medical University, Oral and Maxillofacial Surgery Department, Kaohsiung, Taiwan, ²I-Shou University, Electrical Engineering, Kaohsiung, Taiwan, ³I-Shou University, Biomedical Engineering, Kaohsiung, Taiwan

Introduction: Obstructive sleep apnea (OSA) is characterized by recurrent episodes of partial or complete upper airway obstruction during sleep. This study aimed to investigate the effects of three velum collapse patterns on airway airflow dynamics in patients with OSA using computational fluid dynamics (CFD) analysis.

Materials and methods: A 3D model of the upper airway—including the velum, oropharynx, tongue, and epiglottis region was developed based on a moderate obstructive sleep apnea patient (AHI: 19.3/hr, ODI: 19.0/hr, Minimum oxygen saturation: 86%). The velum region was simulated with three types of 75% airway narrowing: anteroposterior, lateral, and circumferential. Velocity and pressure distributions of the velum region airway structures were investigated.

Tetrahedral element was selected for meshing on the whole airway models. The mesh size and element number of the finite element models were 1.5 mm and 787,274, respectively. A 1.5-second breathing duration was selected in each phase of inspiration and expiration. The initial velocity and pressure at the airway walls were set to zero, and a no-slip condition was applied.

Results: The high velocity (6.51–13.02m/s) of the moderate model occurred at 0.8 seconds in inspiration and 2.2 seconds in expiration, respectively. The major concentrations were detected at the regions of inferior border of velum and anterior border of nasal concha. Comparing peak velocities in the three velum collapse models, the maximum peak velocity (56.11m/s) was detected in the model of the lateral collapse, and the minimum peak velocity (23.05m/s) was detected in the model of the circular collapse. The large velocity was obviously appeared at the inferior border of velum, but area of the peak velocity was significantly increased in each collapse model. For the moderate model, the maximum positive pressure was 65.44Pa at the anterior border of nasal concha during inspiration, and the maximum negative pressure (-59.02Pa) still located at the anterior and posterior border of nasal concha during expiration. The maximum negative pressures of the velum collapse models from large to small were lateral (-1669.70Pa), anteroposterior (-573.87Pa), and circular (-278.42Pa) collapse.

Moreover, the maximum negative was concentrated at the narrowest section of the velum region for three collapse models. The peak positive pressures were confirmed at the upper half airway during inspiration and the lower half airway during expiration. The collapse pattern was demonstrated to affect the fluid performance of airflow entering airway of the velum region.

Conclusions: The worst case of narrow structure in the velum to cause abnormal fluid behavior was significantly obtained in the model of the lateral collapse when the same cross-sectional area of the velum collapses was set. The type of the lateral collapse in the velum could obviously increase resistance of passing airflow by reflecting intensification in positive and negative pressures and high velocities.

AI-rway A Scalable Smartphone based Airway Screening tool for OSA and SDB for use @ Scale in pediatric and adult populations

P. Gopi¹, A. Yoon², E. Phelps³, P. Hwang², B. Lin², V. Mohan¹

¹SoundHealth, Santa Clara, United States, ²Stanford University, Stanford, United States, ³Phelps and Cohen Orthodontics, San Jose, United States

Introduction: Accurate assessment of sinonasal anatomy is foundational to diagnosing nasal obstruction, sleep-disordered breathing, and related dentofacial growth issues. However, the use of CBCT imaging for large-scale screening is limited by cost, radiation exposure, and accessibility—particularly in pediatric populations. To overcome these limitations, we have developed an AI-powered mobile platform that estimates sinonasal anatomy and airway function using only a smartphone's camera and microphone.

Materials and methods: The app combines two key biometric inputs: (1) 3D facial scans captured from standard smartphone cameras, and (2) voice recordings taken in both supine and upright positions. The facial scan module extracts craniofacial landmarks predictive of internal nasal dimensions, enabling a virtual reconstruction of airway structures. The voice module quantifies nasal airflow by analyzing speech resonance patterns to produce a real-time "Voice Nasal Flow Index" (VNFI), sensitive to posture-induced congestion and obstruction.

The integrated platform generates three core scores—upper airway susceptibility (linked to allergen entrapment), lower airway resistance (related to structural narrowing), and the VNFI—each contributing to an overall "Airway Health Score." This summary index provides a simple, actionable indicator for users and providers, with a built-in referral system to direct patients to care as needed.

Designed for scale, the Airway App is optimized for both pediatric and adult use, supporting screening programs in schools, dental practices, and sleep clinics. Its non-invasive, radiation-free design makes it particularly suited for early identification of airway dysfunctions that may influence craniofacial development, orthodontic planning, and sleep quality.

Results: Validation studies comparing the algorithms anatomic estimates to clinical CT scans across both adult and pediatric cohorts showed a mean accuracy of 95% for key nasal airway parameters, including nasal cavity width, palatal height, and septal deviation. The voice-based biomarkers further distinguished normal vs. obstructed airflow with high sensitivity, enabling functional profiling in real-world environments.

Conclusions: In conclusion, the smartphone based Airway screening App offers a breakthrough in accessible airway diagnostics—combining CT-equivalent anatomical estimation with posture-sensitive voice biomarkers. It enables precision screening at population scale, positioning it as a powerful front-line tool in dentofacial and respiratory health.

Alcohol Exacerbated Nocturnal Enuresis Associated with Obstructive Sleep Apnea: A Case Report

E. Ay¹, M. Aksu¹

¹Acibadem Mehmet Ali Aydinlar University, Department of Neurology, Istanbul, Turkey

Introduction: Adult-onset or persistent nocturnal enuresis is an uncommon and often distressing symptom that can be multifactorial in origin. While urologic, neurologic, or psychiatric causes are more commonly considered, sleep-disordered breathing has emerged as an underrecognized contributor. Obstructive sleep apnea (OSA), particularly when compounded by alcohol-induced airway relaxation and hypoxemia, can lead to enuresis due to increased intrathoracic pressure, sleep fragmentation, and autonomic dysfunction. This report describes a patient whose long-standing but intermittent enuresis became exacerbated by alcohol and resolved with CPAP treatment for severe OSA.

Materials and methods: A 27-year-old male presented with a long-standing history of intermittent nocturnal enuresis. He reported that episodes occurred 2–3 nights per week, exclusively after alcohol consumption. The patient had experienced bedwetting since early childhood but had long periods of dryness during adolescence and early adulthood. There was no history of daytime incontinence or urinary urgency. His past medical history was unremarkable. His mother recalled a difficult birth but no early-life diagnoses were established.

The patient had previously trialed imipramine (Tofranil) and oxcarbazepine (Trileptal) with no improvement. Notably, his mother reported loud snoring, witnessed apneas, and frequent arousals during sleep. A diagnostic polysomnography with continuous EEG monitoring was ordered.

Polysomnography Results:

Total sleep time: 376 minutes

AHI: 61 events/hour (severe OSA)

Obstructive apneas: 37, Hypopneas: 344

Minimum SpO₂: 76%, with SpO₂ <90%: 33 minutes

REM latency: 166 minutes

Sleep efficiency: 77%

No parasomnias, motor or cardiac anomalies were noted. Full EEG performed concurrently showed no paroxysmal activity, interictal discharges, or epileptiform abnormalities, ruling out an ictal cause for the enuresis.

CPAP titration was subsequently performed, and the optimal pressure was determined to be 6 cmH₂O, which effectively eliminated apneas and improved oxygenation. After initiating nightly CPAP, the patient experienced complete resolution of enuresis—even on nights when alcohol was consumed.

Results: This case illustrates how enuresis in adults, particularly when episodic and alcohol-triggered, may reflect underlying sleep-disordered breathing. Alcohol acts as a respiratory depressant, reducing pharyngeal tone and increasing the likelihood and severity of apneas. In this patient, despite a misleading history of primary enuresis, the clear temporal association with drinking, the oxygen desaturation severity, and the complete response to CPAP point strongly to OSA as the primary cause.

The presence of enuresis only during apneic nights suggests a mechanistic relationship, potentially involving increased intravesical pressure during arousals, impaired arousal responses, or nocturnal polyuria mediated by atrial natriuretic peptide due to negative intrathoracic pressure.

This case also highlights the limitations of relying solely on symptoms or AHI to determine the need for therapy. While his AHI was in fact severe (61), it is the oxygen desaturation burden and clinical presentation that made treatment urgent. The EEG ruled out a seizure-related mechanism, further narrowing the differential.

Conclusions: In adults presenting with nocturnal enuresis, particularly when associated with alcohol use and snoring, OSA should be considered. CPAP therapy can result in complete symptom resolution. A full sleep study with EEG may help exclude ictal phenomena and clarify the diagnosis. Clinicians should maintain a high index of suspicion and investigate appropriately.

Alterations in Psychomotor Vigilance and Influencing Factors in Mild Obstructive Sleep Apnea

J. Ma¹, J. Huang¹

¹Eye, Ear, Nose, and Throat Hospital of Fudan University, Shanghai, China

Introduction: To investigate the characteristics of cognitive impairment in patients with mild obstructive sleep apnea (OSA) and its influencing factors, providing evidence for early intervention and cognitive health improvement.

Materials and methods: We enrolled patients who underwent polysomnography (PSG) at our sleep center for snoring between November 2022 and August 2024, with an apnea-hypopnea index (AHI) <15. Patients with mild OSA (AHI 5-15 events/hour, n=167) were assigned to the case group, while those with simple snoring (AHI <5 events/hour, n=109) served as controls. Cognitive function was assessed using the Psychomotor Vigilance Test (PVT). PSG recorded sleep parameters, oxygen saturation, and AHI. Additional data including daytime sleepiness (Epworth Sleepiness Scale, ESS), sleep quality (Pittsburgh Sleep Quality Index, PSQI), and subjective snoring impact (Visual Analog Scale, VAS) were collected. Statistical analyses compared cognitive function between groups and examined correlations with various factors.

Results: Compared with controls, mild OSA patients showed significantly prolonged PVT reaction time (504.62 ± 122.96 ms vs 463.95 ± 62.54 ms, $P=0.005$) and increased lapse counts (25.22 ± 20.42 vs 19.29 ± 10.82 , $P=0.001$). The mild OSA group had higher PSQI total scores (7.63 ± 1.96 vs 7.13 ± 1.77 , $P=0.028$), with significant differences particularly in sleep quality ($p=0.04$) and sleep latency ($p=0.006$). Mild OSA patients reported greater subjective snoring severity ($p=0.005$), especially regarding work impact ($P=0.043$), though no significant differences were found in life or family impact. Multivariate analysis identified age and sleep quality as significant predictors of PVT impairment.

Conclusions: Mild OSA patients demonstrate impaired PVT performance compared to simple snorers, with age and sleep quality being key contributing factors. Early identification and intervention targeting these factors may help prevent and mitigate cognitive dysfunction in mild OSA patients.

A Machine Learning Model for Predicting Obstructive Sleep Apnea Using Anthropometric and Bioimpedance Data

L.Y. Tai¹

¹Taipei Medical University, Biomedical Engineering, Taipei, Taiwan

Introduction: Obstructive sleep apnea (OSA) is a prevalent and serious sleep disorder associated with various complications. Polysomnography (PSG) remains the gold standard for diagnosis but is limited by cost, accessibility, and time. This study investigates an alternative method for identifying patients with severe OSA (Apnea-Hypopnea Index [AHI] ≥ 30) using bioelectrical impedance analysis (BIA) and basic outpatient anthropometric data.

Materials and methods: Data were retrospectively collected from patients who underwent both BIA and full-night PSG at Taipei Medical University–Shuang Ho Hospital Sleep Center (N = 6574). Anthropometric features (e.g., age, sex, body mass index, neck and waist circumference) and BIA-derived metrics (e.g., total body water, extracellular/intracellular water ratio, muscle percentage, and basal metabolic rate) were included.

Various machine learning models—including logistic regression (LR), k-nearest neighbors (kNN), Naïve Bayes (NB), support vector machines (SVM), random forest (RF), and XGBoost—were trained to classify OSA severity. Model performance was evaluated via stratified cross-validation and testing set analysis.

Results: Patients with severe OSA (N=3686) had higher values in age and showed elevated BMI, neck and waist circumference, visceral fat level (all $p < 0.01$), compared to non-severe OSA patients (N=2888).

BIA metrics such as reduced total body water, lower muscle percentage, and increased extracellular/intracellular water ratio were significantly associated with severe OSA.

Regarding model performance, Naïve Bayes, Logistic Regression, and XGBoost achieved the best performance. Naïve Bayes showed the highest accuracy (69.20%) and F1-score (67.6%), while Logistic Regression provided the best AUC (77.35%).

Conclusions: This study demonstrates that body composition and anthropometric features obtained from BIA can serve as effective predictors for severe OSA (AHI ≥ 30). The proposed machine learning framework, particularly models such as Naïve Bayes, Logistic Regression, and XGBoost, achieved

clinically acceptable performance in identifying high-risk patients using only outpatient-accessible data. This approach offers a scalable, low-cost, and non-invasive alternative to PSG-based diagnosis.

A Multi-Task Deep Learning Model for Sleep Staging and Apnea Detection Using Single-Channel EEG

H.K. Lee^{1,2}, Y. Na^{1,2}, Y. Lee^{1,2}, S. Lim^{1,2}, S.J. Lee¹, H.-W. Shin^{1,2,3,4}

¹Seoul National University College of Medicine, Obstructive Upper Airway Research Laboratory, Department of Pharmacology, Seoul, Korea, Republic of, ²Seoul National University College of Medicine, Department of Biomedical Sciences, Seoul, Korea, Republic of, ³Seoul National University Hospital, Department of Otorhinolaryngology–Head and Neck Surgery, Seoul, Korea, Republic of, ⁴OUaR LaB, Inc., Seoul, Korea, Republic of

Introduction: Obstructive sleep apnea (OSA) leads to sleep fragmentation and intermittent hypoxia due to recurrent episodes of apnea and hypopnea during sleep. These disruptions impair sleep architecture, resulting in excessive daytime sleepiness, morning headaches, and cognitive dysfunction, ultimately diminishing quality of life. Electroencephalogram (EEG) analysis provides critical insight into both macro- and microstructural changes in sleep, offering a window into the cerebral impact of disordered breathing.

Materials and methods: We utilized the Korea Image-based Sleep Study (KISS) dataset, comprising polysomnography (PSG) data from four hospitals in South Korea (N = 7,745). After excluding records with total sleep time (TST) less than 3 hours (N = 642) and those without EEG data (N = 9), 7,094 PSG recordings were analyzed. The C3-A2 EEG channel was resampled to 128 Hz and normalized using z-scores. EEG signals were decomposed into five canonical frequency bands—Delta (0.5–4 Hz), Theta (4–8 Hz), Alpha (8–12 Hz), Sigma (12–15 Hz), and Beta (15–35 Hz)—to facilitate frequency-specific feature learning. We developed a multi-task deep learning model based on a modified Temporal Convolutional Network (modernTCN) architecture, which concurrently performs binary classification of apnea/hypopnea events (≥ 10 seconds within 30-second windows) and sleep stage classification.

Results: On data from hospital A, the model achieved a macro F1-score of 73.0% and an accuracy of 75.2% for respiratory event detection, demonstrating state-of-the-art performance for single-channel EEG-based approaches. For sleep stage classification, it yielded a macro F1-score of 76.5% and an accuracy of 77.9%. The predicted apnea-hypopnea index (AHI) showed strong correlation with the reference AHI (Pearson $r = 0.86$, $p < 0.001$), with a mean absolute error (MAE) of 17.34. The model also generalized well to external datasets: MAE = 13.97 ($r = 0.83$, $p < 0.001$) on the Hospital B dataset, 16.24 ($r = 0.79$, $p < 0.001$) on Hospital C, and 17.18 ($r = 0.78$, $p < 0.001$) on Hospital D. An ablation study further showed that multi-task learning provided consistent benefits over single-task training, and that using sub-band EEG inputs yielded the most balanced and stable performance across both tasks.

Conclusions: Our findings suggest that a single-channel EEG, when analyzed with a multi-task deep learning model, enables reliable detection of respiratory events and accurate sleep staging. This approach provides a practical and scalable solution for automated sleep scoring, potentially alleviating clinician workload and broadening clinical applicability.

Analysis of Brain Gray Matter Microstructure Alterations in Obstructive Sleep Apnea Patients Based on NODDI

Z. Wang¹, R. Chen¹

¹The Second Affiliated Hospital of Soochow University, Department of Respiratory and Critical Care, Suzhou, China

Introduction: This study aims to explore the changes in brain gray matter microstructure in OSA patients using NODDI technology, analyze the influencing factors and their correlation with cognitive impairment, and investigate the neural mechanisms of cognitive dysfunction in OSA.

Materials and methods: A total of 42 patients in the control group ($AHI < 5/h$), 87 in the mild-moderate OSA group ($5/h \leq AHI < 30/h$), and 77 in the severe OSA group ($AHI \geq 30/h$) were enrolled. Cognitive function was assessed using the Montreal Cognitive Assessment (MoCA) and computerized cognitive tests. Brain MRI data were collected, and tools such as the MRtrix3 toolbox, AMICO, FreeSurfer's recon-all and segmentHA_T1.sh, and fslmaths and fslstats commands were used to extract NDI and ODI values from the cortex, subcortical nuclei, and hippocampal subfields. Differences in NDI and ODI across the three groups were analyzed, and partial correlation analysis was used to examine the relationship between gray matter parameters and cognitive scores. A mediation model was established to analyze the mediating effect of gray matter structure on the relationship between nocturnal intermittent hypoxia, sleep fragmentation, and cognitive impairment.

Results: Patients in the severe OSA group were older, had a higher body mass index (BMI), more years of education, and higher Epworth Sleepiness Scale (ESS) scores. There were significant differences in polysomnography (PSG) parameters among the three groups. Cognitive assessment revealed significant group differences in MoCA total scores, MoCA subscales (visuospatial/executive function, delayed recall), and other cognitive tests (PRM immediate recognition accuracy, PRM immediate recognition reaction time, PRM delayed recognition reaction time, SRM immediate recognition accuracy, SWM double errors, SWM average completion time). Multiple brain regions showed group differences in NDI and ODI, with OSA generally patients exhibiting elevated NDI and ODI in areas such as the bilateral frontal, parietal, temporal, occipital, and insular lobes, globus pallidus, hippocampus, cerebellar cortex, cingulate isthmus, posterior anterior cingulate, left putamen, left thalamus, and right nucleus accumbens. Intergroup differences in NDI were found in the bilateral parasubiculum, molecular_layer_HP-head, HATA, left presubiculum-head, subiculum-head, CA1-head, right GC-ML-DG-head, fimbria hippocampi, and hippocampal tail. Intergroup differences in ODI were observed in the bilateral subiculum-body, left parasubiculum, and molecular_layer_HP-body. Partial correlation analysis (adjusted for age and years of education) showed that MoCA total scores were negatively correlated with NDI in the right supramarginal gyrus, MoCA delayed recall was negatively correlated with NDI in the right hippocampus, right supramarginal gyrus, left hippocampus, right hippocampal tail, left subiculum-head, and left molecular_layer_HP-head. MoCA visuospatial/executive function was negatively correlated with ODI in the right nucleus accumbens, and SRM immediate recognition accuracy was negatively correlated with NDI in the left cingulate isthmus. Mediation analysis revealed that microstructural parameters mediated the relationship between PSG parameters and cognitive test scores.

Conclusions: OSA is associated with altered brain gray matter microstructure, which is one of the neural mechanisms underlying OSA-related cognitive impairment.

Analysis of Polysomnography in Patients with Sleep Disorders Accompanied by Tinnitus

W.Y. Bae¹

¹Dong-A University, Otorhinolaryngology, Busan, Korea, Republic of

Introduction: Tinnitus is a symptom characterized by the perception of sound generated within the body, specifically by the spontaneous depolarization of auditory nerve fibers, without any external auditory stimulus. Although the exact etiology of tinnitus remains unknown, there is a strong electrophysiological hypothesis suggesting that functional changes in the limbic system's amygdala and the cerebral cortex, as well as the subcortical structures, lead to tinnitus through autonomic nervous system dysfunction. Sleep disorders are also known to be influenced by and to influence the complex interactions among the ascending reticular system, central arousal system, cognitive system, and emotional regulating system in the central nervous system. Therefore, based on these theoretical foundations, the authors aimed to analyze the relationship between tinnitus and sleep by examining the association between tinnitus and polysomnography results using the Tinnitus Handicap Inventory (THI). This study intends to elucidate the correlation between tinnitus and sleep disorders.

Materials and methods: A retrospective analysis was conducted on patients who visited the clinic from August 2021 to May 2023 and underwent both polysomnography (PSG) and the Korean version of the Tinnitus Handicap Inventory (THI). The clinical characteristics, polysomnography results, and scores from psychiatric symptom questionnaires were compared between the group with tinnitus and the group without tinnitus. Additionally, the polysomnography results and questionnaire scores were compared based on the THI scores.

Results: There were statistically significant differences in the PLM (Periodic Limb Movement) index, sleep latency, and lowest SpO₂ between the group with tinnitus and the group without tinnitus (Table 1). The tinnitus group exhibited lower PLM index, higher sleep latency, and higher lowest SpO₂ compared to the group without tinnitus. When analyzing the polysomnography results based on THI scores, a significant negative correlation was found between THI and REM latency. There were no significant differences in the average scores of questionnaires (ESS, SSS, PSQI, PSS, PHA-15, BAI, CES-D) between the group with tinnitus and the group without tinnitus. Multiple regression analysis also did not reveal any significant correlations between THI scores and questionnaire scores.

Conclusions: Tinnitus, sleep disorders, and depression are associated with autonomic nervous system overactivity through the limbic system. Studies that examine the relationship between tinnitus, sleep disorders, depression, anxiety, and stress using polysomnography and questionnaires can provide a better understanding of sleep patterns, autonomic nervous system function, and electrophysiological models. Furthermore, such research can contribute to the development of specific treatment approaches aimed at improving the quality of life for these patients.

Analysis of risk factors for white matter hyperintensities in OSA patients

H. Huang^{1,2,3}, M. Zhao^{1,2,3}, Y. Lu^{1,2,3}, Y. Wen^{1,2,3}

¹The People's Hospital of Guangxi Zhuang Autonomous Region, Department of Sleep Medicine, Nanning, China, ²The People's Hospital of Guangxi Zhuang Autonomous Region, Guangxi Clinical Research Center for Sleep Medicine, Nanning, China, ³The People's Hospital of Guangxi Zhuang Autonomous Region, Guangxi Sleep Respiratory Disease Diagnosis and Treatment Center, Nanning, China

Introduction: White matter hyperintensity (WMH) poses significant public health challenges due to its high prevalence and close association with progressive cognitive decline, depression, stroke, and mortality. Obstructive sleep apnea (OSA) is recognized as an independent risk factor for cerebral small vessel disease (CSVD) and WMH pathogenesis. Systematically identifying risk factors for WMH in OSA patients is crucial for understanding disease progression, pinpointing high-risk individuals, and developing early interventions. This study therefore aims to investigate key risk factors for WMH onset/progression in OSA patients, analyze their association with cognitive dysfunction, and provide a scientific basis for risk stratification and targeted interventions.

Materials and methods: This study adopted a cross-sectional design. The subjects were recruited from the Department of Sleep Medicine at the People's Hospital of Guangxi Zhuang Autonomous Region between 2021 and 2023. Patients who met the inclusion criteria underwent polysomnography (PSG). Cognitive function was assessed using the Mini-Mental State Examination (MMSE), and brain magnetic resonance imaging (MRI) data were collected. The severity of WMH was evaluated using the Fazekas visual rating scale. Based on the presence or absence of WMH, OSA patients (with an apnea-hypopnea index [AHI] ≥ 5 events/h) were divided into two groups: OSA patients with WMH and OSA patients without WMH (control group). Differences in the aforementioned indicators between the two groups were analyzed and compared. Multivariate logistic regression analysis was conducted to identify factors associated with WMH in OSA patients. Additionally, a receiver operating characteristic (ROC) curve was constructed to evaluate the predictive performance of the model.

Results: A total of 552 OSA patients were included in the study, including 266 patients (50.0%) in the WMH group and 286 patients (50.0%) in the non-WMH group. The overall median age was 53.0 years (IQR: 46.0-58.0), and 74.3% were males. Compared with the non-WMH group, the WMH group had significantly higher BMI ($P<0.05$) and a higher proportion of insomnia ($P<0.05$). The serum levels of total protein, albumin and prealbumin were significantly lower ($P<0.05$). The patients had longer total sleep time, more hypopnea events, and shorter average duration of obstructive apnea ($P<0.05$). The orientation, memory and total score of MMSE scale were lower in the experimental group than in the control group ($P<0.05$). Multivariate logistic regression showed that: COMISA (OR=2.662, 95%CI: 1.411-5.021), BMI (OR=1.146, 95%CI: 1.056-1.243), numbers of total apnea in stage REM (OR=1.028, 95%CI: 1.003-1.055) were independent risk factors for WMH. The decrease of MMSE score (OR=0.923, 95%CI: 0.868-0.982) was positively correlated with the risk, and total serum protein (OR=0.93, 95%CI: 0.88-0.983) was an independent protective factor.

Conclusions: We propose multimodal interventions targeting COMISA, BMI and numbers of total apnea in stage REM risk factor modulation and total serum protein protection enhancement, combined with dynamic sleep monitoring, to enable early risk stratification and precise prevention of OSA-related WMH, offering new pathways to delay neurodegeneration.

An Analysis of Snoring Characteristics and Their Impact on Obstructive Sleep Apnea

B.H.K. Ng^{1,2}, S.A. Han², J.-Y. Min², S.W. Kim², H.K. Min²

¹Universiti Malaysia Sarawak, Otorhinolaryngology, Kota Samarahan, Malaysia, ²Kyung Hee Medical Center, Seoul, Korea, Republic of

Introduction: Snoring, a common clinical features associated with OSA, has garnered notable interest due to its potential diagnostic and predictive value. About 59% of women and 78% of men snore, making it a widespread condition. The objective of the study is to investigate the impact of snoring characteristics such as snoring intensity and snoring time on the severity of obstructive sleep apnea (OSA), exploring the dynamics and potential associations between these variables and other polysomnographic parameters.

Materials and methods: Retrospective data analysis on patients who had polysomnography (PSG) between June 2019 and February 2020. The apnea-hypopnea index (AHI) was used as a measure of OSA severity. Snoring recordings were achieved by a non-contact directional microphone placed at the head of the bed, 20 cm from the vertex of the patients. Statistical analyses were performed using version 29 of the Statistical Package for the Social Sciences (SPSS) software. Pearson correlation coefficient, Mann-Whitney U test and Jonckheere Trend's test were used for analysis.

Results: A total of 248 patients underwent a PSG in the study period. Mean age was 41.9 ± 19.5 and mean body mass index was 25.4 ± 4.7 . The polysomnographic parameters progressively increase as the patient's age increases ($P < 0.001$). Number of snoring episode and Epworth Sleepiness Scale (ESS) were higher in male patients and reached statistical significance ($P < 0.05$). In terms of snoring intensity, there is not much variation between male and female patients. Older patients have a progressively longer snoring time, higher snoring rate and a greater number of snoring episodes ($P < 0.001$). The mean for snoring time, snoring rate, the number of snoring episodes, snoring intensity and ESS showed a gradual increase with increasing severity of AHI ($P < 0.001$). Polysomnographic parameters which included AHI, RDI, supine AHI, and REM and NREM index showed a positive correlation with snoring intensity ($r = 0.341$, $r = 0.354$, $r = 0.385$, $r = 0.322$, $r = 0.137$ respectively. $P < 0.001$). Number of snoring episodes also showed a positive correlation with AHI, RDI, supine AHI, and REM and NREM index and ($r = 0.391$, $r = 0.360$, $r = 0.309$, $r = 0.375$, $r = 0.355$, respectively. $P < 0.001$). There was no significant correlation between the PSG parameters and snoring time, snoring rate and longest snoring episode.

Conclusions: This study improves our understanding on the relationship between snoring characteristics and OSA severity. It highlights the intricate interactions between snoring and polysomnographic parameters as well as the substantial correlation between certain snoring qualities and the severity of OSA. Importantly, it suggests that snoring could indicate undiagnosed OSA, advocating for snoring to be used not only as a means of screening for OSA but as part of the diagnostic tool for OSA and as an adjunct to assess treatment outcome.

A National Survey on Current Knowledge, Diagnostic Approaches, and Management Practices of Sleep-Related Breathing Disorders Among General Medicine Practitioners and Respiratory medicine practitioners in India (Interim results)

S. Vinod Kuttu¹, N. Nahas¹, R. Gupta², P. T¹, S.H. Shankar³, M. Asif¹

¹All India Institute of Medical Sciences, Mangalagiri, General Medicine, Mangalagiri, India, ²All India Institute of Medical Sciences, Rishikesh, Psychiatry, Rishikesh, India, ³S S Sparsh Hospital, Pulmonary critical care and sleep medicine, Bangalore, India

Introduction: In India, where the burden of non-communicable diseases is rapidly rising, the impact of OSA is particularly concerning. Despite its growing prevalence, OSA remains widely underdiagnosed. General physicians and respiratory physicians often serve as the first point of contact for patients,

especially in rural and resource-limited areas, placing them in a pivotal position to identify and manage sleep disorders. Among non-specialists, knowledge about OSA and other sleep related breathing disorders (SRBDs) tends to be poor, even though attitudes toward the disorder are generally positive; unfortunately, this does not translate into optimal clinical practice. In the context of India, where specialized sleep medicine services are limited and unevenly distributed, enabling general physicians to take a more active role in the assessment and management of sleep disorders could help address significant healthcare disparities.

Materials and methods:

Study Design: Cross-sectional online survey using semistructured Google Forms

Study Population: General physicians and respiratory physicians across India

Survey Tool: Semi structured questionnaire

Content validation was performed by two independent sleep researchers. Following this the questionnaire was piloted amongst 15 physicians, feedback and troubleshooting was performed. Subsequently the survey was shared via emails and social media with general medicine and respiratory medicine practitioners across India. The survey included trainees and practitioners.

Results: Of the 273 responses, the mean age of respondents was 35 years (35.0+/-9.7 years). 63% of the respondents were male. 52.7% of the respondents were from a respiratory medicine background. 86.4% worked in the urban sector. Approximately 60% of respondents worked in academic institutions, of which 54% were in teaching roles.

While more than 90% of the respondents screened patients with snoring and elevated BMI, only 35-60% of respondents screened patients with cardiovascular or cerebrovascular diseases. More than 70% had access to polysomnography, however only about 25% were confident in interpreting the reports. Approximately 70-74% reported that lack of awareness of the disease amongst the community followed by accessibility and cost issues hamper the diagnosis of sleep related breathing disorders. 60-70% of the respondents advise Positive airway pressure (PAP) therapy and lifestyle changes as first line in the management. Only 7% of physicians use dental devices in primary management.

While more than 80% physicians advise PAP therapy, only 24% each are confident or very confident to make this advise. 60-65% respondents followed up their patients at weekly and fortnightly intervals. However, approximately 50% respondents monitor adherence only with symptom resolution. In those who do advise PAP therapy, more than 40% are not confident with troubleshooting.

80-90% of the respondents were aware that untreated SRBDs can lead to vascular diseases and cognitive decline. However as noted earlier, only 35-60 % screened these patients at the outset.

Conclusions: While many Indian doctors are aware of SRBDs, there is lack of clear understanding regarding whom to screen, how to treat, how to manage and how to follow up. There is a felt need to conduct training sessions, develop guidelines and referral systems. Cost of evaluation and management may be circumvented with improved harnessing of telemedicine and Artificial Intelligence.

Acknowledgments: The respondents and my students

A new 3D-printed invisible mandibular advancement device for patients with obstructive sleep apnea: A cohort study

X. Wang¹, H. Chen², R. Ju³, S. Ge¹, P. van der Stelt⁴, K. Orhan⁵

¹Shandong University, Department of Periodontics, Jinan, China, ²Shandong University, Department of Orthodontics, Jinan, China, ³Shandong University, Jinan, China, ⁴Academic Centre for Dentistry Amsterdam (ACTA), Department of Oral Radiology, Amsterdam, Netherlands, ⁵Ankara University Faculty of Dentistry, Department of DentoMaxillofacial Radiology, Ankara, Turkey

Introduction: Mandibular advancement device (MAD) is recognized as an effective treatment option for patients with mild-to-moderate obstructive sleep apnea (OSA). However, traditional MADs are bulky and associated with low patient compliance. To address this, we developed a novel 3D-printed invisible MAD (iMAD). This study aims to evaluate the effects of iMAD on sleep quality and to investigate its working mechanism.

Materials and methods: This cohort study included 27 mild-to-moderate OSA patients. Clinical efficiency was assessed using polysomnography (PSG) recording and the working mechanism was evaluated using cone beam computed tomography (CBCT) at two time points: at baseline and after 3 months of iMAD use. PSG parameters included the respiratory event index (REI), apnea hypopnea index (AHI) and the lowest blood oxygen saturation. CBCT images are used to compare the change of upper airway, especially the minimum cross-sectional area (CSA).

Results: After 3 months of iMAD use, both REI and AHI were significantly decreased ($P < 0.001$), while the lowest blood oxygen saturation significantly increased ($P < 0.05$). Additionally, CBCT images showed that there was a significant increase in the CSA_{min} of the upper airway with iMAD ($p < 0.001$).

Conclusions: The new iMAD improves the upper airway dimension, demonstrating promising clinical efficacy for OSA treatment.

A Novel Intuitive Model of Endotyping in OSA; A Graphical Visualisation of Ventilation Curve and Arousal Surrounding Respiratory Events

V. Koka¹, J. Vanbuis², M. Blanchard²

¹ENT and Sleep Lab, Paris, France, ²CIDELEC, Research Department, St Gemmes sur Loire, France

Introduction: Obstructive sleep apnea (OSA) diagnosis relies on the apnea-hypopnea index (AHI) but overlooks underlying mechanisms. Endotyping identifies key physiological traits – passive ventilation (V_{passive}), active ventilation (V_{active}), arousal threshold (AT), and loop gain (LG) to personalize treatment. This study proposes a visualization method using routine diagnostic clinical polysomnography to map all respiratory event endotypes, aiding targeted, patient-specific OSA therapy.

Materials and methods: Following the Terrils method, the ventilatory drive (VD) was estimated using the ventilation (V_{en}) signal fed into a chemoreflex feedback control model. By linear interpolation of the VD and V_{en} curves over 20 breath cycles surrounding the events, LG1 (LG at one-cycle-per-minute frequency) was calculated in the frequency domain.

To ensure an accurate representation of VD, enhanced event/arousal detection criteria were employed, including the automatic scoring of non-cortical arousals for apneas/hypopneas with ventilatory recovery ($\geq$ eupneic) but no scorable arousal.

Two methods were implemented to assess overall endotype parameters (V_{passive} , V_{active} , AT, LG). In Method 1, the endotype parameters are estimated for each respiratory event throughout the night, and mean values are plotted on a schematic representation based on the average V_{en} and VD curves surrounding respiratory events using linear interpolation. In Method 2, the average V_{en} and VD curves are calculated through a synchronization process that aligns with the end of the events. From these average curves, endotype parameters are then extracted and plotted.

LG1, due to its frequency nature, cannot be visualized in the previously reported phenotype plots. In our study, LG is represented using Wellman's approach to facilitate visualization, allowing all four endotypes to be visible in our graphical models.

Results: The study comprised 12 females and 8 males aged 22 to 72 with moderate obesity (median BMI 27.5 kg/m²) and a median AHI of 37.5/h.

According to Method 1, patients exhibited relatively high collapsibility (45.6 [36.8-56.0] %eupnea), good muscle compensation (22.7 [2.9-36.7] %eupnea), moderate AT (144.4 [131.0-153.5] %eupnea), and relatively low LG (0.58 [0.54-0.74]). The physiological traits derived from Method 2 differed for V_{passive} (higher V_{passive}) and LG (lower LG) compared to Method 1. The correlation coefficients between the two methods are $\rho = 0.2, 0.9, 0.6$, and 0.4 for V_{passive} , V_{active} , AT, and LG, respectively.

Method 1 is based on the average results obtained event by event throughout the night, while Method 2 averages the actual V_{en} and VD curves around the events. Method 2 is more realistic than Method 1 because it allows for observing fluctuations in the V_{en} and VD curves during respiratory events.

Moreover, Method 1 tends to show a higher LG1 than Method 2. This discrepancy can be attributed to the fact that Method 1 relies on instantaneous curves around respiratory events, while Method 2 aligns the curves at the end of these respiratory events.

Conclusions: For the first time, we have developed a novel model of endotyping that incorporates a graphical representation of ventilation and ventilatory drive related to the events, enhancing

visualization and estimation of all four endotypes and facilitating the transition of endotyping from the laboratory to clinical settings.

A novel method to quantify the role of arousal threshold in obstructive sleep apnea pathogenesis

J. You¹, G. Yin², Y. Zhou², J. Ye²

¹Tsinghua University, School of Biomedical Engineering, Beijing, China, ²Tsinghua University affiliated Beijing Tsinghua Changgung Hospital, Beijing, China

Introduction: Obstructive sleep apnea (OSA) is a multifactorial disease. Determining whether a low arousal threshold plays a dominant role in OSA pathogenesis is critical for selecting appropriate treatment strategies. However, there is few accurate method to assess it. This study hypothesizes that in patients with a low arousal threshold, arousal predominantly terminates OSA events, manifested as arousal preceding the activation of upper airway muscle. Therefore, this study analyzed the temporal sequence between submental electromyography (EMG) and electroencephalogram (EEG) changes during OSA event termination and its association with arousal threshold.

Materials and methods: 516 men and women aged 18-85 years were studied. For each OSA event, transfer entropy was applied to determine the temporal sequence between EMG changes and EEG changes. The proportion of OSA events in which EMG preceded EEG was calculated relative to the total number of OSA events. This proportion was then analyzed for correlations with body mass index (BMI) and apnea-hypopnea index (AHI). In 98 cases with drug-induced sleep endoscopy, the mean lowest esophageal pressure was measured as the arousal threshold, and the correlation between the proportion and the arousal threshold was evaluated.

Results: The mean [Q1, Q3] proportion of OSA events with EMG changes preceding EEG changes was 0.78 [0.67, 0.89]. It was negatively correlated with BMI (Pearson correlation coefficient $r = -0.11$, $p < 0.05$), AHI ($r = -0.15$, $p < 0.05$), and positively correlated with arousal threshold ($r = 0.52$, $p < 0.05$).

Conclusions: This study confirmed the hypothesis and proposes a non-invasive quantitative arousal threshold method, which can evaluate the contribution of the arousal threshold in OSA pathogenesis and provide a new direction for revealing the mechanism of OSA.

An Updated Network Meta-Analysis of Pharmacological Therapies for Obstructive Sleep Apnea: Effects on AHI Reduction and Lowest Oxygen Saturation Improvement

D. Kautsarizqi¹, I.A. Virya², N.K. Caksana³, Y.G. Rahmadi¹

¹Universitas Indonesia, Faculty of Medicine, Jakarta, Indonesia, ²Universitas Tanjungpura, Computer System Department, Faculty of Mathematics and Natural Sciences, Pontianak, Indonesia, ³Universitas Indonesia, Faculty of Computer Science, Depok, Indonesia

Introduction: Obstructive sleep apnea (OSA) affects nearly one billion adults worldwide and is linked to cardiovascular, metabolic, and neurocognitive complications. Continuous positive airway pressure (CPAP) remains the gold-standard therapy, but adherence is often poor and its effects are limited to airway collapsibility. Pharmacological treatments have emerged as promising alternatives, targeting multiple pathophysiological mechanisms. Recent trials not only assess the apnea-hypopnea index (AHI) but also SpO₂ nadir, a key marker of nocturnal hypoxemia and cardiovascular risk. This review synthesizes new evidence, offering an updated and clinically relevant evaluation.

Materials and methods: We systematically searched PubMed, Scopus, EBSCO, and Taylor & Francis for studies published between January 2019 and June 2025. Eligible articles were randomized controlled trials in humans, available in full text, written in Bahasa Indonesia and English, and reporting pharmacological interventions for obstructive sleep apnea (OSA) with outcomes including AHI and SpO₂ nadir. Non-pharmacological interventions and incomplete data were excluded. Data extraction followed the PICO framework and PRISMA flowchart. Meta-analyses were performed in R with 95% confidence intervals, and study quality was assessed using Cochrane RoB 2.0.

Results: Nineteen randomized controlled trials (RCTs) involving 446 patients (17 crossover, 2 parallel) were included in this network meta-analysis. The network geometry was predominantly placebo-controlled with minimal heterogeneity observed for both AHI ($\tau^2 = 27.057$, $I^2 = 0.8\%$) and nadir SpO₂ (τ^2

= 0.000, I^2 = 0.0%). For AHI, two regimens demonstrated significant superiority over placebo: atomoxetine 80 mg plus trazodone 50 mg (MD -18.60 events/h; 95% CI -32.99 to -4.21) and atomoxetine 80 mg plus trazodone 100 mg (MD -10.80; 95% CI -21.17 to -0.43). Both achieved the highest SUCRA probabilities (0.917 and 0.753). Other agents, including atomoxetine monotherapy and atomoxetine-oxybutynin, showed non-significant numerical improvements, while sedatives such as morphine, dexmedetomidine, and propofol tended toward AHI worsening with the lowest SUCRA values. For nadir SpO₂, significant improvements were observed with atomoxetine 80 mg plus trazodone 50 mg (MD +5.00; 95% CI 2.99–9.00), atomoxetine 80 mg plus trazodone 100 mg (MD +2.00; 95% CI 1.43–2.57), and atomoxetine 80 mg plus lemborexant 10 mg (MD +2.00; 95% CI 0.99–3.01). In contrast, morphine (-1.30; 95% CI -2.55 to -0.05) and propofol (-1.80; 95% CI -2.94 to -0.66) significantly reduced nadir SpO₂. SUCRA rankings aligned with these findings, positioning atomoxetine-trazodone combinations as most effective and sedatives as least favorable. Both outcomes suggested no likelihood of major publication bias.

Conclusions:

Pharmacological therapy may provide a promising alternative for patients with OSA who struggle to tolerate CPAP. Among the agents studied, atomoxetine-trazodone combinations offered the most consistent improvements in reducing AHI and improving SpO₂ nadir, reflecting a synergistic effect on airway tone and arousal threshold. While these findings highlight potential therapeutic value, the evidence is still limited underscoring the need for larger head-to-head trials to confirm efficacy, safety, and long-term benefits.

A Pilot Study of Personalized Obstructive Sleep Apnea Therapy in Patients with Acute Coronary Syndrome

B.K. Tong^{1,2,3}, G.M. Stewart^{1,2,3}, A. Mohammadi^{1,2,3}, P.A. Cistulli^{1,2,3}

¹Charles Perkins Centre, University of Sydney, Camperdown, Australia, ²Northern Clinical School, Faculty of Medicine and Health, University of Sydney, Camperdown, Australia, ³Department of Respiratory and Sleep Medicine, Royal North Shore Hospital, St Leonards, Australia

Introduction: Recent randomized controlled trials of obstructive sleep apnoea (OSA) treatment for the secondary prevention of cardiovascular disease have produced neutral results. Key limitations of such studies include poor compliance to CPAP treatment, raising the need to broaden treatment options in clinical trial. Hence, we aimed to assess the feasibility and impact of delivering personalised OSA therapy as a strategy to optimize acceptance, compliance, and treatment efficacy in patients with established cardiovascular disease.

Materials and methods: Eligible participants aged 18 to 75 years old with a recent diagnosis (<12 months from hospital discharge) of acute coronary syndrome (ACS) and OSA (oxygen desaturation index 3%>10 events/h) were recruited and randomized to receive either personalized OSA therapy (PT) or usual medical care (UC) with a follow-up at 6-months. The PT group were given a choice of CPAP and/or mandibular advancement device (MAD) therapy for the treatment of OSA in addition to standard medical care for ACS. Treatment optimization strategies including a 4-week run-in period, augmented support and patient engagement tools were implemented with the goal of optimizing therapy, as well as rapid triage between treatment modalities in participants unable to tolerate a therapy. The UC group received standard medical care for ACS and lifestyle modification advice only. The primary outcome of the study was compliance with personalized treatment for OSA reported as mean hours of usage per night and number of therapy days during the 6-month period. Secondary outcomes include treatment effectiveness and cardiovascular markers between baseline and 6-months follow-up.

Results: To date, 40 participants (15 participants in UC and 25 participants in PT) were recruited. Nine participants in PT failed OSA treatment during the run-in period and were withdrawn from the study. Twelve participants in the PT group selected CPAP for the treatment of OSA had a mean usage time of 6.23±0.89 hours per night and CPAP was used 93.0±5.5% of nights during the 6-month period. Four participants selected MAD for OSA treatment, mean usage was 6.7±0.9 hours per night with 96.9±0.01% of nights on therapy during the 6-month period. Nine participants using CPAP and all 4 participants using MAD met the criteria for optimal compliance of ≥5 hours/night usage for ≥70% of

nights during the 6-month period. Greater significant reduction in apnea-hypopnea index (AHI) was observed in the PT group ($AHI=34.5\pm14.0$ versus 7.3 ± 6.3 events/h, $P<0.0001$) compared to UC group ($AHI=30.8\pm16.8$ versus 25.03 ± 17.8 events/h, $P=0.04$) at 6-month follow-up. Central augmentation pressure (-1.5 ± 1.5 mmHg, $P=0.007$) and central pulse pressure (-1.83 ± 2.33 mmHg, $P=0.02$) during wakefulness was increased at 6-month follow up compared to baseline in the UC group. PT group had comparable central blood pressure between baseline and 6-month follow-up. Mean 24-hour blood pressure was comparable to baseline at 6-month follow-up in both UC and PT groups ($P>0.05$).

Conclusions: These preliminary data suggests that it is feasible to implement personalised and optimised OSA therapy in patients with ACS. The impact on cardiovascular risk markers remains to be determined.

Acknowledgments: This study received financial support from ResMed Foundation, equipment support from ResMed and SomnoMed.

Apnea-hypopnea duration changes after Sulthiame - a new biomarker for treatment efficacy?

C. Strassberger¹, K. Theliander¹, S. Sands², K. Stenlöf¹, L. Grote^{1,3}, J. Hedner^{1,3}, D. Zou¹

¹Gothenburg University, Center for Sleep and Vigilance Disorders, Gothenburg, Sweden, ²Brigham and Women's Hospital and Harvard Medical School, Division of Sleep and Circadian Disorders, Boston, United States, ³Sahlgrenska University Hospital, Pulmonary Medicine, Gothenburg, Sweden

Introduction: Sulthiame (STM), a carbonic anhydrase inhibitor, reduced obstructive sleep apnea (OSA) severity in a randomized controlled trial (Hedner et al. 2022). Residual apnea-hypopnea (AH) event duration was increased. We performed a post-hoc analysis to identify predictors of the AH event extension after STM and its relation to the clinical effect of STM in OSA.

Materials and methods: OSA patients (71% males, age 60 ± 10 years, body mass index [BMI] 28 ± 3 kg/m², waist circumference 99 ± 10 cm, apnea-hypopnea index [AHI] 56 ± 22 events/h, AH duration 24 ± 5 sec) were randomized to receive placebo ($n=22$), STM 200mg ($n=12$), or STM 400mg ($n=25$) treatment for 4 weeks, respectively). Baseline anthropometrics and polysomnography measures were analysed to predict the mean AH duration change after STM treatment. Nocturnal hypoxic metrics (ABOSA, Karhu et al. 2022) and OSA endotypic characteristics (PUP, Terrill et al. 2015) were determined. (EudraCT Number: 2017-004767-13)

Results: Placebo, STM 200mg, and 400mg improved overnight mean oxygen saturation by 0.4 ± 1.0 , 1.1 ± 1.0 , 1.1 ± 1.0 %, $P=0.108$, 0.003 , and <0.001 , respectively. The corresponding extension of AH duration after intervention was 1.2 ± 2.6 , 3.6 ± 3.3 , 4.8 ± 4.8 sec, $P=0.046$, 0.003 , and <0.001 , respectively. Desaturation severity was reduced by 0.7 ± 39.3 , 12.7 ± 75.4 , and 27.4 ± 37.9 %, $P=0.411$, 0.104 , and 0.005 , respectively. STM drug concentration was not associated with a change in AH duration. Baseline BMI, waist circumference, and $V_{\min}$ (a low value indicates increased upper airway collapsibility) predicted event extension after STM (Spearman correlation, $r=0.391$, 0.435 , and -0.344 , $P=0.017$, 0.007 , and 0.040 , respectively). In the STM group ($n=37$), AH duration changes were correlated with percentage of AHI reduction and improvement of desaturation severity, as well as increases in circulatory delay ($r=-0.381$, -0.573 , and 0.379 , $P=0.021$, <0.001 , and 0.023 , respectively). Compared to subjects with event extension >5 secs, patients with an AH event extension ≤ 5 secs showed stronger AHI reduction (median [IQR]: -30.0 [-45.3 – -21.1] vs. -54.9 [-64.8 – -26.7] %, $P=0.019$) after STM.

Conclusions: STM is associated with a reduction in sleep-disordered breathing, improved nocturnal oxygenation, and a mild prolongation of residual events. The extension of AH event duration with STM should be further explored as a potential biomarker of treatment efficacy in OSA.

Acknowledgments: The randomized controlled trial was financed by Desitin Arzneimittel, Hamburg, Germany. The analysis was supported by the Swedish Heart-Lung Foundation and the Swedish State Funds for Clinical Research (LUA/ALF).

Apnea/hypopnea-related drops in pulse transit time predicts left ventricular dysfunction in obstructive sleep apnea

M. Su¹, N. Ding¹, J. Xu²

¹The First Affiliated Hospital with Nanjing Medical University, Department of Respiratory and Critical Care Medicine, Nanjing, China, ²The Affiliated Huaian No.1 People's Hospital of Nanjing Medical University, Department of Respiratory and Critical Care Medicine, Huai'an, China

Introduction: Pulse transit time (PTT) is widely used to assess vascular compliance and elasticity. This study aimed to determine whether the respiratory event-related PTT response would identify subclinical Left ventricular (LV) remodeling and dysfunction in obstructive sleep apnea (OSA).

Materials and methods: This retrospective study included OSA patients without pre-existing LV damage who underwent polysomnography between January 2014 and May 2017 at the Affiliated Huaian No.1 People's Hospital and The First Affiliated Hospital of Nanjing Medical University. LV measurements were assessed via echocardiography from December 2023 to May 2024. PTT measurements were validated using SOMNOscreen+ polysomnographic monitoring system. PTT drop magnitude refers to the difference between the initial value of the PTT decrease and the nadir triggered by apneas/hypopneas; PTT drop index is the number of drops per hour; PTT drop rate is the rate of decrease in PTT per second during the descending phase, and PTT area is the area above the waveform after respiratory events. Cox proportional hazard models estimated adjusted hazard ratios for incident LV damage, and receiver operating characteristic (ROC) curves assessed the predictive value.

Results: The sample included 517 individuals with a median (interquartile range) age of 53.0 (43.1-62.4) years and an AHI of 50.6 (32.6-65.5) events/hour. During a median follow-up of 8.3 (7.6-9.3) years, 112 patients (21.7%) had left ventricular hypertrophy (LVH), 249 (48.2%) had left ventricular diastolic dysfunction (LVDD), and none had LV systolic dysfunction. Individuals in the fourth quartile of PTT drop rate had a hazard ratio of 2.53 [95% (CI), 1.47-4.35] for LVH and 4.77 [95% CI, 3.15-7.21] for LVDD, respectively, compared to those in the first quartile. The results remained significant after adjusting for AHI and CVD. In contrast, no consistent associations were found with other PTT metrics, including drop magnitude, nadir, index, or area. In ROC curve analysis, PTT drop rate showed higher accuracy in predicting LVDD than compared to traditional polysomnography metrics.

Conclusions: Respiratory event-related PTT drop rate may be useful for predicting which patients with OSA are at increased risk for LV damage.

Acknowledgments: This work was supported by the NSFC [82070093, 8237089].

Apnea severity is associated with low skin temperature variability

G. Garcia Molina^{1,2}, T. Winger^{3,4}, N. Makaram¹, M.R. Rao¹, P. Chernega⁵, Y. Shcherbakov⁶, L. McGhee³, V. Chellamuthu¹, E. Veneros⁷, R. Mills³, D. Grimaldi¹, K. Reid¹, P.C. Zee¹

¹Sleep Number Labs, San Jose, United States, ²University of Wisconsin-Madison, Psychiatry, Madison, United States, ³Sleep Number Corporation, Minneapolis, United States, ⁴University of Minnesota, Department of Computer Science and Engineering, Minneapolis, United States, ⁵GlobalLogic Ukraine, Kyiv, Ukraine, ⁶GlobalLogic, Spain, Madrid, Spain, ⁷Nanami, Enumclaw, United States, ⁸Northwestern University, Center for Circadian and Sleep Medicine, Department of Neurology, Feinberg School of Medicine, Chicago, United States

Introduction: Higher cutaneous blood flow (vasodilation) causes skin temperature to rise. Conversely, vasoconstriction which indicates reduced cutaneous blood flow is associated with a decrease in skin temperature.

Obstructive and central sleep apnea are associated with sympathetic activation, inflammation, atherosclerosis, and hemodynamic changes which can affect cutaneous blood flow.

Reduced skin temperature variability has been associated with future disease risk in healthy individuals and severity deterioration in patients affected by conditions including sepsis and liver disease.

In this study, we tested the hypothesis that skin temperature variability is associated with apnea severity as measured by the apnea/hypopnea index (AHI). The apnea severity is: Mild for $5 \leq \text{AHI} < 15$; Moderate $15 \leq \text{AHI} \leq 30$; Severe $\text{AHI} \geq 30$.

Materials and methods: The data from 18 participants (9M/9F); mean age 44.5 [standard deviation 6.7] years-old, who recorded two nights in a sleep lab were used in this study. The data included polysomnography (PSG) and skin temperature signals. The latter were collected at a distal location (right foot; DST) and a proximal location (near the left collar bone; PST).

The PSG data were annotated by an expert sleep technician to obtain the sleep stages sequence

(hypnogram) and respiratory events from which the AHI was calculated.

For each sleep session, sleep bouts (i.e., sequences of uninterrupted sleep) were detected from the hypnogram. For each sleep bout that was at least ten-minute long, both proximal and distal skin temperature variability were estimated as the median absolute difference from the median of the skin temperature within the sleep bout: Variability = median($T - \text{median}(T)$), where T is the vector containing the bout's temperature values.

The distal and proximal skin temperature variability (DTV and PTV) for each sleep session were calculated as the mean DST and PST variability across all considered sleep bouts in the sleep session.

Results: Out of the 18 participants, six had AHI < 5. Eight, three and one participants were in the mild, moderate, and severe apnea category respectively.

The Pearson correlation between AHI and DTV was -0.44 ($p < 0.01$) which suggests that high AHI significantly correlates with low DTV. However, no significant associations were found between AHI and PTV (Pearson correlation 0.04 ; $p = 0.82$). This suggests that peripheral blood flow may be more notably affected by apnea compared to proximal blood flow.

The potential for DTV to screen for apnea at AHI levels of ≥ 5 , ≥ 15 , and ≥ 30 was evaluated by estimating receiving-operator curves (ROC) for each AHI level. The corresponding values for the area under the ROC were 0.75 , 0.76 , and 0.80 . For AHI = 5 and DTV threshold of 0.16 °C, the sensitivity and specificity were 0.85 and 0.76 respectively.

Conclusions: We found a significant, negative correlation between AHI and distal skin temperature variability. At a distal skin temperature variability threshold of 0.16 °C, sleep sessions with AHI exceeding five can be detected with sensitivity and specificity of 0.85 and 0.76 respectively. These results are promising since home apnea testing devices have mean 0.90 sensitivity and 0.50 specificity for AHI = 5.

Application of Novel Voice Biomarkers to Predict Site of Airway Collapse in Patients with Obstructive Sleep Apnea

S. Akbari^{1,2}, B. Taghibeyglou^{1,2}, D. Madulid^{1,3}, D. Brown⁴, S. Sands⁵, A. Yadollahi^{1,2}

¹KITE Research Institute- University Health Network, Toronto, Canada, ²University of Toronto, Biomedical Engineering, Toronto, Canada, ³Master University, Hamilton, Canada, ⁴University of Michigan, Department of Neurology, Ann Arbor, United States, ⁵Harvard Medical School, Boston, United States

Introduction: Obstructive sleep apnea (OSA) is a heterogeneous disorder characterized by repetitive upper airway obstruction during sleep, with significant variability in the anatomical site of collapse. These collapse sites, which are the tongue base, the lateral pharyngeal walls, the epiglottis, and the complete concentric collapse of the pharynx, have important clinical implications. Traditional diagnostic tools such as drug-induced sleep endoscopy provide detailed anatomical information but are invasive, costly, and not widely accessible. Even non-invasive methods like snoring acoustics and nasal pressure waveforms require overnight recordings. Given the anatomical and physiological relationship between speech production and upper airway structure, this study explores the use of voice biomarkers analyzed through machine learning to non-invasively predict site-specific airway collapse during wakefulness.

Materials and methods: Twenty adults, diagnosed with OSA and with no history of stroke (10 females, 10 males; BMI: 36.76 ± 6.60 kg/m²; AHI: 43.96 ± 30.84 events/hour) participated in the study. Participants articulated five sustained vowels while being recorded using a 48MP smartphone camera. Audio was extracted at 48 kHz. Additionally, portable level II polysomnography (Nox A1) captured sleep and respiratory signals. Collapse site labels (lateral wall, tongue base, epiglottis, or concentric pharyngeal) were derived from airflow shape analysis.

Spectral, temporal, and time-frequency voice features such as pitch, formants, and jitter were extracted using Librosa and Parselmouth. A machine learning pipeline was constructed using Recursive Feature Elimination (RFE) and Ridge Regression to identify the most predictive features. Bootstrapping was applied to enhance generalizability, and model performance was evaluated using Pearson's correlation (r), Mean Absolute Error (MAE), and Root Mean Squared Error (RMSE).

Results: The ML model demonstrated strong predictive ability for all collapse sites:

- Lateral Wall: $r = 0.93$, MAE = 0.14 , RMSE = 0.17

- Epiglottis: $r = 0.85$, MAE = 0.14, RMSE = 0.19
- Tongue Base: $r = 0.76$, MAE = 0.16, RMSE = 0.20
- Complete Concentric Collapse: $r = 0.80$, MAE = 0.17, RMSE = 0.20

The model's ability to estimate the probability of occurrences of each anatomical collapse site during wakefulness highlights the relevance of speech-derived features for capturing airway physiology. Bootstrapping reduced overfitting and confirmed model robustness despite the modest sample size.

Conclusions: This preliminary study presents a novel, non-invasive method for predicting anatomical sites of airway collapse in OSA using voice biomarkers and machine learning. The approach achieved high correlation with validated airflow-derived collapse classifications and offers a promising, scalable alternative to invasive diagnostics. Future work with larger cohorts is warranted to confirm generalizability and explore integration into personalized OSA management pathways.

A report of hypoglossal nerve stimulation cases in Japan

I. Nakajima¹

¹Dokkyo Medical University, Otorhinolaryngology, Head and Neck Surgery, Center of Sleep Medicine, Shimotsuga-gun, Japan

Introduction: Obstructive sleep apnea (OSA) is a common disorder characterized by repetitive collapse of the upper airway during sleep, resulting in recurrent arousals. Continuous positive airway pressure (CPAP) is the standard of care for treating OSA. Despite the uniform success of CPAP therapy, patient compliance remains a problem. A relatively novel treatment in OSA for patients unable to use CPAP therapy is upper airway stimulation (UAS) therapy using a fully implanted system. The Inspire UAS system (Inspire Medical Systems, Inc, Maple Grove, MN) is an FDA-approved system offered for the treatment of moderate to severe OSA.

Materials and methods: A few years later, the Japanese Ministry of Health, Labour and Welfare has approved for the UAS system since June 2021. This procedure has been shown to decrease the severity and symptoms of OSA in select patients.

Results: With the cooperation of providers and under the control of Japanese Society of Stomato-pharyngology, cadaver surgery training (CST) of UAS is implemented to ensure that safe and appropriate treatment. Treatment facilities are required to submit an entry sheet by the third case to ensure they are following the academic guidelines. A proctor physician is also dispatched to perform the initial implantation, providing an accurate technical evaluation and feedback. It is also important to note that physicians are required to attend a workshop by the Japanese Society of Sleep Research for the long-term management of treatment.

Conclusions: Afterwards, I will report on the treatment progress and the current situation in Japan.

A retrospective service evaluation into non-compliance in patients with mild obstructive sleep apnoea being treated on continuous positive airway pressure (CPAP)

P. Korat^{1,2}, C. Davies³, S. Correr-Muller²

¹Cardiff and Vale University Health board, Wales, Lung Function and Sleep apnoea department, Cardiff, United Kingdom, ²Manchester Metropolitan University, Manchester, United Kingdom, ³Cardiff and Vale University Health board, Wales, Lung function and Sleep apnoea department, Cardiff, United Kingdom

Introduction: Obstructive sleep apnoea is a sleep breathing disorder. It is characterised by episodes of repetitive airway closure which can either be a partial or full closure of the airway. With the repetitive collapse and opening of the airway, this leads onto oxygen desaturations, excessive daytime sleepiness, snoring and nocturia. The primary treatment according to NICE guidelines for OSA is CPAP therapy. This generates airflow to provide a stream of pressurized room air to splint open the upper airway during sleep via a mask. There are two main factors which measure adherence. AHI must be 4 h a night for at least 70%–80% of the night's. With the change in guidance for mild patients being offered CPAP, the audit will look at the following: Is low compliance seen in those who have a low Epworth sleepiness score and Body mass Index. Is there is a link between adherence data to pre-dict future adherence? If

noncompliance is high overall, can the service offer an alternative treatment pathway for Mild OSA patients?

Materials and methods: Data was collected retrospectively from a secure database used by the lung function and sleep department. Patients sleep studies were collected from September 2021 to October 2023. A sample size of 385 was estimated in order to generalise the results to a 95% confidence interval for the Welsh population with OSA. All patient identifiable information was removed. Not all patients were suitable due to the inclusion and exclusion criteria.

Results: Multiple linear regression was used. Initial consultation compliance data showed there was no significant relationship between the ODI and Average Hours ($p = 0.499$), mask fit ($p = 0.843$) and $\% > 4$ h ($p = 0.410$). There was no significant relationship between the ODI and Average hours ($p = 0.372$), mask fit ($p = 0.520$) and $\% > 4$ h ($p = 0.65$) data after 3 months of treatment.

Conclusions: There is no correlation between in compliance in mild patients from their initial consultation and at 6 months and there was no significant correlation between ESS and BMI against adherence data. However, this does give room to explore and develop the service with regards to making alternative pathways and referral in non-adhering patients.

Artificial Intelligence Diagnosis of Obstructive Sleep Apnea: Bayesian Meta-Analyses of 80 Studies with 248 Models

Introduction: Among 1 billion patients worldwide with obstructive sleep apnea (OSA), 90% remain undiagnosed. Their main barrier is the overnight polysomnogram, which requires specialized equipment, skilled technicians and inpatient beds available only in tertiary sleep centers. In recent years, artificial intelligence (AI) has made significant strides, offering promising new avenues for OSA diagnosis.

Materials and methods: We systematically searched PubMed, Embase, Scopus, Web of Science and IEEE Xplore till 20th July 2024. Two blinded reviewers selected English-language articles of studies comparing the diagnostic performance of AI models using 8 inputs (facial recognition, overnight audio, awake speech, electrocardiography, electroencephalography, pulse oximetry, photoplethysmography or multimodal), versus conventional diagnosis [apnea-hypopnea index (AHI) from PSG or home sleep apnea test (HSAT)]. We excluded studies if they only detected apneic events without providing a patient-level diagnosis, or if they did not use a train-test split or k-fold cross-validation for model evaluation. We assessed the risk of bias via QUADAS-2, performed Bayesian bivariate meta-analysis and meta-regression, computed 95% credible intervals, visualized summary receiver operating characteristic curves with 95% prediction regions, assessed publication bias via Copas-like selection modeling, and graded evidence quality via GRADE, following a PROSPERO-registered protocol. Analyses were conducted using R and Stan.

Results: From 6,254 records, we included 80 studies (low-moderate bias) with 248 AI models trained/tested on 35,300/30,420 participants. Across 8 modalities, AI demonstrated good or excellent diagnostic performance compared to conventional diagnosis. The pooled sensitivity (Sn) and specificity

(Sp) of each modality, arranged from the highest to lowest Sn, were: pulse oximetry [Sn: 91.1% (89.4–92.7%), Sp: 86.1% (82.1–89.4%)]; overnight audio [Sn: 90.3% (86.9–93.1%), Sp: 86.7% (83.1–89.7%)]; multimodal inputs [Sn: 89.2% (81.5–94.3%), Sp: 87.1% (82.6–90.8%)]; facial recognition [Sn: 84.9% (77.1–90.7%), Sp: 71.2% (60.7–81.4%)]; awake speech [Sn: 82.9% (80.0–86.4%), Sp: 83.3% (80.7–86.1%)]; electroencephalography [Sn: 81.6% (73.4–88.8%), Sp: 78.2% (64.1–87.0%)]; electrocardiogram heart rate variability [Sn: 79.0% (74.9–82.7%), Sp: 75.0% (67.9–82.3%)]; photoplethysmography [Sn: 70.8% (63.3–77.2%), Sp: 91.7% (86.8–95.1%)]. Bayesian meta-regression demonstrated similar diagnostic performance across AHI cut-offs. Deep learning (convolutional neural networks) was the most accurate classification algorithm for facial recognition (91.1% sensitivity, 79.2% specificity), pulse oximetry (93.7% sensitivity, 89.4% specificity) and photoplethysmography (75.9% sensitivity, 93.5% specificity) models, and performed better than domain expert manual feature extraction for pulse oximetry and electroencephalography models. Overnight audio models were more sensitive when using higher sampling frequencies and non-contact microphones. Smartphone versus professional camera/microphone inputs showed similar performance. Among 30 multimodal AI models, all used pulse oximetry with electroencephalography, electrocardiography, airflow and/or thoracic signals. Performance did not correlate with the number of modalities. Publication bias was shown to be unlikely to alter conclusions. The evidence was of high quality.

Conclusions: AI models trained on overnight audio and pulse oximetry achieved excellent diagnostic accuracy—far superior to STOP-Bang and comparable to common HSATs in clinical practice. Smartphones are a reliable source of images and audio, and AI performance is mainly driven by a small number of essential inputs. Digital medicine should be further explored and externally validated for accessible and equitable OSA diagnosis.

Assessing the correlation between physician seniority and the risk of Obstructive Sleep Apnea (OSA): a cross-sectional study

M. Mizrachi^{1,2}, M. Cohen¹, S. Damti-Geva^{1,2}, E. Sela^{1,2}, A. Dror^{1,2}

¹Bar-Ilan University, Faculty of Medicine, Safed, Israel, ²Galilee Medical Center, Otolaryngology-Head and Neck Surgery, Nahariya, Israel

Introduction: Obstructive sleep apnea (OSA) is a prevalent sleep disorder that remains relatively underdiagnosed, leading to a substantial number of untreated cases with serious economic and health implications. While extensive research has identified various risk factors for OSA, such as age, obesity, and gender, there is a notable gap in the literature regarding the relationship between OSA and the medical profession, specifically concerning the impact of medical career stage and seniority. This study aims to address this gap by exploring the association between medical professional status and the risk of developing OSA.

Materials and methods: A cross-sectional study was conducted at individual medical center, involving medical students, interns, and residents. Participants were surveyed for demographic and clinical data, the Sleep Hygiene Index (SHI) to assess sleep hygiene, and STOP-BANG questionnaire (SBQ) and Epworth Sleepiness Scale (ESS) to assess the risk for OSA and daytime sleepiness, respectively. Data were statistically analyzed, including logistic regression to identify risk factors.

Results: A significant association was identified between career stage and sleep hygiene, with residents, particularly those post-Step A exam, demonstrating poorer sleep hygiene compared to medical students and interns ($P = 0.017$). While no direct or significant relationship between professional seniority and the risk for OSA was observed based on SBQ and ESS scores, multivariate analysis indicated that poor sleep hygiene was a significant independent risk factor for both daily fatigue and OSA ($P < 0.001$). Furthermore, male gender, Jewish ethnicity, and resident status were independently associated with higher ESS and SBQ scores.

Conclusions: This study established a direct relationship between medical seniority and poor sleep hygiene, emphasizing that, in this study, inadequate sleep hygiene is the most significant and consistent risk factor for daily fatigue and OSA. Additionally, male gender, Jewish ethnicity, and residency status emerged as significant risk factors for OSA development. To the best of our knowledge, this study is the first to explore this topic among physicians and medical students, offering novel insights into the interplay between medical career stages and sleep health. These findings highlight the importance of advancing our understanding of the factors contributing to OSA in healthcare professionals and underscore the potential benefits of early risk identification and targeted preventative interventions.

Assessment of a Vibrotactile Device for Positional Therapy in Healthy Volunteers: A Pilot Study

A. Aleksandrov¹, M. Agaltsov², A. Aleksandrova³, I. Kudashov¹, A. Kiselev²

¹Bauman Moscow State Technical University, Moscow, Russian Federation, ²National Medical Research Center for Therapy and Preventive Medicine, Moscow, Russian Federation, ³Peoples' Friendship University of Russia named after Patrice Lumumba, Moscow, Russian Federation

Introduction: Sleep-disordered breathing encompasses a continuum of respiratory pathologies occurring during sleep, ranging from simple snoring, which may progress to more severe conditions such as obstructive sleep apnea (OSA). International studies indicate that the prevalence of obstructive sleep apnea (OSA) is increasing annually due to lifestyle changes, the growing prevalence of obesity, and population aging. A particularly common form is positional obstructive sleep apnea (pOSA), in which symptoms occur exclusively in the supine position. In 50–60% of patients, the severity of apnea and snoring is directly influenced by sleep position. Positional therapy (PT), which aims to prevent supine sleep, represents a promising alternative to continuous positive airway pressure (CPAP) therapy, particularly given the low adherence rates associated with the latter. The aim of this study is to evaluate the effectiveness of the new vibrotactile device “SoftSleep” (LLC SOFTSLEEP, Moscow, Russia) for positional therapy in healthy volunteers. The results may serve as a foundation for future clinical trials and the development of personalized treatment strategies for positional obstructive sleep apnea.

Materials and methods: A single-center clinical-experimental study was conducted with 20 adult volunteers to assess the effectiveness of the vibrotactile positional therapy device “SoftSleep” (LLC SOFTSLEEP, Moscow, Russia). The volunteer group included 14 males (70%). The mean age of the participants was 41.8 ± 11.2 years. Each participant underwent two nights of home-based monitoring using the system for automated polysomnography studies “Astrocard-SomnoSTUDIO” (LLC MEDITEK, Moscow, Russia): one night without the device and one with SoftSleep activated. Body position data were collected via “SomnoSTUDIO”, and subjective sleep quality was assessed using a modified Pittsburgh Sleep Quality Index. Key results included an assessment of total sleep time and time spent in a supine position.

Results: The “SoftSleep” vibrotactile device significantly reduced supine sleep time from 56.0% to 7.8% (-48.2 pp) without affecting total sleep duration ($7:42 \pm 1:19$ vs. $7:39 \pm 1:33$) and subjective sleep quality. In 90% of cases, participants rated sleep as “very good” or “fairly good” during device use. Supine avoidance was achieved via vibrotactile feedback without full awakenings, supporting the arousal-based mechanism of positional therapy. It is also significant that only three participants experienced brief vibration-related awakenings that subjectively did not exceed 3 minutes in duration and did not lead to withdrawal from the study. Variability in individual response suggests future studies should explore factors like sleep depth or baseline sleep position. Despite limitations—small sample, lack of polysomnography, and use of healthy volunteers—these results support “SoftSleep” as an effective, well-tolerated, non-invasive option for positional OSA. Further trials in clinical populations with objective sleep staging are warranted.

Conclusions: The results of the present study demonstrated high efficacy and good tolerability of the SoftSleep vibrotactile device designed for positional therapy of sleep breathing disorders and snoring prevention. The use of the device significantly reduced the duration of sleep in the supine position without adversely affecting the total time and quality of sleep.

Assessment of Sympatho-Vagal Dysfunction in Patients with Obstructive Sleep Apnea and Its Association with Disease Severity

P. Dubey¹, D. Sahu¹, S. De¹, R. Ganga¹, A. Maheswari¹, R.R. Kumar¹, A.K. Behera¹

¹All India Institute of Medical Sciences, Pulmonary Medicine Sleep and Critical Care, Raipur, India

Introduction: Obstructive Sleep Apnea (OSA) is a common but underdiagnosed sleep disorder associated with increased cardiovascular risk. Autonomic imbalance, characterized by increased

sympathetic tone and reduced parasympathetic activity, has been implicated in this pathophysiology. This study aimed to assess autonomic nervous system (ANS) dysfunction during wakefulness in patients with OSA and evaluate its correlation with disease severity.

Materials and methods: Study Design and Participants:

This cross-sectional observational study enrolled **55 adult patients** with polysomnography-confirmed obstructive sleep apnea (OSA; Apnea-Hypopnea Index [AHI] ≥ 5) and **110 age- and sex-matched healthy controls**. Exclusion criteria comprised diabetes, cardiac diseases, neurological disorders, or any condition affecting autonomic function.

A comprehensive autonomic evaluation included cardiac autonomic reflex tests and 5-minute heart rate variability (HRV) analysis. Time-domain and frequency-domain HRV parameters were log-transformed for statistical analysis. Sympatho-vagal imbalance was assessed using both raw and composite autonomic scores.

Results: Patients with OSA showed significantly reduced parasympathetic activity compared to controls. Key findings included lower RSA (0.25 ± 0.19 vs. 0.32 ± 0.13 , $p = 0.0007$), E:I ratio (1.19 ± 0.34 vs. 1.3 ± 0.18 , $p = 0.04$), and Valsalva ratio (2.03 ± 1.00 vs. 2.45 ± 1.20 , $p = 0.019$). Frequency domain analysis revealed reduced HF power ($p = 0.0002$) and elevated The LF/HF ratio (1.83 ± 1.92 vs. 0.85 ± 0.61 , $p = 0.0002$) indicates sympathetic dominance. Over half of the OSA patients (52.7%) had abnormal composite autonomic scores compared to 22.7% of controls ($p = 0.0002$).

Disease severity correlated significantly with autonomic markers. AHI was negatively associated with log HF_norm ($r = -0.305$, $p = 0.0234$) and positively with log LF/HF ratio ($r = 0.318$, $p = 0.0181$). Arousal and desaturation indices were also strongly associated with increased sympathetic and decreased parasympathetic activity.

Conclusions: Patients with OSA exhibit marked sympatho-vagal imbalance even during wakefulness, primarily driven by parasympathetic withdrawal and relative sympathetic overactivity. The extent of dysfunction correlates with the severity of OSA, arousals, and nocturnal desaturation. These findings underscore the utility of autonomic assessment in OSA and highlight the need for early diagnosis and intervention to mitigate cardiovascular risk.

Association between baseline characteristics and subsequent CPAP adherence in OSA patients

S. Wada^{1,2}, T. Mihara^{1,2}, N. Sugita¹, N. Egawa¹, Y. Tsuji², T. Hamano¹, N. Tachibana^{1,2}

¹Kansai Electric Power Hospital, Department of Neurology and Center for Sleep-related Disorder, Osaka, Japan, ²Kansai Electric Power Medical Research Institute, Center for Sleep-related Disorders, Osaka, Japan

Introduction: CPAP is regarded as efficient treatment for reducing incidence of future cardiovascular events in OSA patients so long as good adherence is achieved. The purpose of this study is to explore factors associated with CPAP adherence.

Materials and methods: This is a single-center retrospective observational study. Patients with OSA who was diagnosed by PSG and started CPAP in Kansai Electric Power Hospital between October 2013 and April 2022 were included. The outcomes were 1) graduation from CPAP defined as improving in symptoms by weight loss and termination of CPAP decided by attending physicians, 2) discontinuation of CPAP by patients' judgement during the period from October 2013 to April 2024, 3) good CPAP adherence defined as CPAP usage of ≥ 4 hours for $\geq 70\%$ period for more than one month before the last visit. Patients' follow up was conducted once every one to three months according to Japanese National Health Insurance System. Cox proportional hazard analysis to determine factors associated to each outcome was performed using patients' characteristics, diagnostic PSG data, and CPAP usage log at early phase (2-3 months) from starting CPAP.

Results: There were 247 patients who were administered CPAP (age 57.9 ± 12.4 y.o, male 85.8 %, BMI: 27.4 ± 5.0 kg/m², AHI 44.1 ± 21.3). During the follow-up periods (median: 1532, interquartile range: 782-2352 days), 9 patients (3.6 %) graduated from CPAP, 60 patients (24.3 %) discontinued, and 99 patients (40.1 %) achieved good CPAP adherence. Poor improvement in symptoms at early phase from starting CPAP was associated with both graduation from CPAP and discontinuation of CPAP, and higher body weight and higher CPAP adherence at early phase from starting CPAP were associated with good CPAP adherence. None of age, Epworth Sleepiness Scale, AHI or % time in SpO₂ $< 90\%$ was associated with all outcomes.

Conclusions: Baseline information and adherence at the early phase from starting CPAP may be useful to predict subsequent CPAP adherence.

Association Between Co-Morbid Insomnia and Sleep Apnea (COMISA) and Low Back Pain: Findings from the EPISONO Study

P.K. Morelhão¹, V. Cavalcante-Silva², A.S. Porcacchia², S. Tufik^{1,2}, M.L. Andersen^{1,2}

¹Instituto do Sono, Associação Fundo Incentivo à Pesquisa (AFIP), São Paulo, Brazil, ²Universidade Federal de São Paulo, Departamento de Psicobiologia, São Paulo, Brazil

Introduction: The concomitant occurrence of obstructive sleep apnea (OSA) and insomnia is referred to as COMISA. Its prevalence is estimated at 17.64% when considering all cases of OSA and insomnia, and 2.47% when limited to moderate-to-severe cases. COMISA may have a significant public health impact due to its association with various comorbidities. However, its relationship with chronic pain, particularly low back pain (LBP), the most disabling musculoskeletal condition worldwide—remains understudied. The objective of this study was to investigate the association between COMISA and LBP in a population-based sample.

Materials and methods: This cross-sectional study used data from the 4th edition of the EPISONO study, conducted between 2018 and 2019. OSA was diagnosed using full-night laboratory polysomnography, and insomnia symptoms were assessed with the Insomnia Severity Index (ISI). COMISA was defined by the concurrent presence of mild to severe insomnia symptoms and a confirmed diagnosis of OSA. Data were analyzed using binary logistic regression models.

Results: The sample consisted of 548 participants with a mean age of 48.64 years. Individuals with moderate-to-severe OSA and insomnia had a significantly higher likelihood of experiencing LBP (OR = 2.28, 95% CI: [1.047; 4.993], $p = 0.038$). The results showed that COMISA was associated with a twofold increase in the odds of reporting LBP, compared to those with insomnia alone.

Conclusions: COMISA is significantly associated with an increased risk of LBP. These findings highlight the need for clinicians to consider COMISA in the evaluation and management of patients with LBP.

Association between duration of moderate to severe obstructive sleep apnea and cardio-metabolic comorbidities: A cross-sectional observational study

L.K. Saini¹, K.S. Kumar¹, B. Kumar², K. Sridharan³, R. Gupta⁴

¹All India Institute of Medical Sciences Rishikesh, Pulmonary Medicine, Rishikesh, India, ²All India Institute of Medical Sciences Rishikesh, Cardiology, Rishikesh, India, ³All India Institute of Medical Sciences Rishikesh, Endocrinology, Rishikesh, India, ⁴All India Institute of Medical Sciences Rishikesh, Psychiatry, Rishikesh, India

Introduction: Obstructive Sleep Apnea (OSA) is associated with an increased risk of cardio-metabolic disorders, while the link between OSA and various comorbidities is well-documented, there is a notable gap in research specifically examining the influence of OSA duration on these health risks. The primary objective was to evaluate the association between OSA duration and cardio-metabolic comorbidities, including hypertension, diabetes mellitus, metabolic syndrome, dyslipidemia, coronary artery disease (CAD), arrhythmia, and heart failure.

Materials and methods: This cross-sectional study, approved by the IEC at AIIMS Rishikesh, India, included 279 newly diagnosed moderate to severe OSA patients through in-lab polysomnography, having ≥ 35 years of age and ≥ 20 BMI. OSA duration was estimated using an algorithm given by Olaithe M et al.¹, based on BMI (WHO classification), AHI, and sex. The prevalence of cardio-metabolic comorbidities was analysed across tertiles of estimated OSA duration. Statistical methods included chi-square tests, logistic regression, and Bonferroni correction (α -adjusted p -value < 0.017).

Results: The overall median age of the study population was 52 years (interquartile range [IQR]: 45–58 years). Of the 279 participants, 137 (49.1%) were male and 142 (50.9%) were female. The median AHI was 42.8 (IQR: 24.72–64.9), with 29% and 71% of participants having moderate and severe OSA,

respectively. The median duration of OSA was 18.70 years (IQR: 9.41–27.88 years), ranging from 0.19 to 63.29 years. The median OSA duration in males (25.82 years, IQR: 12.99–36.32) was significantly higher compared to females (14.92 years, with IQR: 8.23–21.51; $U = 5245$, $p = 0.000$).

For comparative analysis, participants were stratified into tertiles based on OSA duration: the lower tertile included those with <12.86 years ($n=93$), the middle tertile with 12.86–25.08 years ($n=93$), and the upper tertile with >25.08 years ($n=93$).

Systemic hypertension (79.5%, $n=222$) and dyslipidemia (78.5%, $n=219$) were the most common comorbidities, followed by metabolic syndrome (74.5%, $n=208$) and diabetes mellitus (50.8%, $n=142$), while CAD, arrhythmia, and heart failure were less prevalent (6.8%, 5%, and 4.3%, respectively). A significant trend was observed in the prevalence of hypertension across OSA duration tertiles as 68.8%, 83.9% and 86% in the lower, middle, and upper tertiles, respectively ($\chi^2 = 610.054$, $p = 0.007$). However, the prevalence of other comorbidities did not differ significantly across the tertiles.

Conclusions: This study highlights a substantial burden of cardiovascular and metabolic comorbidities among individuals with moderate to severe OSA. Notably, a longer duration of OSA was significantly associated with increased prevalence of systemic hypertension, suggesting a potential dose-response relationship. These findings underscore the importance of early identification and management of OSA to mitigate potential long-term cardiovascular risks. The lack of statistical significance in other cardio-metabolic comorbidities suggests that OSA duration alone may not be a key determinant of cardio-metabolic risk.

Association between PLMS and LM-related parameters according to AAMS and WASM criteria in patients with OSA

Y.J. Kang¹, C.-S. Park²

¹Yeouido St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Department of Otorhinolaryngology-Head and Neck Surgery, Seoul, Korea, Republic of, ²St. Vincent's Hospital, College of Medicine, The Catholic University of Korea, Department of Otorhinolaryngology-Head and Neck Surgery, Suwon, Korea, Republic of

Introduction: There were no studies compared limb movements (LMs) related parameters using manual re-scoring by the American Academy of Sleep Medicine rules (mAASM) and World Association of Sleep Medicine criteria (mWASM) for respiratory event-related limb movements (RRLM), periodic limb movements during sleep (PLMS), and limb movements, which were compared to auto-scoring by the AASM (aAASM). We aimed to assess how these different scoring methods (aAASM, mAASM, mWASM) influence the relationship between PLMS and LMs related parameters, particularly in relation to the resolution of respiratory events during continuous positive airway pressure (CPAP) titration.

Materials and methods: We retrospectively re-scored diagnostic and CPAP titration polysomnography (PSG) recordings from 16 patients with obstructive sleep apnea (OSA). Association between PLMS and other LM related parameters were examined using the manual re-scoring with AASM and WASM criteria and automated scoring method by the AASM.

Results: As a result of analyzing the diagnostic PSG results of patients with OSA, as the AHI and respiratory disturbance index (RDI) by aAASM increased, the PLMS tended to decrease significantly. In addition, in aAASM and mWASM, the PLMS significantly increased as the LMs, LM with no association, and LM in NREM2 increased. In the case of mAASM, AHI, RDI, LMs, and RRLM did not have a significant relationship with PLMS in the diagnostic PSG, but in the PSG where respiratory events were resolved by CPAP titration, the PLMS showed a significant relationship as the LMs and RRLM increased.

Conclusions: In the case of mAASM, PLMS may tend to appear worse due to the high correlation between other parameters and PLMS after titration. At this time, it is important to better differentiate PLMS. The criteria for periodic limb movement disorder might be adjusted according to the choice of scoring manual

Association Between Positive Airway Pressure Titration Sleep Data and Adherence to Therapy in Obstructive Sleep Apnea

J.H. Choi¹, S. Shin², Y. Lee², T.K. Ha³, S. Suh²

¹Soonchunhyang University Bucheon Hospital, Otorhinolaryngology-Head and Neck Surgery, Bucheon, Korea, Republic of, ²Sungshin Women's University, Seoul, Korea, Republic of, ³Honeynaps Research and Development Center, Seoul, Korea, Republic of

Introduction: This study aimed to investigate the impact of objective sleep parameters, specifically sleep efficiency (SE), wake after sleep onset (WASO), and sleep latency (SL), derived from the positive airway pressure (PAP) titration, on short-term adherence to PAP therapy in patients with obstructive sleep apnea (OSA).

Materials and methods: A total of 227 subjects diagnosed with OSA underwent overnight PAP titration and were subsequently categorized into adherence or non-adherence groups. Baseline demographics, clinical data, diagnostic polysomnography, and PAP titration data were collected. Paired sample t-tests compared sleep parameters between polysomnography and PAP titration within each group. Binomial logistic regression analyzed the predictive ability of changes in SE, WASO, and SL on PAP adherence, determining optimal thresholds. Chi-square tests examined the association between categorized improvements in SE and WASO and PAP adherence.

Results: The study population was distributed such that 176 (77.5%) participants were in the adherence group and 51 (22.5%) were in the non-adherence group. SE during PAP titration ($83.3 \pm 12.6\%$) was significantly higher than during baseline polysomnography ($80.9 \pm 12.4\%$, $p = .020$), while WASO was significantly lower (63.9 ± 58.9 min vs. 77.7 ± 67.2 min, $p = .016$). SL showed no significant change in either group. Logistic regression revealed that higher SE (OR = 1.025, $p = .039$) and shorter WASO (OR = 0.994, $p = .027$) were significant predictors of adherence, though their predictive ability was limited (AUC = 0.60 for SE; 0.62 for WASO). Thresholds for improved adherence were $\Delta SE \geq 2.39\%$ and $\Delta WASO < -1.5$ min. Subjects with improved SE ($\chi^2=5.296$, $p=.021$) and WASO ($\chi^2=6.877$, $p=.009$) were significantly more likely to adhere to PAP therapy.

Conclusions: This study reveals that objective improvements in sleep quality, specifically increased SE and reduced WASO, during initial PAP titration are significantly linked to short-term PAP adherence in OSA patients.

Association between restorative sleep and sleep fragmentation in obstructive sleep apnea

K. Nagao^{1,2}, T. Yoshiike¹, K. Matsui³, A. Kawamura¹, T. Utsumi¹, A. Kimura³, E. Takahashi², S. Matsushima², M. Nangaku¹, M. Hazumi¹, K. Kuriyama¹

¹National Center of Neurology and Psychiatry, Department of Sleep-Wake Disorders, National Institute of Mental Health, Kodaira, Japan, ²National Center of Neurology and Psychiatry, Department of Psychiatry, National Center Hospital, Kodaira, Japan, ³National Center of Neurology and Psychiatry, Department of Clinical Laboratory, National Center Hospital, Kodaira, Japan

Introduction: It has been suggested that the feeling unrefreshed upon awaking, referred to as non-restorative sleep (NRS), is associated with various worse health outcomes, including mortality. In obstructive sleep apnea (OSA), although the severity does not always reflect subjective symptoms such as NRS and daytime sleepiness, it robustly reflects mortality risks. It has also been suggested that sleep fragmentation, reduced sleep efficiency, decreased N3 sleep, and increased REM sleep are associated with mortality risks. However, the relationship between sleep abnormalities and NRS remains poorly understood in OSA. In addition, OSA patients often present with periodic limb movements (PLM), which also fragments sleep, but the influence of PLM on NRS has not been independently investigated. This study examined (1) the relationship between NRS and sleep abnormalities in OSA patients without PLM, and (2) the influence of comorbid PLM on this relationship in OSA patients.

Materials and methods: Patients diagnosed with OSA who underwent overnight PSG and completed an assessment of restorative sleep at our sleep disorders center between April 2020 and April 2025 were included. The restorative sleep was assessed at the morning after PSG using a 5-point Likert

scale. Total sleep time (TST), WASO (% total sleep period [SPT]), REM sleep (%TST), N2 sleep (%TST), N3 sleep (%TST), and AHI were also assessed by PSG. Parameters such as time in bed, SPT, sleep efficiency, and N1 sleep (%TST) were excluded to avoid multicollinearity. Patients were classified into four groups: severe OSA-only (SG; AHI ≥ 30 , PLM index <15) and mild to moderate OSA-only (LG; AHI < 30 , PLM index <15), severe OSA with significant PLM (SGWP; AHI ≥ 30 , PLM index ≥ 15) and mild to moderate OSA with significant PLM (LGWP; AHI < 30 , PLM index ≥ 15). Multiple regression analyses were conducted, with restorative sleep as the dependent variable and PSG parameters as independent variables, adjusting for age, BMI, and other potential confounders.

Results: Four hundred and sixty-one patients (SG: 78, LG: 223, SGWP: 56, LGWP: 104) were included in the study. Mean restorative sleep ratings were 3.05 for SG, 3.00 for LG, 3.16 for SGWP, and 2.89 for LGWP. In the OSA-only groups (SG and LG), higher WASO was significantly associated with poorer restorative sleep ($\beta = -0.19$, 95% CI: -0.38, -0.01), the relationship remained significant in the LG group ($\beta = -0.24$, 95% CI: -0.45, -0.04) after adjusting for age, AHI, and TST. However, the relationship did not remain significant in the SG group ($\beta = 0.01$). In contrast to the OSA-only group, longer TST was associated with better restorative sleep in the LGWP group, but the significant relationship disappeared in the SGWP group. The OSA with significant PLM groups had significantly shorter TST and higher WASO compared to the OSA-only groups.

Conclusions: Restorative sleep is strongly associated with sleep fragmentation, suggesting potential utility as an indicator of health risks in OSA. However, this relationship may diminish in severe OSA. Increased restorative sleep could indicate a breakdown in homeostasis, even as TST decreases with worsening sleep fragmentation.

Association between Sarcopenia-Related Genetic Variants and Sleep-Breathing Index in Patients with Obstructive Sleep Apnea: A Cross-Sectional Study

J. Huang^{1,2}, X. Li^{1,2}, H. Xu^{1,2}, J. Guan^{1,2}, H. Yi^{1,2}, S. Yin^{1,2}

¹Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Department of Otolaryngology Head and Neck Surgery, Shanghai, China, ²Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai Key Laboratory of Sleep Disordered Breathing, Shanghai, China

Introduction: Obstructive sleep apnea (OSA) and sarcopenia share common pathophysiological features, yet their genetic relationship remains unclear. This cross-sectional study aimed to investigate whether sarcopenia-related single nucleotide polymorphisms (SNPs) are associated with OSA severity and its related traits.

Materials and methods: A total of 4,925 individuals with suspected OSA in the Shanghai Sleep Health Study were enrolled. All participants underwent overnight polysomnography, biochemical testing, physical measurements, and genome-wide genotyping. Ten sarcopenia-associated SNPs that passed quality control were selected from published genome-wide association studies. Linear regression and logistic regression were utilized to assess associations between each SNP and sleep and respiratory related indicators. Functional annotations, protein interactions, and pathway enrichment analyses were conducted using Ensembl, STRING, Metascape, and DAVID databases.

Results: Rs2899611 (located in *ALDH1A2*) was significantly associated with higher AHI ($\beta = 1.480$, $p = 0.006$) and ODI ($\beta = 1.303$, $p = 0.025$) in the overall cohort, and conferred increased odds of severe OSA (OR = 1.264, $p = 0.032$) among OSA subjects. Functional enrichment analyses indicated rs2899611 may influence retinol metabolism and enzyme activities involved in cellular respiration and oxidative metabolism. Rs10952289, located adjacent to *AOC1*, was correlated positively with stage 1 sleep (S1) duration and proportion (S1 duration: $\beta = 4.036$, $p = 0.033$; S1/SPT: $\beta = 0.858$, $p = 0.040$; S1/TST: $\beta = 1.098$, $p = 0.020$) and inversely with stage 3 sleep (S3) metrics (S3 duration: $\beta = -3.120$, $p = 0.030$; S3/SPT: $\beta = -0.660$, $p = 0.039$; S3/TST: $\beta = -0.726$, $p = 0.037$). *AOC1* encodes a primary amine oxidase involved in histamine metabolism, suggesting a potential mechanistic link to sleep architecture.

Conclusions: Genetic variants associated with sarcopenia, rs2899611 and rs10952289, were significantly associated with AHI, ODI, and sleep architecture in OSA patients. The SNPs may alter sleep and respiratory traits by modulating the key biological pathways. Integrating sarcopenia-related genetic screening into OSA management may enhance prevention, early detection, and personalize therapy.

Association Between Tonsillectomy and Risk of Type 1 Diabetes Mellitus: A Multi-center Cohort Study

W. Huang¹, H. Yi¹

¹Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China

Introduction: The role of tonsillectomy in modulating systemic immune responses has been debated, but its association with autoimmune disorders like type 1 diabetes mellitus (T1DM) remains unclear. The study aimed to evaluate the risk of T1DM in patients undergoing tonsillectomy compared to non-surgical controls.

Materials and methods: Using the TriNetX collaborative network, we conducted a retrospective cohort study of patients diagnosed with tonsil/adenoid disorders (ICD-10: J03, J35, J36). Surgical (tonsillectomy/adenoidectomy) and non-surgical cohorts were propensity score-matched (1:1) for age, sex, race, BMI, comorbidities, and socioeconomic status. Outcomes were incidental type 1 diabetes, defined by ICD-10 codes. Cox proportional hazards models and survival analysis were analyzed. Subgroup and sensitivity tests were also performed.

Results: Among 2,240,430 eligible subjects, 252,087 underwent surgery and 1,826,933 did not. After matching, each cohort included 242,838 patients. The surgical group showed a higher cumulative incidence of T1DM (1.71% vs. 1.12%; HR = 1.35, 95% CI: 1.21–1.51). Subgroup analysis revealed elevated risks in individuals aged <18 years (HR = 1.32, 95% CI: 1.17–1.49), females (HR = 1.41, 95% CI: 1.17–1.69), ethnic Black or African American (HR = 1.47, 95% CI: 1.11–1.95), and those with obesity (HR = 1.89, 95% CI: 1.19–3.00). Sensitivity analyses confirmed robustness, and negative outcome controls showed no association.

Conclusions: Tonsillectomy is associated with an increased risk of T1DM, particularly in younger populations, female, ethnic Black or African American and individuals with obesity. Further studies are needed to explore underlying immunological mechanisms.

Acknowledgments: We sincerely appreciate the exceptional cooperation of our study team members and gratefully acknowledge the significant contributions of the TriNetX collaborative network.

Association of Obstructive Sleep Apnea with Cancer Risk & Mortality

B.K.J. Tan^{1,2}, Y.H. Teo², N.K.W. Tan¹, D.W.T. Yap², A.J.Y. Cheong², B.S.Y. Yeo², A. See¹, S.T. Toh^{1,3}

¹Singapore General Hospital, Department of Otorhinolaryngology–Head and Neck Surgery, Singapore, Singapore, ²National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore, ³SingHealth Duke–NUS Sleep Centre, Singapore, Singapore

Introduction: Obstructive sleep apnea (OSA), characterized by intermittent hypoxia and sleep fragmentation, has been biologically implicated as a potential carcinogen. While animal studies support this link, epidemiological findings in humans remain inconsistent. To clarify these associations, we conducted a comprehensive systematic review and meta-analysis assessing the relationship between OSA and cancer incidence and mortality, incorporating a wide range of cancer types and OSA severity metrics.

Materials and methods: We systematically searched PubMed, Embase, Scopus, and the Cochrane Library from inception through June 2021 (updated to November 2023 for urological cancers). We included observational and randomized studies reporting on the association between OSA—defined by diagnostic codes or sleep-study-derived indices—and cancer outcomes in adults. Two independent reviewers screened studies, extracted data, and assessed bias using the Newcastle-Ottawa Scale. We rated the quality of evidence using the GRADE framework and pooled maximally adjusted hazard ratios (HRs) using inverse variance-weighted random-effects models.

Results: Across 20 eligible studies involving over 9 million participants, OSA was associated with increased incidence of several cancer types. Using sleep-derived metrics (time spent with SpO₂ <90%), moderate (T90 >1.2%) and severe nocturnal hypoxemia (T90 >12%) were linked to 28% (HR=1.28, 95%CI: 1.07–1.54) and 43% (HR=1.43, 95%CI: 1.16–1.76) higher all-cancer incidence, respectively. Severe nocturnal hypoxemia also tripled all-cancer mortality (HR=2.66, 95%CI: 1.21–5.85), independent of confounders including obesity.

Cancer-specific analyses revealed the following associations:

- **Breast Cancer:** In six studies (n=5.2 million), OSA was associated with a 36% increased risk (HR=1.36, 95%CI: 1.03–1.80). Subgroup analyses with ≥ 5 years follow-up yielded HR=1.57 (95%CI: 1.14–2.18).
- **Gastrointestinal (GI) Cancers:** Among seven studies (n=5.1 million), OSA was associated with a 70% increased risk of colorectal cancer (HR=1.70, 95%CI: 1.48–1.96), while associations with pancreatic and liver cancers were not statistically significant.
- **Lung Cancer:** Four studies (n=4.8 million) showed OSA increased lung cancer incidence by 25% (HR=1.25, 95%CI: 1.02–1.53). With ≥ 5 years follow-up, the risk rose to 32% (HR=1.32, 95%CI: 1.27–1.37).
- **Melanoma:** Six studies (n=5.3 million) showed a 71% higher incidence (HR=1.71, 95%CI: 1.08–2.69), though heterogeneity was high.
- **Thyroid Cancer:** In three studies (n=1.6 million), OSA tripled thyroid cancer risk (HR=3.27, 95%CI: 2.80–3.82), with up to 22.5% of global cases potentially attributable to OSA.
- **Urological Cancers:** From 12 studies (n=9.3 million), OSA was associated with increased kidney (HR=1.75, 95%CI: 1.21–2.53) and bladder cancer (HR=1.76, 95%CI: 1.05–2.96) incidence, but not prostate cancer (HR=1.29, 95%CI: 0.82–2.04).

Conclusions: Across diverse cancer types, OSA—particularly when characterized by nocturnal hypoxemia—is associated with elevated cancer incidence and, in some cases, mortality. These findings support the carcinogenic potential of OSA and underscore the need for prospective studies to examine cancer-specific mechanisms, dose-response relationships, and the impact of OSA treatment on cancer outcomes.

ASSOCIATION OF UPPER AIRWAY MORPHOLOGICAL PHENOTYPES WITH OBSTRUCTIVE SLEEP APNEA IN MIDDLE-AGED KOREAN ADULTS

J. Choi^{*1}, A. Wan^{*2}, V. Chen², J. Kim³, H.H. Jeon^{*2}, S. Kim^{*4,1}, C. Shin¹

¹Korea University College of Medicine, Institute of Human Genomic Study, Seoul, Korea, Republic of,

²University of Pennsylvania, School of Dental Medicine, Department of Orthodontics, Philadelphia, United States, ³University of Nevada Las Vegas, School of Nursing, Las Vegas, United States, ⁴Seowon University, Department of Paramedicine, Cheongju, Korea, Republic of

Introduction: Obstructive sleep apnea (OSA) is a multifactorial disorder characterized by the recurrent collapse of the upper airway during sleep. It is commonly associated with obesity, enlarged pharyngeal soft tissues, and restricted craniofacial skeletal structures. The present study aims to investigate the relationship between (i) craniofacial morphology and (ii) volumetric measurements of the upper airway and surrounding soft tissues, and the prevalence of OSA in middle-aged Korean adults.

Materials and methods: This cross-sectional study was conducted using data from a population-based cohort of Korean adults. A total of 89 participants (mean age: 61.65 ± 6.27 years; 50 males, 39 females) from the Korean Genome and Epidemiology Study in Ansan were included in the analysis. All participants underwent 1.5-Tesla MRI-based volumetric assessment of the upper airway (Magnetom Espree; Siemens Healthcare, Erlangen, Germany) and overnight in-home polysomnography (Embletta X-100; Embla Systems, Broomfield, CO, USA) between 2014 and 2015. Based on their apnea-hypopnea index (AHI), participants were categorized into two groups: no OSA (AHI <10 events/hour) and OSA (AHI ≥ 10 events/hour). Using Amira 5.4.0 image analysis software, a total of 23 volumetric measurements (airway and surrounding soft tissues) and 15 linear and angular cephalometric measurements were obtained from the upper airway MRI scans.

Results: Based on multivariable linear regression analysis adjusted for age, sex, BMI, diabetes, and cardiovascular disease, several MRI-based volumetric and cephalometric features were significantly associated with the OSA group compared to the non-OSA group. Among the volumetric measurements, the OSA group exhibited a narrower anteroposterior dimension of both the retropalatal and retroglossal airways (β [SE] = -1.88 [0.66] ($p=0.01$); and -2.48 [0.95] ($p=0.01$), respectively), as well as a longer overall airway length (β [SE] = 3.69 [1.61], ($p=0.02$)). In terms of cephalometric

characteristics, the OSA group showed a significantly greater maxillo-mandibular discrepancy and increased upper facial height compared to the non-OSA group (all p-values <0.05).

Conclusions: This study identified distinct craniofacial and upper airway morphological features in individuals with OSA, including reduced anteroposterior airway dimensions and increased airway length. These findings emphasize the important role of upper airway phenotypes in the pathophysiology of OSA in middle-aged Korean adults.

Associations between CPAP use and risk for Major Adverse Cardiac Events in sleep clinic patients? A real-world study

A. Reynor^{1,2}, B. Singh^{1,2}, J. Walsh^{1,2}, K. Maddison^{1,2}, P. Eastwood³, B. Shenoy², S.S. Dhaliwal^{2,4}, N. McArdle^{1,2}

¹University of Western Australia, School of Human Sciences, Perth, Australia, ²West Australian Sleep Disorders Research Institute, Department of Pulmonary Physiology and Sleep Medicine, Sir Charles Gairdner Hospital, Perth, Australia, ³Murdoch University, Perth, Australia, ⁴Curtin Health Innovation Research Institute, Faculty of Health Sciences, Curtin University, Perth, Australia

Introduction: The relationship between continuous positive airway pressure (CPAP) use and risk for long-term major adverse cardiovascular events (MACE) is poorly understood. This study aimed to assess the relationship between CPAP use and MACE among typical patients attending an Australian tertiary centre sleep clinic diagnosed with moderate/severe OSA.

Materials and methods: Design: Observational cohort study - West Australian Sleep Health Study (WASHS).

Participants: Adults (n=2,646) with moderate/severe OSA (AHI ≥15/hour) diagnosed by in-lab polysomnography between 2006–2010.

Follow-up: Median of 7.1 years; endpoint January 2016.

CPAP exposure: CPAP use as continuous variable: Week 1 CPAP (hrs/night) and All CPAP (hrs/night) (mean of all CPAP use over the follow-up period), tertiles of CPAP use: Week 1 and All CPAP (reference: 0 hours).

Outcome: Time to cardiac death or non-fatal hospitalisations due to MACE (a composite of coronary heart disease (CHD), cerebrovascular disease, revascularisation procedures for CHD or cerebrovascular disease, peripheral vascular disease, heart failure, and atrial fibrillation), or end of follow-up/non-cardiac death, based on ICD codes (administrative health databases).

Analysis: Cox proportional hazards models adjusted for: age; sex; body mass index (BMI); socio-economic status; education; prevalent cardiovascular disease; smoking; Epworth sleepiness scale (ESS); self-reported sleep duration; ODI 3%; hypertension; diabetes; cholesterol. Restricted cubic spline analysis was used to explore potential non-linear associations between CPAP use and MACE.

Results: MACE occurred in 18% of participants (n=475).

Each additional hour of Week 1 CPAP use was associated with a 5% reduction in hazard of MACE (HR 0.95, 95% CI: 0.92–0.99; p=0.007). Each additional hour of All CPAP use associated with a 6% reduction in hazard (HR 0.94, 95% CI: 0.91–0.98; p=0.002).

Compared to no use, Week 1 CPAP tertiles showed significantly reduced hazard (T1: 0.01–3.58 hrs/night, HR 0.55, 95% CI: 0.41–0.74, p<0.001; T2: 3.59–6.12 hrs/night, HR 0.62, 95% CI: 0.46–0.82, p=0.001; T3: 6.13–13.86 hrs/night, HR 0.64, 95% CI: 0.48–0.85, p=0.002). Compared to no use, all follow up CPAP use tertiles showed significantly reduced hazard (T1: 0.01–3.60 hrs/night, HR 0.57, 95% CI: 0.42–0.76, p<0.001; T2: 3.61–6.00 hrs/night, HR 0.60, 95% CI 0.45–0.80, p<0.001; T3: 6.02–11.44 hrs/night, HR 0.60, 95% CI 0.45–0.80, p<0.001).

Restricted cubic spline analysis suggested reduced MACE hazard at any level of CPAP use, albeit with lesser risk reduction at intermediate use (>3 to <6hrs/night), compared to low (0-3hrs/night) or high use (≥6 hrs/night).

Conclusions: Increasing CPAP use was associated with lower risk of MACE in sleep clinic patients with moderate/severe OSA. However, benefit appears to occur at very low levels of use and cubic spline analysis suggests more benefit at low and high CPAP use levels, compared with intermediate levels of use. MACE risk reduction from CPAP can be predicted as early as 1 week. These findings highlight the potential importance of supporting CPAP use from treatment outset to reduce risk of long-term MACE.

Acknowledgments: We thank the patients and staff involved in WASHS. Funded by NHMRC (APP1145970). Conducted at WASDRI Sleep Clinic. This research contributes to a UWA PhD project.

Association study of gut microbiota abnormalities and cognitive dysfunction caused by obstructive sleep apnea

W. Yan¹, J. Tai², S. Wang³

¹Capital Institute of Pediatrics, Department of Pediatric Health Care, Beijing, China, ²Capital Institute of Pediatrics, Department of Otolaryngology, Head and Neck Surgery, Beijing, China, ³Capital Institute of Pediatrics, Beijing Municipal Key Laboratory of Child Development and Nutriomics, Beijing, China

Introduction: Obstructive sleep apnea (OSA), the most prevalent sleep-related breathing disorder, induces neurocognitive dysfunction through intermittent hypoxia (IH) mediated mechanisms. Although clinical studies have identified gut microbiota dysbiosis and altered microbial metabolite profiles in OSA populations, the causal relationship between OSA progression and microbiota-metabolite axis dysregulation remains unestablished. Furthermore, the pathophysiological mechanisms linking microbiota-metabolite axis disturbances to OSA-mediated cognitive impairments require systematic elucidation.

Materials and methods: This multi-tiered methodology comprised: (1) Leveraging OSA GWAS data from FinnGen and gut microbiota/metabolome datasets from MiBioGen consortiums, we conducted bidirectional two-sample Mendelian randomization to identify OSA-associated microbial features, followed by multivariate MR analysis adjusting for obesity, sex, and smoking to establish causal relationships; (2) Establishing intermittent hypoxia (IH) murine models with cognitive assessment through behavioral paradigms and neural function evaluation via resting-state fMRI; (3) Multi-omics integration (fecal metagenomics, serum metabolomics, and hippocampal transcriptomics) delineated IH-induced gut-brain axis perturbations, with qPCR validation of key regulatory genes and Luminex cytokine profiling; (4) Therapeutic exploration of sodium butyrate supplementation on IH-mediated cognitive deficits and gut-brain circuitry.

Results: 1. Multiple MR Analysis determined that increased serum levels of three gut microbiota derived metabolites (leucine, epimandrosterone sulfate and 3-dehydrocarnitine) were independently associated with increased risk of OSA, and multiple SCFAs producing bacteria represented by Rumenococcaceae showed independent protective effects on OSA risk even after correction of confounding bias. 2. Behavioral experiments found that IH would lead to learning and memory dysfunction in mice. Functional MRI showed that IH mice showed inconsistent intensity of nerve activity in the whole brain and decreased nerve function in cognitive-related brain areas. Multi-omics analysis revealed multi-dimensional pathological changes in the gut-brain axis of IH mice, including reduced abundance of SCFAs producing bacteria, altered metabolic pathway levels, over-activation of hippocampal microglia, accumulation of inflammatory factors and activation of inflammatory pathways. 3. Exogenous SB supplementation significantly improved the learning and memory dysfunction of IH mice, and up-regulated the level of neural activity in brain regions related to cognitive function; Microbiota remodeling, regulation of metabolic environment, inhibition of microglia activation and expression of inflammatory factors may be the potential mechanisms by which SB improves IH cognitive impairment.

Conclusions: Multiple gut microbiota and derived metabolites have independent causal relationship with OSA. Exogenous SCFAs (butyric acid) supplementation can significantly improve IH-related cognitive dysfunction. This study provides evidence for the association between gut microbiota and OSA and related cognitive dysfunction, and SCFAs supplementation based on gut microbiota metabolites can be used as a potential drug therapy for OSA related cognitive dysfunction.

Asthma, Arytenoid Edema, and Conversion Disorder

C.M. Sung¹, H.C. Yang¹

¹Chonnam National University Medical School and Chonnam National University Hospital, Department of Otolaryngology–Head and Neck Surgery, Gwangju, Korea, Republic of

Introduction: Recurrent intubations for dyspnea typically imply the presence of severe organic airway pathology requiring mechanical intervention. However, when structural abnormalities are mild or insufficient to account for the clinical severity, functional etiologies such as conversion disorder must be considered. We report a unique case of persistent upper airway symptoms resulting in repeated intubations, driven by the complex interplay of asthma exacerbations, mild arytenoid swelling, and conversion disorder.

Materials and methods: Case report

Results: A 23-year-old woman with a history of allergic asthma presented with recurrent episodes of severe dyspnea, leading to multiple intubations and ICU admissions. Initial desaturation was associated with asthma exacerbation confirmed by positive rhinovirus testing. Subsequent evaluations revealed mild arytenoid mucosal swelling but no significant structural airway obstruction. During acute episodes, head rotation immediately improved symptoms, suggesting dynamic upper airway compromise. Later, drug-induced sleep endoscopy (DISE) was performed for diagnostic purposes, confirming mild arytenoid edema and positional airway improvement. Psychological assessment indicated conversion disorder, characterized by la belle indifférence. Symptom recurrence was triggered by allergen exposure and emotional stress events.

Management included asthma control, acute positional therapy for symptom relief, long-term voice therapy to reduce laryngeal tension, and psychiatric intervention targeting functional symptoms and underlying psychological stressors. Surgical intervention was not pursued.

Conclusions: This case highlights the importance of considering both organic and functional components in patients with persistent dyspnea, especially when structural abnormalities are insufficient to explain clinical severity. Dynamic airway evaluation and psychological assessment were essential for diagnosis and tailored management.

A Study on Differentiating Obstructive and Central Sleep Apnea and Identifying Cheyne-Stokes Breathing Using Non-Invasive Fiber Optic Physiological Monitoring Technology and AI

S.-C. Yang¹, L.-W. Ko¹, M. Osama², H.-L. Chan^{2,3}, W.-T. Liu^{4,5,6}, W.-Y. Hsu²

¹Institute of Electrical and Control Engineering, College of Electrical and Computer Engineering, National Yang Ming Chiao Tung University, Hsinchu, Taiwan, ²Chang Gung University, Department of Electrical Engineering, Taoyuan, Taiwan, ³Neuroscience Research Center, Chang Gung Memorial Hospital, Taoyuan, Taiwan, ⁴Sleep Center, Taipei Medical University-Shuang Ho Hospital, New Taipei City, Taiwan, ⁵Division of Pulmonary Medicine, Department of Internal Medicine, Taipei Medical University-Shuang Ho Hospital, New Taipei City, Taiwan, ⁶School of Respiratory Therapy, College of Medicine, Taipei Medical University, Taipei, Taiwan

Introduction: Currently, the detection of sleep apnea primarily relies on polysomnography (PSG) and photoplethysmography (PPG). However, while PSG is considered the diagnostic gold standard, it requires multiple wires attached to the body, significantly disturbing natural sleep and making it unsuitable for long-term or home monitoring, especially for elderly individuals, children, and patients with dementia or psychiatric disorders. Although PPG is more convenient, its signals are easily affected by vascular contractions, skin pigmentation, and improper sensor placement. Moreover, oxygen desaturation alone cannot distinguish between obstructive sleep apnea (OSA) and central sleep apnea (CSA). In addition, the widely used apnea-hypopnea index (AHI) merely counts the number of events without considering the duration, depth, or morphology of respiratory events, potentially underestimating disease severity and failing to accurately identify complex breathing patterns such as Cheyne-Stokes Breathing (CSB).

Materials and methods: This study developed a system integrating non-invasive fiber optic physiological monitoring technology (nFOPT Biosensor) with artificial intelligence (AI) models. Data were collected from 100 subjects, including signals from fiber optic sensing mats placed under the pillow and chest, thoracic and abdominal belts, and oxygen saturation, resulting in a total of 5,685 annotated apnea events. A hybrid CNN-LSTM AI model was constructed to detect apnea events and

classify OSA and CSA. Furthermore, an expert-annotated dataset containing 8,823 data points, along with CNN-DENSE and BiLSTM AI models, was utilized for the identification of CSB.

Results: The proposed AI model achieved detection accuracies of 90.9% for the chest fiber optic biosensors and 89.7% for the pillow biosensors. For the classification of OSA and CSA, the model achieved an overall accuracy of 90.37%, with a sensitivity of 90.92% for OSA and 83.33% for CSA. Regarding CSB identification, the AI model achieved an accuracy of 97.58% and a precision of 86.36%. These results demonstrate that even in the presence of highly variable breathing patterns like CSB, the nFOPT technology combined with AI maintains stable and excellent performance.

Conclusions: This study confirms that nFOPT Biosensor offers significant advantages, including non-contact monitoring, freedom from electromagnetic interference, and high sensitivity. It enables continuous, non-invasive monitoring of respiratory waveforms and precise analysis of the time-frequency characteristics of breathing events. The technology not only overcomes the limitations of traditional PSG and PPG but also allows for accurate differentiation of sleep apnea subtypes and abnormal breathing patterns. In the future, this technology holds great potential for clinical precision diagnostics, remote health monitoring, and cardiovascular risk prediction, representing a groundbreaking innovation in the field of sleep medicine.

Acknowledgments: The research team would like to thank Huijia Health Life Technology Co., Ltd. for providing the nFOPT biosensors and all personnel involved for their support in data collection and analysis.

A Study on Selected Factors and Their Association with the Severity of Obstructive Sleep Apnea in Overweight and Obese Hypertensive Patients at Family Hospital in Vietnam

D. Le Thi Hong¹, T. Vo Thanh¹, G. Nguyen Nhu Ha¹

¹Family Hospital, Da Nang, Vietnam

Introduction: Obstructive sleep apnea (OSA) is prevalent among overweight and obese individuals with hypertension and is associated with an increased risk of cardiovascular, metabolic, and neurological complications. Identifying factors linked to OSA severity can support early diagnosis and improve management strategies. Therefore, this study aims to examine the relationship between various risk factors and the severity of OSA in hypertensive individuals who are overweight or obese.

Materials and methods: A cross-sectional study was conducted on 52 overweight and obese hypertensive patients at Family Hospital, Da Nang, Vietnam, from August 2024 to April 2025. Clinical data, including age, gender, BMI, neck circumference, and blood pressure, were collected. OSA was diagnosed using the American Academy of Sleep Medicine (AASM) criteria, and classified into mild, moderate, and severe by AHI. Statistical analysis included descriptive statistics, binary, and ordinal logistic regression.

Results: Of the 52 patients, 90.4% had OSA, with the majority being male (73.1%) and having grade 1 obesity (61.5%). The average age was 54.6 years $\pm$ 3.9 (95% CI), average systolic blood pressure was 137.5 $\pm$ 6.7 mmHg, diastolic pressure was 78.1 $\pm$ 4.8mmHg (95% CI), and neck circumference was 41.6 $\pm$ 0.5 cm (95% CI). The majority of patients were diagnosed with severe obstructive sleep apnea (61.7%). The mean Apnea-Hypopnea Index (AHI) was 44.2 $\pm$ 8.2 events/hour (95% CI), with values ranging from 2.2 to 117.9 events/hour. The most common symptoms of OSA in obese patients with hypertension included loud snoring (100%), witnessed apneas during sleep (95.7%), excessive daytime sleepiness (93.6%), and daytime fatigue (87.2%). Many patients also had coexisting coronary artery disease.

Binary logistic regression showed that gender, age $\geq$ 60 years, and obesity were associated with OSA risk. Female gender was a potential protective factor (OR = 0.118; p = 0.069), while age $\geq$ 60 (OR = 6.835; p = 0.164) and obesity (OR = 2.661; p = 0.240) were linked to increased OSA risk, though the results were not statistically significant possibly due to a limited sample size. Ordinal logistic regression showed that BMI was significantly associated with OSA severity (OR = 1.24; 95% CI: 1.01–1.52; p = 0.039).

Conclusions: Gender, age $\geq$ 60, and obesity may influence OSA risk in hypertensive overweight/obese patients, though the results were not statistically significant possibly due to a limited sample size, further studies with larger sample sizes are necessary. BMI was significantly associated with OSA severity.

A Tiny Bone with a Pivotal Impact: Boosting Hypoglossal Nerve Stimulation to Improve Upper Airway Function

M.-M. Serghani¹, K. Abu¹, J. Zwein¹, J. Amatoury¹

¹American University of Beirut, Biomedical Engineering, Beirut, Lebanon

Introduction: Obstructive sleep apnea (OSA) is characterized by repeated upper airway collapse during sleep, leading to significant cardiovascular, metabolic and neurocognitive consequences. Although continuous positive airway pressure (CPAP) is the gold-standard treatment, it is poorly tolerated by approximately 50% of those with OSA. Hypoglossal nerve stimulation (HNS) has emerged as an alternative therapy, targeting the genioglossus (GG) muscle - a primary upper airway dilator in the tongue - to maintain airway patency. However, HNS treatment outcomes vary. One factor that may influence HNS effectiveness is the position of the hyoid bone, a mobile structure sitting at the base of the tongue. In individuals with OSA, the hyoid bone is positioned more inferiorly, potentially limiting GG-mediated airway dilation. While HNS stimulation parameters, such as current amplitude, are often adjusted to improve treatment efficacy, the role of hyoid bone repositioning remains unknown. This study aimed to assess how directional and incremental anterior hyoid bone repositioning, combined with different HNS amplitudes, influences upper airway function.

Materials and methods: An anesthetized New Zealand White rabbit model (n=6) was used to investigate upper airway dynamics. Rabbits were positioned supine with head and neck position controlled. Upper airway airflow (V) was measured using a pneumotachograph connected in series with the trachea, while upper airway pressure (Pua) was recorded via a pressure transducer. The hypoglossal nerve was surgically exposed via a midline neck incision and carefully dissected for bipolar hook electrode placement. Stimulation was delivered using an electric stimulator. The hyoid bone was also exposed, and a custom-made device was used to perform anterior repositioning of the hyoid (0, 2, 4 mm) - a direction previously shown to have the greatest impact on upper airway collapsibility. Data were collected during HNS at two current amplitudes (Stim 1; Stim 2 = 2xStim 1), with and without hyoid repositioning. Stimulation was delivered at a frequency of 40 Hz, with pulse widths ranging from 60–500 μ s and current amplitudes of 50–800 μ A for Stim 1, and 100–1600 μ A for Stim 2. Maximal inspiratory flow (Vlmax), nadir upper airway pressure (Pua_min), and upper airway resistance (Rua) were quantified.

Results: Preliminary results indicate that both anterior hyoid repositioning and HNS alone improved upper airway function. When combined, anterior hyoid repositioning generally augmented the effect of HNS on upper airway outcomes, producing greater increases in Vlmax and reductions in Pua_min and Rua compared with stimulation alone. The greatest improvements across all three outcomes were observed with hyoid repositioning of 4 mm.

Conclusions: Anterior repositioning of the hyoid bone tends to improve upper airway patency by increasing airflow and reducing susceptibility to upper airway collapse. The findings highlight the synergistic potential of combining hyoid bone repositioning with HNS and individualized stimulation parameters to boost upper airway function. This combined approach may offer a promising strategy to optimize HNS outcomes and advanced personalized therapies for the treatment of OSA, ultimately helping to reduce the disorder's serious health consequences.

Auto-PAP Adherence in Obese Pediatric Patients with OSA: A Retrospective Study

O. Lacki¹, J. Slaven², A. Bandyopadhyay³, H. Rao³, H. Jalou³

¹Indiana University School of Medicine, Pediatrics, Indianapolis, United States, ²Indiana University School of Medicine, Biostatistics and Health Data Science, Indianapolis, United States, ³Indiana University School of Medicine, Pediatric Pulmonology, Allergy and Sleep Medicine, Indianapolis, United States

Introduction: Long wait times for CPAP (continuous positive airway pressure) titration studies and poor adherence to CPAP machines continue to be major barriers to effective fixed-pressure CPAP therapy in children and adolescents. During the COVID-19 pandemic, auto-titrating CPAP (auto-PAP) gained popularity in adults due to its ease of initiation—eliminating the need for a titration study—and increased comfort during use. However, data on auto-PAP adherence in the pediatric population remain limited. This study aims to identify characteristics associated with improved auto-PAP

compliance in children and adolescents, with the goal of predicting which patients may be optimal candidates for this therapy.

Materials and methods: Charts and PAP adherence data were retrospectively reviewed for 77 obese children and adolescents initiated on auto-PAP therapy between 2021 and 2024. Patients with autism or genetic syndromes associated with global developmental delays were excluded. Collected variables of interest included demographic data (age and gender), baseline apnea-hypopnea index (AHI), and adherence rates at 7, 30, and 90 days following the initiation of therapy.

Results: There were no significant differences in auto-PAP adherence between males and females or between children and adolescents. At day 7, a non-significant trend was observed, suggesting that patients with severe OSA (AHI > 5) were more likely to be adherent. This trend was no longer observed at days 30 or 90. Notably, a higher BMI z-score was significantly associated with poorer adherence at day 30, but not at days 7 or 90.

Conclusions: Auto-PAP adherence in pediatric patients does not appear to differ significantly by gender or age group. A higher BMI z-score may be associated with decreased adherence at the 30-day mark, highlighting a potential at-risk group. While severe OSA may initially correlate with improved short-term compliance, this trend does not persist in the long term. These findings underscore the need for further research to better understand adherence barriers, particularly among patients with higher BMI, and to identify subgroups most likely to benefit from auto-PAP therapy.

Belun Sleep Platform versus In-lab polysomnography for obstructive sleep apnea diagnosis

V. Tirachaimongkol¹, W. Banhira¹, W. Chotinaiwattarakul², S. Rungmanee¹, C. Pimolsri², J. Srikajon², N. Kasemsuk¹

¹Faculty of Medicine Siriraj Hospital, Mahidol University, Otorhinolaryngology, Bangkok, Thailand,

²Faculty of Medicine Siriraj Hospital, Mahidol University, Medicine, Bangkok, Thailand

Introduction: The Belun Sleep Platform (BSP) is an innovative network-based technology for home sleep apnea testing, designed using an artificial intelligence system that analyzes patterns of oxygen saturation, heart rate, and accelerometry signals. Few studies have been conducted to validate the device. This article aims to compare the BSP with full-night PSG for OSA diagnosis.

Materials and methods: Participants without significant cardiovascular or neuromuscular comorbidities scheduled for PSG were recruited. Simultaneous in-laboratory full-night PSG was conducted with the BSP. The diagnostic features, including sensitivity, specificity, PPV, NPV, and accuracy, were determined using IBM SPSS, version 27.

Results: A total of 35 individuals (54.3% male) were enrolled, with an average age of 49.9 years. The accuracy, sensitivity, and specificity with an AHI cut-off value of ≥ 15 events/h were 0.68 (0.51 to 0.83), 0.35 (0.14 to 0.61), and 1.0 (0.81 to 1.0), respectively, for both AASM scoring criteria 1A and 1B with AUROC 0.67. The diagnostic property of BSP with distinct AHI cut-off values of ≥ 5 events/h and ≥ 30 events/h revealed a sensitivity of 0.82 (0.63 to 0.93) and 0.33 (0.07 to 0.70), respectively, and a specificity of 0.14 (0.00 to 0.57) and 1.0 (0.86 to 1.0). The combination of BSP-AHI with STOP-Bang ≥ 3 results in an increased sensitivity of 0.38. The BSP-AHI demonstrated a moderate correlation with the PSG-AHI (ICC = 0.737). Likewise, a good correlation was observed between BSP-ODI and PSG-ODI (ICC = 0.882).

Conclusions: The accuracy of the Belun Sleep Platform in predicting AHI and ODI in patients without significant comorbidities was still controversial. Future research with a larger sample size and the enrollment of participants with comorbidities is recommended to ascertain the role of the BSP as an alternative device for the diagnosis of OSA in high-risk OSA patients.

Acknowledgments: The authors gratefully appreciate the kind contributions of Dr. Suthipol for his comprehensive statistical analysis. The authors also thank all staff members of Department of Otorhinolaryngology and the Siriraj Sleep Center who were involved in this project.

Benefits of Community-Based Intervention for Mild OSA on Cardiac Remodeling: A Secondary Analysis of a Randomized Trial

Q. Ou¹, T. Feng¹, J. Chen¹, L. Wang¹, G. Shan², Y. Hu², M. Lao¹, R. Zhou¹, R. Zhang¹

¹Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China, ²Peking Union Medical College, Chinese Academy of Medical Sciences, Beijing, China

Introduction: Evidence for the efficacy of continuous positive airway pressure (CPAP) therapy in patients with mild obstructive sleep apnea (OSA), particularly in community-based settings, remains limited. This study investigated the effects of CPAP on cardiac remodeling, symptoms, and blood pressure in mild OSA through a secondary analysis of data from a community randomized controlled trial (RCT).

Materials and methods: This study conducted a secondary analysis on a specific subgroup of the population in February 2025, based on the RCT trial published in the journal *SLEEP* in September 2024. A total of 94 participants with mild OSA (apnea-hypopnea index 5–15 events/hour) were randomized to either CPAP therapy (N=44) or routine community management (N=50), with 12-week follow-up. Secondary outcomes focused on left atrial diameter (LAD), Short Form 36 Health Survey (SF-36), Pittsburgh Sleep Quality Index (PSQI), Insomnia Severity Index (ISI), and blood pressure. Analysis of covariance was used to assess between-group differences in outcomes.

Results: The mean age of participants was 55.6 years, with 40.4% male. Compared to baseline, the intervention group showed a mean reduction of 0.1 mm in LAD, while the control group exhibited a mean increase of 0.6 mm, resulting in a between-group difference of -1.2 mm (95%CI: -2.3 to -0.1, $P=0.036$). At 12 weeks, the CPAP group demonstrated significant improvements over the control group in SF-36 physical function score (adjusted $\beta = 3.5$, 95% CI: 0.9 to 6.0), ISI score (adjusted $\beta = -1.8$, 95%CI -3.5 to -0.1), and PSQI score (adjusted $\beta = -1.1$, 95%CI -2.1 to -0.1). Additionally, the CPAP group showed greater reductions in systolic blood pressure (adjusted $\beta = -7.0$, 95%CI: -11.7 to -2.4), diastolic blood pressure (adjusted $\beta = -4.6$, 95%CI: -7.3 to -2.0), and body mass index (adjusted $\beta = -0.3$, 95%CI: -0.6 to -0.0).

Conclusions: Interventions targeting mild OSA can improve cardiac remodeling, while demonstrating multifaceted benefits including enhanced physiological function, improved sleep quality, blood pressure reduction, and decreased insomnia severity.

Benefits of Early Body Weight Reduction in Participants with Obesity and Moderate-to-severe Obstructive Sleep Apnea: A Post Hoc Analysis of SURMOUNT-OSA

Y.N. Lin¹, X.W. Sun¹, S.J. Dai², H.X. Zhuang², J.J. Liu², Q.Y. Li¹

¹Department of Respiratory and Critical Care Medicine, Ruijin Hospital, Shanghai Jiao Tong University, School of Medicine, Shanghai, China, ²Eli Lilly and Company, Shanghai, China, Shanghai, China

Introduction: Previous studies demonstrated that weight reduction within the first year of treating obstructive sleep apnea (OSA) significantly reduced Apnea-Hypopnea Index (AHI). However, further investigation is required to understand the relationship between early weight reduction and OSA outcomes, especially with treatments such as positive airway pressure (PAP) therapy. This post hoc analysis of the SURMOUNT-OSA study explored the association between early weight reduction at Week 20 and OSA improvement in participants with moderate-to-severe OSA and obesity.

Materials and methods: This post hoc analysis of the global multi-center, phase 3, 52-week, double-blind, study SURMOUNT-OSA (NCT05412004) randomized participants to receive either tirzepatide or placebo, with trial 1 enrolling those not receiving PAP and trial 2 enrolling those receiving PAP therapy. Participants were retrospectively categorized based on the percentage of weight reduction at Week 20 into four subgroups: <5%, $\geq 5\%$ <10%, $\geq 10\%$ <15%, and $\geq 15\%$. Least Squares Mean (LSM) change in AHI (events/hour) and percent change in AHI from baseline, as well as OSA remission at week 52, were assessed using mixed model repeated measures.

Results: The analysis included 469 participants, 234 from trial 1 and 235 from trial 2. The baseline characteristics were comparable across subgroups. In trial 1 at Week 20, participants with $\geq 5\%$ <10%, $\geq 10\%$ <15%, and $\geq 15\%$ weight reduction showed significant improvement in AHI with mean change (events/h) of -12.4, -18.8, -30.6 ($p<.001$ for all), and percent change from baseline of -20.0, -38.0, -56.1 ($p<.001$ for all), respectively, compared to the <5% weight reduction group (-6.2; -14.9; $p<.05$ for both). By Week 52, participants in <10%, $\geq 10\%$ <15%, and $\geq 15\%$ weight reduction groups, sustained significant improvements in AHI with mean change of -15.8, -28.5, -32.4 ($p<.001$ for all) and percent change from baseline of -32.2, -56.9, -58.3 ($p<.001$ for all), respectively, compared to the <5% weight reduction group (-6.5; $p=.02$; -9.6; $p=.09$).

Similarly, in trial 2, participants with $\geq 5\% < 10\%$, $\geq 10\% < 15\%$, and $\geq 15\%$ weight reduction at Week 20 showed significant improvement in AHI with mean change from baseline (events/h) of -12.0, -17.0, -27.2 ($p < .001$ for all) and percent change from baseline of -22.7, -37.2, -56.4 ($p < .001$ for all), compared to the $< 5\%$ weight reduction group (-9.5; -17.7; $p < .01$ for both). By Week 52, participants in the $\geq 5\% < 10\%$, $\geq 10\% < 15\%$, and $\geq 15\%$ weight reduction groups sustained improvements in AHI (events/h) with mean change of -14.8, -27.5, -35.2 ($p < .001$ for all), and percent change from baseline of -29.5, -58.5, -74.5 ($p < .001$ for all), respectively, compared to the $< 5\%$ weight reduction group (-10.4, $p < .001$; -13.7; $p < .05$).

In both trials, participants with $\geq 10\% < 15\%$ weight reduction at Week 20 exhibited OSA remission rates of 48.7% and 49.8% by week 52, while those with $\geq 15\%$ weight reduction demonstrated higher remission rates of 50.7% and 75.3%. Participants with $\geq 5\% < 10\%$ and $< 5\%$ weight reduction had $< 30\%$ and $< 15\%$ OSA remission rates, respectively.

Conclusions: In this post hoc analysis, early weight reduction of $\geq 10\%$ was associated with greater AHI improvement. These findings support the importance of early and intensive weight reduction strategies for optimizing sustained improvements in participants with OSA and obesity, with or without PAP therapy.

Beyond AHI: Hypoxic Burden As A Superior marker in the Management of Opioid-Associated Central Sleep Apnea with Acetazolamide

F. Zolfaghari¹, M. Mooziri², F. Mohammadi Inloo³, S. Shabani⁴, Z. Naderpour⁵, P. Adimi Naghan³, H.R. Jammati⁶, M. Mirza Aghazadeh³, T. Zandi Kermanshahi³, M.R. Raoufy⁷

¹Shahid Beheshti University of Medical Science, Tehran, Iran, Islamic Republic of, ²Department of Brain and Cognitive Science, Royan Institute for Stem Cell Biology and technology, ACECR, Tehran, Iran, Islamic Republic of, ³Shahid Beheshti University of Medical Science, Pulmonary and Sleep Medicine, Tehran, Iran, Islamic Republic of, ⁴Shahid Beheshti University of Medical Science, Labbafi Nejad Hospital, Tehran, Iran, Islamic Republic of, ⁵Tehran University of Medical Science, Shariati Hospital Pulmonary Department, Tehran, Iran, Islamic Republic of, ⁶Shahid Beheshti University of Medical Science, Pulmonary, Critical Care, Chronic Respiratory Research Center, Tehran, Iran, Islamic Republic of, ⁷Tarbiat Modares University, Physiology, Tehran, Iran, Islamic Republic of

Introduction: Sleep-disordered breathing (SDB) is common in patients with substance use disorders, but the Apnea-Hypopnea Index (AHI) may not fully reflect the physiological burden—particularly due to challenges in scoring central hypopneas. This study evaluates acetazolamide's effects on central apnea and introduces Hypoxic Burden and Hypoxic Area Under the Curve (**HAUC**) as alternative markers.

Materials and methods: Nocturnal SpO₂ and airflow data were collected from 10 patients with substance use disorder and sleep-disordered breathing (SDB), of which approximately 50% of the respiratory events were central apneas and hypopneas, at Masih Daneshvari Hospital. Across baseline, placebo, and acetazolamide phases, signals were processed using MATLAB. Hypoxic Burden counted distinct desaturation events, while HAUC measured cumulative desaturation severity. Both were compared to AHI.

Results: Acetazolamide significantly improved oxygenation in ~80% of patients. While AHI showed minimal changes, Hypoxic Burden and HAUC revealed marked reductions in event frequency and severity ($p < 0.05$), offering more sensitive indicators of treatment response.

Conclusions: Our findings suggest that reconsideration of the sole reliance on AHI may be beneficial. When evaluating therapeutic outcomes in SDB, particularly in substance-dependent Patients. Metrics such as Hypoxic Burden and HAUC provide more physiologically Meaningful insights and may better reflect real clinical improvements compared to AHI.

Acknowledgments: The author gratefully acknowledges Dr. Raoufy and his colleague for their invaluable support and contributions in achieving the results of this study.

Biomarker Discovery in Obstructive Sleep Apnea: A Bibliometric Mapping of Research Frontiers (2000-2023)

Y. Shen¹, W. Huang², H. Yi²

¹Shanghai Tenth People's Hospital, Shanghai, China, ²Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China

Introduction: Obstructive sleep apnea (OSA) is a harmful, complex and heterogeneous disease with limited diagnostic and therapeutic frameworks. This study analyzed global research output on OSA biomarkers to help advance precision sleep medicine.

Materials and methods: We conducted a keyword search in the Web of Science Core Collection (2000–2023) to identify research and review articles on OSA biomarkers. VOSviewer, CiteSpace, and R were performed to analyze annual publications, citations, contributions, co-authorships, and co-occurrences, identifying the most productive and highly cited countries, authors, institutions, journals, keywords, and references.

Results: The analysis included 1108 publications. Annual publication counts, and citations have consistently increased over the past two decades. The United States of America leads OSA biomarker research in volume and citation impact, with extensive collaboration with China. Dr. Gozal D is the leading author. The University of Chicago is the top institution regarding publications and citations. *Sleep and Breathing*, *Sleep Medicine*, and *Sleep* are the most productive journals. *Sleep* is the most cited, followed by the *American Journal of Respiratory and Critical Care Medicine*, *Chest*, and *Circulation*. Over half of the top journals are high-impact Q1, including *The New England Journal of Medicine*, indicating significant academic interest. Recent research focuses on comorbidities, pathogenic mechanisms, and indicators of phenotype and endotype, which are likely future trends.

Conclusions: We identified research hotspots, trends and leading contributors to OSA biomarkers. These results may benefit further studies to better understand OSA's heterogeneity and improve diagnosis, risk identification, and prognosis prediction.

Acknowledgments: Not applicable.

Body Weight Change and Nocturnal BP Pattern influence the effect of CPAP treatment on 24-Hour Ambulatory Blood Pressure in OSA Patients

H. Yi¹, Z. Li², X. Dong¹, F. Han¹

¹Peking University People's Hospital, Sleep Medicine, Beijing, China, ²Peking University People's Hospital, Emergency surgery, Beijing, China

Introduction: Obstructive sleep apnea (OSA) is associated with elevated blood pressure (BP), and continuous positive airway pressure (CPAP) treatment has shown heterogeneous effects on BP control. To address this variability, a comprehensive evaluation of factors influencing the BP response to CPAP was conducted, with particular emphasis on weight change during treatment and nocturnal BP pattern.

Materials and methods: This study is a post hoc analysis of the Peking University People's Hospital cohort from a randomized, controlled, non-inferiority trial on the effect of telemedicine-based CPAP management on 24-Hour Ambulatory Blood Pressure (ABPM) in Patients with OSA (PKUPH-TM). We included patients for whom 24h ABPM data were available at baseline and 12 weeks after the intervention. Parameters analyzed included weight change, sleep apnea severity, oxygen desaturation burden, nocturnal BP pattern, antihypertensive medication use, and CPAP adherence, to identify predictors of BP reductions following 12 weeks of CPAP therapy.

Results: A total of 256 OSA patients were included in the analysis. Baseline BMI, weight gain, 24-Hour mean arterial pressure (MAP), nocturnal BP pattern, duration of oxygen desaturation below 90%, and CPAP adherence were significantly associated with changes in 24h BP. Among these, logistic regression identified baseline 24h MAP, weight gain, nocturnal BP pattern, and CPAP adherence as independent predictors (all $P < 0.05$). To further clarify the impact of body weight dynamics on BP outcomes, patients were categorized into three groups based on weight change: no weight change ($n = 207$), weight loss ($n = 32$), and weight gain ($n = 17$). The weight loss group exhibited the greatest reduction in 24h BP, while the weight gain group showed the smallest reduction. After adjusting for baseline 24h MAP and CPAP adherence, the difference in daytime mean BP reduction remained significant among the groups (mean reductions: 4.73 mmHg, 6.64 mmHg, and 2.34 mmHg for no weight change, weight loss, and weight gain groups, respectively; adjusted $P = 0.04$). To further assess the impact of nocturnal BP pattern, participants were stratified into dipper and non-dipper groups based on nocturnal BP decline. Compared to dippers ($n = 86$), non-dipper patients ($n = 170$) showed significantly greater reductions in nighttime mean BP (5.51 mmHg vs. 1.54 mmHg in non-dipper and

dipper groups, respectively; estimated difference = 3.96 mmHg; 95% CI: 1.20 to 6.72; adjusted P = 0.004) and nighttime diastolic BP (4.59 mmHg vs. 0.33 mmHg in non-dipper and dipper groups, respectively; estimated difference = 4.25 mmHg; 95% CI: 1.70 to 6.80; adjusted P = 0.001).

Conclusions: Our findings indicate that the effect of CPAP on 24h ABPM in OSA patients is influenced by both weight change and nocturnal BP pattern. Patients who lost weight experienced the greatest benefit in daytime BP reduction, while those with a non-dipping BP pattern demonstrated more pronounced improvements in nighttime BP, particularly in diastolic pressure. These results highlight the importance of individualized BP management strategies in OSA treatment.

Building a Comprehensive Upper Airway Stimulation Program: Beyond the Implant

R. Capasso¹, B. Ibrahim², T. Kaffenberger³

¹Stanford University, Otolaryngology, Stanford, United States, ²University of Montreal, Montreal, Canada, ³University of Pittsburgh, Pittsburgh, United States

Introduction: The expansion of HGNS therapy has highlighted variations in post-implant care delivery and outcome reporting. With increasing implant volumes across practice settings, there is a need to establish clear guidelines for care pathways and standardized outcome measures. Current literature demonstrates the importance of comprehensive care protocols beyond the technical aspects of implantation.

Materials and methods: "Building a Comprehensive Upper Airway Stimulation Program: Beyond the Implant" addresses practical aspects of establishing successful hypoglossal nerve stimulation programs. While surgical aspects are well-standardized, pre and post-implant care pathways can vary significantly. This panel examines key elements for program success: (1) implementing structured pre-operative psychological evaluation for select patients, (2) developing sustainable post-operative care models balancing the roles of sleep physicians, advanced practice providers, and industry representatives, (3) standardizing outcome measures, and (4) creating clear pathways for long-term patient care. We will discuss practical solutions for both academic and private practice settings, including staffing considerations, workflow optimization, and quality metrics tracking.

Results: The team will discuss current literature, which shows wide variation in how programs handle post-implant care and report outcomes, from fully surgeon-managed to sleep physician-led models. Understanding these different models and their outcomes helps surgeons develop sustainable programs appropriate for their practice environment. The session addresses critical questions about staffing, resource allocation, and quality metrics tracking. There is substantial variability on reported outcomes of HGNS, and average AHI at the ideal therapeutic amplitude was significantly lower in tPSG compared to eHST (8.8 vs. 17.6 events/hour, $p < 0.001$). When comparing Sher15 response rates (post-op AHI ≤ 15 and $\geq 50\%$ reduction), 80% met the criterion via tPSG, but only 46% via eHST.

Conclusions: Successful HGNS programs require careful coordination between multiple providers and services. There is an unmet need to understand staffing requirements, workflow optimization, and quality metrics tracking. Recent literature highlights the complexity of measuring program success and the importance of standardized reporting. This knowledge helps all stakeholders develop sustainable programs that maintain high-quality care.

Can Acute Post-Surgical Changes in PSG Features Inform Subsequent Management of Patients with Moderate-to-Severe Obstructive Sleep Apnea? A Pilot Study

Q. Zhu¹, H. Qin¹, X. Zhang¹

¹The First Affiliated Hospital of Guangzhou Medical University, Otolaryngology Head and Neck surgery, Guangzhou, China

Introduction: Obstructive sleep apnea (OSA) is a multifactorial sleep-related breathing disorder. Uvulopalatopharyngoplasty (UPPP) is the predominant surgical intervention for moderate-to-severe

OSA. This study aimed to evaluate acute changes in polysomnography (PSG) characteristics following surgery to predict UPPP efficacy and guide long-term post-surgical management.

Materials and methods: Patients eligible for sleep surgery at Guangzhou Medical University between 2023 and 2025 were enrolled. All underwent in-lab PSG during diagnostic and post-operative night 5 after UPPP. Patients were classified into "surgically effective" or "non-effective" groups based on whether their apnea-hypopnea index (AHI) decreased by ≥ 15 events/hour.

Results: A total of 97 patients who underwent UPPP surgery were included in the final analysis. Based on the surgical outcome defined by a reduction in the apnea-hypopnea index (AHI) of ≥ 15 events/hour, 48 patients were classified into the surgical-effective group, while the remaining 49 patients were categorized into the non-effective group.

Effective group

Patients in the surgical-effective group demonstrated significant improvements across multiple polysomnographic parameters:

Respiratory events: AHI decreased by 35.1 ± 17.2 events/h ($p < 0.001$), REM/NREM AHI reduction > 30 events/h ($p < 0.001$)

Oxygenation Parameters: Oxygen saturation levels showed substantial enhancement. The mean SpO_2 during REM sleep increased by 4% ($p < 0.001$), and the lowest SpO_2 value recorded throughout the study rose by 8.9% ($p < 0.001$).

Non-Effective Group

The non-effective group showed no clinically or statistically meaningful improvements:

Respiratory and Oxygenation Measures: The change in AHI was negligible, with a mean ΔAHI of -0.1 events/hour ($p = 0.944$). Similarly, only minimal improvements were noted in oxygenation measures, which did not approach statistical significance.

Sleep architecture parameters

No statistically significant alterations in sleep architecture were observed in either group following surgery.

Conclusions: OSA patients exhibited significant improvements in respiratory disturbances, oxygen desaturation, and arousal/awakening indices post-operatively, but not in sleep architecture. Whether acute alterations in PSG variables after UPPP surgery predict long-term efficacy remains undetermined. Further large-scale studies are warranted to investigate the clinical implications of acute post-surgical PSG patterns.

Can Awake End-tidal CO₂ Predicts Sleep-related Hypoventilation in Children with Neuromuscular Diseases?

K. Sirisomboonlarp¹, T. Kuptanon¹, A. Preutthipan¹

¹Ramathibodi Hospital, Mahidol University, Sleep Disorder Center, Bangkok, Thailand

Introduction: Children with neuromuscular diseases (NMD) are at risk for hypoventilation, which often first manifests during sleep. Polysomnography (PSG) is the gold standard for detecting sleep-related hypoventilation (SRH) and determining the need for noninvasive positive pressure ventilation. This study aimed to evaluate whether awake end-tidal carbon dioxide (EtCO₂), a simple and noninvasive outpatient measure, can predict SRH in children with NMD. We hypothesized that patients with SRH may exhibit high-normal awake EtCO₂ values.

Materials and methods: We retrospectively reviewed medical records of children (0–18 years) with congenital NMD who underwent diagnostic PSG at Ramathibodi Hospital. From PSG results, SRH was defined as $> 2\%$ of total sleep time (TST) with $EtCO_2 > 50$ mmHg. Children with NMD were divided into those with SRH and without SRH groups. Demographic and anthropometric data and neuromuscular diagnoses were collected. Awake parameters including baseline oxygen saturation (SpO_2), pulmonary function tests (PFTs), awake EtCO₂, venous partial pressure of carbon dioxide (PCO₂), and serum HCO₃ were extracted. The collected variables were compared between the SRH and non-SRH groups.

Results: A total of 50 diagnostic PSG records were included. The mean age was 12.34 ± 3.50 years; 76% were male and 48% had Duchenne muscular dystrophy. SRH was identified in 8 PSGs (16%). Baseline characteristics did not differ significantly between patients with and without SRH. Awake EtCO₂ values were significantly higher in patients with SRH compared to those without SRH ($42.25 \pm$

3.77 vs 33.52 $\pm$ 3.29 mmHg, $p < 0.001$). Serum bicarbonate (HCO_3) levels were also significantly higher in patients with SRH (26.92 $\pm$ 2.53 vs 22.77 $\pm$ 2.56 mEq/L, $p = 0.002$). Venous PCO_2 trended higher in patients with SRH but did not reach statistical significance. ROC analysis showed high diagnostic accuracy for predicting SRH, with AUCs of 0.966 for awake EtCO_2 and 0.892 for serum HCO_3 . An awake EtCO_2 cutoff of 38.5 mmHg yielded 87.5% sensitivity and 95.2% specificity, while a serum HCO_3 cutoff of 25.2 mEq/L yielded 80% sensitivity and 80.8% specificity. Based on the 16% prevalence of SRH in our cohort, the positive predictive value (PPV) and negative predictive value (NPV) were calculated. For awake $\text{EtCO}_2 > 38.5$ mmHg, the PPV was 77.8% and the NPV was 97.6%. For serum $\text{HCO}_3 > 25.2$ mEq/L, the PPV was 44.4% and the NPV was 95.5%. These findings indicate that both awake EtCO_2 and serum HCO_3 have high NPV, suggesting potential utility in stratifying the lower-risk cases.

Conclusions: Our findings suggest that awake EtCO_2 and serum HCO_3 may serve as simple and noninvasive indicators for early SRH detection. These tools could help guide clinical decisions and facilitate timely PSG referral and intervention, especially when PSG is delayed or unavailable.

Acknowledgments: This study was conducted at Ramathibodi Hospital, Mahidol University, Bangkok, Thailand, with no financial support. The authors report no conflicts of interest.

Can oxygen desaturation during gastrointestinal endoscopy under conscious sedation predict obstructive sleep apnea?

H. Choi¹, Y.J. Jung², S.-W. Lee³, D.C. Lee¹

¹College of Medicine, The Catholic University of Korea, Department of Otorhinolaryngology Head and Neck Surgery, Seoul, Korea, Republic of, ²College of Medicine, The Catholic University of Korea, Department of Neurology, Seoul, Korea, Republic of, ³College of Medicine, The Catholic University of Korea, Department of Internal Medicine, Seoul, Korea, Republic of

Introduction: This study explored whether oxygen desaturation during gastrointestinal endoscopy under conscious sedation could serve as a predictive marker for obstructive sleep apnea (OSA).

Materials and methods: In this retrospective chart review, adults who underwent both polysomnography (PSG) and gastrointestinal endoscopy under conscious sedation were divided into two groups based on the lowest oxygen saturation: desaturation group ($\leq 90\%$) and non-desaturation group ($> 90\%$). PSG metrics were compared, and associations between procedural desaturation and OSA severity were analyzed using linear-by-linear association and Pearson correlation tests. Multiple linear regression with stepwise selection was used to identify independent predictors of apnea-hypopnea index (AHI).

Results: Among 48 patients, 22 were in the desaturation group and 26 were in the non-desaturation group. The desaturation group exhibited significantly higher AHI, hypopnea index, respiratory disturbance index, oxygen desaturation index, and cumulative time with O_2 saturation below 90%, indicating more severe OSA-related metrics. A significant linear trend ($P = 0.045$) suggested a higher likelihood of severe OSA in the desaturation group. Additionally, the lowest oxygen saturation during endoscopy correlated negatively with key PSG metrics. In multiple linear regression analysis, the lowest oxygen saturation during endoscopy showed a negative association with AHI, with borderline significance (standardized $\beta = -0.25$, $P = 0.058$, variance inflation factor = 1.173).

Conclusions: Oxygen desaturation during gastrointestinal endoscopy under conscious sedation is associated with more severe OSA and may serve as a useful clinical indicator. PSG should be considered in patients experiencing desaturation during endoscopy.

Cardiovascular Autonomic Function in Patients with Co-morbid Insomnia and Sleep Apnoea

B.K. Tong^{1,2,3}, G.M. Stewart^{1,3,2}, J. Flood^{1,3,2}, Y.S. Bin^{1,2}, P. de Chazal^{1,4}, P.A. Cistulli^{1,3,2}

¹Charles Perkins Centre, University of Sydney, Camperdown, Australia, ²Northern Clinical School, Faculty of Medicine and Health, University of Sydney, Camperdown, Australia, ³Department of Respiratory and Sleep Medicine, Royal North Shore Hospital, St Leonards, Australia, ⁴School of Biomedical Engineering, Faculty of Engineering, University of Sydney, Camperdown, Australia

Introduction: Co-morbid insomnia and sleep apnoea (COMISA) has been associated with increased risk of developing cardiovascular disease. Mechanistic studies of cardiovascular risk in patients with COMISA are lacking. This study aims to compare cardiovascular autonomic function as measured by heart rate variability (HRV) and pulse wave amplitude drop (PWAD) parameters in patients with COMISA, obstructive sleep apnoea (OSA), insomnia, and those without OSA and insomnia.

Materials and methods: Data from the Sydney Sleep Biobank was analysed. Anthropometry, comorbidities, medications, Insomnia Symptoms Questionnaire (ISQ) and overnight polysomnography data were extracted from the database. Patients were categorised into four groups: 1) Insomnia was defined as meeting the criteria of insomnia based on the ISQ; 2) OSA was defined as having an apnoea-hypopnoea index (AHI) of at least five respiratory events per hour of sleep; 3) COMISA was defined as meeting the criteria of both insomnia and OSA; 4) patients who did not meet the criteria of insomnia or OSA. HRV and PWAD parameters were derived from the electrocardiogram and photoplethysmography signals of the overnight polysomnogram. Time and frequency domain measures of HRV were calculated during stage N2 sleep. PWAD measures of the number of PWAD events per hour of sleep (PWAD_{index}), duration (PWAD_{duration}), area under the curve (PWAD_{AUC}) and amplitude (PWAD_{amp}) was calculated during sleep. Polysomnographic, HRV and PWAD measures were compared between patient groups.

Results: Five hundred and eighty-nine patients (mean $\pm$ standard deviation age = 50.0 ± 15.3 years, body mass index [BMI] = 29.7 ± 7.3 kg/m², 62% males) were included for analysis. Forty-two percent of patients had OSA, 19% insomnia, 26% COMISA, and 14% neither insomnia nor OSA. HRV measures of SDNN, pNN50, Total Power, absolute LF power and normalised LF power were significantly different between groups. Specifically, patients with COMISA had significantly lower HRV measures (SDNN, pNN50, Total Power, absolute LF power and normalised LF power) compared to patients with insomnia only. RMSSD, LF:HF ratio, and normalised HF were not different between patient groups. PWAD_{index} and PWAD_{duration} were lower and longer, respectively, in patients with COMISA compared to patients with insomnia only and patients with OSA only. PWAD_{AUC} and PWAD_{amp} were not different between patient groups. Neither HRV or PWAD measures were different between groups after adjusting for age, sex, and BMI.

Conclusions: Elevated cardiovascular risk in patients with COMISA indicated by HRV and PWAD measures are driven by age, sex and BMI which are shared risk factors for cardiovascular disease and OSA. Appropriate management of shared risk factors in patients with COMISA should be considered for managing cardiovascular disease risk. Additional studies are warranted to understand the mechanistic associations of autonomic function in patients with COMISA.

Acknowledgments: The authors thank the Sydney Sleep Biobank investigators for providing access to the data.

CASE REPORT: BILEVEL POSITIVE AIRWAY PRESSURE TREATMENT OF SLEEP APNEA SYNDROME IN A PATIENT WITH CROUZON SYNDROME

T.T. Phan¹, V.G. Vu¹, F. Martin¹

¹Hanoi Medical University, Bach Mai hospital, Pneumology, Hanoi, Vietnam, ²Chantilly – Les Jockeys Hospital, Gouvieux, France

Introduction: Crouzon syndrome (CS) is a hereditary disorder characterized by deformities of the face and skull brought on by syndromic craniosynostosis or the premature fusion of coronal sutures. Pediatric patients with Crouzon syndrome have a high likelihood of developing obstructive sleep apnea (OSAS), primarily due to skeletal hypoplasia and facial dysmorphism. Treatment of OSAS in patients with Crouzon syndrome requires multidisciplinary and sequential treatment planning because Crouzon syndrome often has different phenotypes with varying severity in OSA and facial dysmorphism.

Materials and methods: In this clinical case, we describe the first case of a child with Crouzon syndrome with sleep apnea who was treated with positive pressure ventilation in Vietnam.

Results: A 7-year-old child was diagnosed with Crouzon syndrome and had frequent nocturnal dyspnea and recurrent respiratory infections. The patient underwent craniofacial and otorhinolaryngological (ENT) surgery with tonsillectomy, orthodontics, ENT rehabilitation, posterior arch decompression, cranial vault correction, elevation and positioning. Polysomnography showed severe sleep apnea with an apnea-hypopnea index (AHI) of 41.7/h and a SpO₂ minimum of 63%. After AutoCPAP failed, she

was switched to BiPAP with good treatment tolerance. Subsequent titration showed that this patient's airway pressure was relatively high (IPAP/EPAP: 19/7) with good tolerability and symptom improvement.

Conclusions: This is the first reported case of Crouzon syndrome treated with positive pressure ventilation in Vietnam. Some isolated reports in the world show that tonsillectomy and lymphadenectomy are the first line. Nasal CPAP is used as a treatment modality and it can help improve the quality of life of these children. This clinical case shows the benefit of PAP treatment for sleep apnea in children with Crouzon syndrome. Pressure titration and sleep endoscopy are necessary techniques that we are gradually approaching in the not-too-distant future.

Acknowledgments: No words can express my gratitude to Professor VU Van Giap and Dr Francis Martin for their invaluable support.

I would like to thank the patient and her family for their continued trust in her treatment and for allowing me to use her personal data.

Catathrenia: A Retrospective Case Analysis of a Single Respiratory Sleep Disorders Centre

E. Pakštienė¹, G. Vaitukaitienė¹, S. Miliauskas¹

¹Lithuanian University of Health Sciences, Department of Pulmonology, Kaunas, Lithuania

Introduction: Catathrenia is a rare sleep-related condition characterized by expiratory groaning during sleep. It was previously classified as a parasomnia but is now recognized as an isolated symptom and normal variant under sleep-related breathing disorders in the most recent *International Classification of Sleep Disorders (ICSD-3)*. Its true prevalence is unknown, but according to literature, approximately 0.5% of patients referred to sleep centers present with catathrenia. The underlying pathophysiology remains unclear.

Although it has been proven that catathrenia does not cause direct harm to the patient's health, recognizing and correctly diagnosing the condition is very important — it helps reassure patients and their relatives, as catathrenia often leads to social problems due to unusual sounds during sleep that disturb others.

Materials and methods: Aim: To estimate the prevalence of catathrenia among patients referred for sleep-related breathing disorders and to describe the clinical characteristics .

This retrospective case analysis included patients evaluated at the Sleep Laboratory of the Department of Pulmonology, Lithuanian University of Health Sciences, from 2010 to 2024. All patients underwent:

- Clinical evaluation
- Physical examination
- Completion of the Epworth Sleepiness Scale (ESS)
- Full overnight videopolysomnography

Results: Of the 3873 patients who underwent polysomnographic evaluation, 24 individuals (0.62%) were diagnosed with catathrenia. The gender distribution included 17 males and 7 females. The average age of patients was 32.38 ± 12.02 years, and the average Body Mass Index (BMI) was 27.30 ± 5.61 kg/m². The mean Epworth Sleepiness Scale (ESS) score was 7.25 ± 4.26 .

Isolated catathrenia, without any comorbid sleep disorders, was diagnosed in 8 patients. Snoring was observed in 10 patients. Obstructive sleep apnea (OSA) was identified in 6 individuals—3 with positional OSA and 3 with mild OSA.

The most commonly reported complaints were disturbance of bed partners or roommates due to unusual nocturnal sounds and concern from family members.

Conclusions: The prevalence of catathrenia in our case analysis (0.62%) is similar with previous literature data.

One-quarter (25%) of patients with catathrenia were also diagnosed with OSA.

Although no specific treatment has consistently proven effective, recognizing and correctly diagnosing catathrenia is important — not only to differentiate it from other sleep-related breathing disorders, but also to reassure patients and their relatives that it is a benign condition with no direct health risks.

Causal Relationship Between Female Reproductive Factors and Risk of Obstructive Sleep Apnea

R. Lin¹, M. He², S. Wang², B. Tang³, X. Su², Y. Zhang², M. Yi⁴

¹Central South University, Department of Psychiatry, The Second Xiangya Hospital of Central South University, Changsha, China, ²Central South University, Department of Respiratory & Sleep Medicine, Xiangya Hospital, Changsha, China, ³Central South University, Department of Neurology, Xiangya Hospital, Changsha, China, ⁴Central South University, School of Life Sciences, Changsha, China

Introduction: The association between Obstructive sleep apnea (OSA) and gender related factors has always been a hot research topic. We aim to investigate the causal association between reproductive factors and OSA in women at different reproductive stages.

Materials and methods: We applied two-sample Mendelian Randomization for analysis. The genome-wide association studies summary datasets were mainly obtained from the UK biobank and FinnGen. Inverse-Variance Weighted approach was used as the primary analysis, while heterogeneity and horizontal pleiotropy were evaluated using the Cochran Q test and the MR-Egger intercept, and sensitivity analysis included a single SNP analysis and a leave-one-out analysis.

Results: After false discovery rate correction ($P_{FDR} < 0.05$), we found that earlier age at menarche (OR = 0.86; 95% CI, 0.82 to 0.91), age at first sexual intercourse (OR = 0.78; 95% CI, 0.65 to 0.93) and age at first live birth (OR = 0.92; 95% CI, 0.87 to 0.97) were associated with increased risk of OSA, while individuals with higher risk of OSA were likely to have earlier age at menarche (beta = -0.21; 95% CI, -0.32 to -0.10), higher age at menopause (beta = 0.30; 95% CI, 0.06 to 0.53), and longer years of ovulation (beta = 0.80; 95% CI, 0.32 to 1.29). However, there were no positive results between sex hormone levels and OSA.

Conclusions: In the prevention and treatment of OSA, we should pay more attention to those with early age at menarche and long years of ovulation, and to those influences other than hormone levels.

Causal relationships between circulating micronutrients and obstructive sleep apnea

S. Wang¹, M. He¹, M. Yi¹, Y. Zhang¹, X. Su¹

¹Central South University, Department of Respiratory & Sleep Medicine, Xiangya Hospital, Changsha, China

Introduction: Previous observational studies have linked several circulating micronutrients to obstructive sleep apnea. However, this causality was subjected to residual confounding and reverse causation. Hence, this study aims to evaluate the causal impact of genetically predicted serum micronutrients on OSA.

Materials and methods: A two-sample Mendelian randomization (MR) was carried out to evaluate the causal impact of circulating micronutrients on OSA. Genome-wide association studies (GWAS) summary statistics related to six types of minerals (iron, selenium, copper, zinc, magnesium and calcium) and nine types of vitamins (vitamins B6, B12, C, A, D, E, K and β -carotene) were included. More specifically, inverse variance weighting (IVW) was considered the primary result for causality. Weighted median, MR-Egger, and MR-PRESSO were applied to complicate potential violations of MR assumptions. Then, heterogeneity and horizontal pleiotropy were evaluated by Cochran's Q heterogeneity test, Egger-Intercept, and MRPRESSO Global test. After outliers were removed, the analysis above was performed again.

Results: By IVW analysis, the serum calcium is a protective factor against OSA, with the per one SD increment in the genetically-determined serum calcium level causing an 8% disease in the risk of OSA (OR= 0.92, 95%CI [0.86, 0.98], $p=0.011$). This finding was also robust after removing outliers. As for other micronutrients, we observed little evidence supporting the associations between the two, micronutrient and OSA.

Conclusions: Among common circulating micronutrients, calcium could protect from OSA risk.

Central Sleep Apnea Before and After Atrial Fibrillation Ablation: Association with Cardiac Function Improvement

Y. Tomita^{1,2}, Y. Kimura¹, S. Kasagi¹

¹Toranomon Hospital, Sleep Center, Tokyo, Japan, ²Toranomon Hospital, Cardiovascular Center, Tokyo, Japan

Introduction: Sleep-disordered breathing (SDB), linked to atrial fibrillation (AF), is recognized as a risk factor for recurrence following AF ablation. Furthermore, given that AF is a risk factor for central sleep apnea (CSA) irrespective of heart failure, the pattern of sSDB may alter before and after ablation, but the specifics are not well defined.

Materials and methods: We examined individuals who underwent both AF ablation and polysomnography between November 2016 and May 2023. We gathered echocardiographic parameters prior to and following AF ablation. We used echocardiography after the ablation for post-ablation polysomnography and before the ablation for pre-ablation polysomnography to assess the link between polysomnography and echocardiographic parameters.

Results: The study comprised 95 patients: 82 males and 13 females, with a mean age of 62.7 ± 8.9 years and a mean body mass index (BMI) of $26.1 \pm 3.8 \text{ kg/m}^2$. Before the ablation, 58 patients had paroxysmal AF and 37 had chronic AF, with an average left ventricular ejection fraction (LVEF) of $57.2 \pm 9.3\%$ and an average left atrial diameter (LAD) of $41.7 \pm 9.3\text{mm}$. In comparing the pre-ablation polysomnography group (25 cases) with the post-ablation polysomnography group (70 cases), there were no significant differences in age, sex, or pre-ablation cardiac function. However, the average number of combined central and mixed respiratory events per hour (CMAHI) was 11.5 for the pre-ablation group and 5.0 for the post-ablation group, with the pre-ablation group showing a significantly higher rate ($p=0.039$). The analysis of heart ultrasound results before and after the procedure showed an increase in LVEF from 57.2% to 59.9% and a decrease in LAD from 41.7mm to 39.9mm. Creating a model to predict CMAHI values showed links to being older ($\beta=0.32$, $p=0.037$) and having a lower LVEF ($\beta=-0.56$, $p<0.001$), but there were no links found with sex, BMI, LAD, or AF during polysomnography.

Conclusions: Central respiratory events were documented more frequently during polysomnography before AF ablation compared to after, suggesting that this may result from changes in rhythm and improvements in cardiac function post-ablation.

Acknowledgments: This work was supported by the Okinaka Memorial Institute for Medical Research Foundation. The funding source has no other roles in this study.

Central Sleep Apnea caused by low dosage of Baclofen : a case report

X. Luo^{1,2}, Q. Ding², Y. Liu², F. Han², C. Li¹, X. Dong²

¹Chongqing Traditional Chinese Medicine Hospital, Sleep Medicine Center, Chongqing, China, ²Peking University People's Hospital, Department of Sleep Medicine, Beijing, China

Introduction: Baclofen can relax muscle spasticity by inhibiting the transmission of both mono- and polysynaptic reflexes at the spinal cord. It has been increasingly used off-label for the management of spinal cord lesions or neurologic disorders. However, the expansion use has led to an increase in baclofen-associated complications. Here we report a case of CSA induced by low dose baclofen orally.

Materials and methods: A 60-year-old female patient was admitted to the department of Respiratory and Sleep Medicine, Peking University People's Hospital due to CSA on December 10, 2023. She suffered from nocturnal choking and daytime sleepiness for more than 5 years, and her left lower limb cramped intermittently, as well as cramping of the lower back accompanied by numbness. On November 13, 2023, she underwent a nocturnal PSG in a local hospital which showed AHI 65.5 events/h and the main respiratory events were central apnea. The patient was titrated on continuous positive airway pressure (CPAP) treatment (ResMed, S10). With a pressure of 10 cmH₂O, the reports downloaded from the device showed residual AHI 18.8 events/h, of which CAI 14 events/h. After that, we tried BiPAP (9/5cmH₂O), CPAP (6 cmH₂O) with oxygen 2 L/min, CPAP 7 cmH₂O in sequence. However, the residual AHI has not reached the satisfactory level.

We conducted a series of examinations, including head MRI, echocardiography, long-term video electroencephalogram, lung function and other examinations. we ruled out common causes of CSA. One of the drugs she used "baclofen", aroused our suspicions. Obtaining the patient's consent, baclofen was discontinued. Three days after the withdrawal, a second PSG was conducted and showed a significant decrease of CAI to 1.5 events/h. Then the patient was treated with CPAP (7 cmH₂O). Three days after discharge, we followed up the patient and found that she was well tolerated by CPAP

treatment. The downloaded data of the CPAP device showed the AHI dropped to 4.5 events/h, CAI to 1.1 events/h. Therefore, we further confirmed that the CSA in this patient is associated with baclofen.

Results: Baclofen was associated with a higher risk of CSA in patient with preexisting sleep-related breathing disorders. After withdrawal of baclofen, CSA can be significantly improved.

Conclusions: More attention should be paid to the adverse reactions on respiratory control of baclofen even with low dosage. Regular polysomnography before and after prescription of baclofen is helpful to detect the effects of baclofen on sleep and breathing.

Cephalometric differences between REM and NREM OSA patients may help in choosing the right surgical candidate

S.o.C. Hong¹, M.-H. Lee¹, J.-I. Byun^{2,3}, Y.-J. Jee^{4,1}, W.C. Shin^{2,3}

¹Kyung Hee University Hospital at Gangdong, Oral and maxillofacial surgery, Seoul, Korea, Republic of,

²Kyung Hee University College of Medicine, Neurology, Seoul, Korea, Republic of, ³Kyung Hee University Hospital at Gangdong, Neurology, Seoul, Korea, Republic of, ⁴Kyung Hee University College of Dentistry, Oral and maxillofacial surgery, Seoul, Korea, Republic of

Introduction: Obstructive sleep apnea (OSA) is a prevalent disorder characterized by recurrent upper airway collapse, leading to intermittent hypoxemia and disrupted sleep. Factors such as age, gender, body mass index (BMI), and lifestyle contribute to the severity of OSA, while body position and rapid eye movement (REM) state have been shown to influence its occurrence. The purpose of this study was to find the relationship between anatomical features observed on cephalometry and polysomnographic data in OSA patients.

Materials and methods: This retrospective cohort study included 74 OSA patients who were confirmed with polysomnographic evaluation and took lateral, PA cephalometric and panoramic radiographs. Patients were classified into positional and non-positional OSA categories based on their supine and lateral AHI values. REM-dependent and NREM-dependent OSA status was determined based on the REM and NREM AHI values. Demographic, polysomnographic, and cephalometric data were analyzed, and correlations were explored using Pearson's correlation coefficient.

Results: The study found no significant differences in cephalometric and panoramic parameters between positional and non-positional OSA patients. However, REM-dependent OSA patients showed shorter N-ANS length, shorter perpendicular distance between the anterior hyoid bone and mandibular plane, and longer tongue length compared to NREM-dependent OSA patients. Logistic regression analysis revealed that a narrower nasal cavity and maxilla width, relative to the mandibular width, were significant risk factors for non-positional OSA. In addition, the posterior and inferior position of the hyoid bone and longer tongue length were identified as risk factors for REM-dependent OSA.

Conclusions: The study suggests that anatomical factors, such as the width of the nasal cavity and maxilla, as well as the position of the hyoid bone and tongue length, are associated with the severity and type of OSA. These findings may contribute to the development of targeted treatment strategies, including surgical interventions, for improving upper airway space in OSA patients.

Challenges of acute non-invasive ventilation in patients with schizophrenia

R.Y. Soh¹, A. Piper², O. McGuiness^{2,3}, C. Menadue², B.J Yee^{2,4}

¹Sengkang General Hospital, Respiratory Medicine, Singapore, Singapore, ²Royal Prince Alfred Hospital, Respiratory and Sleep Medicine, New South Wales, Australia, ³University of Sydney, Respiratory and Sleep Medicine, New South Wales, Australia, ⁴University of Sydney, Faculty of Medicine and Health, New South Wales, Australia

Introduction: Acute hypercapnic respiratory failure (AHRF) is a life-threatening emergency. Non-invasive ventilation (NIV) is the standard of care, but its delivery can be challenging in patients with significant psychiatric comorbidity. We aim to evaluate the acute outcome for patients with schizophrenia presenting with AHRF requiring NIV

Materials and methods: We conducted a retrospective longitudinal observational cohort study of consecutive admissions to a single tertiary centre for AHRF requiring acute NIV from 1st January 2017 to 31st December 2019. Cases were included if they had underlying chronic obstructive pulmonary

disease (COPD) or overlap between COPD and obstructive sleep apnea (Overlap). We excluded patients requiring invasive ventilation or admissions to intensive care units.

Results: Among the 261 admissions, there were 110 recurrent admissions from 37 individual patients, of which 40.5% had schizophrenia. COPD (83.8%) was the predominant underlying chronic respiratory condition. Patients with schizophrenia were significantly younger (63.7 ± 9.8 vs 76.1 ± 8.7 , $p = 0.000$) and less likely to be on domiciliary respiratory support (26.7% vs 59.1 %, $p = 0.052$). Mean initial pH from blood gas was 7.3 in both but patients with schizophrenia were assessed to have lower level of consciousness and to be more challenging for acute NIV therapy. Patients with schizophrenia had shorter duration of hospitalisation (7 vs 9.5 days, $p = 0.004$) and acute NIV therapy (3 vs 5 days, $p = 0.026$). They also had shorter median time to readmission (18 vs 69 days, $p = 0.017$). Multivariate log regression showed chronic schizophrenia was the only independent predictor of recurrent admissions for acute NIV therapy (odds ratio 7.277, $p = 0.008$).

Conclusions: Patients with comorbidity of chronic schizophrenia may pose a unique challenge to acute NIV therapy. Though the duration of acute NIV therapy and hospitalization may be shorter, they have a higher risk of recurrent admissions for AHRF requiring acute NIV.

Change in Peripheral Apnea-Hypopnea Index (pAHI), and Body Weight in Participants with moderate-to-severe OSA with Obesity from SURMOUNT-OSA

A. Malhotra¹, B. E. Winger², C. Battioui², X. Dang², J. P. Dunn², B. Falcon², S. Chakladar², J. Bednarik²

¹University of California San Diego, Division of Pulmonary, Critical Care, and Sleep Medicine, Department of Medicine, San Diego, United States, ²Eli Lilly and Company, Indianapolis, United States

Introduction: Obstructive sleep apnea (OSA) is a breathing disorder associated with cardiovascular comorbidity and mortality. Obesity represents a major modifiable risk factor for OSA. SURMOUNT-OSA is a master protocol guiding 2 placebo-controlled trials investigating the efficacy and safety of tirzepatide in participants with OSA and obesity. Each trial had the primary endpoint of change in apnea-hypopnea index (AHI) measured by laboratory polysomnography (PSG). In this pre-specified analysis of SURMOUNT-OSA, we also report the change in peripheral apnea-hypopnea index (pAHI) measured using WatchPAT, a home sleep study device which uses peripheral arterial tone technology, and the corresponding change in body weight.

Materials and methods: SURMOUNT-OSA master protocol guided two double-blind, randomized, placebo-controlled phase 3 clinical studies including participants with moderate-to-severe OSA and obesity to determine the efficacy and safety of once-weekly (QW) tirzepatide at the maximum tolerated dose (MTD). Study 1 included those unable or unwilling to use PAP therapy and Study 2 included those on PAP therapy at study entry. WatchPAT measurements were collected at Week 0, 4, 12, 20, and 52 for participants in Study 1 ($n = 117$ at baseline, $n = 59$ assigned to tirzepatide and $n = 58$ on placebo). The mixed model repeated measures (MMRM) statistical analysis was conducted based on the data points from modified intent-to-treat (mITT) participants, collected on treatment and not on PAP for Study 1.

Results: The change from baseline in pAHI and percent change from baseline in body weight among participants in Study 1 are reported. A statistically significant change in pAHI versus baseline was observed as early as at week 4 (-2.2 , $p = 0.455$) and week 12 (-6.5 , $p = 0.064$), statistically significant change vs placebo was observed at week 20 (-10.8 , $p < 0.001$) and week 52 (-15.1 , $p < 0.001$) in participants treated with tirzepatide. Even with a smaller sample size ($n = 31$ and $n = 32$ for tirzepatide and placebo at Week 52, respectively), the effect size is comparable to previously reported PSG data collected at baseline, Week 20 and Week 52. Reductions in pAHI with tirzepatide treatment were accompanied by a statistically significant and clinically relevant decreases in body weight at all timepoints measured ($p < 0.001$ versus placebo).

Conclusions: Treatment with tirzepatide reduced pAHI in participants with moderate-to-severe OSA and obesity as early as in Week 4 after treatment initiation, with statistical significance in comparison with placebo from Week 20. Reductions in pAHI were accompanied by a statistically significant decrease in body weight.

Changes in EEG functional connectivity in patients with obstructive sleep apnea and cardiovascular diseases

A. Orlova¹, M. Zhuravlev^{1,2,3}, A. Runnova^{1,2,3}, A. Kiselev¹, M. Agaltsov¹, O. Drapkina¹

¹National Medical Research Center for Therapy and Preventive Medicine, Moscow, Russian Federation,

²Saratov State Medical University, Saratov, Russian Federation, ³Saratov State University, Saratov, Russian Federation

Introduction: Obstructive sleep apnea (OSA) and cardiovascular diseases (CVD) are among the most common comorbid conditions. They share several risk factors, including obesity, smoking, and alcohol consumption, as well as overlapping pathophysiological mechanisms such as sympathetic hyperactivation, hypoxemia, and alterations in intrathoracic pressure and haemodynamics (Zamarrón C. et al. *Pulm Med.* 2013). Beyond their systemic effects, both OSA and CVD contribute to impaired cognitive functioning and disrupted sleep architecture, which further exacerbates patients' quality of life and disease progression (Lal C. et al. *Chest.* 2012; Pinsky MR. *Chest.* 2002).

The study aimed to evaluate the effects of OSA and CVD on the central nervous system during sleep through quantitative EEG analysis of polysomnography (PSG) data.

Materials and methods: A total of 154 patients aged 18–75 years were enrolled in the study.

According to the study design, participants were divided into four groups: conditionally healthy controls (n = 39), patients with significant (AHI ≥ 15 events/h) OSA (n = 23), patients with CVD (n = 25), and patients with both significant OSA and CVD (n = 67).

Quantitative EEG analysis of PSG recordings included wavelet bicoherence calculation (Zhuravlev M. et al. *Clocks Sleep.* 2024). Wavelet bicoherence was computed for the entire recording period pairwise between 6 EEG channels across 14 frequency bands (Table 1). These bands corresponded to typical EEG rhythms observed during sleep.

Results: Interhemispheric brain connectivity:

Occipital (O2–O1): Significant decrease in OSA patients across low-frequency bands (0.2–8.0 Hz, $p < 0.05$), most pronounced at 1.0–4.0 Hz ($p = 0.001$). Patients with CVD and comorbid patients showed a similar trend, but without significant differences compared to healthy controls.

Central (C4–C3): Significant decrease in OSA and OSA+CVD groups across a wide frequency range (Δf_1 – Δf_8 , Δf_{12}), with the strongest differences at 1.0–4.0 Hz and 4.0–6.0 Hz ($p < 0.001$). In CVD patients, significant reduction was observed at 6.0–8.0 Hz.

Frontal (F4–F3): A general trend toward reduced connectivity across all patient groups compared to healthy controls; significant only at 0.2–1.0 Hz ($p = 0.034$).

Left frontal – right occipital (F3–O2): Increase in patients with CVD and OSA+CVD compared to controls across Δf_5 – Δf_7 ($p < 0.001$).

Significant patterns of intrahemispheric brain connectivity:

Right fronto-occipital (F4–O2): Increase in patients with OSA+CVD across a wide frequency range (Δf_2 – Δf_{14} , $p < 0.05$). Patients with OSA showed an increase predominantly in alpha range (8.0–14.0 Hz, $p < 0.05$).

Left fronto-occipital (F4–O2): Increase in patients with OSA+CVD across a wide frequency range (Δf_2 – Δf_{10} and Δf_{12} – Δf_{14} , $p < 0.05$).

Conclusions: The study demonstrated that patients with OSA and CVD exhibit distinct alterations in EEG functional connectivity during sleep. Interhemispheric connectivity was reduced in frontal, central, and occipital regions, particularly in low-frequency bands, while intrahemispheric connectivity showed compensatory increases, especially in comorbid patients. These findings highlight disrupted neural

communication in OSA and CVD and suggest that quantitative EEG measures such as wavelet bicoherence may serve as useful markers of brain functional alterations in these pathologies.

Characteristics of Obstructive Sleep Apnea Syndrome in Patients with Chronic Obstructive Pulmonary Disease

T.T. Phan¹, V.G. Vu¹

¹Hanoi Medical University, Bach Mai hospital, Pneumology, Hanoi, Vietnam

Introduction: The combination of chronic obstructive pulmonary disease (COPD) and obstructive apnea syndrome during sleep is called the overlap syndrome.

Objectives: To describe the clinical features and clinical approach of COPD patients without or with obstructive apnea syndrome during sleep (overlap syndrome). And: To assess the polygraphs among two groups.

Materials and methods: A descriptive study in 60 patients with COPD who were chosen in the Respiratory Center at Bach Mai Hospital in 8 months.

Results: Proportion of the Epworth score ≥ 10 in patients with sleep apnoea syndrome (overlap) 32.5%. Rate SAS/COPD: 66.7%. Median AHI of the overlap: 16.6 ± 10.2 . SpO₂ min in group overlap is lower than COPD without sleep apnoea syndrome (79.9 ± 13.9 and 86.3 ± 7.8 ; $p < 0.05$). The difference of pulmonary artery pressure between the groups was statistically significant: AHI < 5 : 41.2 ± 10.1 ; $5 \leq \text{AHI} < 15$: 36.2 ± 7.5 ; $15 \leq \text{AHI} < 30$: 38.9 ± 9.3 ; AHI ≥ 30 : 75.7 ± 21.1 ; $p < 0.005$.

Conclusions: The association between SAS and COPD increased the risk of night-time hypoxemia and pulmonary arterial hypertension.

Acknowledgments: I would like to thank Professors VU Van Giap for his great support in this research project.

I sincerely thank all the patients who participated in this study.

Finally, I would like to thank all those who contributed to the success of this study.

Characterization of Craniofacial Skeletal Phenotype of Adult Obstructive sleep apnea

K.-W. Park¹, J.-Y. Roh¹, J.-M. Park¹, S.-H. Yu¹, S.-J. Kim¹

¹KyungHee University Dental Hospital, Department of orthodontics, Seoul, Korea, Republic of

Introduction: To analyze three-dimensional craniofacial characteristics influencing the severity of obstructive sleep apnea (OSA) and to investigate the differences in craniofacial features and various polysomnography (PSG) indices indicating OSA severity between craniofacial skeletal phenotype (CSP) and non-craniofacial skeletal phenotype (N_CSP).

Materials and methods: The frequency distribution of three-dimensional skeletal patterns was analyzed based on Sex, BMI, and OSA severity using CBCT of 142 adult OSA patients. Among them, demographic, PSG, and CBCT characteristics of the final 100 patients were classified by sex, OSA severity, and skeletal pattern, and comparisons were made between groups. Multiple linear regression analysis was performed to characterize the three-dimensional craniofacial features of CSP.

Results: Sagittally, patients with skeletal Class II pattern exhibited more severe OSA severity compared to those with Class I, despite being younger. Vertically, patients with hyperdivergent pattern showed higher OSA severity than those with normodivergent pattern, despite being younger and less obese. Transversely, the group with Transverse Skeletal Discrepancy (TSD) showed more severe OSA severity. After adjusting for age, sex, and obesity, multiple linear regression analysis revealed that ANB, Pharyngeal Minimal Cross-Sectional Area (PMCA), and Transverse Discrepancy Index (TDI) were craniofacial predictors of OSA severity. CSP_{2D} group exhibited higher OSA severity in all PSG variables except the hypopnea index compared to N_CSP group, despite being younger and less obese. CSP_{3D} group, which included TSD, showed more severe OSA severity than CSP_{2D} group, with smaller nasal airway volume and PMCA, and longer pharyngeal airway length.

Conclusions: This study is the first attempt to comprehensively analyze TSD and to characterize CSP_{2D} and CSP_{3D} OSA groups by incorporating three-dimensional information of both the nasal / pharyngeal airways and relating upper airway features to PSG variables. This provides evidence for a phenotype-

based precision approach, which should be the foundation for the diagnosis and treatment of OSA patients.

Characterizing blood pressure responses to sleep apnea by sleep stage and sleep position

A. Sajan¹, J. Kwon¹, E. Kim¹, Y. Kwon¹

¹University of Washington, Seattle, United States

Introduction: Obstructive sleep apnea (OSA) events trigger a cascade of physiological responses that involve autonomic system, leading to fluctuations in blood pressure (BP). These fluctuations, combined with sustained autonomic changes, can contribute to the development of hypertension and increase the risk of cardiovascular complications. Conventional belief is that at the end of an apneic event, BP increases as a result of sympathetic surge. However, our observation has been that BP responses to OSA event are heterogeneous. Given different autonomic modulation across sleep stages and OSA intensity across sleep positions, we hypothesized that post-apneic BP responses would differ by sleep stages and sleep positions.

Materials and methods: Prospectively enrolled patients with a history of OSA underwent research home polysomnography studies. Continuous BP was estimated by pulse arrival time using a commercially available software (DOMINO software). For the purpose of this analysis, post-event period was defined by the period from the onset of an apneic event to first 10 seconds post-event. Pre-event period was defined by 10 second period preceding the onset of an apneic event. The outcome of interest was the systolic BP (SBP) (peak BP in either direction during apneic and post apneic period minus mean SBP during pre-apneic period). Changes were classified as drop (≤ -1 mmHg), modest rise (1–10 mmHg), or large rise (> 10 mmHg). Events were categorized by sleep stage, sleep body position, and pre-event baseline BP (hypertension: SBP >140 vs. Normotensive: SBP 90–140 vs. hypotensive: SBP <90 mmHg).

Results: We included 24 subjects (mean age: 48 years, female 25%) with various OSA severity (median Apnea hypopnea index [AHI] 10/hr), contributing a total of 2086 apneic events (either apnea or hypopnea). Overall, the most common pattern of BP response was modest rise (63.1%), followed by large rise (20.7%), and decrease (16.2%). The distribution of post event BP pattern was not different across sleep stages (N1: 68 vs. 20.3 vs. 11.7%; N2: 62.5 vs. 21.1 vs. 16.4%; N3 62.1 vs. 21.2 vs. 16.7%; REM: 60 vs. 20 vs. 20%, $p=0.76$). Similarly, the distribution of post event BP pattern was not different across sleep positions (supine: 62.8 vs. 21 vs. 16.2%; left: 66.2 vs. 17.6 vs. 16.2%, ; right: 57.8 vs. 25.9 vs. 16.4%, $p=0.236$). However, the distribution was different based on the pre-event baseline BP status. (hypertension: 56.8 vs. 25.4 vs. 17.9%; normotensive: 69.2 vs. 14 vs. 16.8%; hypotensive: 17.9 vs. 82.1 vs. 0%, $p<0.0001$). Pre-event baseline hypotension was associated with the absence of post-event BP decrease.

Conclusions: BP responses to apneic events were heterogeneous but largely showed the expected rise. Modest rise was the most common post-event BP response, followed by large rise, and decrease. This finding was consistent across sleep stages or sleep positions. In contrast, post-event BP pattern was significantly different based on the pre-event BP level.

Chronic Intermittent Hypoxia Impairs Genioglossus Activity and Alters Upper Airway Negative Pressure Reflex in a Rat Model

J. Xiao¹, D. Li¹, J. Xu¹, C. Zhao¹, Y. Zhang¹, G. Yin¹, J. Ye¹

¹Tsinghua University, Department of Otolaryngology–Head and Neck Surgery, Beijing Tsinghua Changgung Hospital, Beijing, China

Introduction: This study aimed to investigate the effects of chronic intermittent hypoxia (CIH) on upper airway neuromuscular regulation in a rat model. Electromyographic activity of the genioglossus muscle was recorded to assess functional changes. Additionally, graded negative pressure was applied to the pharyngeal cavity to evaluate alterations in the negative pressure reflex, providing insight into how CIH may influence upper airway stability in sleep-disordered breathing.

Materials and methods: In this study, 34 healthy male Sprague-Dawley rats were randomly assigned to either a control group (n=10) or a CIH group (n=24). Chronic intermittent hypoxia (CIH) was induced by exposing rats to alternating hypoxic/normoxic conditions (7%–21% O₂) for 8 hours daily (9:00–17:00) over a 10-week period. Custom-designed unilateral nasal blockers of varying sizes were used to increase inspiratory effort by partially obstructing nasal airflow, thereby simulating increased negative pharyngeal pressure. Pharyngeal pressure gradients under different obstruction conditions were recorded. Electromyographic (EMG) activity of the genioglossus muscle was measured at baseline and under graded negative pressure stimulation applied to the pharyngeal cavity at weeks 4, 7, and 10. The control group was maintained under normoxic conditions. At the end of the study, all rats were euthanized, and genioglossus muscle samples were harvested for histological analysis via hematoxylin and eosin (HE) staining.

Results: At week 4 of CIH exposure, genioglossus EMG activity significantly increased ($96.36 \pm 6.78 \mu\text{V}$ vs. $59.55 \pm 3.76 \mu\text{V}$, $P < 0.001$), indicating compensatory activation. However, EMG activity declined significantly by week 7 ($64.36 \pm 3.30 \mu\text{V}$), and returned to baseline by week 10 ($58.64 \pm 17.17 \mu\text{V}$, $P > 0.05$). In both control and CIH groups, EMG activity increased in response to graded negative pharyngeal pressure ($P < 0.05$), though this reflex weakened over time in the CIH group. Histological analysis revealed that CIH caused muscle fiber disarray, irregular morphology, and disrupted nuclear distribution in the genioglossus.

Conclusions: Upper airway negative pressure enhances genioglossus activity in a pressure-dependent manner. Short-term CIH induces compensatory neuromuscular activation, but prolonged hypoxic exposure impairs this response and leads to structural muscle damage. These findings highlight the time-dependent impact of CIH on upper airway dilator muscle function, providing insights into the pathophysiology of OSA-related upper airway collapse.

Clinical Application of Pediatric Sleep Endoscopy: An International Survey

Introduction: To investigate through an international survey the actual clinical application of drug-induced sleep endoscopy (DISE) in pediatric patients with obstructive sleep apnea (OSA) and to clarify the use, application, clinical indications, and protocol of pediatric DISE.

Materials and methods: A specific survey about pediatric DISE was initially developed by five international otolaryngologists with expertise in pediatric sleep apnea and drug-induced sleep endoscopy and was later spread to experts in the field of sleep apnea, members of different OSA-related associations.

Results: A total of 101 participants who answered all the survey questions were considered in the study. Sixty-four sleep apnea experts, equivalent to 63.4% of interviewed experts, declared they would perform DISE in pediatric OSA patients. A total of 81.9% of responders agreed to consider the DISE as the first diagnostic step in children with persistent OSA after adenotonsillectomy surgery, whereas 55.4% disagreed with performing DISE at the same time of scheduled adenotonsillectomy surgery to identify other possible sites of collapse. In the case of young patients with residual OSA and only

pharyngeal collapse during DISE, 51.8% of experts agreed with performing a velopharyngeal surgery. In this case, 27.7% disagreed and 21.4% were neutral.

Conclusions: Pediatric DISE is internationally considered to be a safe and effective procedure for identifying sites of obstruction and collapse after adenotonsillectomy in children with residual OSA. This is also useful in cases of patients with craniofacial malformations, small tonsils, laryngomalacia or Down syndrome to identify the actual site(s) of collapse. Despite this evidence, our survey highlighted that pediatric DISE is not used in different sleep centers.

Clinical Characteristics and Management Outcomes of Congenital Central Hypoventilation Syndrome: A Single-Center Case Series

[N. Panichapat](#)¹, [W. Niyomkarn](#)¹, [W. Boonjindasup](#)¹

¹Chulalongkorn University, Division of Pulmonology, Department of Pediatrics; King Chulalongkorn Memorial Hospital, The Thai Red Cross Society, Bangkok, Thailand

Introduction: Congenital central hypoventilation syndrome (CCHS) is a rare disorder of autonomic nervous system dysregulation caused by mutations in the PHOX2B gene. It manifests with central alveolar hypoventilation, cardiac arrhythmias, gastrointestinal dysmotility, and neurocognitive impairment. Although typically presenting in the neonatal period, atypical presentations such as obstructive sleep apnea (OSA) prior to hypoventilation have been reported. Advances in early genetic diagnosis, multidisciplinary ventilatory strategies, and annual respiratory evaluations have significantly improved outcomes. This study aimed to describe the clinical characteristics, genetic findings, ventilatory management, comorbidities, neurocognitive outcomes, and long-term outcomes of patients with CCHS treated at King Chulalongkorn Memorial Hospital, Thailand.

Materials and methods: This retrospective chart review included patients diagnosed with CCHS between July 2005 and June 2025, confirmed by PHOX2B genetic testing. Data collected included demographics, genotype, initial clinical presentations, ventilatory modalities, associated comorbidities, neurodevelopmental assessments, and outcomes from annual respiratory evaluations. Descriptive statistics were used to summarize findings.

Results: A total of seven patients were included. The median age at diagnosis was birth. Six patients were diagnosed in the neonatal period, and one was diagnosed at 7 years of age. Four patients (57.1%) were male. Genetic testing revealed that all patients (100%) had polyalanine repeat mutations (PARMs); no non-polyalanine repeat mutations (NPARMs) were identified. Initial manifestations included neonatal hypoventilation and desaturation. Six patients (85.7%) initially required positive-pressure ventilation via tracheostomy (PPV-T). Three patients (50%) successfully transitioned to noninvasive ventilation (NIV) following structured protocols, with a mean transition age of 6.5 years. Comorbidities included Hirschsprung disease (14.3%) and neurodevelopmental delays (57.1%), while no cardiac arrhythmias were observed. Annual respiratory evaluations led to modifications in ventilatory management in all patients (100%). At the latest follow-up, six patients (85.7%) required nighttime-only ventilation, while one patient (14.3%) remained on continuous support. No deaths were observed.

Conclusions: CCHS presents with a heterogeneous and evolving clinical phenotype. Early identification of PHOX2B mutations, vigilant monitoring for autonomic comorbidities, neurodevelopmental surveillance, and proactive respiratory management are essential for optimizing long-term outcomes.

Combined anterior palatoplasty with barbed suspension pharyngoplasty in the treatment of obstructive sleep apnea

[P. Thanachaikun](#)¹, [N. Charakorn](#)²

¹Nakornping Hospital, Otolaryngology-Head and Neck Surgery, Chiang Mai, Thailand, ²Chulalongkorn University, Otolaryngology, Bangkok, Thailand

Introduction: Surgery is an alternative treatment to positive airway pressure therapy for obstructive sleep apnea (OSA) patients. Various palatal surgical techniques have been developed. However, medical literature has limited accounts on the use of a combination of these techniques to improved outcomes.

Materials and methods: Data of OSA patients who underwent a combined anterior palatoplasty (AP) with barbed suspension pharyngoplasty (BSP) between July 2020 to May 2024 were retrospectively reviewed. The surgical outcomes, including apnea-hypopnea index (AHI), lowest oxygen saturation (LSAT), snoring scores, Epworth Sleepiness Scale (ESS), and post-operative complications were collected.

Results: Twenty-four patients which showed retropalatal or oropharyngeal obstruction were included in our study, with thirteen patients (54.2%) underwent post-operative polysomnography with a mean follow-up time of 5.8 ± 2.2 months. The median (IQ-IIIQ) AHI decreased non-significantly from 27.3 (19.8-53.2) to 20.2 (14.4-37.0) events/h ($p = 0.216$) post-operatively. The median (IQ-IIIQ) snoring scores significantly improved from 6.0 (4.0-8.0) to 3.0 (0-4.0) ($p < 0.001$) and ESS decreased from 11.0 (9.2-14.8) to 6.5 (4.0-9.8) ($p < 0.001$). LSAT did not change in this study. There were no serious post-operative complications.

Conclusions: The combined technique of AP and BSP was safe and significantly improved snoring scores and reduced daytime sleepiness in OSA patients with retropalatal and oropharyngeal obstruction. Improvement in AHI was observed in some patients.

Acknowledgments: The authors would like to thank the patients who provided verbal informed consent to have their information published in this report.

Combined Hypoglossal Nerve and Ansa Cervicalis Stimulation Outperforms Single Interventions in Maintaining Airway Patency in Patients with Obstructive Sleep Apnea

Y. Li¹, A. Schwartz^{1,2,3}, M. Shotwell⁴, C. Lindsell⁵, S. Bellotto¹, D. Zealear¹, H. Budnick¹, C. Wells¹, K. Estes¹, D. Kent¹

¹Vanderbilt University Medical Center, Department of Otolaryngology—Head and Neck Surgery, Nashville, United States, ²University of Pennsylvania Perelman School of Medicine, Department of Otorhinolaryngology, Philadelphia, United States, ³Universidad Peruana Cayetano Heredia School of Medicine, Limaperuu, Peru, ⁴Vanderbilt University Medical Center, Department of Biostatistics, Nashville, United States, ⁵Duke University, The Duke Clinical Research Institute, Durham, United States

Introduction: Ansa cervicalis stimulation (ACS) is emerging as a promising neurostimulation therapy for obstructive sleep apnea (OSA). ACS enhances pharyngeal patency by mimicking the caudal tracheal traction effect. Research indicates that ACS is particularly effective at reducing airway collapsibility in the palatal, oropharyngeal lateral wall, and epiglottic regions, whereas hypoglossal nerve stimulation (HNS) primarily targets tongue-driven airway obstruction at the tongue base and velopharynx. Given their distinct mechanisms, we hypothesize that ACS and HNS may interact to further enhance airway stability. This study aims to determine whether combining ACS and HNS improves airway patency more effectively than either method alone in patients with OSA.

Materials and methods: Fifty-three participants with moderate-to-severe OSA (Age: 55.4 ± 10.2 years; Male: 36; body mass index [BMI]: $32.1 \pm 3.2 \text{ kg/m}^2$; apnea-hypopnea index [AHI]: 39.8 ± 19.9 events/hour) underwent unilateral HNS and bilateral ACS via hook-wire percutaneous electrodes during drug-induced sleep endoscopy. Stimulation was individually titrated to optimize airway dilation without causing arousal. Maximum inspiratory airflow (V_{imax}) was measured with a pneumotachometer during flow-limited breathing while lowering nasal pressure (P_N) in a stepwise fashion. The V_{imax} vs. P_N relationship was constructed to quantify pharyngeal collapsibility as the critical closing pressure (P_{CRIT}) and the opening pressure (P_{OPEN}). A linear mixed-effect model was used to evaluate airflow changes per breath, and univariate regression to assess the influence of patient characteristics—including age, sex, BMI, and AHI—on P_{CRIT} and P_{OPEN} responses.

Results: Combining HNS and ACS significantly reduced airway collapsibility, decreasing P_{CRIT} (median [Q1, Q3]: -4.1 [-7.5, -2.4] cmH_2O) and P_{OPEN} (-5.7 [-7.4, -3.2] cmH_2O) from baseline ($p < 0.001$). The decreases were greater than those observed with HNS alone (ΔP_{CRIT} : -2.1 [-5.2, -1.0] cmH_2O , $p = 0.004$; ΔP_{OPEN} : -3.2 [-5.6, -0.7] cmH_2O , $p < 0.001$) and ACS alone (ΔP_{CRIT} : -2.1 [-3.7, -1.1] cmH_2O , $p < 0.001$; ΔP_{OPEN} : -2.8 [-5.4, -1.4] cmH_2O , $p < 0.001$). In 10 patients, combined stimulation completely abolished

flow limitation, bringing P_{CRIT} and P_{OPEN} below atmospheric pressure. The mixed-effect model exhibited a significant increase in V_{max} by 301.7 mL/s ($p < 0.001$) compared to baseline, surpassing the improvements achieved with ACS (145.2 mL/s, $p = 0.006$) and HNS (85.7 mL/s, $p < 0.001$). The enhancement in airway stability during combined stimulation was superior to either stimulation alone ($\Delta\Delta P_{CRIT} = -1.7$; $\Delta\Delta P_{OPEN} = -2.3$ cmH₂O for ACS, $\Delta\Delta P_{CRIT} = -1.0$; $\Delta\Delta P_{OPEN} = -1.8$ cmH₂O for HNS, $p < 0.005$). Patient characteristics did not significantly impact the combined stimulation response.

Conclusions: The combined use of HNS and ACS significantly reduced pharyngeal collapsibility beyond the effects of either intervention alone. Importantly, its efficacy remained independent of baseline BMI and AHI, highlighting its potential for widespread application across diverse patient groups. These results further support the feasibility of combined HNS and ACS as an effective neurostimulation therapy for OSA.

Acknowledgments: N/A

Combined Ventilatory Control and Upper Airway Mechanical Therapy for Obstructive Sleep Apnea: A Randomized-Controlled Mechanistic Trial

S. Sands¹, L. Thomson², D. Vena¹, A. Gikas³, R. Radmand¹, N. Calianese¹, L. Hess¹, J. Collet², D. Gilbertson¹, N. Lawrence¹, S. Landry², S. Joosten⁴, G. Hamilton⁴, A. Wellman¹, B. Edwards²

The University of Melbourne., Melbourne, Australia, ⁴Monash Lung and Sleep, Monash Medical Centre and School of Clinical Sciences, Monash University, Melbourne, Australia

Introduction: Treatment of obstructive sleep apnea (OSA) is hampered by poor adherence to continuous positive airway pressure therapy. Although OSA arises from both upper airway collapsibility and ventilatory control instability, few randomized trials have addressed both mechanisms simultaneously. We evaluated whether combining a ventilatory control intervention (supplemental oxygen) with a mechanical intervention targeting the upper airway (mandibular advancement device, MAD) could enhance treatment effectiveness.

Materials and methods: In a multicenter randomized crossover trial, 41 individuals with moderate-to-severe OSA (apnea-hypopnea index [AHI] >20 events/hour, scored without requiring oxygen desaturations) underwent polysomnography across four single-night interventions: supplemental oxygen (4 L/min), mandibular advancement device (MAD), combination therapy, and sham (air). The primary analysis assessed the percent change in AHI from baseline, comparing combination therapy with MAD monotherapy. Secondary outcomes included the arousal index and sleep quality as rated by a visual analog scale (VASSQ). Baseline pathophysiological traits, measured using gold-standard methods (oronasal mask and pneumotach plus esophageal pressure catheter), facilitated mechanistic subgroup analyses.

Results: Of the 41 patients randomized (14 female, 27 male; baseline AHI: 49 [29, 62] events/hour; median [interquartile range]), 38 completed all intervention nights. Compared to sham, AHI was reduced with oxygen (estimate [CI]: -33% [-46, -17]), MAD (-54% [-64, -41]), and the combination therapy (-68% [-77, -57]); the combination yielded a significantly greater reduction than MAD alone (-14% [-23, -4], $P = 0.009$). Similar improvements were observed using AHI scored with 3% desaturation or arousal criteria (-73% [-81, -62] vs. sham; -17% [-25, -7] vs. MAD). Combination therapy also reduced arousal index (-36% [-43, -27] vs. sham, -6.5% [-13.9, 1.6] vs. MAD), improved self-reported sleep quality (VASSQ: +0.98 [0.39, 1.58] vs. sham; +0.3 [-0.3, 0.9] vs. MAD), plus exploratory outcomes including reduced stage 1 sleep proportion (-10.9% [-15.7, -6.1] vs. sham; -2.7% [-7.4, 2.1] vs. MAD), lowered morning mean arterial blood pressure (-2.7 [-5.3, -0.1] mmHg vs sham, -2.9 [-5.5, -0.3] mmHg vs MAD), and improved EEG-based measure of wake-versus-sleep likelihood (-0.45 [-0.88, -0.03] units vs. sham; -0.19 [-0.61, 0.23] units vs MAD); note only morning blood pressure was improved by more with MAD alone. Combination therapy effects were most pronounced in participants with higher loop gain and greater upper airway collapsibility. Further mechanistic analysis revealed that MAD monotherapy responders had distinctly different traits compared with oxygen monotherapy responders. Formal assessment of interactions illustrated a additive effects of oxygen and MAD, with no less-than-additive component.

Conclusions: Combining a ventilatory control intervention (supplemental oxygen) with an upper airway intervention (MAD) is a promising approach to markedly attenuate OSA severity beyond that offered by each intervention alone. This treatment approach yields additive results and provides a novel strategy to benefit patients with the most severe ventilatory control and upper airway mechanical deficits who are otherwise the most challenging to treat.

Comparative Analysis of Three Hypoxic Burden Calculation Methods and Their Association with Incident Congestive Heart Failure

P. Rocha¹, D. Domingues¹, S. Giampá², P. Santos¹, P. Genta^{1,2}, G. Lorenzi-Filho^{1,2}

¹Biologix Sistemas S.A., Sao Paulo, Brazil, ²Instituto do Coração, InCor, Hospital das Clínicas HCFMUSP, Universidade de São Paulo, Laboratório do Sono, LIM 63, Divisão de Pneumologia, Sao Paulo, Brazil

Introduction: The apnea-hypopnea index (AHI) is a widely used metric for assessing obstructive sleep apnea (OSA) severity but has limitations in capturing the physiological burden of intermittent hypoxia. Hypoxic burden (HB), which quantifies the depth of all oxygen desaturations, is a better marker of cardiovascular risk. However, HB calculation methods vary between studies and have not been standardized. Some argue that only oxyhemoglobin saturation (SpO₂) levels below 90% are relevant for prediction of cardiovascular risk. This study compares the prognostic performance of AHI and three different HB calculation methods in predicting incident congestive heart failure (CHF) in a large, population-based cohort.

Materials and methods: We analyzed data from 5,791 participants in the Sleep Heart Health Study (SHHS), excluding those with prior CHF, treated apnea or missing data, resulting in a final cohort of 5,256. HB was automatically derived from overnight SpO₂ signals using three methods: (1) HB-1, calculated as the area between the desaturation curve and a linear interpolation from the SpO₂ value at desaturation onset to the recovery point; (2) HB-2, calculated as the area between the desaturation curve and a horizontal baseline defined by the highest SpO₂ value within 100 seconds prior to desaturation onset; and (3) HB-3, calculated as the area above the SpO₂ curve and below a fixed 90% SpO₂ threshold. Time-to-event analyses were performed using Cox proportional hazards models, adjusted for age, sex, and race to assess the association between each HB and incident CHF. Both HB and AHI were examined as continuous variables using log₁₀-transformation to address nonlinearity. Model predictive performance was assessed using concordance (C) statistics. Hazard ratios (HR), 95% confidence intervals (CI), and p-values were calculated to assess variable-outcome associations, with significance set at p-value <0.05.

Results: The analysis revealed that all three HB methods were significantly associated with incident CHF. In the adjusted model, HB-1 (HR 1.802, 95% CI: 1.187–2.735; p=0.006) demonstrated a stronger association with CHF compared to AHI (HR 0.804, 95% CI: 0.553–1.169; p=0.253). Similar findings were observed for HB-2 (HR 1.774, 95% CI: 1.195–2.634; p=0.005) versus AHI (HR 0.802, 95% CI: 0.554–1.159; p=0.240). HB-3 (HR 1.135, 95% CI: 1.013–1.271; p=0.023), was also significantly associated with CHF, although less predictive than HB-1 and HB-2. AHI (HR 1.110, 95% CI: 0.861–1.430; p=0.422) showed no significant association and with lower predictive power compared to the other HB methods. C-statistics for the adjusted model showed a high concordance (C=0.807, SE=0.008), indicating that the model had strong predictive performance. HB-1 and HB-2 remained significant predictors of CHF, HB-1 being the most predictive. In comparison, AHI did not show a significant association with CHF, emphasizing that HB was a better and more reliable predictor than AHI.

Conclusions: The method used to calculate HB significantly influences its predictive value for incident CHF. The restriction of SpO₂ levels below 90% (HB-3) has a worse performance than previous reported methods (HBI-1 and HBI-2). Our findings confirm that HB is a superior predictor of cardiovascular outcomes compared to AHI.

Acknowledgments: Cohort data provided by SHHS.

Comparative Assessment of Diaphragm Morphofunctional Alterations in Obstructive Sleep Apnea, Chronic Obstructive Pulmonary Disease, and Overlap Syndrome

Z. Chen¹, W. Xie², N. Ding²

¹The Affiliated Hospital of Xuzhou Medical University, Department of Respiratory and Critical Care Medicine, Xuzhou, China, ²The Affiliated Hospital with Nanjing Medical University, Department of Respiratory and Critical Care Medicine, Nanjing, China

Introduction: Obstructive Sleep Apnea (OSA) and Chronic Obstructive Pulmonary Disease (COPD) are both prevalent respiratory disorders globally. Their coexistence as Overlap Syndrome (OS) imposes a higher risk of nocturnal hypoxemia, morbidity, and mortality. While diaphragm dysfunction is well-established in COPD, its morphofunctional status in OS patients remains unclear. This study aimed to systematically compare diaphragm morphology and function among OSA, COPD, OS patients, and healthy controls using ultrasonography.

Materials and methods: We conducted a single-center cross-sectional study at the Sleep Center of a general hospital. Participants underwent overnight polysomnography (PSG) and spirometry. Based on PSG and pulmonary function test results, participants were categorized into four groups: OSA (n=50), COPD (n=22), OS (n=15), and healthy controls (n=16). Diaphragm morphology (thickness and thickening ratio) and function (mobility during quiet and deep breathing) were assessed using standardized ultrasonography protocols by experienced operators blinded to clinical data. Sleep indices, pulmonary function parameters, and diaphragm metrics were compared among groups. Spearman correlation analysis was performed to examine the associations between diaphragm parameters, AHI, and pulmonary function indicators.

Results: COPD patients exhibited significantly reduced diaphragm thickness and mobility compared to all other groups ($P<0.001$). OS patients showed preserved diaphragm thickness but impaired diaphragmatic mobility versus healthy controls ($P<0.05$). AHI positively correlated with diaphragm thickness ($r=0.572$, $P<0.01$), while FEV1/FVC and FEV1%pred were significantly associated with both diaphragm thickness and mobility ($P<0.001$). OS patients demonstrated the longest duration of nocturnal $SpO_2<90\%$, highlighting their unique hypoxemic burden.

Conclusions: COPD patients exhibited significantly reduced diaphragm thickness, which was inversely correlated with pulmonary function severity. In contrast, OS patients showed preserved diaphragm morphology, including thickness and thickening ratio comparable to healthy controls, but demonstrated significantly reduced diaphragmatic mobility, indicating functional impairment despite morphological preservation. These findings highlight the distinct diaphragm morphofunctional profiles among OSA, COPD, and OS patients, underscoring the need for targeted diaphragm function assessment in OS patients to guide early interventions.

Comparative Effects of Nasal and Oronasal Masks on Airway Collapse and Oxygenation During CPAP-Assisted DISE

H.C. Yang¹, S.C. Lim¹, K.i. Nam², C.M. Sung¹, S.S. Ryu¹

¹Chonnam National University Hospital, Department of Otolaryngology-Head and Neck Surgery, Gwangju, Korea, Republic of, ²Chonnam National University, Department of Anatomy, Gwangju, Korea, Republic of

Introduction: Mask type can influence the effectiveness of CPAP therapy in patients with obstructive sleep apnea (OSA). However, how nasal versus oronasal masks differ in their anatomical and physiological effects remains unclear. We aimed to compare their impact on site-specific upper airway collapse and oxygen saturation during CPAP titration using drug-induced sleep endoscopy (DISE).

Materials and methods: In this randomized crossover study, 30 patients with OSA underwent DISE and polysomnography using both nasal and oronasal masks. CPAP was delivered in incremental steps (0–20 cmH_2O), and airway collapse at four VOTE regions (Velum, Oropharynx, Tongue base, Epiglottis) was scored at each pressure level. Pharyngeal opening pressure (PhOP) was defined as the pressure required to reduce VOTE score 2 obstruction. Oxygen saturation was simultaneously monitored.

Results: Nasal masks significantly improved obstruction at the velum, oropharynx, and tongue base at 10 cmH_2O , whereas oronasal masks improved only oropharyngeal collapse. The PhOP required to alleviate velum obstruction was significantly lower with nasal masks (Vap: 6.0 [4.0–10.0] vs 16.0 [11.0–

22.0] cmH₂O, $p < 0.001$). Nasal masks also yielded significantly higher SpO₂ between 6–12 cmH₂O. No mask type adequately resolved epiglottic collapse.

Conclusions: Compared to oronasal masks, nasal masks more effectively resolved airway obstruction and improved oxygenation during CPAP titration. These findings support the preferential use of nasal interfaces when feasible and suggest the need for individualized mask selection based on anatomic response and physiological outcome.

Comparative efficacy, safety and benefit/risk of alerting agents for excessive daytime sleepiness in patients with obstructive sleep apnoea: A network meta-analysis

J.-L. Pépin¹, P. Leher², R. Ben Messaoud³, M. Joyeux-Faure³, C. Caussé⁴, J. Asin⁵, F. Barbé⁶, M. Bonsignore⁷, W. Randerath⁸, J. Verbraecken⁹, S. Craig¹⁰, Y. Dauvilliers¹¹

¹Grenoble Alpes University Hospital, Cardio-Respiratory Functional Exploration Laboratory (EFCR), Grenoble, France, ²Faculty of Medicine, Melbourne, Australia, ³Grenoble Alpes University Hospital, Grenoble, France, ⁴Bioprojet, Paris, France, ⁵Center for Sleep Medicine, Department of Pulmonary Diseases, Breda, Netherlands, ⁶Hospital Arnau de Vilanova de Lleida, Chair Respiratory Medicine, Lleida, Spain, ⁷University of Palermo, Palermo, Italy, ⁸University of Cologne, Bethanien Hospital, Solingen, Germany, ⁹University of Antwerp, University Hospital Antwerp, Antwerp, Belgium, ¹⁰Aintree University Hospital NHS Foundation Trust, Liverpool, United Kingdom, ¹¹University of Montpellier, Sleep and Wake Disorders Centre, Department of Neurology, Gui de Chauliac Hospital, Montpellier, France; INSERM Institute Neuroscience, Montpellier, France

Introduction: Obstructive sleep apnoea (OSA) is a common chronic respiratory disease associated with a high burden of disabilities related to sleepiness and reduced quality of life. Despite first-line treatment with continuous positive airway pressure (CPAP) therapy, many patients experience residual EDS. Pharmacological treatment options authorised in Europe and/or the United States are modafinil/armodafinil, solriamfetol, and pitolisant. In the absence of head-to-head trials, the relative efficacy and safety of these agents is largely unknown.

Materials and methods: Randomised controlled trials (RCTs) that compared the efficacy and safety of authorised medications for OSA were analysed using network meta-analysis. The primary efficacy endpoint was combined Epworth Sleepiness Scale (ESS) and Oxford Sleep Resistance (OSLER)/Maintenance of Wakefulness Test (MWT) Z-scores. Quality of life (QoL), overall and cardiovascular safety, and benefit-risk ratios were calculated.

Results: Of 4017 studies identified, a total of 20 RCTs involving 4015 subjects were included. Analysis of combined subjective (ESS) and objective (OSLER/MWT) efficacy outcome Z-scores showed that solriamfetol (150 mg; effect size [ES]=0.66 [95% CI: 0.36, 0.96]), and pitolisant (20 mg; ES=0.66 [95% CI: 0.44, 0.88]), modafinil (200 mg; ES=0.53 [95% CI: 0.33, 0.73]); 400 mg; ES=0.53 [95% CI: 0.42, 0.64]) had a clinically meaningful improvement in efficacy. P-scores ranked placebo, then pitolisant, modafinil 200 mg, modafinil 400 mg and solriamfetol for overall safety; and pitolisant, then solriamfetol, modafinil 400 mg and modafinil 200 mg for benefit-risk ratio.

Conclusions: Pitolisant, solriamfetol and modafinil had comparable efficacy for maintaining wakefulness in patients with OSA. Pitolisant had a better safety profile and benefit-risk ratio compared with solriamfetol and modafinil. The overall and cardiovascular safety risk ratios suggest that pitolisant might be the best candidate for OSA patients with multiple cardiovascular comorbidities.

Comparative study of the prognostic value of hypoxic burden, nocturnal desaturation and apnea-hypopnea index on incident cardiovascular events. The HARPA score

Introduction: Several retrospective, population-based studies suggest that hypoxic burden (HB) provides greater prognostic value for cardiovascular events (CVE) than traditional indices such as the apnea-hypopnea index (AHI) or oxygen desaturation index (ODI) in patients with obstructive sleep apnea (OSA).

HB is a novel metric that integrates the cumulative impact of nocturnal desaturations considering their frequency, depth, and duration, and may offer superior predictive accuracy.

We aimed to compare the prognostic performance of HB with conventional polygraphic parameters, including AHI and nocturnal desaturation, for incident CVE in patients with OSA.

Materials and methods:

We conducted a single-center, prospective, longitudinal study in consecutive patients with OSA, excluding those on well-tolerated CPAP therapy. Sleep studies were performed using respiratory polygraphy, and HB was calculated with dedicated software as the total area under the oxygen desaturation curve from a pre-event baseline, accounting for the number, depth, and duration of respiratory events. Participants were classified into tertiles according to HB, AHI, oxygen desaturation index $\geq 3\%$ (ODI3%), and percentage of sleep time with saturation $< 90\%$ (Tsat90%) for comparative analysis.

The primary outcome was a composite of ischemic heart disease, stroke, pulmonary embolism, heart failure, atrial fibrillation, and hypertensive crisis (fatal or non-fatal). Incident CVE were recorded over a median follow-up of 15 months (IQR 13–17). Cox proportional hazards models were used to assess the prognostic value of HB, AHI, ODI3%, and Tsat90% for CVE risk. Patients were followed until the pre-specified minimum of 85 CVE was reached.

Results: Of the 739 patients included, 93 patients experienced at least one CVE, of which 85 were first-ever events: 39 hypertensive crises, 19 heart failures, 18 atrial fibrillations, 17 ischemic heart diseases, and 8 strokes. There were 15 deaths (5 cardiovascular).

Those patients in the highest tertile of HB showed a significantly greater risk of CVE compared to lower tertiles (HR 3.11; 95%CI 1.91-4.09; p 0.0001), outperforming AHI in prognostic value. Tsat90% also independently predicted CVE (HR 2.68; 95%CI 1.11-3.9; p 0.023).

A new prognostic score, the HARPA Score, was developed based on HB and Tsat90% values, age (> 63 years), hypertension, and previous CVE, this score showed strong prognostic value (AUC-ROC 0.86), exceeding that of its individual components, and demonstrated good discriminative capacity in patients with OSA.

Conclusions: Hypoxic burden and nocturnal desaturation (Tsat90%) are valuable independent predictors of cardiovascular events in OSA patients, capturing distinct aspects of intermittent and sustained hypoxemia. The HARPA Score, combining these metrics with established cardiovascular risk factors, provides robust prognostic capability for incident cardiovascular events.

Comparing apnea and hypopnea is akin to comparing apples and oranges

R. Soori¹, G.B. Hosmane², N. Belur³, N. Bhushan⁴

¹K S Hegde Medical Academy, Anaesthesiology, Mangalore, India, ²K S Hegde Medical Academy, Pulmonary Medicine, Mangalore, India, ³L1 ID Solutions, Director, Bengaluru, India, ⁴Craffitti consulting pvt ltd, Founder director, Bengaluru, India

Introduction: Sleep being recognized as sixth vital sign and obstructive sleep apnea (OSA) is attaining pandemic proportions with ever increasing lifestyle disorders. Assessing severity of OSA holds key in appropriate management of this global health crisis. However widely accepted "AHI scale" for severity

assessment uses apnea or hypopnea as a single unit without correlating physiological impact caused by each event. It is very clear that an event of 10 seconds duration may not result in heart rate variability or drop in saturation to the extent as compared to an event of 40 seconds duration. In background of this fundamental flaw in severity assessment of OSA, we undertook this study to analyze varying physiological impacts of apnea/hypopnea based on duration of these events.

Materials and methods: Confirmed cases of OSA following overnight level 1 polysomnography (PSG) were included. PSGs were recorded at a tertiary care hospital. Sleep study data including AHI, apnoea frequency and duration, hypopnea frequency and duration, number of relative desaturations, mean SPO2 recorded in sleep, minimum SPO2 recorded in sleep, minimum, average and maximum heart rate in sleep, sleep onset, total sleep time, sleep efficiency were retrieved from the system. A total of 853 events out of 1458 events were analyzed to obtain equal sample size between apnea and hypopnea and events were randomly chosen. Non parametric Kruskal Wallis test between apnoea and hypopnea events with respect two direct objective measures namely changes in oxygen saturation (SPO2) and Heart rate (HR) were studied. While assessing SPO2, delta SPO2 and maximum drop in SPO2 was studied. In case of heart rate change in heart rate (delta HR) and direction (increase or decrease in heart rate) was taken to account

Results: In our study we found that correlation coefficient between AHI and mean SPO2 in sleep is - 0.4542 which is moderate correlation and correlation between AHI and minimum SPO2 is - 0.45577 which is again only a moderate correlation. We found in our study that statistically significant difference between apnoea and hypopnea with respect to delta SPO2 ($p=0.002$) and maximum drop in SPO2 ($p=0.035$) for each event. Duration of apnoea has a moderate correlation with mean and minimum SPO2 in sleep. Regression analysis with one way ANOVA was applied to 20- 40 second events and compared with delta heart rate of apnoea and hypopnoea showed statistically significant difference. Similarly for apnoea and hypopnea events of more than 40 second there was statistical significant difference for delta heart rate.

Conclusions: Apnoea or hypopnea can have varying physiological consequences. Further based on duration of the each event physiological consequences like heart rate variability and drop in oxygen saturation varies with statistical significance. For precise severity assessment of OSA, there has to be distinction between apnoea and hypopnea events. Further apnoea/hypopnea events has to be segregated based on their duration and factor accordingly in severity scoring

Comparison of SONNO® home sleep test with in-laboratory polysomnography in the diagnosis of obstructive sleep apnea syndrome

S. Sharma¹, T. Kwong¹, A. Conflitti¹, A. Sharma², G. Abraham³, H. Garg⁴

¹Centre for Sleep and Chronobiology, Toronto, Canada, ²University of Medicine and Health Sciences, St. Kitts, Saint Kitts and Nevis, ³DentCare Dental Lab Pvt Ltd., Kerala, India, ⁴Sleep Care Solutions, Southport, Australia

Introduction: In-laboratory, polysomnography (PSG) is the gold standard for diagnosing obstructive sleep apnea syndrome (OSAS). However, the long waiting lists, inconvenience of sleeping away from home and high costs of testing make patients hesitate to undergo the examination, thereby delaying diagnosis. The home sleep test (HST) enables subjects to be tested at home, a familiar and comfortable environment, without a long waiting list and at much less cost. This study investigated the accuracy of SONNO® HST in diagnosing OSAS and identified factors affecting the diagnostic accuracy.

Materials and methods: This prospective study included 57 patients with clinically suspected OSAS. All patients were studied with the PSG and HST on the same night. The apnea-hypopnea index (AHI) measured through PSG was used as the standard. The sensitivity, specificity, and accuracy of the HST in diagnosing and evaluating the severity of OSAS were analyzed.

Results: Among the 57 patients, no significant difference was noted in the average AHI values obtained using PSG and the HST ($p = 0.08$). The AHI obtained from HST was significantly correlated with that obtained from PSG, with the correlation coefficient being 0.79 ($p < 0.01$). The sensitivity, specificity, and accuracy of the HST in diagnosing OSAS were 93.2%, 84.7%, and 91.0%, respectively. In diagnosing moderate to severe OSAS; sensitivity, specificity, and accuracy of the HST was 82.5%, 96.1%, and 77.6%. Furthermore, the difference in AHIs measured using the two tests were positively correlated with the severity of sleep apnea.

Conclusions: The SONNO® HST used in the screening of patients with suspected OSAS achieved an accuracy of >90%. For patients with moderate to severe OSAS, the accuracy was below 90%. Therefore, for patients who receive an OSAS diagnosis through the HST, in-laboratory PSG is recommended for assessing severity of the OSAS and appropriate treatment recommendations.

Comparison of the 1st Half of the Night Polysomnography (3 Hours) vs. Full Night Analysis in Asian Population: A Cohort Study

S. Kijtorntam¹, V. Tantrakul¹, S. Liamsombut¹, P. Tanayapong¹

¹Ramathibodi Hospital, Mahidol University, Division of Sleep Medicine, Department of Internal Medicine, Bangkok, Thailand

Introduction: Although full-night polysomnography (FN-PSG) is the gold standard for diagnosing obstructive sleep apnea (OSA), split-night polysomnography (SN-PSG) is generally used in practice given the limitations in resource and time. However, the diagnostic accuracy and cut-off threshold of the SN-PSG remains unclear, particularly in Asian populations. This study aimed to study the correlations of apnea-hypopnea index (AHI) analyzed from the SN-PSG to that of the FN-PSG. Diagnostic accuracy was analyzed using various AHI cut-off thresholds.

Materials and methods: Three-hundred-and-ninety-seven FN-PSGs conducted with the NOX-A1 system during November 2020–August 2024 at Ramathibodi Sleep Disorders Center were identified. To represent SN-PSG, data from the FN-PSG were divided for the first 3-hours to be analyzed and re-generated. Sleep and respiratory parameters between the first 3-hour-SN-PSG and FN-PSG were compared using concordance correlation coefficients (CCC). Analyses for specific phenotype including REM/NREM AHI, supine/non-supine AHI were performed. Sensitivity and specificity were calculated for 3-hour-AHI and oxygen desaturation index (ODI) against FN-PSG data.

Results: The CCC between 3hour-AHI and FN-AHI was 0.93 with higher correlation for NREM-AHI (CCC = 0.95) than REM-AHI (CCC = 0.79). The higher correlation was seen in supine-AHI (CCC = 0.89) than non-supine-AHI (CCC=0.60). Across severity of OSA the CCC were 0.71, 0.63, 0.60, and 0.86. for no-OSA, mild, moderate, and severe OSA respectively.

Sensitivity and specificity for 3hour-AHI cut-off threshold of ≥ 5 , ≥ 15 , and ≥ 30 events/hour were 72.7%/87.2%, 70.6%/91.3%, and 93.3%/96%, respectively. Sensitivity and specificity for 3-hour-ODI cut-off threshold of ≥ 5 , ≥ 15 , and ≥ 30 events/hour were 69%/91.5%, 75.5%/97.4%, and 94.7%/99.7%, respectively. The combination of 3hour-AHI with 3hour-ODI at the cut-off threshold of ≥ 15 improved specificity to diagnose moderated OSA to 98.3%, with lower sensitivity of 18.7%.

Conclusions: Overall, 3hour-AHI provide a reliable estimate of full-night-AHI, particularly for severe OSA. The high correlation of 3hour-AHI occurred for NREM-AHI, and supine-AHI but not for REM-AHI and non-supine -AHI. The best accuracy for OSA diagnosis were at the cut-off threshold of ≥ 30 for both 3-hour-AHI, and 3-hour-ODI. However, combining 3-hour-AHI with 3-hour-ODI at the threshold of ≥ 15 improved specificity markedly. This data may guide the decision to perform SN-PSG in the real-world practice.

Acknowledgments: We would like to express our sincere gratitude to our mentors and all the staff at the Ramathibodi Sleep Disorders Center for their support in data acquisition throughout the study period, especially the certified sleep technicians for their diligent work in data recording. This research would not have been possible without everyone's dedication.

Comparison of the impact of nasal and pharyngeal surgery on CPAP treatment parameters and quality of life

Y. Hagiwara^{1,2}, K. Ikeda^{1,2}

¹Atsugi City Hospital, Kanagawa, Japan, ²Jikei University School of Medicine, otorhinolaryngology, Tokyo, Japan

Introduction: It has been reported that approximately 30% of patients with obstructive sleep apnea (OSA) have upper respiratory tract diseases such as nasal disease or enlarged palatine tonsils. Although continuous positive airway pressure (CPAP) therapy is the first-line treatment for patients with

moderate or severe OSA, there have been few reports comparing CPAP therapy and patient quality of life before and after nasal or pharyngeal surgery. In this study, we retrospectively compared the effects of CPAP application and treatment parameters and subjective symptom changes before and after surgery in patients who underwent nasal or pharyngeal surgery during CPAP treatment.

Materials and methods: We retrospectively analyzed CPAP use before and after surgery and the Japanese version of the Epworth Sleepiness Scale (JESS), which measures daytime sleepiness, in patients who underwent OSA nasal or pharyngeal surgery at Atsugi City Hospital between April 2022 and September 2024 (nasal surgery: 13 cases, pharyngeal surgery: 8 cases).

Results: Postoperative CPAP pressure and postoperative leakage were significantly lower in both pharyngeal surgery groups. The nasal surgery group showed no significant difference, but there was a trend toward an increase in postoperative use for more than 4 hours. JESS, a measure of daytime sleepiness, tended to improve in the nasal surgery group. Furthermore, subjective symptoms such as xerostomia and nasal obstruction tended to improve after surgery, but not in patients undergoing pharyngeal surgery.

Conclusions: Nasal and pharyngeal surgery for patients on CPAP may have an additional effect of improving sleepiness and reducing CPAP pressure. When patients complain of subjective symptoms such as drowsiness, nasal obstruction, or xerostomia during routine CPAP treatment, it is important to examine whether nasal or pharyngeal surgery is indicated and to explain to patients that CPAP may improve their therapeutic effects and quality of life.

Computational fluid dynamics analysis of differences in airflow dynamics in upper airways between maxillo-mandibular advancement and genioglossus advancement

K. Yamagata^{1,2,3}, K. Shinozuka², M. Suzuki⁴, T. Tanuma³, M. Tonogi², H. Kitano¹

¹Nihon University School of Medicine, Division of Oral surgery, Itabashiku, Japan, ²Nihon University School of Dentistry, Oral surgery1, Chiyodaku, Japan, ³Teikyo University, Division of Advanced Research Organization, Itabashiku, Japan, ⁴Teikyo University, Division of Otorhinolaryngology, Itabashiku, Japan

Introduction: Maxillomandibular advancement (MMA) surgery and Genioglossus advancement (GA) surgery as a sleep surgery is useful for treating patients with obstructive sleep apnea (OSA). However, preoperative analysis and evaluation to make decisions about the direction and distance of maxillomandibular movement has previously consisted primarily of morphological analysis, and physiological functions have not been evaluated. In our study, we performed computational fluid dynamics (CFD) analysis of airway changes associated with MMA+GA to evaluate the effectiveness of MMA+GA.

Materials and methods: In this study, CFD simulation was conducted for 9 patients who had undergone MMA and MMA+GA surgery, had undergone 3D-CT and rhinomanometry before surgery and more than one year after surgery, and had given informed consent to participate. To evaluate jaw and airway morphology before and 1 year after surgery, 3D-CT was carried out using the Asteion Super 4 (Toshiba Corporation). A CFD mesh was prepared using HEXPRESS™ (version 11.2; NUMECA International). CFD simulation was carried out using FINE™/Open (version 11.2; NUMECA International). The airway model created by CFD was divided into six boundary sections, and the cross-sectional area of each boundary section was measured. In addition, at the boundary section where the change in cross-sectional area was the greatest, the airflow velocity, static pressure, total pressure, and airway resistance were measured and compared. This study was approved by Nihon University School of Dentistry Ethics Committee (Tokyo, Japan; approval no. EP16D007).

Results: After MMA and MMA+GA, the airway cross-sectional area from the upper end of the palate pharynx to the upper end of the epiglottis clearly increased. In addition, the airway flow rate decreased, the flow rate became uniform throughout the upper airway, and the airflow rectification was also observed. In particular, at the lowest point of the soft palate, where an increase in cross-sectional area was observed, static pressure and total pressure decreased significantly, and airway resistance also decreased. Compared to MMA, MMA+GA showed greater effects.

Conclusions: It was suggested that MMA and MMA+GA reduce the force tending to collapse the airway wall, making the airway more stable and less likely to collapse, and facilitating ventilation within the airway, providing evidence that they are effective treatments for OSA. CFD analysis makes it possible to identify areas of airway narrowing and areas of high static pressure before surgery, and is

thought to be able to warn of the possibility of airway obstruction and provide useful predictive data for considering the amount and direction of surgical movement.

Concomitant Instantaneous heart rate decrease, and proximal skin temperature increase during apnea events

G. Garcia Molina^{1,2}, T. Winger^{3,4}, P. Chernega⁵, N. Makaram¹, M.R. Rao¹, Y. Shcherbakov⁶, L. McGhee³, V. Chellamuthu¹, E. Veneros⁷, R. Mills³, D. Grimaldi⁸, K. Reid⁸, P.C. Zee⁸

¹Sleep Number Labs, San Jose, United States, ²University of Wisconsin-Madison, Psychiatry, Madison, United States, ³Sleep Number Corporation, Minneapolis, United States, ⁴University of Minnesota, Department of Computer Science and Engineering, Minneapolis, United States, ⁵GlobalLogic Ukraine, Kyiv, Ukraine, ⁶GlobalLogic, Spain, Madrid, Spain, ⁷Nanami, Enumclaw, United States, ⁸Northwestern University, Center for Circadian and Sleep Medicine, Department of Neurology, Feinberg School of Medicine, Chicago, United States

Introduction: Apnea events during sleep, trigger autonomic (sympathetic and parasympathetic) nervous system responses that result in heart rate and vascular tone fluctuations. The instantaneous heart rate (HR) during apnea events can decrease due to higher vagal tone or baroreceptor reflexes responding to changes in blood gases and intrathoracic pressure. The sudden absence of airflow and the buildup of carbon dioxide signal the parasympathetic system to slow heart rate. Concurrent changes in vascular tone help redistribute blood to vital organs.

Materials and methods: Sleep data from eighteen participants (9M/9F, mean age of 44.5 [SD: 6.7] years-old) that spent two nights in a sleep lab were used in this study. The dataset included polysomnography signals (PSG), and skin temperature measured at two sites: on the foot (distal) and near the left-collar bone (proximal). Sleep stages and respiratory events were annotated by a sleep expert.

To evaluate the correlation between changes in instantaneous heart rate (IHR) and changes in both distal and proximal skin temperature (DST and PST respectively), apnea events with duration $\geq T$ ($T=20$ and 30 seconds) were considered.

For each apnea event, we considered the IHR curve within a 40-second window (20 seconds before to 20 seconds after the event onset), with a sampling rate of 1 Hz. In contrast, PST and DST curves were considered within a 360-second window (180 seconds before to 180 seconds after event onset), also sampled at 1 Hz. The shorter analysis interval for IHR reflects its more rapid variability compared to PST and DST.

Baseline correction to IHR, PST and DST curves was applied by subtracting the corresponding mean values across the 20-second pre-event window. Baseline-corrected curves were smoothed using Locally Weighted Scatterplot Smoothing. Post minus Pre changes were then calculated for IHR, DST, and PST.

The Spearman correlation (r), the statistical significance thereof, and the coefficient of determination (R^2) were calculated for 1) IHR-change versus DST-change, and 2) IHR-change versus PST-change.

Results: For $T=20$ seconds:

A significant ($p=0.04$) correlation between IHR-change and PST-change was found $r=-0.22$ and $R^2=0.05$.

A non-significant ($p>0.05$) correlation ($r=0.169$ and $R^2=0.03$) between IHR-change and DST-change was found.

For $T=30$ seconds:

A trending ($p=0.06$) correlation between IHR-change and PST-change was found $r=-0.44$ and $R^2=0.19$.

A non-significant ($p>0.05$) correlation between IHR-change and DST-change was found $r=-0.24$ and $R^2=0.05$.

Conclusions: We examined the relationship between IHR and temperature fluctuations at distal and proximal locations during apnea events that last at least 20 and 30 seconds. For the former, a significant negative correlation was found between IHR changes and proximal skin temperature (PST) changes suggesting that increased parasympathetic activity during these events is associated with reduced PST. No significant correlations were observed between IHR and distal skin temperature (DST). The results indicate that PST may be a more sensitive biomarker for autonomic responses during severe apnea episodes.

Continuous Positive Airway Pressure Air Leak Phenotypes In A Cohort Of Obstructive Sleep Apnea Patients

I. Rosanelli¹, A. Monare¹, M. Yanagimori¹, M. Fernandes¹, G. Grad¹, P. Mariano¹, L. Guimarães², M.V. Castellano², G. Lorenzi Filho¹, P. Rodrigues Genta¹

¹University of São Paulo, São Paulo, Brazil, ²Hospital do Servidor Público Estadual, São Paulo, Brazil

Introduction: Nasal masks are first-line options for obstructive sleep apnea (OSA) treatment with continuous positive airway pressure (CPAP). Excessive leak during nasal CPAP is common and is associated with poorer adherence. Excessive leak can occur due to mask and mouth leak. Mouth leak has a distinct overnight graphical profile characterized by sharp increases in leak followed by an abrupt resolution of leak. Those oscillations are caused by mouth opening, during sleep transition, and closing, precipitated by arousals from sleep. The distinction between mask and mouth leak has important clinical significance as they require different treatment approaches. We hypothesized that distinct air leak phenotypes can be detected through the analysis of overnight leak profiles.

Materials and methods: CPAP and patient demographic data from a cohort of OSA patients under nasal CPAP treatment were retrieved from the online CPAP data platform. Subjects that were using oronasal masks or a chinstrap and those that were not using CPAP during any of the last 30 days were excluded. Thirty-day CPAP data summary and detailed CPAP data of the last 7 nights were retrieved from each subject. Unintentional leak, residual apnea-hypopnea index and 30-day adherence were recorded. Mouth leak (ML) episodes were determined by the identification of abrupt leak reductions ($>10\text{L/min}$ per drop) during each overnight leak profile graph. ML index was defined by the total number of ML episodes divided by hours of CPAP use. Excessive leak was defined as a 95th leak percentile $\geq 15\text{L/min}$. Mask leak was defined as $\text{ML index} < 1/\text{h}$ and the presence of excessive sustained leak. Mouth leak was defined as $\text{ML index} \geq 1/\text{h}$ in the absence of sustained excessive leak. Mixed leak was defined as $\text{ML index} \geq 1/\text{h}$ and the presence of sustained excessive leak. A multiple linear regression model was used to test age and CPAP level as independent predictors of ML index. These variables have been shown to predict overall excessive leak.

Results: A total of 385 CPAP users were evaluated. Of these, 154 were excluded due to the use of CPAP devices lacking telemonitoring capability. Forty-six patients were excluded for using oronasal masks ($n=11$), chin straps ($n=26$), or for not using CPAP on at least 7 of the last 30 days ($n=9$). Oral leak occurred in 121 (60.2%) individuals - 60 with exclusive mouth leak and 61 with combined mouth and mask leak. Only 44 patients (21.9%) did not have excessive leak. Four CPAP leak phenotypes were identified: no leak, mask, mouth and mixed ([Table 1](#)). Multiple linear regression models considering 95th Percentile or ML index as dependent predictors and age and CPAP level ($R^2=0.211$, $p<0.001$).

Conclusions: Analysis of overnight CPAP leak profile allowed the distinction of 4 different phenotypes. More episodes of mouth leak were observed among elderly individuals and those with higher CPAP levels. Distinguishing between the different causes of excessive air leak allows appropriate treatment of the underlying cause.

Acknowledgments: This research was supported by CAPES.

CPAP compliance trends from Cloud data: Who is on Cloud Nine?

G. Prakash Kothari¹, N.K.M. Nileena^{2,3}, E.J. Sree Kumar³, N. Ramakrishnan^{1,2}

¹Apollo Hospitals, Chennai, India, ²Nithra Institute of Sleep Sciences, Chennai, India, ³Sri Ramachandra Institute of Higher Education & Research, Chennai, India

Introduction: Positive Airway Pressure (PAP) therapy is the preferred treatment for managing moderate to severe obstructive sleep apnea (OSA), but adherence varies. This study analyzes remotely accessed data from the Cloud on patients using ResMed device with an aim to explore factors which may affect PAP compliance including sex, age, mask type, daily usage patterns, and comorbidities.

Materials and methods: We analyzed data from 107 OSA patients (96 males, 11 females; mean age 56.7 years, range 24–86) over 364 days in 2024. Data included usage days, average daily usage (hours), maximum pressure, 95th percentile leak, maximum leak, mask type (nasal mask, full face mask, nasal pillow), and comorbidities (Obesity, hypertension, diabetes and coronary artery disease). Compliance was assessed across sex, age groups (20–39, 40–59, 60–69, 70+), mask types, daily usage duration (<4 ,

4–5, 5–6, 6–7, 7–8 hours), total usage (<70% vs. ≥70% of days), and comorbidities. Bayesian ANOVA was used, with Bayesian factor (BF_{10}) indicating the likelihood of reported interpretations.

Results: No significant sex-based differences in compliance were found. Age impacted usage: patients aged 60–69 used PAP for fewer hours daily ($BF_{10}=2.23$), had lower maximum pressure ($BF_{10}=14.42$), and higher 95th percentile and maximum leaks ($BF_{10}=4.03, 1.92$) compared to younger patients in the 20–39 age group. Patients over 70 had increased 95th percentile leaks ($BF_{10}=4.12$). Mask type influenced adherence: full face mask (FFM) ($BF_{10}=4.16$) and nasal mask (NM) users ($BF_{10}=2.7$) had longer total usage days than nasal pillow (NP) users; NM users also noted to have longer hours of daily usage ($BF_{10}=51$). Daily usage duration affected compliance: 6–7 hours/day users had longer total usage than <4 or 4–5 hours/day users ($BF_{10}=8.99, 513.73$). Those using 7–8 hours/day had longer total usage ($BF_{10}=3.03, 51.56$), higher maximum pressures ($BF_{10}=2.55$), and lower leaks ($BF_{10}=4.96, 1.82$) compared to 4–5 hours/day. Total usage (<70% vs. ≥70%) showed no differences in leaks or pressures. Obese patients used PAP longer ($BF_{10}=22$) and ≥70% during the year ($BF_{10}=50.72$) compared to non-obese, though daily usage time was similar.

Conclusions: Age, mask type, daily usage duration, and obesity significantly affect PAP compliance. Obese patients had higher compliance. Older patients (60–69, 70+) show reduced usage and increased leaks. FFM and NM users, and those with 6–8 hours daily usage duration, exhibit overall better adherence. Remote monitoring of compliance to identify issues earlier and providing personalized strategies will help to better manage patients with OSA.

CPAP Effect on Sleep Regularity, Blood Pressure Variability, and Cardiovascular Biomarker: A Randomized Trial

P.-L. Lee^{1,2}, J. Gooley³, C. Lin⁴, M.-T. Lin^{5,1}, Y.-H. Chen¹, H.-C. Chiu⁶, P.-K. Liu⁶, B.-W. Ku⁶, C.-H. Chang⁷, C.-J. Yu^{8,2}

¹National Taiwan University Hospital, Center of Sleep Disorder, Taipei, Taiwan, ²National Taiwan University, College of Medicine, Taipei, Taiwan, ³Duke-NUS Medical School, Singapore, Singapore, ⁴National Central University, Taoyuan City, Taiwan, ⁵Hsiao Chung-Cheng Hospital, Taipei, Taiwan, ⁶MediaTek Inc., Hsinchu, Taiwan, ⁷National Taiwan University Hospital, Taipei, Taiwan, ⁸National Taiwan University Hospital, Hsin-Chu Branch, Taipei, Taiwan

Introduction: Studies showed continuous positive airway pressure (CPAP) had differential effect on circadian pattern of blood pressure in obstructive sleep apnea (OSA). It is unknown if CPAP effect on BP depends on sleep/wake regularity. This open-label randomized trial evaluated the CPAP effects on sleep regularity, 24-hour ambulatory blood pressure (ABP), and cardiovascular biomarker.

Materials and methods: Patients with OSA were randomized (1:1) to 12-week CPAP or inactive control. The outcomes included actigraphy-measured sleep/wake regularity (onset, offset, midsleep time, and sleep regularity index [SRI]) and ABP, along with their variability (via standard deviation), and biomarkers. CPAP effects were assessed as baseline-adjusted between-group differences using intention-to-treat analysis. A sensitivity analysis of completers was also performed.

Results: Of 52 randomized participants, 45 completed the study. Compared to control, CPAP had no effect on sleep/wake regularity and absolute ABP value, it reduced variability of awake systolic ($P=0.026$), diastolic ($P=0.024$), mean ($P=0.013$), asleep systolic ($P=0.033$) BP. The reduction in BP variability was observed in subgroup of early midsleep time but not than late midsleep time. No change was observed in plasma norepinephrine, natriuretic peptide, and inflammatory biomarker.

Conclusions: Our findings that CPAP reduced ABP variability, particularly in those with early midsleep times, suggest that midsleep time may influence the ABP response to CPAP. Our findings support the importance of monitoring sleep/wake regularity during CPAP follow-up.

CPAP to reduce the risk of cancer in OSA? – a meta-analysis of 3 RCTs

J. Theorell-Haglow^{1,2}, Y. Peker^{3,4,5,6}, N. Marshall²

¹Uppsala University, Department of Medical Sciences, Respiratory, Allergy and Sleep Research, Uppsala, Sweden, ²Woolcock Institute for Medical Research and Macquarie University, Sleep and Circadian Research Group, North Ryde, Australia, ³Koc University School of Medicine, Department of Pulmonary Medicine, Istanbul, Turkey, ⁴University of Gothenburg & Sahlgrenska Academy, Department of Molecular and Clinical Medicine, Institute of Medicine, Goteborg, Sweden, ⁵Lund University School of Medicine, Department of Clinical Sciences, Respiratory Medicine and Allergology, Lund, Sweden, ⁶University of Pittsburgh School of Medicine, Division of Pulmonary, Allergy, and Critical Care Medicine, Pittsburgh, United States

Introduction: Obstructive sleep apnea (OSA) has been hypothesized to promote cancer via intermittent hypoxia and assessing what happens when OSA is controlled by continuous positive airway pressure (CPAP) may provide valuable insight. To date no randomized controlled trials (RCTs) have been specifically designed to address this question however, exploring and utilizing data from RCTs with adverse event data on cancer may provide a useful option if meta-analyzing this data. This also provides a superior option to meta-analyzing data from observational studies which are inherently prone to selection bias and, by design, addresses a different research questions than a meta-analysis of RCTs. The three large RCTs, all assessing CPAP for OSA, can provide an opportunity to We aimed to test whether controlling OSA via CPAP reduces cancer incidence inside a robust randomized design with a control group.

Materials and methods: We conducted a meta-analysis of three randomized controlled trials (SAVE [NCT00738179], RICCADSA [NCT00519597], and ISAACC [NCT01335087]) assessing cancer incidence from adverse event data on neoplasms, among OSA patients randomized to continuous positive airway pressure (CPAP) versus control.

Results: Within the SAVE trial, a total of 42 (3.1%) cancers were reported in the CPAP arm and 34 (2.5%) in the control arm ($p=0.36$). The RICCADSA trial reported 2 (1.6%) events in the CPAP group versus 1 (0.8%) in the control group ($p=0.56$). Finally, the ISAAC trial reported 15 (2.4%) events in the CPAP arm and 24 (3.8%) in the control arm ($p=0.05$). Thus across trials, cancer incidence was not different between groups, and meta-analysis showed no statistically significant difference (CI 0.55 to 1.68).

Conclusions: Treating sleep apnea with CPAP in high-quality randomized controlled trials does not appear to markedly reduce (or worsen) the risk of incident cancers thereby offering no support to the hypothesis that OSA causes or accelerates cancers. The result of this meta-analysis is clearly an unsatisfying answer as the confidence limits are quite wide because these trials are too short/underpowered to provide a definitive answer. However, in the absence of any large suitable RCT currently recruiting, this uncertainty is likely the answer we will have to live with for the foreseeable future.

Acknowledgments: Disclosure Statement Dr Peker declares institutional grants from ResMed Foundation. Dr Theorell-Haglow and Dr Marshall have nothing to declare. Funding Dr Theorell-Haglow's time in this work was funded by the Swedish Heart-Lung Foundation.

CPAP Treatment Coverage and Adherence for Obstructive Sleep Apnea in French Polynesia: A Geographical and Health System Perspective

J.-A. Micoulaud-Franchi¹, P. Desvergnès¹, J. Coelho¹, G. Detrunc²

¹Bordeaux University Hospital, Neurosciences Cliniques, Bordeaux, France, ²Bordeaux University, Family Medicine, Bordeaux, France

Introduction: The effective management of Obstructive Sleep Apnea (OSA) with Continuous Positive Airway Pressure (CPAP) faces logistical and geographical challenges in remote regions. French Polynesia, a French overseas territory, is composed of 118 islands scattered over 4 million square kilometers in the Pacific Ocean, with a population of approximately 260,000. Despite this vast and sparsely populated area, CPAP treatment is supported by a health system modeled after the French national system. This study investigates whether CPAP treatment coverage and adherence remain satisfactory in this unique context, and examines their association with geographical isolation from the capital, Papeete, where the main homecare service providers are located.

Materials and methods: We conducted a cross-sectional retrospective analysis of CPAP treatment data across several islands in French Polynesia. Two primary indicators were assessed: (i) prevalence of CPAP equipment provision for diagnosed OSA cases, and (ii) adherence rates based on telemonitoring data (≥ 4 hours/night on $\geq 70\%$ of nights). We also analyzed the correlation between these indicators and the distance from Papeete using geospatial mapping and regression models.

Results: Preliminary findings indicate relatively high rates of CPAP coverage and adherence across the islands, with moderate variability. Islands closest to Papeete showed slightly higher adherence rates, but no strong linear correlation was found between distance and adherence. Notably, some remote islands achieved adherence rates comparable to central islands, suggesting compensatory factors such as local health support and patient education.

Conclusions: The study suggests that CPAP treatment can be effectively deployed and maintained in ultra-peripheral territories when supported by a robust and centralized healthcare system. Despite the extreme geographical dispersion, coverage and adherence remain acceptable, highlighting the resilience and adaptability of the French model in this unique setting. These findings may inform strategies for delivering sleep medicine care in other isolated or underserved regions.

Acknowledgments: We thank the healthcare providers and technical teams in French Polynesia who supported data collection and patient follow-up. This project is part of a broader reflection on access to care and health equity in remote regions, supported by Bordeaux University.

Craniofacial Phenotype of Responders to Position-Responding Mandibular Advancement Device in Patients with Obstructive Sleep Apnea: A Prospective Study

Introduction: Obstructive sleep apnea (OSA) is a disorder characterized by recurrent upper airway collapse during sleep, leading to impaired respiratory function. Generally, positive airway pressure (PAP) is known as the treatment of choice for OSA patients with excessive daytime sleepiness, impaired sleep-related quality of life, or hypertension. However, despite the high efficacy of CPAP in eliminating respiratory events, its effectiveness is lowered by inadequate adherence to CPAP therapy. In the present study, we evaluated the clinical efficacy of a newly developed MAD that autotitrates depending on its position in patients with OSA. This study also aimed to evaluate the effectiveness of an auto-titrating mandibular advancement device (AMAD) by analyzing cephalometric changes and polysomnographic outcomes in OSA patients.

Materials and methods: A prospective, single-arm study was conducted on 16 OSA patients. The study included polysomnography and cephalometric measurements before and three months after AMAD treatment. Polysomnography included assessments of apnea-hypopnea index (AHI), respiratory disturbance index (RDI), arousal index (AI), oxygen desaturation index (ODI), and minimum oxygen saturation (SpO₂). Cephalometric analysis included measurements of hyoid-mandibular plane distance (H-MP), anteroposterior airway width (AP), square area (SA), and airway cross-sectional area (AWA), sella-nasion-point A (SNA) angle, sella-nasion-point B (SNB) angle, point A-nasion-point B (ANB) angle, maxillomandibular plane (MMP) angle, distance from the posterior nasal spine to the mandibular plane (PNS-MP), distance from the posterior nasal spine to the hyoid (PNS-H). Also in the sagittal view of the CT, soft palate length, soft palate thickness, and tongue cross-sectional area were measured.

Results: AMAD significantly reduced AHI (33.4 ± 20.5 to 15.2 ± 11.2 , $p < 0.05$), RDI (35.6 ± 19.8 to 16.6 ± 11.6 , $p < 0.05$), AI (34.8 ± 19.4 to 17.4 ± 8.6 , $p < 0.05$), and ODI (26.4 ± 20.5 to 11.9 ± 8.7 , $p < 0.05$), while minimum SpO₂ increased ($80.1 \pm 6.2\%$ to $83.9 \pm 5.3\%$, $p < 0.05$). Cephalometric analysis showed a significant decrease in H-MP (1.73 ± 0.72 cm to 0.96 ± 0.51 cm, $p < 0.05$), along with increases in AP (1.42 ± 0.43 cm to 1.64 ± 0.39 cm, $p < 0.05$), SA (3.76 ± 2.13 cm² to 4.77 ± 1.94 cm², $p < 0.05$), and AWA (2.45 ± 1.48 cm² to 3.13 ± 1.17 cm², $p < 0.05$). In the responder and non-responder

groups, H-MP significantly decreased from 2.05 ± 0.75 cm and 1.58 ± 0.46 cm before treatment to 0.98 ± 0.45 cm and 0.98 ± 0.53 cm after treatment, respectively. The change in H-MP was -1.07 ± 0.53 cm in the responder group and -0.60 ± 0.33 cm in the non-responder group, with a statistically significant difference between the two groups. Tongue cross-sectional area significantly decreased in the responder group from 32.67 ± 4.35 cm² to 30.41 ± 3.02 cm² after treatment, while no significant change was observed in the non-responder group.

Conclusions: AMAD could be an effective alternative for the treatment of OSAS and has been found to significantly improve several PSG parameters such as AHI, lowest oxygen saturation, and arousal index. AMAD improved polysomnographic parameters by elevating the hyoid and expanding the airway space, suggesting its potential as an alternative treatment for OSA patients who are intolerant to PAP therapy.

Cumulative brain desaturation: time to consider brain derived parameter to measure daytime sleepiness in obstructive sleep apnea

R. Khatami¹, M. Qi¹, G. Hügli¹, Z. Zhang¹

¹Clinic Barmelweid, Center for Sleep Medicine, Sleep Research, and Epileptology, Barmelweid, Switzerland

Introduction: The change in cerebral hemodynamics induced by sleep apneas and hypopneas may contribute to the daytime sleepiness in patients with obstructive sleep apnea (OSA). However, previous studies failed to discovery their relationship. We propose and test a new parameter, the cumulative brain oxygen desaturation, which may contribute to OSA patient's daytime sleepiness.

Materials and methods: 22 patients with severe OSA (apnea-hypopnea index (AHI) at diagnosis [mean $\pm$ standard deviation, std.]: 52.1 ± 21.6 /h, median: 45.1/h, interquartile range: 34.4–60.2/h) were monitored by polysomnography during routine continuous positive airway pressure titration. The reductions of brain tissue oxygen saturation (StO₂) in all respiratory events at baseline sleep were measured by frequency-domain near-infrared spectroscopy (NIRS). The cumulative brain desaturation was calculated as AHI times the mean StO₂ desaturation. Similarly, the cumulative peripheral desaturation was also calculated, i.e., AHI times the mean reduction of peripheral arterial oxygen saturation (SpO₂). The correlations between Epworth sleepiness scale (ESS) and AHI, the mean StO₂ desaturation, the cumulative brain desaturation, and the cumulative peripheral desaturation were tested, respectively. Linear regression was applied to predict ESS using the cumulative brain and peripheral desaturation, with age and BMI as covariates.

Results: ESS significantly correlates to the cumulative brain desaturation (Pearson's correlation coefficient: 0.68, $p=0.00056$), not the other parameters. Regression analysis only finds significant association between ESS and the cumulative cerebral desaturation ($p=0.00195$) but not the cumulative peripheral desaturation ($p=0.71$).

Conclusions: The cumulative brain oxygen desaturation, which comprehensively combines total sleep time, the frequency of apnea and hypopnea events, and the severity of cerebral oxygen desaturation, may be a new indicator for daytime sleepiness in severe OSA.

Decline in CD4⁺ Naïve T Cell Levels Correlates with OSA Severity in Adult and Pediatric Patients

K. Huang¹, Y.N. Lin², M.Y. Li², S.Q. Li², Y. Wang², X.X. Chen², Z.X. Hua², X.W. Sun², Y.J. Ding², Q.Y. Li²

¹Ruijin hospital, Shanghai Jiao Tong University School of Medicine, Department of Respiratory and Critical Care Medicine, Shanghai, China, ²Ruijin Hospital. Shanghai Jiao Tong University School of Medicine, Department of Respiratory and Critical Care Medicine, Shanghai, China

Introduction: Studies on naïve T cells in Obstructive sleep apnea (OSA) patients still remain limited. This study was designed to explore the circulating levels of CD4⁺ naïve T cells in patients with OSA across ages.

Materials and methods: The study involved participants from both adult and pediatric populations. For adult patients, we applied the CIBERSORT deconvolution algorithm to infer the relative abundance of

cell types based on microarray data. For children, we leveraged the previous pediatric single-cell transcriptome data to quantify cell type proportions. Weighted gene co-expression network analysis (WGCNA) was performed to explore potential significant gene modules associated with CD4⁺ naïve T cells. The correlation analysis was utilized to explore the relationship between CD4⁺ naïve T cell levels and OSA severity. Functional enrichment analyses were conducted to elucidate potential cell biological processes of CD4⁺ naïve T cells in both adult and pediatric patients.

Results: The CD4⁺ naïve T cell subset exhibited a decline trend and was closely linked to the characteristics of OSA in both adult and pediatric patients. The levels of CD4⁺ naïve T cells were negatively correlated with Apnea-Hypopnea Index (AHI) in adults ($R = -0.441$, $p = 0.017$) and pediatric patients ($R = -0.559$, $p = 0.010$). Functional enrichment analyses revealed that oxidative stress was a common biological feature in CD4⁺ naïve T cells shared by adult and pediatric patients with OSA.

Conclusions: CD4⁺ naïve T cells exhibited an age-independent depletion in OSA patients and correlated with OSA severity.

Deep Learning-based Identification of Severe Obstructive Sleep Apnea using Sagittal MRI Images

T. Mikami¹, K. Yonezawa²

¹National Institute of Technology, Tomakomai College, Tomakomai, Japan, ²NHO Hakodate Medical Center, Hakodate, Japan

Introduction: Obstructive sleep apnea (OSA) is a common disorder caused by repeated upper airway obstruction during sleep, often due to soft tissue collapse. It results in oxygen desaturation, daytime sleepiness, and cardiovascular complications. The gold standard diagnostic test, polysomnography (PSG), requires overnight hospitalization and is affected by the first night effect, where an unfamiliar environment alters sleep patterns. Imaging-based methods have been studied to complement PSG. X-ray cephalometry is useful for skeletal features but cannot clearly depict soft tissues, even though enlarged soft tissue often causes airway obstruction. Magnetic resonance imaging (MRI) visualizes soft tissue well, yet there is no standard method to interpret its relation to OSA severity, and diagnosis still depends on physician experience.

The aim of this study was to design a lightweight and transparent convolutional neural network (CNN) for classifying severe OSA from MRI images, and to evaluate its performance against standard deep CNN models such as VGG16 and ResNet-50.

Materials and methods: We analyzed 132 patients with OSA at Hakodate Medical Center, including 66 severe cases (apnea-hypopnea index, AHI ≥ 30) and 66 non-severe cases. All patients underwent PSG and MRI. The tongue region was extracted from MRI and resized to 224×224 pixels, with augmentation by rotation and translation.

Our CNN consisted of a single convolutional layer with a 29×29 kernel, followed by batch normalization, ReLU activation, and max pooling. Feature maps were divided into severe and non-severe groups, then aggregated by global average pooling and passed to a 2-unit softmax layer. Each unit corresponded to one filter with fixed weights, improving transparency. Dropout and L2 regularization were applied to reduce overfitting.

The model was trained with Adam optimizer (initial learning rate 0.005, decayed exponentially) for 300 epochs, with a batch size of 10. Performance was evaluated by 10-fold cross-validation repeated five times. For benchmarking, transfer learning with VGG16 and ResNet-50 was also performed.

Results: The proposed CNN had about 23,000 parameters, compared to 138 million in VGG16 and 25 million in ResNet-50. Despite being lightweight, our model achieved an average accuracy of 76% in classifying severe vs. non-severe OSA, comparable to both VGG16 and ResNet-50.

The variance of accuracy was slightly larger in our model, reflected by a higher standard deviation, but overall classification performance was maintained. Importantly, the transparent structure of our CNN allows direct association between filters and classes, providing the potential to analyze clinically relevant features after training.

Conclusions: This study demonstrates that accurate classification of severe OSA from MRI can be achieved not only with large deep CNNs but also with a lightweight and transparent CNN model. Although performance was similar among the three models, our model required far fewer parameters, offering efficiency and interpretability.

These findings suggest that CNN-based MRI analysis may provide an objective method for OSA assessment and reduce reliance on physician experience. Future work will focus on analyzing learned

filters to clarify the relationship between soft tissue morphology and OSA severity, aiming to support clinical diagnosis.

Acknowledgments: This study is supported by JSPS KAKENHI, Grants-in-Aid for Scientific Research (C) No. 23K11311.

Demographic and Baseline Disease Characteristics of SynAIRgy: A Phase 3 Trial of Aroxybutynin and Atomoxetine (AD109) in Obstructive Sleep Apnea

P.J. Strollo Jr.^{1,2}, J. Cronin³, H. Pho³, L. Taranto-Montemurro³, R. Farkas³

¹University of Pittsburgh Medical Center, Department of Medicine, Pittsburgh, United States, ²VA Pittsburgh Health Care System, Pittsburgh, United States, ³Apnimed, Inc., Cambridge, United States

Introduction: AD109 is a combination of a novel antimuscarinic, aroxybutynin (aroxy; R-enantiomer of oxybutynin), and the selective norepinephrine reuptake inhibitor atomoxetine (ato). We report the sample characteristics of the fully enrolled SynAIRgy trial, a Phase 3 study to examine the efficacy, safety, and tolerability of AD109 (aroxy 2.5mg/ato 75 mg) in OSA.

Materials and methods: SynAIRgy (NCT05813275) is a randomized, double blind, placebo-controlled, 6-month parallel-arm clinical trial in adults with OSA who do not accept or adhere to positive airway pressure therapy. Participants were enrolled over the full range of OSA severity as measured by apnea-hypopnea index with 4% desaturation (AHI₄) >5 with no upper limit. Participants must have had a Patient Reported Outcomes Measurement Information System (PROMIS) -Fatigue raw score ≥17, and a body mass index (BMI) between 18.5–40 kg/m² for men, or 18.5–42 kg/m² for women. The primary efficacy endpoint is the change from baseline in AHI₄ at Week 26. Secondary efficacy endpoints include change from baseline in oxygen desaturation index based on 3% desaturation (ODI₃), PROMIS-Fatigue, hypoxic burden based on 4% desaturation (HB₄), and PROMIS-Sleep Impairment (a measure of functional impairment during daytime).

Results: SynAIRgy enrolled 646 participants that were randomized to AD109 or placebo. At baseline, the mean (SD) age was 57.1 (11.0) years, and mean BMI (SD) was 32.3 (5.0) kg/m² with a balanced proportion of female (n=317, 49.1%) and male (329, 50.9 %) participants. The study enrolled a population representative of the diverse demographic composition of the United States with 67.2% being White, 20.4% Black/African American, 7.4% Asian, 1.1% American Indian/Alaskan Native, and 0.6% Native Hawaiian/Other Pacific Islander. The mean (SD) AHI₄ at baseline was 22 (11) with 34.4%, 42.4%, and 23.2% of participants having mild (AHI₄ 5–<15) moderate (AHI₄ 15–<30), or severe (AHI₄ ≥30) OSA, respectively. The mean (SD) ODI₃ was 29.0 (13.0), mean (SD) PROMIS-Fatigue T-score was 59 (7), mean (SD) HB₄ was 43 (40), and mean (SD) PROMIS-Sleep Impairment T-score score was 59 (7).

Conclusions: The baseline demographic characteristics of participants enrolled in SynAIRgy are representative of the general population of adults living with OSA, and the baseline AHI₄ scores and symptom profiles reflect those of a typical sleep clinic referral OSA population.

Acknowledgments: This study is funded by Apnimed, Inc.

Demographic profile and burden of comorbidities in patients with Obstructive Sleep Apnea (OSA)

K. Raghavachari Suresh¹, G. Dhamodaran¹, N. Namboodiripad Kakkattu Mana^{1,2}, E.J. Sree Kumar², N. Ramakrishnan¹

¹Nithra Institute of Sleep Sciences, Chennai, India, ²Sri Ramachandra Institute of Higher Education & Research, Chennai, India

Introduction: Obstructive sleep Apnea (OSA) is commonly associated with comorbidities such as Hypertension (HTN), type 2 Diabetes Mellitus (DM), Heart Disease (HD), and Obesity. Despite an estimated 11% prevalence in India (~104 million), detailed demographic and comorbidity profiling is limited. This study compares OSA demographics, comorbidities, and correlations in Indian patients.

Materials and methods: Retrospective study of patients diagnosed with OSA from a tertiary sleep center between the years 2022 and 2024. Data collected included demographic details, Body Mass Index (BMI), Apnea Hypopnea Index (AHI), along with comorbidities. OSA was classified based on the AHI values. Patients were classified as children (<18 years), young adults (18 to 39 years), middle aged (40 to 64 years), elderly (65 to 79 years) and old (>80 years). The comorbidities considered were

obesity, overweight status, HTN, DM, thyroid disorders, and HD.

Bayesian statistical analysis (JASP Version 0.19.3) was applied to evaluate the likelihood of the hypothesis using Bayes Factor (BF_{10}). Bayesian Mann-Whitney test was used for continuous variables, and Bayesian Contingency tables were used for discrete variables.

Results: Among 1,041 OSA patients, 79.9% were males. Majority were middle-aged (60.7%), followed by young adults (22.1%), elderly (14.8%), with children and the old making up ~1% each. Compared to males, females presented later (56 vs 49 years, $BF_{10}=113.77$), had a higher BMI (35.9 vs 31.0 kg/m², $BF_{10}=98.98$), and a higher prevalence of obesity (61% vs 44%, $BF_{10}=1657$). There were no significant differences between the sexes in AHI (42.4 vs 35.3 low $BF_{10}=1.6$), hypertension (49.7% vs 40.7%), diabetes (36.3% vs 28%), or heart disorders (9.57 % vs 9.38%). Thyroid disorders were more in females (32.06% vs 10.71 %, $BF_{10}=23.31$). Females had higher rates of moderate (30.6% vs 21.6%, $BF_{10}=26.07$) and mild OSA (23.9% vs 17.8%, $BF_{10}=22.79$) whereas severe OSA was more in males (58.7% vs 44%, log (BF_{10}) =145). Unclassified cases were ~1.6% in both sexes. Children had a relatively even distribution of mild (36.36%), moderate (27.27%), and severe (27.27%) OSA. In contrast, severe OSA predominated in young (52.17%), middle-aged (56.42%), and elderly (61.04%) adults. The oldest group (>80) showed a decrease in severe OSA (50.00%) and an increase in mild OSA (28.57%).

Conclusions: The higher mean age of OSA presentation and greater burden of comorbidities among females may be attributed to postmenopausal status. Obesity was the most prevalent comorbidity, followed by hypertension, overweight status, diabetes, thyroid dysfunction, and heart disease. Females more often had obesity and thyroid disorders, but milder OSA, while males presented earlier with more severe disease. The significant gender disparity in diagnosis indicates potential under recognition of OSA in women, highlighting the need for improved awareness and targeted interventions given the high prevalence of obesity and comorbidities observed in females.

Determining the Minimum Nights Required for Reliable Wearable-Based Assessment of Sleep Architecture and HRV in OSA, Insomnia, and COMISA

H.K.B. Young¹, C.Y.I. Kwok², C.-W. Tsai³, L. Leung³, C. Cheung³, P.L.A. Kwok⁴

¹Tung Wah Eastern Hospital, Department of Medicine and Rehabilitation, Hong Kong, Hong Kong, SAR of China, ²Tung Wah Eastern Hospital, Department of Clinical Psychology, Hong Kong, Hong Kong, SAR of China, ³Belun Technology Company Limited, Hong Kong, Hong Kong, SAR of China, ⁴Pamela Youde Nethersole Eastern Hospital, Department of Clinical Psychology, Hong Kong, Hong Kong, SAR of China

Introduction: Single-night polysomnography (PSG) often fails to capture the full spectrum of sleep architecture and autonomic variability due to night-to-night variability, particularly in patients with OSA, insomnia, or co-morbid insomnia with obstructive sleep apnea (COMISA). While wearable devices now provide a scalable solution for multi-night assessment, the optimal number of nights required for reliable measurement remains uncertain. This study aims to determine the minimum number of nights needed to achieve stable estimates of sleep parameters and heart rate variability (HRV) metrics using the Belun Ring (BR) in individuals with OSA, insomnia, or COMISA.

Materials and methods: A cohort of 123 adults (median age: 61 years; 52% female; median BMI: 24.7; 30% OSA, 52% insomnia, 18% COMISA) underwent multi-night BR monitoring (median: 6 nights; IQR: 5-7; ≥ 100 minutes/night) following screening by a clinical psychologist and pulmonologist. Insomnia was defined by an Insomnia Severity Index (ISI) ≥ 15 or a diagnosis per ICSD-3 criteria, and COMISA was defined as meeting insomnia criteria with AHI ≥ 15 events/h. Sleep metrics included total sleep time (TST), sleep efficiency (SE), REM sleep, wake time, sleep onset latency (SOL), wake after sleep onset (WASO), and HRV time-domain metrics. Reference values were derived from the average of all available nights. The concordance correlation coefficient (CCC) was used to evaluate agreement between N-night averages and reference values, with 1,000 bootstrapped simulations performed for each N-night scenario.

Results: Across all participants, most metrics achieved a lower 95% CI of CCC ≥ 0.85 by the third night, with simulations confirming that three nights were sufficient for stable estimates. SOL exhibited the highest variability, requiring more than six nights to reach comparable precision. Stratified analyses revealed that participants with insomnia or COMISA required three nights for reliable estimation of insomnia-related metrics, whereas OSA patients required four or more nights for WASO to reach CCC

≥ 0.85 . While two nights of recording substantially improved accuracy, three nights effectively minimized night-to-night variability in both sleep architecture and HRV metrics.

Conclusions: This study is the first to establish evidence-based recommendations for the minimum number of nights required for reliable wearable-based assessment of sleep and HRV in patients with OSA, insomnia, and COMISA. Our findings demonstrate that three nights of wearable monitoring provide robust and stable estimates, offering a practical and scalable alternative to single-night PSG. These results have significant clinical implications for optimizing insomnia management and enhancing COMISA detection in both psychiatric and sleep medicine practice.

Development and Validation of a Facial-Recognition-Based Screening App for Obstructive Sleep Apnea (OSA)

C. Li¹, F. Wang¹, F. Qi¹, S. Kang¹

¹DrBreath Medical Technology Co., Ltd., Technical Department, Beijing, China

Introduction: Obstructive sleep apnea (OSA) is a common sleep disorder affecting nearly 1 billion individuals worldwide. Although polysomnography (PSG) remains the diagnostic gold standard, its high cost and operational complexity limit its accessibility in primary care and home settings. This study proposes and validates a contactless, facial-recognition-based mobile application for rapid OSA screening, aiming to provide a scalable and user-friendly solution.

Materials and methods: We constructed a machine learning model based on a dataset of 3,265 facial images paired with corresponding sleep monitoring data collected during 2023–2024. Facial landmarks (106 key points) were extracted using the InsightFace framework and aligned via affine transformation. A face segmentation algorithm was then applied to isolate key regions covering the lower face and neck.

Image features were extracted using a modified ResNet50 architecture, followed by classification using a support vector machine (SVM) to assess OSA risk. Five-fold cross-validation was conducted for performance evaluation. To enhance interpretability, we employed Grad-CAM to visualize model attention and examine its alignment with known anatomical risk factors.

Based on this model, we developed a smartphone app for fast screening. The app incorporates a 3D pose estimation algorithm to automatically capture facial images at optimal angles, ensuring image quality while maintaining ease of use.

Results: The model demonstrated strong performance in identifying patients at moderate to high risk of OSA, with a sensitivity of 79.4% and a specificity of 84.1%. Grad-CAM visualization revealed that the model's attention focused primarily on anatomical regions relevant to OSA, such as the lower jaw and neck width.

The trained model has been successfully integrated into a public-facing app named "Sleepok" enabling users to complete screening in less than 10 seconds by simply taking a photo with their mobile device.

Conclusions: This study presents a low-cost, efficient, and scalable alternative to traditional PSG-based screening through a facial-recognition-based OSA risk assessment model and mobile app. The tool supports at-home use and may significantly enhance early detection rates for OSA. These findings demonstrate the practical potential of artificial intelligence in preventive healthcare and early disease intervention.

Development and Validation of a Reversible Obstructive Sleep Apnea Pig Model Using Cross-Linked Sodium Hyaluronate

J. Shang¹, X. Ma¹, C. Yang¹, R. Li¹

¹Beihang University, The Key Laboratory for Biomechanics and Mechanobiology of Ministry of Education, Beijing Advanced Innovation Center for Biomedical Engineering, School of Biological Science and Medical Engineering, Beijing, China

Introduction: Obstructive sleep apnea (OSA), affecting >900 million adults globally, lacks translational animal models that accurately replicate human pathophysiology. Current models (e.g., rodents, canines, monkeys) suffer from anatomical mismatches, irreversibility, or ethical constraints. This study introduces a method to induce upper airway obstruction by injecting a cross-linked sodium hyaluronate

mixture into the pharynx and palate of Bama pigs, creating an animal model that simulates recurrent upper airway collapse in patients with OSA. This model features a definable and controllable obstruction plane with a reversible degree of obstruction. The modeling effect was evaluated by polysomnography (PSG), upper airway computed tomography (CT), and HIF-1 α , which provided assurance at the clinical presentation, imaging, and biochemical levels for subsequent studies in this animal model. Histopathologic analysis of various respiratory tract locations, combined with monitoring of TNF- α and IL-6 in upper airway secretions and serum, helped to determine the respiratory system response to OSA conditions.

Materials and methods:

- **Model Design:** Palatal-pharyngeal injections of sodium hyaluronate/iohexol/penicillin (19.25 ml avg.) in Bama pigs (n=4) under Zoletil®/Remimazolam anesthesia.
- **Validation Metrics:**
 - Polysomnography (PSG) quantifying AHI/ODI and SpO₂ desaturation.
 - Serial CT imaging measuring airway volume/cross-sectional area.
 - Histopathology (H&E/Masson staining) and ELISA for HIF-1 α , IL-6, TNF- α in serum/airway secretions.
- **Reversibility:** Longitudinal monitoring over 28 days post-injection.

Results:

1. **Effective Obstruction Induction:**
 - AHI surged to 23.25 ± 2.99 events/hr ($p=0.003$) post-injection, with minimum SpO₂ dropping to $72.25 \pm 14.18\%$.
 - CT confirmed airway narrowing (min. cross-section: 157.48 ± 29.14 mm² $\rightarrow$ 46.18 ± 10.91 mm², $p=0.0112$).
2. **Reversible Physiology:**
 - Gradual AHI normalization to 8.00 ± 1.41 events/hr by day 14, correlating with airway volume recovery ($5,420 \rightarrow 11,157$ mm³, $p=0.0308$).
3. **Inflammatory Pathways:**
 - Serum HIF-1 α and IL-6 surged acutely post-obstruction.
 - Histopathology revealed lymphocytic infiltration, alveolar septal thickening ($p=0.0118$), and pharyngeal hyperkeratosis.
4. **Key Correlations:**
 - AHI strongly linked to airway anatomy (cross-section: $R^2=0.7421$, $p<0.001$).
 - TNF- α in secretions correlated with AHI ($R^2=0.3949$, $p=0.003$).

Conclusions: In this study, we successfully established a reversible, safe, and reliable animal model of OSA using a novel technique involving the precise multi-point injection of a cross-linked sodium hyaluronate mixture into the palatopharyngeal region of pigs via the oral cavity. This model accurately simulates upper airway collapse, leading to obstruction, closely mimicking the pathophysiology of OSA in patients. Consequently, it serves as an invaluable tool for future research on OSA.

Development of a Wavelet-Based Classifier for Sleep Apnea Subtypes Using EEG and ECG

N.T.H. Trang¹, T.T.D. Linh², D.Q. Vu¹, B.T.H. Loan³, N.N. Vinh², T.N. Dang⁴

¹University of Medicine and Pharmacy at Ho Chi Minh city, Ho Chi Minh city, Vietnam, ²University of Medicine and Pharmacy at Ho Chi Minh city, Center of Family Doctors, Ho Chi Minh city, Vietnam,

Vietnam, ⁴University of Medicine and Pharmacy at Ho Chi Minh city, Faculty of Public Health, Ho Chi Minh city, Vietnam

Introduction: Sleep apnea is a common sleep disorder that negatively impacts health and quality of life. It includes distinct respiratory events such as obstructive sleep apnea (OSA), central sleep apnea (CSA), and hypopnea, each requiring specific diagnostic and therapeutic approaches. Accurate classification of these events is essential for effective management.

Materials and methods: We analyzed 201 full-night polysomnography (PSG) recordings. Electrocardiogram (ECG) and electroencephalogram (EEG) signals were segmented into non-overlapping epochs, filtered using a Butterworth bandpass filter, and normalized. Discrete wavelet transform (DWT) was applied to EEG, and wavelet packet analysis (WPA) to ECG signals to extract statistical and nonlinear features. Feature selection was performed using Neighborhood Component Analysis (NCA). Classification models were trained using ensemble bagged tree algorithms. Three models were developed: EEG-only, ECG-only, and a combined EEG-ECG model. Their performance was compared to a deep learning model trained on ECG spectrograms. Two classification strategies were tested: (1) three-class (OSA-hypopnea-normal or OSA-CSA-normal) and (2) binary (OSA vs hypopnea or OSA vs CSA), in both NREM and REM sleep stages.

Results: The combined EEG-ECG model consistently outperformed models using single signals or spectrogram-based deep learning across both sleep stages and classification tasks. In the three-class classification, the model achieved **93.0% accuracy** for distinguishing OSA, hypopnea, and normal events during REM sleep, with high sensitivity (91.2% for OSA, 87.3% for hypopnea) and specificity (up to 99.5% for normal). For the task of distinguishing OSA, CSA, and normal events, performance further improved, reaching **97.0% accuracy** in REM with an F1-score of **0.96–0.97** across all classes. In the two-class classification, the model achieved **84.7% accuracy** for separating OSA from hypopnea during NREM and **98.8% accuracy** for distinguishing OSA from CSA in REM sleep, with corresponding F1-scores of **0.86** and **0.99**, respectively. These results demonstrate the model's high precision and generalizability across sleep stages and apnea types.

Conclusions: The findings highlight the effectiveness of combining non-linear features from ECG and EEG signals for classifying various sleep-related events, offering improved reliability for real-world applications. A proposed machine learning model provides significantly precise classification.

Acknowledgments: This work was supported from the Korea International Cooperation Agency (KOICA), under the project entitled "Education and Research Capacity Building Project at the University of Medicine and Pharmacy at Ho Chi Minh City," conducted from 2024 to 2025 (Project No. 2021-00020-3)

Diaphragmatic dimensions as predictors of severity of obstructive sleep apnea: A cross-sectional study

R. Chakraborty¹, D. Sahu¹, S. Kumar Pati², S. De¹, A. Kumar Behera¹, R. T Ganga¹

¹All India Institute of Medical Sciences, Raipur, Pulmonary, Critical Care and Sleep Medicine, Raipur, India, ²All India Institute of Medical Sciences, Raipur, Dept. of Radiodiagnosis, Raipur, India

Introduction: Obstructive Sleep Apnea (OSA) is a sleep disordered breathing that involves a decrease or complete halt in airflow despite an ongoing effort to breathe. The Apnea –hypopnea index (AHI) is the standard metric used to describe the severity of sleep apnea. It represents the combined number of apnea and hypopnea that occurs per hour of sleep. OSA is classified into mild, moderate and severe according to AHI.

Mild OSA : AHI 5 to <15

Moderate OSA : AHI 15 to <30

Severe OSA : > 30

USG or ultrasonography is a simple non invasive tool. In our study we have tried to establish the association between diaphragmatic dimensions like thickness, excursion and thickness fraction with the severity of OSA.

Materials and methods: Objectives

- To find the association of Diaphragmatic thickness, excursion and thickness fraction with Apnea-Hypopnea Index

Study design : Cross-sectional

Methodology

In this cross-sectional study 40 patients (between 18-70yrs age) diagnosed as OSA by overnight inlab polysomnography were recruited after written consent. Patients having neurological disorder, hemodynamic instability, other lung diseases, pregnant females or patients already on PAP therapy were excluded. USG of diaphragm has been carried out by experienced sonologist. Diaphragmatic

thickness measurement done by B Mode USG using linear transducer while participants in supine position. To record the thickness of Right hemidiaphragm liver has been used as window with probe placed between the midclavicular and midaxillary line in Right subcostal margin. For the left hemidiaphragm spleen was used as window with probe placed subcostally between anterior and post axillary lines. The diaphragm is identified by 3 layered structure with two parallel echogenic line. Diaphragmatic thickness has been measured on both side at peak of inspiration, expiration . Diaphragmatic excursion :M mode used to display motion of diaphragm along the above mentioned areas on right and left side. It was also measured in supine position. To measure excursion the calliper was first placed on the foot of the slope of diaphragm echoic line and second calliper was placed at the apex. The Spearmen r coefficient was used to measure the degree of association between diaphragmatic thickness, excursion and thickness fraction on both side with AHI.

Results: Data from a sample of 40 patients (62.5%male, 37.5%female) were analysed. Mean age group 47.48 ± 9.28 , mean BMI 33.05 ± 6.72 , mean neck circumference 41.09 ± 2.50 •

•Positive correlation has been found between Right hemidiaphragmatic thickness on end inspiration with AHI ($r=0.298$, $p=0.0654$).

•Statistically significant correlation has been found between end inspiratory thickness of left hemidiaphragm with AHI ($r=0.381$, $p=0.016$) and end expiratory thickness of left hemidiaphragm with AHI($r=0.342$, $p=0.0333$)

•Statistically significant correlation has been found between Right hemidiaphragmatic Thickness Fraction with AHI ($r=0.358$, $p=0.023$)

• No significant correlation has been found between diaphragmatic excursion and AHI.

Conclusions: Our study depicted inspiratory thickness of diaphragm positively correlated with AHI which is a severity marker of OSA. Positive association also have been found with right diaphragmatic thickness fraction with AHI. However our study has been limited of small sample size and parameters have been taken in supine and awake conditions, there might have variations of anatomical measurements during sleep.

Differences in physiological endotypes between REM related and NREM related obstructive sleep apnea: Results from Shanghai Sleep Health Study cohort

X. Wang¹, H. Yi², W. Huang²

¹Department of Otolaryngology, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China, ²Department of Otorhinolaryngology Head and Neck Surgery, Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China

Introduction: According to the occurrence of apnea or hypopnea during rapid eye movement (REM) and nonrapid eye movement (NREM) sleep stages, OSA can be divided into REM predominant OSA (REM_{OSA}), NREM (NREM_{OSA}) predominant OSA and uniform OSA. We aimed to evaluate the endotypic differences of different OSA subgroups and changes of endotypes with sleep stages in Chinese population.

Materials and methods: Within the Shanghai Sleep Health Study cohort, individuals with OSA were recruited and classified as REM_{OSA}, NREM_{OSA} or uniform OSA. Non-invasive assessments of endotypes, including ventilatory control (loop gain, [LG]), arousal threshold (ArTH), pharyngeal collapsibility (V_{passive}), and muscle compensation (V_{comp}) were calculated using polysomnography.

Results: 1363 subjects were included in the analysis. REM_{OSA} participants exhibited lower loop gain ($0.51 [0.43-0.61]$ VS $0.58 [0.48-0.69]$, $p=0.001$), arousal threshold ($129.35 [114.27-155.63]$ VS $143.16 [118.71-179.36]$ %Veupnea, $p=0.001$), and upper airway collapsibility (higher V_{passive}; $91.55 [85.94-94.72]$ VS $87.82 [79.02-93.29]$ %Veupnea, $p<0.001$) than NREM_{OSA}; but the muscle compensation ($9.54 [4.09-19.94]$ VS $8.20 [-1.60-20.92]$ %Veupnea, $p=0.070$) did not have significant difference. The effects of sleep stage changes on the endotypes were different among OSA subgroups. Compared with NREM sleep, upper airway collapsibility (lower V_{passive}; $82.78 [69.64-91.53]$ %Veupnea in REM and $93.27 [88.15-95.71]$ %Veupnea in NREM; $p<0.001$) tended to increase in REM_{OSA} participants during REM sleep while the ArTH ($151.69 [123.15-195.87]$ %Veupnea in REM and $123.13 [111.77-141.61]$ %Veupnea in NREM; $p<0.001$) and V_{comp} ($14.12 [2.91-32.86]$ %Veupnea in REM and $9.93 [4.71-20.89]$ %Veupnea in NREM; $p=0.001$) showed elevation. In NREM_{OSA} participants, the LG ($0.59 [0.46-0.71]$ in NREM and $0.43 [0.34-0.52]$ in REM; $p<0.001$) , ArTH ($141.80 [120.80-175.56]$ %Veupnea in NREM and $125.77 [108.50-152.37]$ %Veupnea in REM; $p=0.001$), upper airway

collapsibility (lower V_{passive} ; 87.42[80.19–93.57] %Veupnea in NREM and 91.33[81.53–96.68] %Veupnea in REM; $p=0.02$) were higher in NREM sleep than those in REM sleep, while V_{comp} (7.51[–2.31–21.67] %Veupnea in NREM and 9.10[3.13–20.61] %Veupnea in REM; $p=0.002$) decreased in NREM compared to that in REM sleep. Fully adjusted generally linear mixed model analyses showed that the interactions between subgroups and sleep stages were significant (P for interactions all <0.001), this further conformed that effects of NREM to REM sleep stage changes on endotypic traits were different between NREM_{OSA} and the other two subgroups. Uniform OSA had the highest loop gain, highest arousal threshold, most collapsible upper airway (lowest V_{passive}), lowest muscle compensation among the three subgroups.

Conclusions: The different endotypic traits and different effects of sleep stage changes on endotypes among OSA subgroups can facilitate the understanding of the mechanism in OSA subgroups.

Differential effects of drugs for Insomnia and Sleep apnea : A Focus on sleep macrostructure and microstructure in rat

H. Hiya¹, T. Kimpara¹, R. Tamano¹, E. Kasai¹, K. Ogawa¹

¹Shionogi&Co., Ltd., Laboratoty of Drug Discovery and Disease Research, Osaka, Japan

Introduction: Various drugs are used to treat insomnia, contributing not only to the induction and maintenance of sleep but also to improvements in sleep quality. These therapeutic effects are often characterized by changes in sleep macrostructure, such as increased total sleep time (TST), shortened sleep latency, and alterations in sleep architecture. However, macrostructure alone may not fully represent the qualitative aspects of sleep. Microstructural change such as sleep fragmentation, which is caused by interruptions due to arousals, is also considered to influence sleep quality. This is particularly important for sleep disorders like sleep apnea syndrome (SAS), where frequent arousals can disrupt sleep sufficiency and reduce overall sleep quality.

Focusing on microstructural changes may help reveal new therapeutic potentials and contribute to evaluate the appropriate drugs for specific sleep disorders. In this study, we examined several compounds, including those developed for insomnia and those studied for SAS, to assess their effects on both sleep macrostructure and microstructure.

Materials and methods: Rat electroencephalogram (EEG) from the frontal cortex and neck electromyogram (EMG) were obtained and sleep stages were scored using SleepSign. Recordings were conducted during the light phase, and drug effects were evaluated for five hours post-administration. Sleep parameters including total sleep time (TST), sleep latency, sleep architecture for the macrostructure, and sleep bout duration, number of arousals for microstructure. We also analyzed EEG power changes. Lemborexant was assessed as a drug for insomnia, and trazodone was evaluated as a drug studied for both sleep and SAS. Atomoxetine and acetazolamide were assessed as drugs studied for SAS.

Results: Lemborexant shortened sleep latency and showed a tendency to increase total sleep time (TST), without altering sleep architecture. Trazodone did not affect TST but increased NREM sleep. Regarding sleep microstructure, lemborexant did not change sleep bout duration or the number of arousals, whereas trazodone increased bout duration and reduced arousals. Atomoxetine and acetazolamide did not significantly affect sleep microstructure, but atomoxetine altered sleep architecture. Changes in delta power during sleep were observed in trazodone and atomoxetine, consistent with the alteration in sleep architecture.

Conclusions: Both lemborexant and trazodone modulate sleep, but their effects on sleep macrostructure and microstructure differ. Given that these drugs have different mechanisms of action, their distinct effects on sleep macrostructure and microstructure may suggest that each is suited to different types of sleep disorders. While macrostructural changes are considered important for insomnia, microstructural aspects may also play a meaningful role. In contrast, for other disorders such as SAS, microstructural changes such as sleep bout duration and the number of arousals may provide even more relevant indicators of treatment effects.

It is important to appropriately select assessment methods that correspond to the pathophysiology of each disorder. By focusing on both macrostructure and microstructure, we can gain deeper insights into promising pharmacological approaches for various sleep disorders.

Acknowledgments: This study was conducted as part of a research project commissioned by Shionogi-Apnimed Sleep Science (SASS).

Digital Health Engagement and CPAP Adherence: Analysis of Patient Interaction with the myAir App

Y. Tomita^{1,2}, T. Kasai², H. Yoshimine³, S. Chiba⁴

¹Toranomon Hospital, Sleep Center, Tokyo, Japan, ²Juntendo University School of Medicine, Department of Cardiovascular Medicine, Tokyo, Japan, ³Inoue Hospital, Department of Respiratory Medicine, Nagasaki, Japan, ⁴Ota Memorial Sleep Center, Kanagawa, Japan

Introduction: Adherence is a crucial indicator in assessing the efficacy of continuous positive airway pressure (CPAP) therapy for sleep apnea. Although telemedicine enhances adherence and mobile apps represent a viable approach, individual variations may exist in the level of engagement with these apps.

Materials and methods: A retrospective chart analysis was performed on patients utilizing the myAir app, compatible with ResMed CPAP devices, across four hospitals in Japan from January 2023 to April 2024. Patients can track their CPAP usage and obtain guidance on appropriate use by employing the app. The app has a function whereby patients receive a maximum of five inquiries monthly regarding their sleepiness, which they can evaluate on a five-point scale, and their responses are transmitted to medical institutions. We classified patients who did not respond within a one-month period as having poor engagement. We transformed responses on a 5-point scale about how sleepy they were into 1–5 points, with larger scores denoting more sleepiness. The average of multiple replies indicated post-treatment sleepiness. We extracted data on usage from medical records for the initial month following the beginning of treatment. Good adherence was characterized by using the device for four or more hours during a minimum of 70% of the observation period. Patients were divided into two groups according to adherence, and comparisons were made for background characteristics, app engagement, and pre- and post-treatment sleepiness.

Results: The study comprised 62 patients: 56 males and 6 females, with a mean age of 51.3 ± 12.3 years, a mean apnea-hypopnea index (AHI) upon diagnosis of 44.5 ± 18.4 events per hour, and a mean body mass index (BMI) of 28.3 ± 5.1 kg/m². Within one month of CPAP therapy, 27 patients had good adherence, while 35 exhibited poor adherence. Age, sex, AHI, and BMI were not significantly different between the groups. However, the group with poor adherence had significantly higher leak levels (10.4 vs 18.1 L/min, $p=0.002$) and a significantly higher percentage of poor app engagement (18.5% vs 42.9%, $p=0.042$). Excluding patients with poor app engagement, 22 individuals in the good adherence group and 23 in the poor adherence group reported on sleepiness via the apps. Post-treatment sleepiness scores were 2.0 and 2.8 points, respectively, on a 5-point scale, with the poor adherence group exhibiting significantly higher sleepiness ($p=0.009$).

Conclusions: Reduced leak levels and good app engagement were proposed as indicators of favorable short-term CPAP adherence. Furthermore, among patients exhibiting good app engagement, individuals in the poor adherence category demonstrated minimal improvement in sleepiness.

Distinct Salivary Microbial Signatures Associated with Anatomical Sites of Upper Airway Obstruction Caused by Lymphoid Hypertrophy in Children

Y. Xu¹, G. Wang², H. Wang², F. Zhang², J. Zhang², X. Gao¹

¹Peking University School and Hospital of Stomatology, Department of Orthodontics, Beijing, China, ²Beijing Children's Hospital, Capital Medical University, National Center for Children's Health, Department of Otolaryngology, Head and Neck Surgery, Beijing, China

Introduction: Adenoid hypertrophy and tonsillar hypertrophy are the most common causes of upper airway obstruction in children and are major risk factors for pediatric obstructive sleep apnea (OSA). Clinical observations and previous studies have shown that children with obstruction at different anatomical site often exhibit distinct craniofacial morphological features. In addition, earlier research has identified characteristic salivary microbiota profiles in children with OSA compared to healthy controls. While these findings suggest a potential link between airway obstruction and biological signatures such as microbiota composition, the specific influence of the obstruction site on the salivary microbial environment remains unexplored.

Materials and methods: A total of 92 children (mean age 7.79 ± 2.41 years) were categorized into four groups: tonsillar hypertrophy (TH, $n=26$), adenotonsillar hypertrophy (ATH, $n=21$), adenoid hypertrophy

(AH, n=23), and healthy controls (n=22). Unstimulated saliva samples were collected and analyzed using 16S rRNA sequencing targeting the V3–V4 regions. Microbial diversity and composition were assessed and correlated with polysomnographic and hematologic parameters. Comparative analysis across obstruction sites was emphasized.

Results: Significant differences in α -diversity (Chao1, Faith's PD, Shannon, and Observed species) were observed among the groups, with TH group showing increased richness and diversity compared to AH, ATH and control groups ($p < 0.05$). β -diversity analysis revealed distinct microbial community structures associated with the site of obstruction ($p < 0.05$). Notably, *Firmicutes*, particularly genera such as *Gemella*, *Parvimonas*, and *Dialister*, were enriched in TH group. These findings suggest a potential link between microbial composition and immune activity at different obstruction sites. No substantial microbiota variation was found across different severities within the same anatomical site.

Conclusions: Salivary microbiota composition varies according to the location of upper airway obstruction in children, indicating that the anatomical site of hypertrophy plays a more pivotal role in shaping microbial profiles, offering novel perspectives for future related research.

Acknowledgments: This study was funded by the National Natural Science Foundation of China (82170102).

Distraction Osteogenesis Maxillary Expansion (DOME) in Isolated and Personalized Multilevel Surgery for Obstructive Sleep Apnea: The First Clinical Case Series in Thailand

S. Poomkonsarn^{1,2}, K. Kanokpongsak³, P. Jariyapongpaiboon³, T. Likkasittipan^{1,2}

¹Rajavithi Hospital, Otolaryngology Head and neck surgery, Bangkok, Thailand, ²Rangsit University, College of Medicine, Bangkok, Thailand, ³Rajavithi Hospital, Dental department, Bangkok, Thailand

Introduction: Obstructive sleep apnea (OSA) is frequently associated with transverse maxillary deficiency, manifesting as a high-arched, narrow palate that compromises nasal airflow and contributes to tongue crowding. Distraction Osteogenesis Maxillary Expansion (DOME) enables skeletal midpalatal expansion in skeletally mature adults. This study presents the first clinical case series in Thailand utilizing DOME as part of a personalized, multilevel surgical strategy for OSA. We aimed to evaluate the one-year outcomes, safety, and feasibility of this approach.

Materials and methods: Six adult OSA patients (mean age: 31 years; 5 males, 1 female) with high-arched, constricted maxilla underwent DOME using customized bone-anchored palatal expanders secured with mini-implants. Minimally invasive osteotomies were performed to allow gradual midpalatal expansion. DOME was integrated into individualized treatment plans, and combined with site-specific procedures such as nasal surgery, tonsillectomy, uvulopalatopharyngoplasty, genioglossus advancement, or bimaxillary osteotomies, based on anatomical needs. Some procedures were staged separately when simultaneous surgery was not feasible due to anatomical or procedural constraints. Pre- and post-operative evaluations included polysomnography, dental arch analysis, and craniofacial measurements. Measured parameters included dental class, skeletal facial profile, intercanine and intermolar widths, maxillary base width, palatal expansion distances, and maximum diastema width. Occlusion and facial profiles were assessed clinically.

Results: All patients achieved successful midpalatal suture separation, with a median diastema width of 9.5 mm (range: 7–10 mm), confirming skeletal expansion. Mean maxillary skeletal base width increased from 63.60 mm to 67.81 mm; mean intermolar width expanded from 50.04 mm to 58.10 mm. Intercanine width increased across all cases, with an average gain of 7.4 mm. Palatal expansion at anterior, midline, and posterior points reached mean values of 10.15 mm, 7.29 mm, and 4.55 mm respectively.

Dental occlusion remained stable in five patients; one improved from Class III to Class I. Two patients experienced facial profile correction from convex to straight. Three device-related complications occurred: two required reoperation due to insufficient expansion from short midline screws, and one had posterior screw loosening resolved with screw replacement. No major complications were observed. Minor complications included transient numbness, which resolved without lasting effects. At one-year follow-up, median AHI decreased from 33.0 to 15.1 events/hour (55% reduction). Four patients achieved a >50% AHI reduction, with one reaching normalized AHI <5. Oxygenation improved in most cases (median ODI from 9.7 to 5.6 events/hour), and responders demonstrated increased REM sleep percentage (mean REM% from 14% to 26%). Quality of life, assessed by a VAS scale (–10 to +10), showed consistent improvement in all cases (median +7; range +5 to +9), with better sleep continuity,

reduced mouth breathing, and improved daytime functioning.

Overall, the combined approach resulted in anatomical, functional, and symptomatic improvements in the majority of patients.

Conclusions: DOME provides effective maxillary expansion with preservation of occlusion, supporting its integration into multilevel OSA surgery. This first Thai case series affirms DOME as a safe and effective modality to correct transverse maxillary deficiency in adult OSA. Larger studies are warranted to validate these findings.

Distribution and characteristics of habitual snoring from a global population

F. Cepeda¹, R. Santos-Silva¹, M. Kudo¹, S. Alves¹, T.C. Souza¹, B. Purificação¹, W. Lee², J. Choi², H. Pak², M. Kim²

¹Samsung Eletronica da Amazonia, Campinas, Brazil, ²Samsung Electronics, Suwon, Korea, Republic of

Introduction: Evidence suggests that occasional snoring varies significantly in prevalence, ranging from 2% to 86%, largely due to self-reported measurement methods. To better understand snoring features, studies using objective records from large population samples are essential. This research aimed to investigate the distribution and characteristics of snoring among general worldwide users of the Samsung Health application over a five-month timeframe, under real-life conditions.

Materials and methods: Data were sourced from Samsung servers, including users with sleep data updated from February to June 2024. Eligible users recorded at least one sleep session ≥ 20 minutes with a Samsung Galaxy Watch (version 4 or later) and updated demographic details (age, weight, height, and gender). Users < 20 years old were excluded. Users were categorized based on weekly snoring frequency: (1) Frequent snorers, individuals who experienced snoring on ≥ 3 days per week; and (2) Non-frequent snorers, including those who snored < 3 days per week or had no snoring events detected. Oxygen saturation (SpO₂) measurements were assessed in a sub-dataset. Statistical analyses used PySpark 2.4.7, with normalized data presented as frequency/percentage for categorical variables and mean $\pm$ SD for continuous variables. The Ordinary Least Squares test evaluated age and body mass index (BMI) significance ($p < 0.05$), while the Mann-Whitney U test analyzed SpO₂, snoring duration, and BMI, adjusted for Bonferroni correction.

Results: The analysis included 6,084,029 users: 5,397,593 non-frequent snorers and 686,436 frequent snorers, totaling 130,146,432 snoring sessions. From the total group, 58% were males and 48% were between 20-40 years old. The mean BMI was 27.3 ± 6.1 kg/m² (27.5 ± 5.1 for males, 27.1 ± 6.1 for females) and 62% were classified as pre-obesity to obesity III. Males presented a higher proportion (67%) in the BMI categories of pre-obesity to obesity III compared to females (55%). Users were geographically distributed across all continents, with Europe (39%), the Americas (30%), and Asia (27%) being the most represented. Frequent snorers comprised 11.3% of the total group (11.5% males, 10.9% females). For both males and females, snoring proportion increased with age up to the 50s, and frequency in males was higher in all of age groups. Pre-obesity to obesity III prevalence was 54% in females and 73% in males in the frequent snorers group. Snoring sessions duration and frequency progressively increased with BMI in both genders. SpO₂ levels during sleep were significantly ($p < 0.05$) lower in frequent snorers ($93.57 \pm 2.62\%$) compared to non-frequent snorers ($93.80 \pm 2.66\%$), with significant ($p < 0.05$) decreases in SpO₂ correlating with BMI severity in frequent snorers.

Conclusions: Global data from over 6 million wearable device users (with > 130 million snoring sessions assessed) showed that snoring was prevalent in both genders, with higher frequency and duration of the snoring sessions as BMI categories increases. These findings suggest that objective snoring data, measured by wearable devices used in real-world and free-living conditions, are reliable tools for understanding and monitoring snoring patterns, echoing previous controlled studies.

Acknowledgments: The results presented in this work were funded by Samsung Eletronica da Amazonia Ltda., under the terms of Brazilian Informatics Law 8.248/91.

Does enlarging the pharyngeal lumen or bony enclosure translate to better airflow in obstructive sleep apnea? A State-of-the-Art Review

Y. Nishimura¹, M. Suzuki¹, R. Capasso², A. Schwartz^{3,4}

¹Teikyo Chiba Medical Center, Otorhinolaryngology, Chiba, Japan, ²Stanford University School of Medicine, Sleep Surgery Division, Department of Otorhinolaryngology-Head and Neck Surgery, Palo Alto, United States, ³University of Pennsylvania Perelman School of Medicine, Otorhinolaryngology, Philadelphia, United States, ⁴Universidad Peruana Cayetano Heredia, Sleep and Breathing Technologies, Lima, Peru

Introduction: This review aims to assess the efficacy of airway reconstructive surgeries—both intra-pharyngeal (soft tissue) and extra-pharyngeal (craniofacial)—in improving respiratory airflow and alleviating obstructive sleep apnea (OSA) symptoms.

Materials and methods: Data Sources: A literature search was conducted using databases such as PubMed, MEDLINE, and Scopus, focusing on studies evaluating uvulopalatopharyngoplasty (UPPP), maxillomandibular advancement (MMA), hyoid myotomy with mandibular suspension (HS), and hyoidthyroidpexy (HTP). Keywords included "OSA surgery," "airway enlargement," "respiratory airflow dynamics," and "pathophysiological mechanisms."

Methods: Selected studies were analyzed for evidence of airway structural changes, impact on airflow dynamics, and reductions in OSA severity. A simplified static respiratory geometric model, represented as a cylindrical conduit, was applied to synthesize the data and understand how each procedure influences airflow.

Results: Both intra- and extra-pharyngeal surgeries were found to induce structural modifications that reduce airway resistance and improve airflow. However, these interventions alone may not fully address the multifactorial nature of OSA. Factors such as airway collapse and occlusion persist despite surgical enlargement of the upper airway lumen.

Conclusions: Airway reconstructive surgeries contribute to improved respiratory airflow by reducing airway resistance. However, a comprehensive understanding of the underlying pathophysiological mechanisms is essential for optimizing treatment outcomes. Combining surgical interventions with adjunct therapies may offer a more holistic approach to managing OSA.

Does OSA severity reflect symptom burden? Clinical equivalence in REM- and non-REM-predominant OSA

J. Manners¹, B. Lechat¹, B. Toson¹, S. Proctor^{1,2}, K. Loffler³, A. Reynolds¹, A. Leviton¹, A. Vakulin¹, J. Fitton¹, R. Adams^{1,2}, S. Mukherjee^{1,2}, D. Eckert¹

¹Adelaide Institute for Sleep Health and FHMRI: Sleep Health, Flinders University, Bedford Park, Australia, ²Southern Adelaide Local Health Network, Department of Respiratory, Sleep and Ventilation, Bedford Park, Australia, ³Flinders Clinical Trials, Bedford Park, Australia

Introduction: REM-predominant Obstructive Sleep Apnea (REM-OSA) is often treated as a distinct clinical phenotype, yet evidence for clinically meaningful impacts on symptoms, comorbidities, or prognosis remains inconsistent. Moreover, traditional null hypothesis testing may be insufficient to address this knowledge gap. Equivalence testing may be helpful to assess whether people with REM-OSA differ from those without REM-predominant OSA (nREM-OSA) across common clinical and patient-reported outcomes.

Materials and methods: Data were drawn from 77 participants with suspected OSA from the Simplified Assessment and Monitoring of OSA (SAMOSA) observational cohort study. REM-OSA was defined as a REM/non-REM apnea-hypopnea index (AHI) ratio >2 and a non-REM AHI <15 events/h on polysomnography, while all others with a REM or non-REM AHI >5 events/h but not meeting REM-OSA criteria were classified as nREM-OSA. Participants with both REM and nREM AHI <5 events/h were excluded. Outcomes included the Epworth Sleepiness Scale (ESS), Insomnia Severity Index (ISI), Functional Outcomes of Sleep Questionnaire-10 items (FOSQ-10), the EQ-5D visual analogue scale (EQ-5D-VAS), mean systolic (SBP) and diastolic blood pressure (DBP), and self-reported diagnoses of depression and anxiety. To assess similarity, two one-sided tests of equivalence were conducted between REM-OSA and nREM-OSA groups on each outcome based on *a priori* minimally important differences (MIDs). These were defined as ESS=2 points, ISI=6 points, FOSQ-10=1.8 points, EQ-5D-VAS=5 points, SBP/DBP=2mmHg, and depression/anxiety=2-fold greater odds. Where equivalence was not established, group differences were compared using linear models. All analyses were run both unadjusted and adjusted for age and sex.

Results: Of the initial cohort, nine participants were excluded due to no REM or nREM OSA (AHI<5 events/h). 68 participants were included in final analyses (age[mean±SD] = 54±14 years; 51% male, 49% female). The REM-OSA group had significantly lower overall AHI (8±6 events/h) than the nREM-OSA group (32±29 events/h), $p<.001$. Despite this, REM-OSA was equivalent to nREM-OSA within predefined MIDs on outcomes of FOSQ-10 and ISI scores. Equivalence within MIDs was not established for ESS, EQ-5D-VAS, blood pressure, anxiety, and depression. Indeed, rates of self-reported anxiety were significantly higher in REM-OSA vs. nREM-OSA (48 vs.19%, $p=.02$). No significant differences between REM- and nREM-OSA were present for EQ-5D-VAS (70±21 vs. 73±14), SBP (122±11 vs. 127±12 mmHg), DBP (80±8 vs. 81±7 mmHg), or rates of depression (23 vs. 32%).

Conclusions: Using equivalence testing, we show that insomnia severity and sleep-related daytime functional impairment in REM-OSA are equivalent to nREM-OSA within MIDs, despite substantially lower overall AHI values in the people with REM-OSA. Moreover, rates of self-reported anxiety were higher in REM- compared to nREM-OSA. These findings challenge assumptions that lower OSA severity determined by the overall AHI necessarily translates to lower symptom burden. These results highlight the potential for high symptom burden in REM-predominant OSA, irrespective of overall OSA severity, that is phenotypically distinct from non-REM-predominant OSA.

Dramatic Improvement of Obstructive Sleep Apnea Following Kidney Transplantation in an ESRD Patient: A Case Report

U.-c. Heo¹, J.-H. Oh¹

¹Jeju National University Hospital, Jeju, Korea, Republic of

Introduction: Obstructive sleep apnea (OSA) is a prevalent condition in patients with end-stage renal disease (ESRD), with estimated prevalence rates nearing 50%. Recent research suggests a bidirectional relationship between OSA and chronic kidney disease (CKD), in which renal dysfunction contributes to OSA pathophysiology and vice versa. However, clinical evidence demonstrating improvement of OSA following restoration of renal function remains limited. This case highlights a patient with ESRD whose OSA significantly improved following kidney transplantation.

Materials and methods: A 51-year-old male with ESRD on peritoneal dialysis presented with severe snoring, fragmented sleep, and excessive daytime sleepiness. Despite prior surgical intervention (uvulopalatopharyngoplasty and tonsillectomy), symptoms persisted. Initial polysomnography (PSG) confirmed severe OSA. The patient underwent treatment with multiple modalities of positive airway pressure (PAP) therapy, including automatic (APAP), continuous (CPAP), and bi-level (BiPAP) devices, but showed minimal subjective or objective improvement over a six-month period.

Results: Sixteen months after the second PSG, the patient underwent deceased donor kidney transplantation. Postoperatively, he reported spontaneous and sustained improvement in sleep quality and resolution of apnea-related symptoms. Follow-up PSG showed a marked reduction in AHI and oxygen desaturation index (ODI), with severity improving from severe to mild OSA. The patient continues to be monitored under APAP therapy, though pressure requirements and symptom burden have significantly decreased.

Conclusions: This case supports the hypothesis that renal dysfunction plays a contributory role in the pathogenesis and persistence of OSA. The improvement observed following kidney transplantation—despite the failure of prior PAP therapies—suggests that fluid overload and uremic status may be key reversible factors. Clinicians should consider underlying renal pathology when evaluating OSA severity and treatment response in ESRD patients. Additionally, ODI may serve as a useful complementary marker alongside AHI in assessing disease burden in this population.

Dynamic Changes in Pulse Propagation Time Following Respiratory Events are Associated with Cortical Arousals in Obstructive Sleep Apnea

C. Strassberger¹, D. Zou¹, J. Bergqvist¹, J. Hedner^{1,2}, L. Grote^{1,2}

¹Gothenburg University, Center for Sleep and Vigilance Disorders, Gothenburg, Sweden, ²Sahlgrenska University Hospital, Pulmonary Medicine, Gothenburg, Sweden

Introduction: Cortical arousals significantly impact obstructive sleep apnea (OSA) pathophysiology and cardiovascular consequences, often mediated by sympathetic activation. While pulse oximetry (PPG) provides an accessible reflection of autonomic responses such as changes in pulse rate (PR) and pulse wave amplitude (PWA), the dynamic influence on other vascular indices remains less explored. Pulse Propagation Time (PPT), (interval from the systolic to the diastolic peak of the PPG pulse wave) is known to reflect modulation in vascular stiffness during sleep. This study examines dynamic changes in PPG-derived PPT following respiratory events (apneas/hypopneas) and evaluates the association with EEG-based cortical arousals in patients with OSA.

Materials and methods: Polysomnography data from 87 patients referred for suspected OSA were analyzed. A total of 18,275 apnea and hypopnea events were identified. Beat-to-beat PPG signals were processed to extract percentage changes in PWA, PR, and PPT following each respiratory event, alongside changes in SpO₂. EEG-based cortical arousals coinciding with event termination were manually scored. Statistical comparisons (t-tests) and logistic mixed-effect models were used to assess the association between PPT parameter changes and EEG arousals, controlling for age, gender, BMI, event type, SpO₂ change, and other PPG parameters.

Results: The mean percentage change (shortening, vascular stiffening) of the PPT following respiratory events was significantly greater when accompanied by an EEG arousal compared to events without arousal (-20.1% vs. -17.3%, $p < 0.001$; $N=18275$ events). This difference remained significant when analyzing apneas (-21.0% vs -17.9%, $p<0.001$) and hypopneas (-19.4% vs -17.0%, $p<0.001$) separately. In the multivariate logistic model, the change in PPT emerged as an independent predictor of EEG arousal presence ($p < 0.001$ with scaled odds ratio: 0.87; 95% CI: 0.83-0.92), after accounting for changes in PWA, PR, SpO₂, and other covariates.

Conclusions: Dynamic, short-term changes in PPG-derived PPT are significantly associated with cortical arousals following respiratory events in OSA patients. This parameter provides independent predictive information beyond established PPG metrics like PWA and PR, potentially reflecting rapid, arousal-induced alterations in vascular tone. These findings highlight a novel PPG-based marker that could contribute to non-EEG based assessment of arousal responses in OSA.

Effectiveness of drug-induced sleep endoscopy in improving outcomes of barbed pharyngoplasty for obstructive sleep apnea surgery: a prospective randomized trial

T. Perrone¹, G. Magliulo², G. Cammaroto³, G. Meccariello³, A. De Vito³, S. Pelucchi⁴, A. Ciorba⁴, A. Maniaci⁵, S. Cocuzza⁵, G. Gulotta², A. Pace², R.M. Corso⁶, A. Bahgat⁷, C. Vicini³, G. Iannella²

Introduction: To observe the effectiveness of preoperative drug-induced sleep endoscopy in improving surgical results of patients undergoing single-level barbed pharyngoplasty surgery for OSA, using a prospective randomized model.

Materials and methods: A single-center randomized controlled trial with two prospective arms was carried out to compare functional results in patients treated with barbed reposition pharyngoplasty (BRP) surgery without a preoperative drug-induced sleep endoscopy (DISE) evaluation vs patients treated with BRP surgery performed after DISE evaluation of sites/patterns of collapse.

Results: We compared 50 patients who underwent BRP without a preoperative DISE evaluation (Group A) and 42 patients (Group B) treated with BRP surgery but preoperatively selected by means of a preoperative DISE. In this second group of patients, after DISE evaluation, 70% of patients were selected for single-level BRP surgery because they showed an isolated velopharyngeal collapse at the DISE evaluation, without obstruction at other upper airway levels evaluated. Both groups of patients showed a statistically significant difference between preoperative and postoperative values of AHI, ODI, and LOS ($p<0.05$ in all cases). Comparing Group A and Group B patients, the therapeutic success rate was found to be 60% in patients treated without preoperative DISE evaluation and 83% in patients treated with preoperative DISE ($p = 0.02$).

Conclusions: DISE appears to improve the surgical results of single-level velopharyngeal surgery due to the possibility of excluding patients with obstruction of the base of the tongue, the hypopharynx, and the epiglottis/larynx.

Effectiveness of Inflatable Positional Therapy Device in Patients with Position-Dependent Obstructive Sleep Apnea

K. Terziyski¹, [A. Draganova](#)¹, T. Georgiev¹, K. Avramov¹

¹Medical University - Plovdiv, Pathophysiology, Plovdiv, Bulgaria

Introduction: Continuous positive airway pressure (CPAP) remains the gold standard treatment for obstructive sleep apnea (OSA). However, a substantial proportion of patients exhibit poor compliance, particularly those with mild-to-moderate and oligosymptomatic disease, often associated with positional dependency. In such cases, positional therapy may be beneficial.

The main objective of this study is to evaluate the effectiveness of a novel positional therapy device (a pillow with an inflatable core) in patients with position-dependent obstructive sleep apnea (POSA).

Materials and methods: Eighteen ambulatory patients (17 males, 1 female; age: 48.6 ± 14.1 years; BMI: 28.5 ± 2.8 kg/m²) diagnosed with POSA were enrolled. POSA was defined as an apnea-hypopnea index (AHI) in the supine position at least twice that in the non-supine position, with non-supine AHI < 30 events/h.

Exclusion criteria included: 1. Other sleep disorders; 2. Significant somatic or psychiatric comorbidities and 3. <10% time spent in the supine position during total sleep time

Baseline home respiratory polygraphy was conducted using the NoxA1 system (NoxMedical, Iceland), with recordings scored according to standard guidelines (version 2.3 of the American Academy of Sleep Medicine criteria). Participants then used a TED BED EAD positional pillow (inflatable core, worn like a backpack) for 4–7 nights. A second polygraphy was performed under treatment conditions. Normality of differences (POST–PRE) was tested using the Shapiro–Wilk test. Paired t-test was applied for normally distributed variables and the Wilcoxon signed-rank test for non-normal distributed variables. A significance level of $p < 0.05$ was used. Normally distributed data are presented as Mean $\pm$ SD and non-normally distributed data as Median (25th–75th percentile). All comparisons are presented as (after vs before).

Results: Significant reductions were observed in AHI (9.4 ± 8.4 vs 21.7 ± 13.3 , $p < 0.001$), oxygen desaturation index (ODI) (6.4 (5.3 – 9.6) vs 15.6 (12.0 – 23.6), $Z = -3.724$, $p < 0.001$), and time of SpO₂ under 90% (SpO₂ < 90%) (0.6 (0.1 – 3.3) % vs 2.5 (0.6 – 12.4) %, $Z = -3.054$ $p = 0.002$).

These effects were primarily attributed to a significant reduction in supine sleep time (9.7 ± 12.3 % vs 46.4 ± 24.2 %, $p < 0.001$), while the total sleep time was not statistically different (415.1 ± 74.4 min with treatment vs 456.4 ± 54.7 min at baseline, $p = 0.074$).

Additionally, improvements in supine oxygenation levels were also found: ODI in supine position (6.3 (0 – 13.3) vs 29.7 (19.3 – 55.2), $Z = -2.865$, $p = 0.004$) decreased and the average SpO₂ (94.1 (92.4 – 93.4) % vs 93.2 (92.3 – 93.4) %, $Z = -2.486$, $p = 0.013$) and minimal SpO₂ (90.0 (86.0 – 92.5) % vs 83.0 (76.8 – 86.3) %, $Z = -3.177$, $p = 0.001$) in supine position increased. No significant differences were detected in non-supine oxygenation parameters.

Conclusions: A positional therapy pillow with an inflatable core significantly reduces AHI and improves oxygenation in patients with POSA, offering a promising alternative to CPAP therapy in selected cases.

Acknowledgments: We thank TED BED EAD for designing the positional therapy pillow with inflatable core.

Effect of adenotonsillectomy on lipid profile in children with obstructive sleep apnea

[C.h. Lee](#)^{1,2}, [W.-C. Hsu](#)^{3,4}

¹Taipei Hospital, Ministry of Health and Welfare, Department of Otolaryngology and Sleep Medicine, New Taipei City, Taiwan, ²Hsin Sheng Junior College of Medical Care and Management, School of Oral

Hygiene, Taoyuan, Taiwan, ³National Taiwan University Hospital, Department of Otolaryngology, Taipei, Taiwan, ⁴National Taiwan University, College of Medicine, Taipei, Taiwan

Introduction: Limited evidence addressing effects of adenotonsillectomy (T&A) on lipid profiles in childhood obstructive sleep apnea (OSA). The aim of this study is to elucidate changes in lipid profiles after surgery in children with OSA.

Materials and methods: Children aged 4-16 years with clinical symptoms and polysomnography (PSG)-diagnosed OSA (apnea-hypopnea index, AHI >1) were recruited from a tertiary medical center and received T&A as the treatment for OSA. All children had the postoperative PSG studies, and examined for lipid profiles (i.e. total cholesterol, triglyceride, low-density lipoprotein [LDL], and high-density lipoprotein [HDL]) before and 6 months after surgery.

Results: This study included 124 children (mean age, 6.3±3.0 years; 65% boy). T&A resulted in a significant reduction of the AHI from 12.3±17.9 to 2.9±5.7 per hour ($P < 0.001$). After surgery, total cholesterol (162.9 to 164.4 mg/dL, $P = 0.51$), triglyceride (79.3 to 79.9 mg/dL, $P = 0.87$), and LDL (97.0 to 96.5 mg/dL, $P = 0.75$) were not significantly changed. The HDL was significantly increased from 53.3 to 55.7 mg/dL after surgery ($P = 0.03$). Moreover, the LDL/HDL ratio was significantly decreased from 1.99 to 1.87 after surgery ($P = 0.004$).

Conclusions: Adenotonsillectomy (T&A) treatment may provide beneficial effects on lipid profiles in children with obstructive sleep apnea (OSA).

The author would like to thank anonymous reviewers and the editor for their comments.

Effect of Continuous Positive Airway Pressure on Intraocular Pressure in Patients with Obstructive Sleep Apnea – A Systematic Review and Meta-Analysis

J.H. Chan¹, B.S.Y. Yeo¹, W.K. Lau², M.C. Lau², J.H. Koh¹, A.C.W. Ng^{3,4,5}, L.C. Goh⁶, M. Uataya⁷, A. Tin^{8,9}, S.T. Toh^{3,4,5}

¹National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore, ²Nanyang Technological University, Lee Kong Chian School of Medicine, Singapore, Singapore, ³Singapore General Hospital, Department of Otorhinolaryngology - Head and Neck Surgery, Singapore, Singapore, ⁴Singapore General Hospital, SingHealth Duke-NUS Sleep Centre, Singapore, Singapore, ⁵Duke-NUS Medical School, Surgery Academic Clinical Program, Singapore, Singapore, ⁶University of Malaya, Department of Otorhinolaryngology, Faculty of Medicine, Kuala Lumpur, Malaysia, ⁷Siriraj Hospital, Mahidol University, Department of Otorhinolaryngology, Faculty of Medicine, Bangkok, Thailand, ⁸Singapore National Eye Centre, Department of Ophthalmology (Glaucoma), Singapore, Singapore, ⁹National University of Singapore, Duke-NUS Medical School, Singapore, Singapore

Introduction: While the association between Obstructive Sleep Apnea (OSA) and glaucoma has been well studied, the long-term effects of Continuous Positive Airway Pressure (CPAP) therapy on Intraocular Pressure (IOP) and glaucoma progression is less known. With the increasing prevalence of both OSA and glaucoma globally, along with varying reports in the literature of the effect of CPAP therapy on IOP, an in-depth review of existing literature in this present moment is of utmost clinical importance. Clarification of the relationship between CPAP therapy and IOP may help to guide patient management and improve health outcomes. This study aims to systematically synthesise evidence to clarify the association between CPAP therapy and IOP.

Materials and methods: PubMed, Embase, The Cochrane Library, CINAHL, Scopus and Web of Science were searched through 26 March 2025 for interventional studies evaluating the effect of CPAP on IOP among OSA adult patients. Two independent authors selected relevant articles, extracted data and evaluated the quality of evidence using the Newcastle-Ottawa Scale (NOS), Cochrane Risk-of-Bias Tool for Randomised Trials (RoB 2) and Grading of Recommendations Assessment, Development and Evaluation (GRADE). Inverse variance meta-analyses were conducted using random effects. I^2 values were used to evaluate for heterogeneity. To account for potential sources of heterogeneity, further

subgroup analyses were performed. Additional leave-one-out analysis and cumulative analysis were also conducted to evaluate the impact of omitting each study on the overall effect size and the stability of the pooled effect size over time respectively. To assess for publication bias, visual inspection for funnel plot asymmetry was conducted.

Results: This study included 16 studies, pooling a cohort of 602 patients. The risk of bias of studies ranged from low-moderate and the quality of evidence was moderate on GRADE. CPAP therapy significantly increased IOP levels overnight (MD: -4.14; 95% CI: -7.76, -0.52; $I^2=76\%$; $p=0.04$), and after one month (MD: -0.78; 95% CI: -1.21, -0.35; $I^2=0\%$; $p=0.60$). IOP levels remained unchanged with CPAP therapy of more than one month. Our findings remained significant and stable through the various subgroup and sensitivity analyses, with no publication bias noted.

Conclusions: While short-term CPAP therapy of one month or less in OSA patients was associated with elevated IOP, minimal long-term effects were observed after one month. Nonetheless, these findings underscore the importance of exercising caution when administering CPAP therapy on IOP especially in glaucomatous patients. Further studies are needed to investigate whether CPAP affects the risk of glaucoma directly.

Acknowledgments: All authors have made substantial contributions to all of the following: (1) the conception and design of the study, or acquisition of data, or analysis and interpretation of data, (2) drafting the article or revising it critically for important intellectual content, (3) final approval of the version to be submitted. Jun He Chan and Brian Sheng Yep Yeo contributed equally as co-first authors. Song Tar Toh is the corresponding author, and is responsible for conceiving the study and provided advice on the study.

Effect of CPAP on Subjective and Objective Cognitive Deficits in Post-COVID Patients with Obstructive Sleep Apnea

V. Krishnamurthy¹, K. Wilckens¹, S.M. Nouraie¹, P. Garbioglu¹, S. Vaidya¹, S. Swanger¹, A. Whitehead¹, S. Patel¹

¹University of Pittsburgh, Pittsburgh, United States

Introduction: Cognitive deficits are reported in up to 60% of patients with post-COVID syndrome. Obstructive sleep apnea (OSA), which commonly co-occurs in this population, may further exacerbate these cognitive symptoms. This study aimed to evaluate whether treatment of OSA with continuous positive airway pressure (CPAP) improves subjective and objective measures of cognitive fog in post-COVID patients with comorbid OSA.

Materials and methods: Patients meeting the WHO criteria for post-COVID syndrome, who reported cognitive fog and were diagnosed with OSA, were recruited for the study. Neuropsychological testing was conducted at baseline and again at 4 ± 2 weeks after initiating CPAP therapy. We assessed key domains of executive function, including working memory (Digit Span Backward), task switching (Trail Making Test Part B), and inhibition (Stroop Color-Word Test). Additional cognitive measures included Processing speed (Digit Symbol Substitution Test), Vigilance (Psychomotor Vigilance Test), and Episodic memory (Benson Complex Figure Delayed Recall Test). Patient-reported cognitive fog was evaluated using the PROMIS Cognitive Function scale.

Results: Among 17/20 recruited patients who completed the study, the mean age was 49 ± 14 years; 55% were women, 15% were Black, the median AHI was 12 (9.6–30), and the mean BMI was 34.5 ± 9.9 . The average nightly CPAP usage was 6 hours and 14 minutes ± 2 hours and 24 minutes. Executive functions improved following CPAP therapy across multiple domains: working memory assessed by the Digit Span Backward test (post: 8.1 ± 0.7 vs pre: 7.1 ± 0.4 ; $p = 0.08$), task switching by the Trail Making Test Part B (post: 60.8 ± 4.3 vs pre: 69.7 ± 5.3 ; $p = 0.06$), and inhibition by the Stroop Color-Word Test (post: 45.8 ± 2.9 vs pre: 40.7 ± 2.8 ; $p < 0.01$). There were significant improvements in other cognitive domains including Processing speed assessed with Digit Symbol Substitution Test (post: 59.8 ± 2.5 vs pre: 51.8 ± 2.7 ; $p < 0.01$), Episodic memory measured with Benson Complex Delayed Recall Test (post: 13.8 ± 0.5 vs pre: 12.2 ± 0.4 , $p = 0.02$) and substantial improvement in Vigilance measured by Psychomotor Vigilance Test-Mean Reaction Time (post: 238.3 ± 6.3 msec vs pre: 254.6 ± 7.5 msec, $p < 0.01$). Additionally, patient-reported cognitive function significantly improved as measured by the PROMIS Cognitive Function scale (post: 26.7 ± 2.1 vs pre: 17 ± 1.6 ; $p < 0.01$). Improvement in PROMIS scores correlated with nightly CPAP use ($r = 0.5$, $p = 0.04$).

Conclusions: Our findings suggest that treating comorbid OSA among patients with post-COVID syndrome can decrease cognitive fog in post-COVID patients.

Acknowledgments: The authors would like to acknowledge the Breathe PA organization for funding this study.

Effect of Neck-Bending on Upper Airway Caliber and Surrounding Soft Tissues in Controls and Apneics

A. Schwab¹, T. Lin¹, B. Keenan¹, A. Wiemken¹, S.H. Tang¹, R. Schwab¹

¹University of Pennsylvania, Division of Sleep Medicine, Philadelphia, United States

Introduction: Head and neck flexion and extension influence upper airway size, but the underlying mechanisms remain unclear. This study aims to investigate changes in airway caliber and the movement of surrounding soft tissues during head and neck flexion and extension in individuals with and without obstructive sleep apnea.

Materials and methods: Upper airway MRI was obtained in 24 controls (AHI<5; 1.5±1.5 events/hour) and 33 apneics (AHI≥5; 33.2±28.7 events/hour) with the neck in flexion, extension, and neutral positions. Differences in airway measures and soft-tissue movement were assessed.

Results: During extension, controls and apneics showed increased minimum cross-sectional area (CSA) and anteroposterior (AP) and lateral dimensions in the retropalatal ($p\leq 0.002$) and retroglossal ($p\leq 0.010$) airways. During flexion, both groups showed reduced lateral dimensions in the retropalatal ($p\leq 0.017$) and retroglossal ($p\leq 0.013$) airways; controls had reduced retroglossal CSA ($p=0.0001$) and apneics had reduced retroglossal AP dimension ($p=0.019$). In associations with degree of head/neck bending, moving from flexion to extension resulted in increased retropalatal/retroglossal airway sizes (all $p<0.0001$), less lateral wall narrowing ($p\leq 0.0001$), and more anterosuperior movement of soft palate and tongue ($p\leq 0.0001$). Results were generally consistent in controls and apneics, although each 1° change from flexion to extension resulted in greater increases in retropalatal airway size and more lateral movement of the lateral walls in controls (interaction $p\leq 0.005$).

Conclusions: Controls and apneics showed reductions in airway caliber during neck flexion and increases during extension, primarily due to movement of the soft palate, tongue, and lateral pharyngeal walls. These data provide important insights into the role of head and neck position on upper airway caliber.

Acknowledgments: No Acknowledgements

Effect of orofacial myofunctional therapy (OMT) on chewing efficiency, lip strength and tongue strength in participants of the "OMT with autofeedback for obstructive apnea" (OMTAOSA) randomized controlled trial

U. Tinbød^{1,2}, D.D. Hansen^{1,3}, X. Feng^{1,3}, T. Dammen^{2,4}, A.S. Islind⁵, H. Hrubos-Strøm^{1,3}

¹Akershus University Hospital, Department of Otorhinolaryngology, Nordbyhagen, Norway, ²University of Oslo, Department of Research and Innovation, Division of Mental Health and Addiction, Oslo, Norway, ³University of Oslo, Faculty of Medicine, Institute of Clinical Medicine, Campus Akershus University Hospital, Nordbyhagen, Norway, ⁴University of Oslo, Faculty of Medicine, Institute of Clinical Medicine, Oslo, Norway, ⁵Reykjavik University, Department of Computer Science, Reykjavik, Iceland

Introduction: Obstructive sleep apnea (OSA) is a prevalent condition, estimated to affect nearly one billion people worldwide. OMT represents a novel, non-invasive approach to the treatment of OSA. Improving chewing function and oral muscle strength is a key objective in OMT. Accordingly, we hypothesized that chewing efficiency, lip- and tongue strength would improve after 12 weeks of OMT.

Materials and methods: The "OMT with autofeedback for OSA" multicenter randomized controlled trial (OMTAOSA RCT) included 104 newly diagnosed participants with mild to moderate OSA. Eligibility criteria included an apnea-hypopnea index (AHI) from 5 to 30 and body mass index (BMI) below 30. Participants adherent to a two-week electronic sleep diary pre-screening were randomized to a 12-week standardized OMT protocol or waitlist. Sleep was measured with self-applied polysomnography three consecutive nights at project start and end. Masticatory efficiency was assessed by a

standardized test measuring number of chewed particles (NP) and average particle size (PS), where higher NP and lower PS indicated better efficiency. Maximal anterior tongue strength (MTS) and maximal lip strength (MLS) were measured by the Iowa Oral Performance Instrument (IOPI) which measures pressure (kPa) exerted on a small air-filled bulb. Analyses followed the intention-to-treat principle. Between-group differences in effect of OMT were analyzed with independent t-tests and within-group changes with paired t-tests.

Results: Patients were randomized to a treatment group (n=52; mean age=46,3 years; BMI=26,4; AHI=13,77; 72,9% male) or a waitlist group (n=52; mean age=48 years; BMI=26,1; AHI=15,10; 66,0% male). Randomization was successful with no significant differences in age, BMI, AHI or gender. Between-group differences in post-intervention outcomes were not significant for NP (treatment: 493 vs. waitlist: 473; p=0,67), PS (31,9 mm² vs. 35,2 mm²; p=0,38), MTS (57,6 kPa vs. 57,6; p=1,00) or MLS (34,5 kPa vs. 33,3 kPa; p=0,38). Within-group analyses showed significant NP increase in both treatment (pre: 438; post: 493; p=0,02) and waitlist groups (pre=420; post=473; p<0,01), but no significant PS changes (treatment: p=0,40 vs. waitlist: p=0,14). MTS increased significantly only in the waitlist group (pre=55,4kPa; post=57,6kPa; p=0,04), but not in the treatment group (pre=56; post=57,6; p=0,18). No significant changes were observed in MLS within either group (treatment: pre=33,4kPa; post=34,5kPa; p=0,06 vs. waitlist: pre=33,4kPa; post=33,3kPa; p=0,83).

Conclusions: The hypothesis that twelve weeks of OMT would improve chewing function, lip strength, or tongue strength was not supported by the results. Surprisingly, there were very small differences between groups. Future analyses are pre-specified and will examine per-protocol and subgroup potential effects after adjustment for treatment adherence and baseline OSA severity.

Acknowledgments: We are grateful to the Academy of Orofacial Myofunctional Therapy for the guidance in the process towards OMT-certifications for the first and second author. We also deeply appreciate the cooperation and valuable contribution from our colleagues in the Sleep Revolution project.

Effect of Self-Viewing Sleep Videos on CPAP Adherence: A Prospective Real-World Study in Patients with Sleep Apnea Syndrome

K.T. Kim¹, H.-I. Kim¹, Y.W. Cho¹

¹Keimyung University School of Medicine, Neurology, Daegu, Korea, Republic of

Introduction: Adherence to positive airway pressure (PAP) therapy in obstructive sleep apnoea (OSA) remains suboptimal. Previous cognitive behavioural therapy (CBT) has relied on passive education approaches and has yielded mixed results. To evaluate whether personalised video footage showing one's own sleep-disordered breathing events (Self-Viewing of Sleep Apnea Videos, SVSV) improves PAP adherence.

Materials and methods: In this randomised controlled trial, 228 treatment-naïve patients with moderate to severe OSA were assigned to either the SVSV or standard CBT-only (control) group. All participants received standard CBT before PAP initiation. The SVSV group additionally viewed video footage of apnoeas from their own diagnostic polysomnography. The primary outcome was good adherence, defined as ≥4 hours of sleep per night on ≥70% of nights for 90 days. Secondary outcomes included the number of days with adequate use, mean daily usage time, and apnoea-hypopnoea index (AHI) during PAP. Statistical analysis was performed using independent t-tests and chi-square tests. A p-value < 0.05 was considered statistically significant.

Results: Good adherence was achieved in 89.5% of the SVSV and 78.1% of the control group (absolute difference, 11.4%; 95% confidence interval (CI), 1.94% to 20.86%). Compared with the control group, the SVSV group had more days with adequate usage (mean difference of 9.05 days; CI, 2.29 to 15.81) and longer daily usage (mean difference of 0.55 hours; CI, 0.13 to 0.98). AHI during PAP therapy was similar between the two groups.

Conclusions: This study supports the clinical utility of patient-specific visual feedback to improve PAP adherence. SVSV—a simple, low-cost, and scalable strategy—resulted in a higher proportion of patients achieving good adherence and greater nightly usage.

Acknowledgments: This study was supported by a grant from Korean Neurological Association (KNA-22-SK-17).

Effect of Surgical Therapy of Sleep Apnea Syndrom in Patient Treated by Noninvasive Ventilation

J. Kalhous¹, J. Kordik²

¹Krajska zdravotní a.s., Masaryk Hospital, Clinic of ENT and Head and Neck Surgery, Ústí nad Labem, Czech Republic, ²Krajska zdravotní a.s., Nemocnice Teplice, Dept. of Internal Medicine, Teplice, Czech Republic

Introduction: The method of choice in patients with sleep apnea syndrome is Positive Airway Pressure (PAP - CPAP / BPAP), surgical intervention is usually a last resort. Some patients with PAP, who are treated suboptimally, may also benefit from concomitant surgery.

Materials and methods: The study included 25 patients with severe obstructive sleep apnea syndrome (age 17 - 72, baseline AHI 31 – 120, av. 66., baseline pressure on PAP 8-20 mbar) who were indicated for PAP therapy and whose treatment for various reasons was suboptimal. All patients underwent oropharyngeal surgery (tonsillectomy, uvulopalatopharyngoplasty, radiofrequency-assisted uvuloplasty, or a combination thereof). Two months after the operation, a controlled limited polygraphy and off-line retitration of the ventilation device were performed. Monitored parameters: 1. subjective difficulties, preventing further use of PAP treatment. 2. AHI before and after surgery. 3. The level of pressure on the PAP device before and after surgery.

Results: 1. None of the patients in our group had problems preventing further use of the ventilation device. 2. In all patients there was a statistically significant reduction in AHI after surgery ($p < 0.000012$). The mean reduction in AHI was 45 ($\pm 26,68$). Five patients did not continue treatment with CPAP / BPAP because it reached the limit of the indicative criteria for PAP (in Czech Rep. it is limit AHI 15), so their treatment can be considered successful. In seventeen of the remaining 20 patients, it was possible to reduce the pressure on the device after retitration, in three it was left at the original level. The mean pressure drop on the PAP device after retitration was 3,3 mBar (± 3.3), the average percentage reduction was 20% . The difference between the values before and after surgery is statistically significant ($p < 0.00294$)

Conclusions: The results of our pilot study show that patients with OSAS, who are treated with non-invasive ventilation and whose treatment is suboptimal, can benefit from concomitant surgical therapy. None of the patients in our cohort had problems with postoperative use of PAP therapy, while all had a decrease in AHI and most had a decrease in pressure on the PAP device.

Effect of waterless humidification via heat and moisture exchangers on long-term adherence to PAP therapy: a 12-month home-based study

J.K. Bindra¹, D. Tellez², L. Camacho², J. Mastellone¹, N. Banodkar¹, R. Deas¹, X. Zhu¹, L. Willes³, C. Kelly³, F.S. Kuniyoshi²

¹Resmed Science Center, Sydney, Australia, ²Resmed Science Center, San Diego, United States, ³Willes Consulting Group, San Diego, United States

Introduction: Adherence to Positive Airway Pressure (PAP) treatment is essential to realising its full clinical benefits in patients with Obstructive Sleep Apnoea (OSA), including improved symptoms and long-term health outcomes. While humidification enhances comfort and may improve adherence, maintaining active humidification systems can be burdensome. Waterless humidification through heat and moisture exchangers (HMX) offers a low-maintenance alternative. This study aimed to evaluate the effect of HMX on 12-month PAP adherence and user experience in the home setting.

Materials and methods: This decentralised, prospective cohort study enrolled US-based established PAP users using cloud-connected devices, non-heated tubing and a patient-engagement app. Participants used an HMX device with their home PAP device and were followed remotely for 12 months.

Objective PAP therapy data including Apnoea-Hypopnoea Index (AHI), leak, pressure and usage were collected. Average nightly usage was assessed at baseline (3 months pre-enrolment) and tracked monthly during the 12-month follow-up. Usability, comfort, and ease of use were assessed monthly via 11-point Likert scale questionnaires. HMX discontinuation rates were assessed, and exploratory analyses examined the influence of seasonality, absolute humidity, and patient-app engagement. At study completion, participants were propensity-score matched to a retrospective control group using

active humidification. Analyses were conducted on intention-to-treat (ITT), per-protocol (PP), and as-treated (AT) populations using appropriate statistical methods.

Results: In the PP population (n=87), 12-month usage did not differ significantly from controls (6.8 vs. 6.7 hours/night; $p=0.64$), with a statistically significant increase from baseline (+18 minutes; $p=0.010$), although not clinically relevant.

In the AT population, consistent HMX users maintained PAP adherence comparable to controls ($\Delta=-12$ minutes; $p=0.39$), while non-users had significantly lower PAP adherence (5.2 vs. 6.9 hours/night; $\Delta=-108$ minutes; $p=0.0001$).

In the ITT population (n=164), average nightly usage at 12 months was significantly lower than in matched controls (5.6 vs. 6.5 hours/night; $\Delta=-54$ minutes; $p<0.0001$). Usage stabilised at approximately 5.5 hours/night after month 3, with early discontinuation (43.8%) occurring primarily in the first 3-4 months. Baseline usage <6 hours/night significantly predicted discontinuation ($p=0.021$).

Therapy parameters (AHI, leak, pressure) remained stable across all groups. No significant associations were found between adherence and seasonality, absolute humidity, or patient-app engagement. Positive usability ratings were sustained throughout 12-month follow-up, with participants rating the HMX favourably for breathing comfort, ease of use, and overall performance.

At study completion, 92.6% of participants preferred HMX during winter, 99.2% were satisfied with air temperature, and 87.6% with humidification. Participants were highly likely to recommend the HMX (Net Promoter Score [NPS]: 74), and moderately likely to purchase out-of-pocket (NPS: 25.6). No safety concerns were identified.

Conclusions: Patient populations that completed 12-month follow-up (PP) and consistently used HMX (AT) experienced no deterioration in long-term adherence, comfort, or therapy efficacy, with outcomes comparable to traditional humidification. Although early discontinuation affected the overall adherence in the full cohort, results suggest that HMX is a safe, low-maintenance alternative to active humidification for adherent users, particularly during colder months or for travel. These findings highlight the potential of HMX as part of a personalised approach to PAP therapy.

Effects of acute exercise performed at different times of day on respiratory, blood pressure, and cardiac autonomic modulation outcomes in patients with obstructive sleep apnea: a randomized crossover trial

J.L. Aguiar¹, J.R. Almeida², E. da Silva¹, R. Pedrosa¹, O. Lins-Filho², B. Farah³

¹University of Pernambuco, Health Sciences, Recife, Brazil, ²Federal University of Pernambuco, Physical Education, Recife, Brazil, ³Federal Rural University of Pernambuco, Physical Education, Recife, Brazil

Introduction:

Obstructive sleep apnea (OSA) is a prevalent sleep disorder associated with increased cardiovascular risk, including elevated blood pressure and impaired autonomic regulation. While physical exercise is recognized for its cardioprotective effects, the influence of exercise timing on sleep-related and cardiovascular outcomes in individuals with OSA remains unclear. This study investigated the acute effects of aerobic exercise performed at different times of the day on sleep respiratory parameters, blood pressure, and cardiac autonomic modulation in patients with OSA.

Materials and methods: In this randomized cross-over trial, 22 patients (age 57.4 ± 11.1 years old, body mass index 32.1 ± 6.1 kg/m²) with OSA (AHI 34.2 ± 23.8 events/hour) were recruited and completed four experimental sessions in random order: aerobic exercise and control in the morning (8:00- 11:00 AM) and in the afternoon (3:30-6:30 PM). Each exercise session consisted of 40 minutes of aerobic exercise on a treadmill at 54-59% heart rate reserve; each control session consisted of seated rest for 40 minutes. Measurements were taken in the supine position before and after each session for clinic and central BP and cardiac autonomic modulation (by heart rate variability). After each session, all patients underwent at-home polysomnography using a portable polygraph.

Results: Clinic systolic BP decreased following both morning (-16.1 mmHg; 95%CI = -22.5 to -9.7 mmHg; $p<0.001$) and afternoon exercise sessions (-11.4 mmHg; 95%CI = -16.8 to -5.9 mmHg; $p=0.03$). In addition, central systolic BP showed a decrease at both morning (-13.3 mmHg; 95%CI = -21.6 to -5.0 mmHg; $p=0.002$) and afternoon session (-13.9 mmHg; 95%CI = -20.1 to -7.7 mmHg; $p<0.001$). No significant changes were observed regarding diastolic BP, respiratory, or heart rate variability parameters ($p>0.05$ for all).

Conclusions: In conclusion, acute aerobic exercise has no effect on obstructive sleep apnea, but it does lead to a reduction in Clinic and Central BP, regardless of time of day.

Acknowledgments:

The authors would like to thank the Fundação de Amparo a Ciência e Tecnologia do Estado de Pernambuco (FACEPE) – Brazil – for the financial support and the Graduate Program in Physical Education at the Federal University of Pernambuco (PPGEF/UFPE) and the PROCAPE Tertiary Hospital for their institutional support throughout the development of this study.

Effects of adaptive servo-ventilation on sleep architecture in patients with central sleep apnoea and treatment-emergent periodic limb movements in sleep

A. Lindner¹, C. Schindler¹, M. Arzt¹

¹University Hospital Regensburg, Regensburg, Germany

Introduction: In some patients with heart failure and reduced ejection fraction, adaptive servo-ventilation (ASV) is associated with an increase in periodic limb movements with arousal (PLMA). The aim of this study was to analyse the impact of ASV therapy on PLMA and to investigate the effects of treatment-emergent PLMA on sleep fragmentation and architecture in patients with central sleep apnoea (CSA).

Materials and methods: In 56 consecutive patients, three polysomnographies were retrospectively analysed (1. diagnostic, 2. on continuous positive airway pressure (CPAP), and 3. on ASV therapy). Patients with and without heart failure were included. Polysomnographic data were evaluated according to the 2017 criteria of the American Academy of Sleep Medicine. Treatment-emergent PLMA were defined as an increase in PLMA on ASV.

Results: Treatment-emergent PLMA under ASV occurred in 31 out of 56 patients (55%) (mean $\pm$ standard deviation: age 65 ± 12 years, body mass index 31 ± 5 kg/m², male 89%, heart failure 36%). The PLMA index increased significantly from the diagnostic night to the ASV night (median [25th; 75th percentile]: 5 [2; 7] vs. 7 [2; 16]/h, $p=0.018$), but not between the CPAP and ASV nights. From diagnostic to ASV PSG, patients without emergent PLMA showed a greater decrease in stage N1 sleep ($\Delta N1$: -13 [-25; -8]% vs. -5 [-16; 7]%, $p=0.015$) and greater increases in N3 and REM sleep ($\Delta N3$: 8 [1; 17]% vs. 3 [-8; 6]%, $p=0.003$; ΔREM 10 [4; 15]% vs. 5 [-3; 10]%, $p=0.043$) compared to patients with treatment-emergent PLMA. A further increase in N3 and REM sleep was observed from the CPAP night to the ASV night ($\Delta N3$: 4 [0; 12]% vs. 0 [-3; 6]%, $p=0.091$; ΔREM 3 [-1; 11]% vs. 0 [-6; 7]%, $p=0.057$ in patients without treatment-emergent PLMA compared to those with treatment-emergent PLMA).

Conclusions: Treatment-emergent PLMA on ASV affect more than half of patients with CSA, both with and without heart failure. ASV therapy significantly improves sleep architecture compared to the diagnostic night and showed an additional benefit over CPAP but only in patients without treatment-emergent PLMA. Treatment-emergent PLMA may be an important modifier for the effect of ASV on sleep architecture.

Effects of Continuous Positive Airway Pressure Treatment on Gut Microbiota and Metabolome in Obstructive Sleep Apnea Patients

L. Su¹

¹China-Japan Friendship Hospital, Beijing, China

Introduction: Obstructive sleep apnea (OSA) is associated with gut dysbiosis and metabolic disturbances. Continuous positive airway pressure (CPAP) therapy is the standard treatment for OSA, but its impact on the gut microbiome and metabolome remains underexplored. This study aimed to investigate the effects of 6 - month CPAP treatment on fecal microbiota and metabolites in OSA patients and their correlations with clinical parameters.

Materials and methods: Fecal samples from 14 OSA patients were collected at baseline and after 6 months of CPAP treatment (n=28 in total). 16S rRNA gene sequencing was performed to analyze the microbiota, while untargeted metabolomics (LC-MS) identified metabolic profiles. Alpha and beta diversity indices were calculated, and group differences were assessed using PERMANOVA. Linear discriminant analysis effect size (LEfSe) identified differentially abundant bacteria, and orthogonal partial least squares discriminant analysis (OPLS-DA) was used to detect metabolic changes.

Results: CPAP treatment significantly increased gut microbiota alpha diversity ($p<0.05$) and altered the community structure (PERMANOVA, $p<0.01$). LEfSe analysis revealed that *Lachnospira* was the most discriminantly abundant genus (LDA score >4.0), with higher relative abundance after CPAP treatment. Particularly, the baseline abundance of *Lachnospira* was positively correlated with AHI ($r = 0.68$, $p<0.01$). Untargeted metabolomics detected 326 metabolites, of which 58 showed significant differences between baseline and post - treatment groups ($p<0.05$). Pathway analysis highlighted alterations in amino acid metabolism, lipid oxidation, and short-chain fatty acid (SCFA) biosynthesis pathways. Although canonical SCFAs were not directly identified, increased *Lachnospira* abundance may indicate enhanced SCFA production, potentially contributing to improved gut health.

Conclusions: CPAP treatment modulates the gut microbiota and metabolome in OSA patients. The positive correlation between *Lachnospira* and AHI highlights its potential as a biomarker for OSA severity. Further studies are warranted to elucidate the causal relationship between *Lachnospira* - associated metabolic alterations and OSA pathophysiology.

Acknowledgments: This work was supported by the Elite Medical Professionals Project of China-Japan Friendship Hospital (NO.ZRJY2024-QMPY14) ; National High Level Hospital Clinical Research Funding. We thank the patients for their participation.

Effects of CPAP on Neuroimaging Biomarkers and Cognition in adult OSA: A Randomized Controlled Trial

S. Yin¹, H. Xu¹, J. Guan¹, H. Yi¹

¹Shanghai Jiao Tong University School of Medicine Affiliated Sixth People's Hospital, Shanghai, China

Introduction: Obstructive sleep apnea (OSA) is associated with cognitive impairment. The effects of continuous positive airway pressure (CPAP) on neuroimaging biomarkers and cognitive performance among middle-aged patients with OSA and normal cognition remain unclear. The aim of our study was to investigate the effects of CPAP therapy over 12 months on neuroimaging biomarkers and cognitive performance.

Materials and methods: In this multicenter, randomized clinical trial, we randomly assigned 148 participants with normal cognition and an apnea-hypopnea index ≥ 15 /hour into two groups: patients receiving CPAP with best supportive care (BSC); and patients receiving BSC alone. The primary endpoint was the MoCA score at 6 months after enrollment. The secondary endpoints were intranetwork functional connectivity (FC) of the default mode network (DMN) and cortical thickness assessed by functional and structural magnetic resonance imaging, other neuroimaging biomarkers and neurobehavioral tests.

Results: Between 2017 and 2021, 148 patients were recruited from 5 hospitals. Linear mixed models showed that there was no significant difference in MoCA scores at 6 months between the CPAP and BSC groups (difference, -0.04, 95% confidence interval (CI), -0.72 to 0.65, $P=0.91$). However, there were significant differences in the FC of DMN (difference, -13.73, 95% CI, -23.40 to -4.06, $P=0.01$) and cortical thickness (difference, -0.06, 95% CI, -0.10 to -0.01, $P=0.02$) between the CPAP and BSC groups at 6 month after treatment. No serious adverse events occurred.

Conclusions: CPAP improved cortical thickness and FC of DMN, suggesting that patients with OSA may recover from brain atrophic processes following CPAP treatment. However, no improvement in MoCA scores was found.

Effects of Obstructive Sleep Apnea Treatment on Blood Biomarkers of Alzheimer's Disease: A Prospective Clinical Study

Y.-T. Wang¹, L.-A. Lee², H.-Y. Li², M.-S. Tsai¹

¹Chiayi Chang Gung Memorial Hospital, Department of Otolaryngology - Head and Neck Surgery, Chiayi County, Taiwan, ²Linkou Chang Gung Memorial Hospital, Department of otolaryngology-Head and Neck Surgery, Taoyuan, Taiwan

Introduction: The relationship between obstructive sleep apnea (OSA) and Alzheimer's disease (AD) has attracted increasing attention. Intermittent hypoxia and sleep fragmentation associated with OSA may accelerate neurodegenerative changes and increase the risk of AD. This study aimed to investigate whether OSA treatment, particularly surgical intervention, influences blood biomarkers associated with AD and other neurodegenerative diseases.

Materials and methods: This three-year prospective, non-randomized study enrolled 73 patients with severe OSA (AHI ≥ 30) at Chiayi Chang Gung Memorial Hospital. Patients received either CPAP, sleep surgery, or conservative treatment, with an additional group of patients with dementia as a reference. Plasma levels of several biomarkers—including amyloid $\beta 1-40$ ($A\beta 1-40$), amyloid $\beta 1-42$ ($A\beta 1-42$), Tau protein, neurofilament light chain (NFL), and TDP-43—were measured at baseline and at 3, 6, and 9 months post-treatment using immunomagnetic reduction (IMR) technology.

Results: Significant reductions in the $A\beta 1-42/A\beta 1-40$ ratio were observed in both the CPAP and surgical groups at 6 and 9 months post-treatment ($p < 0.05$). In the surgical group, the ratio decreased by 18.4% at 6 months (95% CI: -30.7% to -6.0%) and 22.1% at 9 months (95% CI: -34.0% to -10.1%). In the CPAP group, reductions of 14.7% (95% CI: -28.6% to -0.9%) at 6 months and 19.5% (95% CI: -33.3% to -5.7%) at 9 months were noted. Additionally, the $A\beta 1-42$ concentration in the surgical group showed a significant decline of 17.9% at 9 months (95% CI: -29.8% to -6.0%). No statistically significant changes were observed in Tau, NFL, or TDP-43 across all groups and timepoints, suggesting limited short-term response.

Conclusions: This study indicates that effective treatment of OSA, especially through surgery, may help reduce blood-based biomarkers linked to Alzheimer's disease, particularly $A\beta 1-42$ and its ratio to $A\beta 1-40$. These findings suggest potential clinical value in AD prevention. However, changes in other neurodegenerative markers such as Tau and TDP-43 were not significant in the short term, highlighting the need for longer follow-up to elucidate long-term effects.

Effects of Reboxetine alone and in combination with Oxybutynin on quantitative electroencephalogram measures of alertness in obstructive sleep apnea

J.E.C. Tan¹, T.J. Altree^{2,3,4}, A.L. D'Rozario⁵, D.J. Eckert², A. Vakulin²

¹National University Health System, Singapore, Singapore, ²Flinders Health and Medical Research Institute/Adelaide Institute for Sleep Health, Adelaide, Australia, ³The Queen Elizabeth Hospital, Respiratory Medicine Unit, Woodville South, Australia, ⁴University of Adelaide, Adelaide Medical School, Adelaide, Australia, ⁵Woolcock Institute for Medical Research, Centre for Integrated Research and Understanding of Sleep, Sydney, Australia

Introduction: Obstructive sleep apnoea (OSA) often causes excessive daytime sleepiness, which can have major consequences on health, safety and productivity. Recent studies of noradrenergic and antimuscarinic agents to treat OSA have been promising, however subjective assessments of sleep quality and daytime sleepiness with these agents have shown inconsistent results. This study aimed to assess the effects of the noradrenergic agent reboxetine alone and in combination with the antimuscarinic oxybutynin on next-day alertness through objective assessment of quantitative electroencephalography (qEEG) power during resting wakefulness. We hypothesised that these agents would improve next day alertness through reduced wake EEG delta and theta power.

Materials and methods: 16 people with OSA from a double-blind, randomized, three-way crossover trial of 4mg reboxetine, placebo or 4mg reboxetine with 5mg oxybutynin completed morning and evening Karolinska Drowsiness Tests (KDT). Drug administration occurred after the evening KDT. Power spectral analysis of resting wake EEG data during eyes open and eyes closed conditions, and across the entire KDT was conducted with linear mixed models. EEG power in delta (0.5 – 4 Hz) and

theta (4 - 8 Hz) frequency ranges during the morning KDT tests were the primary alertness variables of interest.

Results: There was no significant main effect of treatment (Reboxetine vs placebo vs Reboxetine-Oxybutynin) on slow EEG frequencies during the morning KDT. There was no treatment by test time interaction, however there was a significant effect of testing time on EEG metrics. Delta EEG power during eyes open ($F[1, 54.3] = 35.9$; $p < 0.001$) and the entire KDT was significantly higher ($F[1, 58.8] = 32.5$; $p < 0.001$), during morning compared to the evening. Theta power was also higher during the eyes open condition in the morning ($F[1, 59.5] = 8.8$; $p = 0.004$).

Conclusions: Reboxetine with and without oxybutynin did not improve or impair morning alertness as measured by delta and theta EEG power during resting wakefulness. Despite the lack of improved alertness, these findings support the safety profile of these agents.

Effects of strength training on blood pressure and arterial stiffness in adults with moderate to severe obstructive sleep apnea: a randomized controlled trial

J.R. Almeida¹, J.L. Aguiar², E. dos Santos², D. Ferreira¹, E. Nazario¹, V. Lima¹, N. Silva¹, R. Pedrosa², B. Farah³, O. Lins-Filho¹

¹Federal University of Pernambuco, Physical Education, Recife, Brazil, ²University of Pernambuco, Health Sciences, Recife, Brazil, ³Federal Rural University of Pernambuco, Physical Education, Recife, Brazil

Introduction: Obstructive Sleep Apnea (OSA) is a sleep disorder characterized by partial (hypopnea) or complete (apnea) interruptions in airflow through the upper airways during sleep, leading to reduced oxygen saturation. OSA is closely associated with cardiovascular complications, such as elevated blood pressure (BP) and increased arterial stiffness—mainly driven by sleep fragmentation and intermittent hypoxia. Although continuous positive airway pressure (CPAP) is the first-line treatment for OSA, its effectiveness is often limited by poor adherence. Consequently, physical exercise—particularly strength training (ST)—has emerged as a promising non-pharmacological strategy to improve cardiovascular health in different populations. In individuals with OSA, ST may reduce body fat—especially in the cervical region—through exercise may alleviate upper airway narrowing. However, it remains unclear whether ST can reduce BP and arterial stiffness in adults with OSA. Thus, this randomized controlled trial aimed to evaluate the effects of an eight-week ST program on ambulatory, office, and central BP, as well as arterial stiffness, in adults with moderate to severe OSA.

Materials and methods: Participants aged 18 years or older with a confirmed diagnosis of moderate to severe OSA (based on the apnea-hypopnea index; AHI) were recruited from a sleep laboratory. Stratified by sex and OSA severity, participants were randomly assigned to either a ST group or a control group (CG). The ST group performed three sessions per week, consisting of eight resistance exercises, while the CG participated in two sessions per week of stretching exercises. OSA severity was assessed using full overnight polysomnography. Additionally, systolic and diastolic [BP (ambulatory, office, and central)] and arterial stiffness were evaluated. Generalized Estimating Equations (GEE) were used to analyze group-by-time interactions, with a significance level set at $p < 0.05$.

Results: A total of 26 adults (mean age: 54.6 ± 7.2 years; BMI: 36.1 ± 7.9 kg/m²; AHI: 52.2 ± 27.4 events/hour) were included. Significant group-by-time interactions were found for 24-hour systolic BP (CG: $+5.3 \pm 2.4$ mmHg vs. ST: -2.9 ± 3.2 mmHg; $p = 0.041$), daytime systolic BP (CG: $+4.6 \pm 2.5$ mmHg vs. ST: -2.8 ± 2.8 mmHg; $p = 0.050$), and daytime mean BP (CG: $+3.7 \pm 1.6$ mmHg vs. ST: -2.3 ± 2.0 mmHg; $p = 0.021$). In addition, a significant reduction was also observed in OSA severity (AHI CG: -3.5 ± 3.8 events/hour vs. ST: -20.9 ± 6.1 events/hour; $p = 0.015$). No significant differences were observed between groups regarding office and central BP, or arterial stiffness.

Conclusions: An eight-week strength training program significantly reduces ambulatory blood pressure and OSA severity in adults with moderate to severe OSA, even without changes in arterial stiffness. These findings support the role of strength training as a potential adjunct non-pharmacological intervention for cardiovascular risk management in this population.

Acknowledgments: The authors would like to thank the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES) – Brazil – for the financial support and the Graduate Program in Physical Education at the Federal University of Pernambuco (PPGEF/UFPE) for their institutional support throughout the development of this study.

Effects of Transvenous Phrenic Nerve Stimulation in patients diagnosed with Central Sleep Apnea and Atrial Fibrillation

S. Javaheri^{1,2,3}, S. McKane⁴, R. Germany⁴

¹Bethesda North Hospital, Division of Sleep and Pulmonary Medicine, Cincinnati, United States,

²University of Cincinnati, Cincinnati, United States, ³Ohio State University Medical School, Columbus, United States, ⁴ZOLL Respicardia, Inc., Minnetonka, United States

Introduction: The prevalence of atrial fibrillation (AF) in patients diagnosed with central sleep apnea (CSA) has not been systematically studied. The purpose of this retrospective analysis is to report the prevalence of AF in a cohort of patients diagnosed with CSA and describe the potential effects of treatment of CSA with phrenic nerve stimulation (PNS) on patient symptoms in this cohort.

Materials and methods: In the randomized, double-arm, parallel group design pivotal trial of the implantable **remedē** System to treat CSA, all patients were implanted with the transvenous PNS system. The PNS therapy was activated in the active arm after 1 month and remained off in the control arm for 6 months. PNS was then activated in the control group and all patients were followed up to 12 months. Two quality of life metrics, Patient Global Assessment (PGA) and Epworth Sleepiness Scale (ESS), were evaluated.

In-laboratory polysomnograms were obtained at baseline to determine eligibility and after 6 and 12 months to determine effectiveness. All sleep studies were blindly scored by a central core laboratory.

Results: Of 151 participants diagnosed with predominant CSA and enrolled in the study, 42% (64/151) had AF, including 32 in the active arm and 32 in the control arm. The apnea hypopnea index and central apnea index decreased significantly from medians of 49 and 20 events/hour of sleep at baseline to 21 and 1/hour of sleep after 6 months of PNS therapy (within group change from baseline $p < .001$ for each test), respectively. In parallel, changes in arousal index (48 at baseline vs. 25/hour of sleep at 6 months, $p < .001$) and percent of sleep time with oxygen saturation less than 90% (8% vs. 4%, $p = 0.071$) improved. There were no significant changes in sleep metrics in the control group. Marked or moderate improvement on the PGA was noted by 54% of the active participants compared to 11% in the control group (between group $p < .001$). Although most patients did not report excessive daytime sleepiness at baseline, the ESS improved by 2.0 points in the active arm ($p = 0.025$) while there was no change in the control arm. After 12 months of therapy, the active participants had sustained improvements in the sleep metrics, PGA and ESS endpoints. The control group, who had therapy activated after the 6-month visit, experienced similar improvements as well. Serious adverse events related to the device, procedure or therapy were reported by 8% (5/64) of participants through 12 months and all events resolved without sequela. The events included an implant site infection, impending pocket erosion, lead displacement, feeling stimulation in area remote from diaphragm, and a concomitant device interaction.

Conclusions: Atrial fibrillation was highly prevalent in this cohort of patients diagnosed with CSA. Compared to the control arm, after 6 months of therapy with PNS, sleep metrics, quality of life, and daytime sleepiness improved significantly in this retrospective subgroup analysis. Similar improvements were observed in the control group after 6 months of active therapy and the safety profile was acceptable in both groups.

Efficacy of Line Official Account on Adherence of PAP therapy in Obstructive Sleep Apnea Patients

V. Lertritdech¹, P. Chindamporn¹

¹Phramongkutklao Hospital, Division of Pulmonary and Critical Care Medicine, Department of Internal Medicine, Bangkok, Thailand

Introduction: Positive airway pressure (PAP) therapy is the mainstay treatment for obstructive sleep apnea (OSA), however, the compliance in the use of PAP machine is consistently low. Previous study

has shown that the benefits from using a PAP machine if it is used adequately and continuously. Good compliance is indicated by the patient uses the machine at least 70% of the total number of nights and least 4 hours/night. We study efficacy of Line official account on PAP adherence among OSA patients in Thailand.

Materials and methods: A randomized study was conducted in obstructive sleep apnea patients indicated in PAP therapy at outpatient in Phramongkutklao hospital. They were divided into two groups. The use of Line official account was added in the first group. The second group was treated with standard treatment. Both were followed up at the fourth week of treatment. Patients diagnosed with obstructive sleep apnea who received treatment at Phramongkutklao Hospital from March 2023 to February 2024. Inclusion Criteria: 1. Patients diagnosed with obstructive sleep apnea based on criteria for positive airway pressure machine usage 2. Patients aged between 20 and 80 years old. 3. Possession of a mobile phone capable of using the Line application. Exclusion Criteria: 1. Central sleep apnea . 2. Patients with contraindications for PAP machine usage.

Results: A total of 58 patients were enrolled, There was no difference between the basic characteristics of the two groups: mean age (51.14 ± 14.43 vs 51.86 ± 14.32 , $p = 0.849$), male (58.6% vs 62.1%, $p = 0.788$), neck circumference (38.61 ± 4.24 vs 40.84 ± 5.29 , $p = 0.082$), epworth sleepiness scale (9.24 ± 4.71 vs 8.41 ± 4.84 , $p = 0.512$). The average apnea-hypopnea index did not differ between the two groups. The Line official account group had less AHI than the standard treatment group (49.4 ± 26.2 vs 54.9 ± 33.7 ($p = 0.496$)), however both ranged in severe OSA. In addition, CPAP use > 4 hr/night was more than 70% of the use in the Line official account group 62.21%, compared to the standard treatment group 48.3% ($p = 0.291$).

At fourth-week follow-up, there was no significant different in % CPAP use > 4 hr/night between the Line official account group (70.73 ± 28.82) and the standard treatment group (61.5 ± 30.47), $p = 0.241$.

Conclusions: The use of Line official account did not significant differ from standard treatment in improving adherence of PAP therapy of patients with obstructive sleep apnea.

Acknowledgments: We thank the involved patients and their families for their contribution to the study.

Efficacy of Novel Oral Appliance and Novel Oral Positive Expiratory Pressure Accessory at reducing sleep apnea-specific hypoxic burden, a metric predictive of cardiovascular morbidity and mortality

S. Sharma¹, H. Reiter¹, A. Sharma¹, G. Abraham², H. Garg³, A. Conflitti¹

¹Centre for Sleep and Chronobiology, Toronto, Canada, ²DentCare Dental Lab Pvt Ltd., Kerala, India,

³Sleep Care Solutions, Southport, Australia

Introduction: Evidence suggests that moderate to severe OSA patients have increased risk of major adverse cardiovascular events (MACE; composite of coronary heart disease, heart failure, stroke, or cardiovascular mortality) and that sleep apnea-specific hypoxic burden (SASHB) is associated with increased risk of cardiovascular disease mortality. SASHB appears to be more predictive of OSA-related risk than AHI but has not been extensively studied as a measure of therapeutic efficacy in patients treated with oral appliance therapy.

O2Vent Optima is a novel oral appliance that incorporates both mandibular advancement to reduce pharyngeal collapsibility and an air channel that allows airflow through the device to circumvent nasopharyngeal obstruction. The ExVent is an optional accessory to the novel oral appliance and provides oral Expiratory Positive Airway Pressure (EPAP) to support upper airway by passive dilatation of the airway, which reduces flow limitation.

This is the first assessment of combination therapy with novel oral appliance combined with an Oral EPAP accessory to reduce SASHB, rather than AHI, to define therapeutic efficacy.

Materials and methods: Data obtained from a clinical study to assess efficacy of the combination therapy with novel mandibular advancement device and novel oral EPAP accessory in the treatment of OSA were analyzed. Forty-four study participants with OSA (moderate = 28, severe = 16) completed a diagnostic PSG study to obtain the baseline AHI and confirm a diagnosis of moderate to severe OSA. Subjects used the combination therapy at home for >3 months and logged usage hours. Subsequent to the home use, subjects underwent an in-lab PSG sleep night while using the combination therapy.

Results: Treatment with the combination therapy with novel mandibular advancement device and novel oral EPAP accessory reduced AHI from 28.5 ± 6.4 /hr. to 12.9 ± 2.7 /hr. ($p < 0.001$) and SASHB from 82.3 ± 31.1 %min/hr. to 16.7 ± 9.4 %min/hr. ($p < 0.001$). Average reduction in AHI with the combination therapy was 75%. Using an AHI-based definition of therapeutic efficacy (AHI < 10 /hr.), 81% of participants achieved efficacy with the combination therapy. However, when the risk based SASHB definition of therapeutic efficacy (SASHB < 53 %min/h) was utilized, therapeutic efficacy with combination therapy with novel mandibular advancement device and novel oral EPAP accessory increased to 92%.

Conclusions: Therapeutic efficacy with combination therapy with novel mandibular advancement device and novel oral EPAP accessory significantly improved to 92% by SASHB criteria as compared to 75% by AHI reduction criteria. Our study demonstrated that the use of AHI measurement would have misclassified a substantial number of individuals who responded to the combination therapy with novel mandibular advancement device and novel oral EPAP accessory based on more meaningful SASHB reduction of OSA-related risk.

Efficient and Effective Telemonitoring System for CPAP Adherence Using Digital Transformation

H. Nakamura¹, K. Nakamura¹, K. Tohyama¹, T. Kinzyou¹, C. Takara¹, C. Iseki¹, K. Iseki¹

¹HSR Nakamura clinic, Sleep Respiratory Center, Urasoe, Japan

Introduction: In Japan, the national Health Insurance System began covering CPAP therapy with mandatory monthly clinic visits in 1998, later permitting visits once every two months in 2013 and every three months during the COVID-19 pandemic in 2022. These regulatory adjustments resulted in a substantial increase in CPAP users. Previously, our clinic depended predominantly on manual methods to collect adherence data from multiple providers, necessitating improvements in monitoring efficiency and effectiveness. To address these challenges, we developed the Remote Monitoring Network for CPAP Adherence. Additionally, we conducted a comparative analysis of CPAP usage between individuals demonstrating good and poor adherence before and after three months of enrollment in tele-monitoring to assess its impact.

Materials and methods: The Remote Monitoring Network for CPAP Adherence utilizes 3G connectivity (SIM) to integrate adherence data from CPAP devices into individual provider cloud servers. This data is efficiently transferred to medical charts using Application Programming Interfaces (APIs) and Robotic Process Automation (RPA). It enables a seamless flow of information and remote adjustment of CPAP pressure without in-person visits.

For analysis, patients were classified as good users ($\geq 70\%$ monthly CPAP use) or poor users ($< 70\%$). In line with insurance guidelines, physicians contacted poor users monthly to offer personalized support and address barriers such as mask discomfort, nasal congestion, and psychological resistance.

To minimize manufacturer-related bias, that could affect data collection and interpretation, our analysis focused exclusively on 1,589 Philips CPAP users from our total patient population. Of these patients 1,314 (82%) were categorized as good users and 273 (18%) as poor users. For assessment of the tele-monitoring impact, we selected random samples, comprising 473 good users and 142 poor users. These samples were not adjusted for gender and age, to maintain real-world representation in our patient population. We evaluated the adherence changes before and after three months implementation of tele-monitoring.

Results: Between June 2020 and April 2025, 67.2% (2,909 out of 4,330) of CPAP users transitioned to remote monitoring, exhibiting a consistent upward trajectory. Following tele-monitoring implementation, adherence remained stable among good users, with 83.5% (395 out of 473) maintaining their status and 16.5% (78 users) shifting to poor adherence. Among poor users, 63.4% (90 out of 142) sustained low adherence, while 36.6% (52 users) improved to good adherence.

Conclusions: Remote tele-monitoring for CPAP adherence is both feasible and effective, reducing clinic visit frequency and related costs, enhancing time management and operational efficiency for patients and healthcare providers alike with improving productivity. Disclosure of APIs and RPAs by each company is essential to the success of this initiative. The predominance of good users in our cohort may reflect the effectiveness of our clinical protocol.

Tele-monitoring did not notably affect patient attitudes toward CPAP adherence in this study. Defining adherence and motivating low-use patients remain ongoing issues, and integrating Digital

Transformation (DX) with Artificial General Intelligence (AGI) is needed to enhance care quality and efficiency.

Acknowledgments: We thank DX section members especially Tetsuyoshi Ishimine and Hiroto Isagawa for their work on this project, and Kumi Wada and Kumiko Kudo for their invaluable support and insights.

Electroencephalographic response to respiratory events is associated with all-cause mortality in obstructive sleep apnea

M. Hajipour¹, N. Ayas², M. Mehrjoo³, S. Redline¹, A. Azarbarzin¹

¹Harvard University, Brigham and Women's Hospital, Department of Medicine, Boston, United States,

²University of British Columbia, Department of Medicine, Vancouver, Canada, ³University of Manitoba, Computer Engineering, Winnipeg, Canada

Introduction: Obstructive sleep apnea (OSA)-associated hypoxic burden (HB) has been shown to predict increased mortality. In those with increased HB, there is variability in electroencephalographic (EEG) response to respiratory events, with preliminary studies suggesting worse outcomes in those with a blunted EEG response. We hypothesized that those with a high HB but a blunted EEG response, are at increased risk of all-cause mortality when compared to: 1) those with low HB, and 2) those with high HB and high EEG response.

Materials and methods: The sample included participants in the Sleep Heart Health Study who underwent baseline polysomnography (PSG) with follow-up survival data. HB was quantified as the sum area under the event-related desaturation curve per hour of sleep. EEG responses to respiratory events were quantified by calculating the EEG power ratio (post-event power / pre-event power)) across frequency ranges (i.e., delta, theta, alpha, beta and gamma). The total event-related EEG response was defined as the sum of power ratios across all frequency ranges. Finally, the Brain Response to Event (BReTE) was defined as the mean within individual event-related EEG responses. We examined the risk of all-cause mortality in those with high HB (HB>60%min/h) (a previously defined threshold) and levels of BReTE (per quartiles) versus those with low HB (HB≤60%min/h). Finally, within the high HB subgroups, we compared the risk of all-cause mortality in those with lower quartiles of BReTE versus the highest quartile. Cox regression models were used to estimate the hazard ratios, controlling for relevant confounders including age, sex, race, BMI, baseline EEG, hypertension, diabetes, and smoking status.

Results: The sample (n=5592) had a median [interquartile range] age=63[55, 72] years and a mean ±standard deviation (SD) of follow-up time=11±3.1 years. Cox regression models revealed the highest hazard ratio for high HB/lowest quartile of BReTE vs. low HB (HR=1.44 [1.18,1.76]; p<0.001) with a dose-response relationship for other quartiles. Within the high HB group, the lowest quartile of BReTE exhibited a significantly higher mortality hazard ratio than the highest quartile of BReTE.

Conclusions: Within individuals with high OSA-related hypoxemia, the lowest EEG response was associated with an increased risk of all-cause mortality. Future studies are needed to understand whether blunted response to hypoxemia is a risk marker of accelerated aging or adaptation to untreated OSA, or is a direct risk factor for increased mortality.

Elevated level of pro-Brain Natriuretic peptide (pro-BNP) is associated with History of Major Adverse Cardiovascular Events (MACE) in subjects with Obstructive Sleep Apnea

J. Sunderram¹, F. Romero Castillo², H. Romero Castillo², S.S. Ravi², K. Martillo², A. De Resende³, A. Legard³, A.E. Mullins², M. McLaughlin², R.E. de la Hoz², S.-E. Lu⁴, R.-C. Wang⁴, I. Udasin³, D.M. Rapoport², I. Ayappa²

¹Rutgers Robert Wood Johnson Medical School, Medicine, New Brunswick, United States, ²Icahn School of Medicine at Mt. Sinai, Medicine, New York, United States, ³Rutgers University, Environmental and Occupational Health Institute, Piscataway, United States, ⁴Rutgers University, School of Public Health, Piscataway, United States

Introduction: Patients with untreated obstructive sleep apnea (OSA) are at increased risk for major adverse cardiovascular events (MACE). Additionally, sleep disturbance in non-OSA subjects and certain

clinical symptoms of OSA have also been associated with a higher risk for MACE. Finally, multiple biomarkers have been shown to be associated with increased risk for cardiovascular (CV) events. However, the association between OSA status, biomarker profile, sleep symptoms and MACE has not been carefully delineated. In this preliminary analysis of the ongoing WTCCOMISA study, we examined the association between sleep symptoms, OSA status, biomarkers of CV risk (highly sensitive c-Reactive Protein (hs-cRP), Troponin I and pro-BNP) and MACE.

Materials and methods: 172 subjects enrolled in the ongoing WTCCOMISA study were studied. OSA status was determined either by a prior history or was confirmed to be negative by home sleep testing. Sleep symptoms were determined on the basis of the Epworth Sleepiness Score (ESS) and the Insomnia Severity Index (ISI) and patients classified as: Asymptomatic (ESS<10, ISI<8), Sleepy (ESS>10) or Disturbed sleep (ISI>8). MACE (obtained by history) was defined as any of the following: Stroke, arrhythmia, coronary artery disease, cardiac procedure, myocardial infarction, congestive heart failure. Comorbid conditions, perceived stress levels, diet and physical activity, smoking status and medications as well as hs-CRP, Troponin I and pro-BNP were obtained from all subjects. Biomarker values were log-transformed as they were significantly right skewed. Data were analyzed using logistic and linear regression analyses, with adjustment for age, sex, BMI, cardiac risk factors and medications, where appropriate.

Results: 97 subjects without OSA (mean age: 62, 92.5% M, mean BMI: 30.7) and 75 subjects with untreated OSA were enrolled (mean age:61, 81.2% M, man BMI: 27.5). The proportion of asymptomatic, sleepy and disturbed sleep in OSA versus non-OSA subjects was 45.4% versus 52%, 23.7% versus 13.3% and 30.9% versus 34.7% . A history of MACE was present in 11.6% (20/172). No significant differences were present in subjects with and without OSA in history of MACE (12.3% versus 10.7%). No significant differences and no association was noted with a history of MACE in levels of hs-CRP and Troponin I in all subjects with or without OSA. In subjects with OSA and a history of MACE, adjusting for multiple covariates, log pro-BNP was significantly higher compared to non-OSA (mean (CI) 4.78 (4.27-5.30)versus 3.67 (3.14-4.20) or subjects with or without OSA without MACE. Log proBNP was significantly higher in asymptomatic subjects with OSA compared to symptomatic subjects (disturbed sleep or sleepy), and compared to those without OSA adjusting for multiple covariates.

Conclusions: Preliminary data from our ongoing WTC COMISA study suggests that elevated levels of novel cardiovascular biomarkers, such as pro-BNP is associated with a history of MACE in those with OSA without sleep symptoms.

Elevated levels of proBNP may reflect cardiac dysfunction in OSA subjects with a history of MACE. Elevated pro-BNP in asymptomatic OSA subjects, may serve as a marker of cardiac dysfunction.

Endoscopic titration technique of mandibular advancement device treatment for obstructive sleep apnea

K. Okuno^{1,2}, K. Wada², M. Kono³, L. Wang², R. Kobuchi², A. Masago², A. Himejima³, K. Takahashi²

¹Osaka Dental University, Center for Dental Sleep Medicine, Osaka-city, Japan, ²Osaka Dental University, Department of Geriatric Dentistry, Osaka-city, Japan, ³Osaka Dental University, First Department of Oral and Maxillofacial Surgery, Osaka-city, Japan

Introduction: Mandibular advancement device (MAD) therapy is a treatment option for patients with obstructive sleep apnea (OSA). The treatment mechanism for MAD is to advance the mandible in order to reduce the collapsibility of the upper airway during sleep. Protrusion of the mandible with an MAD is the most important factor in achieving maximum treatment effects for OSA. Some studies have reported that more protrusion of the mandible leads to larger improvements in OSA. However, excessive mandibular protrusion leads to side effects, including temporomandibular joint, muscle, and tooth problems. This suggests that the degree of mandible protrusion needs to be titrated for each patient. Our group has reported that an increase of the airway volume at the velopharynx with mandibular advancement as shown by endoscopy is key to successful MAD therapy. This study presented the mandibular titration technique for MAD to effectively treat OSA by using endoscopy to evaluate the change in the airway at the velopharynx with simultaneous recording of mandibular position.

Materials and methods: This titration technique was applied to 83 consecutive OSA patients (Age=53.7±13.0 years old, BMI=25.4±5.2 kg/m², AHI=28.3±16.9/h) and the percentage of maximum

forward movement of the determined mandibular position was calculated. The titration technique using endoscopy is as follows: (1) Spray topical anesthesia (4% lignocaine) into one nasal passage. With the patient in the supine position in the dental chair, insert the flexible nasoendoscope (FNL-10RP3; Pentax) into the nostril to the velopharynx. (2) Position the occlusal registration tool (George gauge; Great Lakes Orthodontics Ltd) intraorally. This tool allows the degree of mandible protrusion to be measured and records the mandibular position with a millimeter indicator. The operator can preset the moveable incisal notches so that when the patient occludes into them, the mandible is automatically brought to the desired point on the protrusive path. (3) With the chin in a rest position, observe the cross-sectional area at the velopharynx with endoscopy. (4) Protrude the mandible from the rest position until the airway at the velopharynx widens and record the George gauge measurement.

Results: The percentage of mandibular position determined by this titration technique was $69.8 \pm 10.4\%$. The patients were divided into three groups based on the value of the percentage of mandibular forward movement ($<66.6\%$, $66.6\text{--}75\%$, $>75\%$) and compared for age, BMI, and AHI. There were no significant differences among the three groups in age and BMI, while AHI was significantly different among the three groups ($\text{AHI} = 21.4 \pm 10.3/\text{h}$ in $<66.6\%$, $30.0 \pm 18.3/\text{h}$ in $66.6\text{--}75\%$, $37.2 \pm 18.2/\text{h}$ in $>75\%$; $p = 0.0076$).

Conclusions: It was considered important to titrate the mandibular position for each patient using an objective measure of endoscopic airway assessment.

Endothelial-dependent vasodilation is associated with sleep apnea-specific blood pressure variations in patients with severe OSA

N. Ding¹, J. Xu²

¹The First Affiliated Hospital with Nanjing Medical University, Department of Respiratory and Critical Care Medicine, Nanjing, China, ²The Affiliated Huaian No.1 People's Hospital of Nanjing Medical University, Department of Respiratory and Critical Care Medicine, Huai'an, China

Introduction: Obstructive sleep apnea (OSA) can lead to frequent acute blood pressure (BP) variations that may advance organ damage. However, a subset of patients with OSA can maintain nocturnal BP homeostasis. Data to disclose the underlying mechanisms for different clinical nocturnal BP phenotypes in patients with OSA are limited. We investigate the association between OSA event-triggered BP variation profiles and vascular function, including endothelial/smooth muscle vasodilation function and sympathetic activity in a cohort of patients with severe OSA without comorbidities.

Materials and methods: Brachial artery flow-mediated dilation (FMD) and nitroglycerine-induced vasodilation (NID) were measured to assess endothelial and smooth muscle function, respectively. Event-triggered BP variation parameters, including BP surges, nocturnal BP fluctuations (NBPFs), NBPF/apnea-hypopnea index (AHI), and BP peaks and valleys were collected. Comparisons between subgroups, stepwise multiple regression, and ordinal logistic regression analysis were used to explore factors associated with event-triggered BP variation.

Results: A total of 177 patients with severe OSA and without comorbidities were studied. In patients with normal endothelial function ($\text{FMD} \geq 10$), NBPFs, NBPF/AHI, and BP surges were significantly associated with FMD (all P s < 0.05). The relationships between nocturnal BP variations and vasodilation function were not significant in patients with impaired endothelial function ($\text{FMD} < 10$). However, sympathetic activity markers were independently associated with BP variations in both subgroups (all P s < 0.05). In ordinal logistic regression analysis, severe nocturnal BP variation in the normal endothelial function group was associated with increased sympathetic activity and higher FMD and drowsiness. In the impaired endothelial function group, only elevated sympathetic tone was associated with an increased risk of high BP variation.

Conclusions: This study has discovered that sympathetic activity is independently associated with OSA event-triggered BP variations regardless of vasodilation function. In patients with normal endothelial function, a high sleep apnea-specific BP variation may be partly associated with endothelial-dependent dilation.

Enhancement of slow wave sleep after bariatric surgery: OSA remission may not be the sole benefit after weight loss

D. NEU^{1,2,3,4}, F. OTETE DJAMBA^{1,5,6}

¹CHIREC Delta Hospital, Center for the Study of Sleep Disorders, Brussels, Belgium, ²Erasme Academic Hospital Université Libre de Bruxelles, Sleep Laboratory Department of Neurology, Brussels, Belgium, ³Université Libre de Bruxelles, Neurosciences Institute, Brussels, Belgium, ⁴Centre Hospitalier Le Domaine ULB, Braine L'Alleud, Belgium, ⁵University of Bern, Faculty of Medicine, Bern, Switzerland, ⁶Università della Svizzera Italiana, Faculty of Biomedical Sciences, Luganoswi, Switzerland

Introduction: Despite diverse etiopathogenic components, the prevalence of obstructive sleep apnea (OSA) ordinarily increases concomitantly with the increased prevalence of obesity. Altered sleep has been documented in both OSA and in obese patients without OSA. Possible OSA remission has previously been documented after substantial weight loss in obese OSA patients. Former evidence further suggests that bariatric surgery is often more effective than non-surgical treatments in severe or morbid obesity, particularly in case of prior failure of alternative weight reduction attempts. Whether a body mass index (BMI) reduction, following bariatric surgery, may also exhibit effects on sleep that are not necessarily related to OSA, remains yet to be determined.

Materials and methods: Within the framework of a cross-sectional study, we recruited 35 obese patients (24 females and 11 males ; mean age of 46.5), all with a BMI above 35kg/m². All included patients displayed clinically significant OSA with an obstructive apnea-hypopnea index (OAHI) >15/h. All patients underwent bariatric surgery by means of a gastric bypass (GBP). Full polysomnographies (PSG) were carried out at baseline (before GBP) and performed after bariatric surgery (at least 6 months after GBP). BMI, sleepiness levels (assessed with the Epworth Sleepiness Scale) and sleep variables (PSG) were compared between baseline (prior to surgery) and one year later (>6 months after GBP). Associations between variables were investigated exploratively.

Results: Expectedly, mean BMI decreased significantly from 39.7 to 26.7 (p<.005) after GBP. Concomitantly, both OAHI (from 46.7 to 8.6) and oxygen desaturation index (from 32.2 to 6.8) also dropped significantly after the surgical intervention (all p<.005). While improving numerically, after one year, sleepiness levels did not show statistically significant variations in our sample (Epworth scores reducing from 12.2 to 8.4). While total recorded sleep time and REM sleep durations did not significantly differ between both PSG measurements, sleep fragmentation and sleep efficiency significantly improved after GBP (p<.05). In addition, slow wave sleep (absolute duration and relative percentage of sleep time) significantly increased after GBP (p<.005).

Conclusions: Following GBP, the post-surgical weight loss, led to relative remission of OSA in most patients. Conversely, sleep fragmentation and efficiency also significantly improved in our sample. In addition, slow wave sleep durations expanded significantly within similar total sleep times. Hence, along with obvious metabolic upsides and improvements of ventilatory mechanics, our results also suggest that potential health benefits of surgically induced weight loss, may imply sleep-related neurological improvements way beyond respiratory parameters.

Eupneic Submental EMG as a Marker of OSA Severity: KISS & MrOS Cohorts

H. Lee^{1,2}, H.K. Ahn^{1,2}, H.K. Lee^{1,2}, Y. Na^{1,2}, Y. Lee^{1,2}, S. Lim^{1,2}, H.-W. Shin^{1,2,3,4}

¹Seoul National University College of Medicine, Obstructive Upper airway Research Laboratory, Department of Pharmacology, Seoul, Korea, Republic of, ²Seoul National University College of Medicine, Department of Biomedical Sciences, Seoul, Korea, Republic of, ³Seoul National University Hospital, Department of Otorhinolaryngology-Head and Neck Surgery, Seoul, Korea, Republic of, ⁴OUaR LaB Inc, Seoul, Korea, Republic of

Introduction: Obstructive sleep apnea (OSA) is conventionally diagnosed and graded by the apnea-hypopnea index (AHI), yet event counts provide limited information on how the upper airway is stabilized during normal breathing. Submental surface electromyography (sEMG), routinely recorded during polysomnography but rarely quantified, may serve as a bedside marker of compensatory upper-airway muscle tone. We hypothesized that as pharyngeal collapsibility increases, median submental sEMG during event-free breathing rises monotonically with OSA severity. We tested this hypothesis in two large community cohorts (KISS and MrOS).

Materials and methods: We analyzed overnight polysomnography from 7,523 adults in the Korea Image-based Sleep Study (KISS) and 2,831 adults in the Osteoporotic Fractures in Men Study (MrOS).

sEMG signals were extracted during eupneic periods, defined as respiratory event- and arousal-free segments in supine or lateral positions across sleep stages (Wake, N1, N2, N3, REM). Signals were segmented into non-overlapping 1-second windows, and the mean absolute value (MAV) was computed. For each subject and stage, the median MAV across all windows was taken as the representative sEMG activity.

Results: Subjects were categorized into five OSA severity groups based on the apnea-hypopnea index (AHI): normal, mild, moderate, severe, and very severe (AHI ≥ 60). Eupneic submental EMG activity increased progressively with OSA severity, from 1.19 μV [1.00–1.56] in the normal group to 2.93 μV [2.09–4.10] in the very severe group in KISS, and from 1.25 μV [1.01–1.91] to 2.48 μV [1.65–3.50] in MrOS. When stratified by sleep stage, the same trend was observed, most prominently during N2 sleep (KISS: 1.30 μV [1.08–1.77] in normal vs. 3.26 μV [2.33–4.53] in very severe; MrOS: 1.41 μV [1.11–2.13] vs. 2.75 μV [1.84–3.85]). Similar stage-dependent increases were also noted in N1, N3, and REM sleep.

Conclusions: In conclusion, sEMG activity increased with OSA severity, reflecting elevated global muscle tone and possibly upper airway muscle tone. Notably, this pattern persisted even when stratified by sleep stage. The presence of heightened activity during eupneic, event-free periods suggests adaptive compensatory mechanisms in OSA patients. These findings highlight submental EMG as a promising non-invasive biomarker for disease severity and pathophysiology.

Acknowledgments: This research was supported partly by AI-Bio Research Grant through Seoul National University.

Evaluating Patient-Reported Outcomes and PAP Adherence in Obstructive Sleep Apnea Treatment Using an Interactive Care Plan

B. Colaco¹, W. Fan², J. Grimm³, M. Holets⁴, S. Harper⁵, T. Morgenthaler⁶

¹Mayo Clinic, Sleep Medicine, Jacksonville, United States, ²Mayo Clinic, Biostatistics, Rochester, United States, ³Mayo Clinic, Biostatistics, Rochester, United States, ⁴Mayo Clinic, Epidemiology, Rochester, United States, ⁵Mayo Clinic, Health Administration: Artificial Intelligence and Biomedical informatics, Rochester, United States, ⁶Mayo Clinic, Sleep Medicine, Rochester, United States

Introduction: Patient-reported outcome measures (PROMs) are underutilized in obstructive sleep apnea (OSA) management, often overshadowed by compliance with positive airway pressure (PAP) therapy and residual apnea-hypopnea index (AHI). This study investigates the utility of the PROMIS-10 score (physical and mental domains) and the Epworth Sleepiness Scale (ESS) in assessing health outcomes before and after PAP therapy initiation. An interactive care plan (ICP) that interacts with our electronic health record and delivered via an internet portal was used to deliver education, motivation, and to monitor patient adherence and health outcomes.

Materials and methods: This retrospective analysis included 181 OSA patients enrolled in an ICP upon PAP therapy initiation. The ICP provided educational resources, tracked task completion, and enabled clinician intervention. PAP adherence was defined as ≥ 4 hours of use on $\geq 70\%$ of nights over 30 days, measured using PAP device data. The study assessed adherence during an initial 30-day period, compared baseline and post-PAP therapy PROMIS-10 and ESS scores with paired t-tests, and used linear regression to evaluate potential associations of compliance data with changes in PROMIS-10 scores.

Results: 181 patients diagnosed with OSA and enrolled in the ICP were identified. A total of 123 had ESS data and 100 had PROMIS-10 scores, of which 78 had complete compliance data and PROMIS-10 scores. The mean compliance rate for the initial 30-day period was 27.1 out of 30 days (SD = 4.3). The average 4-hour compliance rate was 79.8% (SD = 22.2%), with an average of 6.2 hours of PAP use per night (SD = 1.5 hours). There was no significant change in the PROMIS 10 scores following initiation of PAP therapy (physical: $p = 0.46$ and mental: $p = 0.43$), whereas the ESS significantly decreased ($p = 0.02$). Neither AHI, nor 4-hour compliance percentage were significantly associated with a change in physical or mental PROMIS-10 scores after adjusting for the first PROMIS-10 score and days between PROMIS-10 scores (respectively, AHI - physical: $p=0.84$ and mental: $p=0.34$, 4-hour compliance percentage physical: $p=0.55$ and mental: $p=0.75$).

Conclusions: Despite high PAP adherence rates, further improvements in patient engagement may be necessary. The ICP was valuable for patient education and digital interaction, promoting data collection and supporting adherence. However, the lack of significant association between adherence and

improvements in PROMIS-10 scores suggests the need for additional or alternative metrics to assess the broader benefits of PAP therapy. It is also likely that focusing only on airway-directed therapy may not address all symptoms and manifestations of OSA. Tailored education, multi-modal treatments, and proactive follow-up are critical for optimizing treatment outcomes and long-term disease management. Future studies should incorporate control groups to evaluate the impact of structured support on adherence and treatment effectiveness, focusing on metrics that capture a broader spectrum of health improvements.

Exploring the Intensity of Arousals in Patients with Obstructive Sleep Apnea: Based on Odds Ratio Product

Y. Shi^{1,2}, X. Gao^{1,2}, J. Liao^{1,2}, Y. Li^{1,2}, D. Han^{1,2}

¹Beijing Tongren Hospital, Capital Medical University, Sleep Medical Center, Beijing, China, ²Capital Medical University, Key Laboratory of Otolaryngology Head and Neck Surgery, Ministry of Education, Beijing, China

Introduction: Obstructive sleep apnea (OSA) is characterized by recurrent upper airway obstruction during sleep, resulting in frequent arousals and sleep fragmentation. However, traditional frequency-based metrics are inadequate to precisely quantify the intensity of arousal events. The Odds Ratio Product (ORP), a validated electroencephalographic marker that provides a continuous measure of sleep depth, offers a novel approach for quantifying arousal intensity in OSA patients. This study aims to establish the feasibility and clinical utility of ORP-derived arousal intensity and to explore its associations with respiratory event characteristics and subjective sleepiness.

Materials and methods: We retrospectively analyzed data from 1,057 untreated OSA patients (median age 52.0 years; BMI 30.74 [IQR 27.17–36.19] kg/m²; AHI 34.40 [20.20–54.30]/h) from the APPLES cohort. EEG (C3/C4) power spectra in the δ , θ , α - σ , and β frequency bands were processed every 3 seconds to compute ORP values across the sleep period. Arousal intensity was quantified for each annotated arousal event using the positive area deviation (PAD) of the ORP curve compared to the pre-arousal baseline. Associations of arousal intensity with respiratory event characteristics (type, duration), sleep stage, and inter-individual variability were analyzed using mixed-effects models. The relationship between baseline (subject-level) arousal intensity and subjective daytime sleepiness (Epworth Sleepiness Scale, ESS) was evaluated with multivariate regression.

Results: A total of 258,121 arousal events were identified, of which 171,346 were linked to respiratory events. The mean arousal intensity was 2.25 ± 3.28 , exhibiting significant inter-individual variability ($\eta^2 = 0.257$, $p < 0.001$). Arousal intensity increased progressively with the duration of preceding respiratory events (obstructive apnea: ORP +0.84; mixed apnea: +0.78; central apnea: +0.70; all $p < 0.001$). All apnea subtypes induced significantly stronger arousals than hypopneas. Central and mixed apneas were associated with more pronounced and variable arousal responses than obstructive events. Deepening sleep stage significantly attenuated arousal intensity ($\beta = -0.765$, $p < 0.001$). Baseline arousal intensity at the individual level was independently associated with increased daytime sleepiness ($\beta = 0.072$, $p = 0.023$, adjusted for confounders). The mixed effects explained 16.9% of the variance in arousal intensity.

Conclusions: ORP-derived arousal intensity offers a robust and objective biomarker for the quantification of sleep fragmentation in OSA. Arousal intensity is closely governed by respiratory event type and duration, sleep stage, and inter-individual neurophysiological traits. Furthermore, heightened baseline arousal intensity independently predicts greater subjective sleepiness, underscoring its clinical significance. These findings support the use of ORP as a quantitative tool in sleep research and facilitate a deeper understanding of the mechanistic links between arousal dynamics, sleep quality, and neurocognitive outcomes in OSA.

Exploring the Synergistic Impact of Obstructive Sleep Apnea and Mental Health Conditions on Cardiometabolic Risk: Insights from the Canadian Longitudinal Study on Aging

T. Kendzerska¹, R. Mallick², W. Li², R. Robillard³, V. Taler³, C. Webber², J.G. Fiedorowicz¹, T.T. Dang-Vu⁴, P. Tanuseputro⁵

¹The Ottawa Hospital Research Institute / University of Ottawa, Ottawa, Canada, ²The Ottawa Hospital Research Institute, Ottawa, Canada, ³University of Ottawa, Ottawa, Canada, ⁴Concordia University / Centre de recherche de l'Institut universitaire de gériatrie de Montréal, Montreal, Canada, ⁵The University of Hong Kong, Hong Kong, Hong Kong, SAR of China

Introduction: Obstructive sleep apnea (OSA) and mental health conditions have complex, bidirectional relationships and are each recognized as risk factors for cardiometabolic morbidity. However, the combined effects of these conditions on cardiometabolic health remain unexplored. This study evaluates whether the combined presence of high risk for OSA and mental health conditions increases cardiometabolic risk and, if so, whether this co-occurrence has synergistic clinical relevance.

Materials and methods: We conducted a secondary analysis of the Canadian Longitudinal Study on Aging, a national cohort study collecting information on the biological, medical, psychological, social, lifestyle, and economic aspects of middle-aged and older adults (aged 45-85 at baseline), utilizing data from Baseline Comprehensive Survey (2011-2015) and Follow-up 1 (2015-2018).

Individuals with at least two self-reported symptoms of snoring, daytime somnolence, being observed to stop breathing in sleep, or hypertension were categorized as **high risk for OSA (OSA+)**. **Mental health conditions** were defined based on a combination of standardized questionnaires (Center for Epidemiologic Studies Short Depression Scale [CESD-10] ≥ 10 and Kessler Psychological Distress Scale [K10] ≥ 20), self-reported clinical diagnoses and taking medication for depression (Mental Conditions+). **Cardiometabolic morbidity** was defined through relevant self-reported clinical diagnoses (diabetes, heart disease, peripheral vascular disease, angina, cerebrovascular accident) and medications.

We used multivariable logistic regression models to compare odds between four mutually exclusive groups: (1) OSA+ Mental Conditions+; (2) OSA+ Mental Conditions-; (3) OSA- Mental Conditions+, and (4) OSA- Mental Conditions- (reference for comparison). Relative excess risks due to interaction (RERI) were calculated to test for additive interaction. We assessed how these exposure groups were associated with prevalent cardiometabolic conditions (at baseline and follow-up separately) and incident cardiometabolic conditions (in participants without cardiometabolic conditions at baseline), controlling for covariates (sociodemographic and lifestyle measures, medical conditions, sleep complaints and other sleep disorders aside from OSA).

Results: We included 26,945 baseline participants (6,958 [25.8%] OSA+; 9,220 [34.2%] mental conditions+; and 6,493 [24.2%] with cardiometabolic conditions) and 24,575 follow-up participants (7,348 [29.9%] OSA+; 7,968 [32.4%] mental conditions+; and 6,610 [27.0%] with cardiometabolic conditions). Among the 16,678 participants free of cardiometabolic conditions at baseline, 1,251 (7.5%) reported new cardiometabolic conditions at follow-up.

In all statistical models, OSA+ Mental Conditions + was associated with the greatest odds of prevalent or incident cardiometabolic conditions (odds ratios [ORs] 1.50-1.93; 95% confidence intervals [CIs]: 1.23-2.14) compared to each exposure considered separately (OSA+ Mental Conditions-: ORs 1.24-1.52; 95% CIs: 1.04-1.66; OSA- Mental Conditions+: ORs 1.05-1.24; 95% CIs: 0.96-1.45), using OSA- Mental Conditions- as a reference. RERI estimates above zero (0.03-0.19) suggested a positive additive interaction, but were not statistically significant.

Conclusions: In this national community-based study of middle-aged and older adults, individuals at higher risk for OSA with comorbid mental health conditions were at higher cardiometabolic risk compared to either exposure condition alone. While estimates of additive interaction were positive, suggesting potential synergy, they were not statistically significant, warranting further investigations. These findings underscore the importance of integrated screening and management strategies to mitigate cardiometabolic risks in individuals with these coexisting conditions.

Exploring the treatment journey of Obstructive Sleep Apnoea: A scoping review on the perspectives of Chinese patients

X. Zhu¹, Y.S. Bin^{2,3}, L. Smith¹, P.A. Cistulli^{2,3}, J.M. Cheung^{1,2}

¹The University of Sydney, Sydney Pharmacy School, Faculty of Medicine and Health, Sydney, Australia, ²The University of Sydney, Sleep Research Group, Charles Perkins Centre, Sydney, Australia, ³The University of Sydney, Northern Clinical School, Faculty of Medicine and Health, Sydney, Australia

Introduction: Globally, obstructive sleep apnoea (OSA) is a common sleep-related breathing disorder, thought to affect up to 23.6% of patients of Chinese ethnicity. However, little is known about the perspectives of the Chinese patient population and the key factors underpinning their health behaviours and treatment engagement. This scoping review aims to systematically synthesise the literature to understand Chinese patient perspectives towards OSA and its management.

Materials and methods: A systematic search was conducted in Jul 2023 and May 2024 across CINAHL, Embase, Medline, PsycINFO, and Scopus in Chinese and English for studies including the concepts: obstructive sleep apnoea, adult Chinese patients, treatments (CPAP, surgery, mandibular devices, pharmacotherapy, positional therapy, complementary therapies, lifestyle changes), and psycho-social-behavioural factors. Search results were screened and data extracted by 2 independent reviewers. Publications meeting the following criteria were included in this review: adult patients (≥ 18 years) self-identifying as Chinese with OSA (sample); patient experiences of various OSA treatments (phenomenon of interest); primary studies published in a peer-reviewed journal and written in English or Chinese (design); inclusion of a patient-reported outcome related to their OSA treatment at any stage of the treatment trajectory (evaluation).

Results: From the 976 results, 49 studies were retrieved, comprising of 16,239 adults (mean age: 47 years, 80% male); conducted primarily in China, Hong Kong, Taiwan and Singapore. Studies were broadly synthesised into the following patient-centred domains: beliefs about OSA, treatment preferences, acceptance, satisfaction, and adherence. Considerable heterogeneity was observed in the measurement of treatment acceptance and satisfaction, coupled with insufficient reporting of factors influencing treatment preference. Notable limitations included the under-representation of older women and migrant Chinese populations and the limited coverage of health beliefs and health behavioural change.

Conclusions: Factors influencing patient engagement with OSA treatments are multifactorial. Patients' health beliefs and sociocultural factors play an important role in treatment acceptance and adherence. Future research should focus on patient-centred approaches to identify strategies to promote behavioural change and provide culturally sensitive care.

Facial Aesthetic Outcomes of Counterclockwise Maxillomandibular Advancement in Asians with Obstructive Sleep Apnea: An Objective Analysis

I.N. Ismail¹, C.-H. Lin¹

¹Chang Gung Memorial Hospital, Craniofacial Center, Department of Plastic & Reconstructive Surgery, Taoyuan City, Taiwan

Introduction: Counterclockwise maxillo-mandibular advancement (CCW-MMA) is the most effective surgical management to enlarge the pharyngeal airway space in obstructive sleep apnea. However, the facial aesthetic consequences in Asians whose craniofacial morphology and cultural ideals differ from Western norms remain under represented.

Materials and methods: A retrospective cohort of 54 Asian adults (18 years and above; apnoea-hypopnoea index > 5) treated with CCW-MMA were reviewed. Pre-operative (T0) and 6-months post-operative (T1) lateral cephalograms were analysed. Soft-tissue landmarks including pogonion (Pog'), subnasale (Sn'), upper lip (ULs'), lower lip (LLs'), and nasion (N') positions were measured relative to the Zero Meridian Line (ZML) and E-line. Facial angles including nasolabial, Z-, facial-convexity and gonial angles were also measured. Patients were stratified by skeletal class I, II, and III. Soft tissue deviations from the Caucasian normative values were recorded. Intra-rater reliability was verified (intraclass correlation coefficient > 0.90). Paired t-tests were used to assess T0-T1 changes. Postoperative soft tissue changes and facial angles across all skeletal classes were compared to the Caucasian normal values using paired t-tests. ANOVA and multivariate regression was then used to examine between skeletal classes.

Results:

There were significant changes in the soft tissue landmarks between T0 and T1 across all skeletal classes with mean ($\pm$ SD) anterior translation of Pog' 5 ± 2 mm, Sn' 3 ± 1 mm, ULs' 3 ± 1 mm, and LLs' 3 ± 1 mm. The facial convexity angle decreased by $4^\circ \pm 2^\circ$, while the nasolabial angle increased by $8^\circ \pm 2^\circ$, indicating forward rotation of the lower face and profile straightening. Postoperatively, 85% of subjects had Pog' within the Zero meridian harmony. The Z-angle improved from a mean of 65° to the

aesthetic ideal of 75–80°, confirming enhanced chin–lip projection. Class II patients showed the greatest Pog' advancement (8 ± 2 mm), with 90% of subjects achieving Pog' alignment within ± 2 mm of the ZML. In Class III patients, a notable reduction in Pog' (-5 ± 2 mm) and LLs' (-5 ± 2 mm) was observed, while Sn' and ULs' showed notable forward movement toward the ZML. Class I subjects demonstrated a forward shift of Pog' relative to the ZML, which significantly exceeded the expected normative variation. They also displayed significant changes in the Z-angle, facial convexity angle, and gonial angle. Other landmarks did not show significant changes or deviations from the Caucasian norm.

Conclusions: Although facial angles and soft tissue profiles demonstrated balanced and improved projection comparable to Caucasian norms, Class I Asian patients exhibited slight overprojection of the facial profile as a compensatory outcome for pharyngeal airway enlargement. These findings highlight the importance of skeletal class-specific surgical planning to optimize both functional and aesthetic outcomes, particularly in Asian OSA patients. Further research incorporating subjective aesthetic assessments is warranted to better define ideal facial aesthetics within Asian populations.

Factors affecting level II polysomnography (PSG) outcomes in a tertiary referral sleep centre in Australia: A retrospective cohort study

B. Varcoe^{1,2}, C. Huang^{1,3}, B. Brew^{4,5}

¹Canberra Hospital, Respiratory and Sleep Department, Garran, Australia, ²John Hunter hospital, Respiratory and Sleep Medicine, New Lambton, Australia, ³Australian National University, School of Medicine and Psychology, Acton, Australia, ⁴Hunter Medical Research Institute, Asthma and Breathing, New Lambton, Australia, ⁵University of Newcastle, School of Medicine, Callaghan, Australia

Introduction: Obstructive sleep apnoea (OSA) has a significant prevalence and associated healthcare cost in Australia and globally. In Australia Level II polysomnography (PSG) studies, provide an accessible and affordable way to help diagnose OSA. However, level II PSG's often have higher failure rates than in-lab sleep studies with recent data from Australia and New Zealand showing failure rates of 5-8%. Factors that may contribute to failed level II PSG have not been clearly identified in the literature with limited anecdotal evidence guiding clinician decisions with their patients. We conducted a single centre retrospective cohort study to assess which factors are more prevalent in failed level II PSG compared to successful tests with the aim to establish a more robust evidence base in this area to ultimately improve the success rate of level II PSG.

Materials and methods: The study population included 496 from patients > 18 years of age who had performed a level II PSG through our hospital's sleep laboratory between January 2022 and January 2024. Failed tests identified using a standardised criteria by the sleep technician analysing the test. Factors to be assessed included clinical factors (Age, gender, weight, BMI, co-morbidities, smoking status, Epworth score, STOP-BANG score) environmental factors (season, average daytime temperature, distance from the sleep laboratory in km) and technical factors (test unit used). Comorbidities were categorised into none, one or more than one and included asthma, hypertension, diabetes, gastro-oesophageal reflux disease (GORD), atrial fibrillation, heart disease and chronic obstructive pulmonary disease (COPD). Statistical tests comparing factors of failed and successful tests included t-tests for continuous variables and chi-square tests for categorical variables. The statistical significance level was set at $p < 0.05$.

Results: Of the 496 studies analysed, there were 16 (3.2%) failed tests and 480 (96.8%) successful tests. There were 254 (51.2%) female patients and 242 (48.8%) male patients with an average patient age of 52.41 (SD +/- 16.2) years. There was no significant difference between the failed and successful tests for the clinical factors of age ($p = 0.96$), BMI ($p = 0.81$), gender ($p = 0.54$), smoking status ($p = 0.49$), Epworth score ($p = 0.69$), STOP-BANG score ($p = 0.22$) and co-morbidities ($p = 0.52$). In regard to environmental factors there was a significant difference between seasons ($p = 0.05$), with 14/16 (87.5%) failed tests occurring in autumn or winter. There were no significant differences for distance from the sleep laboratory ($p = 0.90$), daytime temperature ($p = 0.16$), or which sleep unit was used ($p = 0.31$).

Conclusions: Although the failure rate of the level II PSG in our study was lower than previous studies, analysis of relevant factors found no differences between the failed and successful tests except for season which showed that autumn and winter seasons in the local area were more highly associated

with failure. This suggests that aspects related to colder seasons such as increased bedding or clothing may be attributable for the failure rate but this requires further research

Acknowledgments: Acknowledge the sleep scientists and staff at the Canberra hospital for contributing data to the paper

Factors Associated with Worsening of Sleep-Disordered Breathing in Patients with REM Sleep Behavior Disorder

H. Nakayama¹, A. Usui¹, Y. Inoue¹

¹Tokyo Medical University, Department of Somnology, Tokyo, Japan

Introduction: REM sleep behavior disorder (RBD), like obstructive sleep apnea (OSA), is more prevalent in older adults and males. Although OSA is frequently comorbid with RBD, it has been reported that due to the presence of REM sleep without atonia (RWA), the severity of OSA tends to be mild in these patients. In this study, we investigated the factors associated with worsening sleep-disordered breathing (SDB) in patients with underlying RBD.

Materials and methods: We retrospectively analyzed patients diagnosed with RBD who underwent multiple polysomnographic (PSG) studies for follow-up, with a baseline apnea-hypopnea index (AHI) <20/h, which is below the indication for CPAP therapy in Japan. Worsening of OSA was defined as an increase in the severity category (e.g., from mild to moderate, or from moderate to severe). Patients were divided into two groups: those with worsening OSA and those without. Background characteristics were compared using the Mann-Whitney U test. Multivariate regression was performed to identify factors associated with OSA worsening, using sex, BMI change, interval between PSGs (age change), and clonazepam use as covariates.

Results: Among 61 RBD patients (46 males; mean age 66.1 years; BMI 23.2 kg/m²; ESS score 6.4), the mean interval between PSG studies was 5.3 years. The AHI significantly increased from 4.7 ± 4.3 to 8.5 ± 9.6/h (mean ± SD, $p < 0.001$). Worsening of OSA was observed in 23 patients (38%). No significant differences were found in sex or BMI between the worsening and non-worsening groups; however, age tended to be higher (68.0 ± 8.4 vs. 65.0 ± 6.3 years, $p < 0.08$) and interval between PSGs was significantly longer (6.0 ± 2.2 vs. 4.8 ± 1.8, $p < 0.04$). Multivariate regression analysis showed that only interval between PSG studies were significant predictors of OSA worsening.

Conclusions: AHI may increase even when RWA increases over time. Aging plays a significant role in the worsening of OSA in patients with underlying RBD. Even in the absence of weight gain, periodic reassessment of OSA is warranted in this population.

Five-year, prospective, multicenter, real-world study to assess initial delivery, management and long-term effectiveness of a CAD/CAM, 3-D printed oral appliance in the treatment of obstructive sleep apnea: Interim Analysis Update

F. Gagnadoux¹, M. Fortin², R. Woidtke³, M. Arias⁴

¹Angers University Hospital Center, Angers, France, ²Panthera Dental Inc., Quebec City, Canada, ³RVW Clinical Consulting, California, United States, ⁴Axonal Biostatem, Nanterre, France

Introduction: Oral appliance therapy (OAT) continues to be a mainstay of therapeutic options in the treatment of obstructive sleep apnea (OSA). The provision of OAT requires a multidisciplinary approach to care involving a qualified sleep dental provider and a prescribing sleep specialist. This trial supports this methodology in a real-world, observational, longitudinal study of the Panthera D-SAD. The patients' therapeutic journey will be followed by providing data from first-time fit and delivery to ongoing adherence. Long-term adherence is essential for any OSA therapy to contribute to overall health and well-being. This study will fulfill French reimbursement requirements. Ethics committee approval was obtained.

Materials and methods: OAT naïve individuals with moderate OSA (AHI 15-30) or those with severe OSA (AHI > 30) who decline CPAP and meet all other criteria will be included. Sites will follow the standard of care in France to provide OAT. The Panthera D-SAD is a CAD/CAM, 3D printed biocompatible nylon appliance allowing for a patient-matched design. Fifteen centers in France will enroll 217 participants via consecutive sampling. A Somnologist will assess participants for entry

criteria, and a prescription for OAT obtained. A dental evaluation for suitability is conducted (V0). Initial OAT fitting occurs at Visit 1. Evaluation time points are (V2) three to six months (medical/sleep/dental), yearly follow-up to four years (dental visit/phone calls), and five years (medical/dental). Secondary endpoints include side effects, oxygenation metrics, quality of life, self-reported adherence, and subjective symptoms.

Results: Enrollment is complete (n=257). Baseline demographics n=239 (mean/SD): Age 50.7 (12.8), BMI 26.6 (4.7), F 49%, AHI 22.7 (9.0), ODI 17.0 (11.4), lowest SpO₂ 84.6% (6.8), ESS >10 42.4% (n=198). No changes to the OAT at delivery were required in 84.3%, with 82.3% of participants indicating that the device was comfortable and that only minimal adjustments were required. Within two post-delivery visits, 88.3% of participants were fully titrated. Change from baseline in sleep respiratory variables (n=179) to sleep testing (3-6 Mos): AHI reduction $\geq 50\%$ (60.3%). Additionally, 87.8% of moderate and 83.4% of severe transitioned to a lower AHI classification, with AHI <15 (80.9%), <10 (58.5%), <5 (20.8%). ODI decreased to 9.7 (8.4). Daily usage of ≥ 4 hours per night was reported by 96.2% of participants at three months and 94.8% at six months. During the routine annual call, 94.7% confirmed wearing the device all night. The average number of nights per week with device usage was 6.6 (1.2) at 3 months, 6.4 (1.4) at 6 months, and 6.2 (1.7) at one year, demonstrating sustained adherence over time. Satisfaction with treatment was 82.8% at three months and improved at one year (91.9%). At three months, ESS >10 24.5% (n=139).

Conclusions: These data represent insight into an ongoing, real-world observational study. Participants had improvement in their OSA and high satisfaction levels regarding wearing the device. The continued robust self-reported adherence confirms sustained therapy over time. Limitations include variances from site to site. However, in an observational study, these are expected findings. The last participants enrolled have not finalized titration. Additional data will be forthcoming.

Flow Reduction Indicator: A Novel Metric for Predicting Cardiovascular Mortality in Sleep Apnea Patients

Y. Na^{1,2}, Y. Kim¹, H.K. Lee^{1,2}, Y. Lee^{1,2}, S. Lim^{1,2}, H.K. Ahn¹, H.-W. Shin^{1,2,3,4}

¹Seoul National University College of Medicine, Obstructive Upper airway Research Laboratory, the Department of Pharmacology, Seoul, Korea, Republic of, ²Seoul National University College of Medicine, Department of Biomedical Sciences, Seoul, Korea, Republic of, ³Seoul National University Hospital, Department of Otorhinolaryngology-Head and Neck Surgery, Seoul, Korea, Republic of, ⁴OUaR LaB Inc, Seoul, Korea, Republic of

Introduction: Obstructive sleep apnea (OSA) is a well-established risk factor for cardiovascular morbidity and mortality. However, its standard severity metric, the Apnea-Hypopnea Index (AHI), has limited predictive power for these outcomes, as it merely counts respiratory events without considering their duration and degree of flow reduction. Hypoxic Burden (HB) captures only the cumulative hypoxic stress of OSA. Ventilatory Burden (VB) measures inspiratory flow limitation using a fixed 50% threshold, which may fail to detect subtler events that nonetheless elicit cardiovascular responses, including heart rate elevation and arousal. To overcome aforementioned limitations, we propose the Flow Reduction Indicator (FRI). FRI quantifies the severity of airflow reduction by measuring the magnitude of reductions and the duration of each event.

Materials and methods: We calculated FRI from overnight polysomnography recordings in the Sleep Heart Health Study (SHHS; n = 3,882) and the Osteoporotic Fractures in Men Study (MrOS; n = 1,647). Unlike AHI, FRI assigns a variable weight to each respiratory event based on duration and flow reduction magnitude. Cardiovascular mortality risk was assessed using Cox proportional hazards regression.

Results: In unadjusted analysis (Model 0), when each metric was entered as quintile-based categories, FRI yielded the highest likelihood ratio tests values (SHHS: 54.26; MrOS: 26.93) compared to AHI (SHHS: 42.81; MrOS: 17.31), HB (SHHS: 38.11; MrOS: 23.64), and VB (SHHS: 42.29; MrOS: 10.43). In Model 1, which was adjusted for demographic factors (age, BMI, race, smoking status and sex only in SHHS), time in bed, lipid-lowering medications, and comorbidities (hypertension, stroke, chronic obstructive pulmonary diseases, myocardial infarction, asthma, diabetes and coronary angioplasty only in SHHS), FRI also showed the highest risk estimates among all metrics, with a Q5 hazard ratio (HR) of

1.83 (95% CI: 1.11–3.01) in SHHS and 1.54 (95% CI: 1.13–2.09) in MrOS. By comparison, the Q5 HRs for other metrics were substantially lower: AHI (SHHS: 1.49; MrOS: 1.48), HB (SHHS: 1.64; MrOS: 1.53), and VB (SHHS: 1.35; MrOS: 1.32). FRI also retained statistical significance when modeled as continuous variables in both cohorts (Model 0 and Model 1: $p < 0.05$). Finally, in Model 2 (covariates in Model 1 + AHI, HB, VB, and FRI as continuous predictors), only FRI remained statistically significant in SHHS (HR = 1.02; 95% CI 1.01–1.03).

Conclusions: Our findings suggest that FRI outperforms AHI, HB, and VB in predicting cardiovascular mortality. By integrating both the flow reduction and event duration, the 'FRI', which can be easily derived from flow signals in overnight sleep study, predicts cardiovascular disease mortality across populations.

Acknowledgments: This research was supported partly by the Creative-Pioneering Researchers Program through Seoul National University, partly by the AI-Bio Research Grant through Seoul National University.

From hypoxia to hyperglycemia: the molecular interface of obstructive sleep apnea and type 2 diabetes via *miRNA-181a*, *SIRT1*, and adiponectin

F. Karuga¹, P. Kaczmarek¹, M. Sochal¹, B. Szmyd², P. Białasiewicz¹, A. Gabryelska¹

¹Medical University of Lodz, Department of Sleep Medicine and Metabolic Disorders, Lodz, Poland,

²Medical University of Lodz, Department of Pediatrics, Oncology, and Hematology, Lodz, Poland

Introduction: Obstructive sleep apnea (OSA) is an established independent risk factor for type 2 diabetes mellitus (T2DM), with the prevalence of T2DM approximately two times higher among individuals with OSA compared to those without. This study aimed to elucidate the molecular mechanisms linking OSA with T2DM development by investigating oxygen metabolism dysregulation through hypoxia-sensitive *miRNA-181a* expression and associated enzymatic pathways involving sirtuin 1 (SIRT1) and adiponectin. Previous studies have also suggested a positive correlation between adiponectin, metformin intake, and SIRT1 expression.

Materials and methods: All participants underwent standard physical examination and polysomnography. Based on the apnea-hypopnea index (AHI) and T2DM status, participants were categorized into three groups: OSA (AHI >30, $n=26$), OSA+T2DM (AHI >30 and diagnosed T2DM, $n=29$), and control (AHI <5, $n=32$). Blood samples were collected in the evening and morning. An additional morning sample was obtained after at least three months of continuous positive airway pressure (CPAP) therapy ($n=21$). Total RNA was isolated from the buffy coat, and the expression of *SIRT1* and *miRNA-181a* was quantified via RT-qPCR. Protein levels of SIRT1 (intracellular) and adiponectin (serum) were assessed using ELISA. Statistical analyses included the Mann-Whitney U test, Kruskal-Wallis test, and Spearman's rank correlation.

Results: Evening *miRNA-181a* expression differed significantly across the groups: OSA (36.74, IQR: 18.1–108.4), OSA+T2DM (16.78, IQR: 13.5–27.5), and controls (25.61, IQR: 7.1–114.1); $p=0.041$. *SIRT1* expression varied significantly both in the evening (OSA: 44.12×10^{-6} , IQR: 27.9–267.9; OSA+T2DM: 506.60×10^{-6} , IQR: 165.6–1176.8; controls: 323.08×10^{-6} , IQR: 32.5–1136.5; $p=0.012$) and in the morning (OSA: 84.44×10^{-6} , IQR: 48.5–156.5; OSA+T2DM: 553.75×10^{-6} , IQR: 206.2–1254.6; controls: 214.86×10^{-6} , IQR: 46.1–1055.1; $p=0.008$). Adiponectin levels were significantly reduced in OSA and OSA+T2DM groups compared to controls, both in the evening (OSA: 3849.01 ng/ml, IQR: 2812.6–6048.1; OSA+T2DM: 3170.35 ng/ml, IQR: 2658.2–4366.9; controls: 5907.54 ng/ml, IQR: 4142.6–8347.6; $p=0.001$) and in the morning (OSA: 3327.04 ng/ml, IQR: 2678.9–5013.1; OSA+T2DM: 2953.49 ng/ml, IQR: 2296.6–3915.3; controls: 5207.78 ng/ml, IQR: 3604.9–7138.8; $p=0.001$). A weak negative correlation was found between evening *SIRT1* and *miRNA-181a* expression ($r = -0.28$, $p=0.01$). Intracellular SIRT1 protein was undetectable (threshold: 0.31 ng/ml). *SIRT1* expression was significantly higher in OSA patients treated with metformin ($n=23$, $p=0.037$). After CPAP therapy, only *miRNA-181a* showed a significant increase (16.17, IQR: 10.49–32.21 vs. 43.87, IQR: 22.59–86.21; $p=0.047$), while SIRT1 and adiponectin levels remained unchanged.

Conclusions: Elevated *miRNA-181a* expression in OSA patients was associated with reduced *SIRT1* expression, potentially contributing to increased insulin resistance and subsequent T2DM development. Paradoxically, *SIRT1* expression was higher in patients with established T2DM, possibly reflecting metformin use or compensatory mechanisms. Notably, this increase was not accompanied by

elevated adiponectin, suggesting incomplete metabolic adaptation. CPAP therapy was associated with a rise in miRNA-181a expression, with no significant effect on *SIRT1* or adiponectin levels.

From Resistance to Collapse: Prevalence and 8-Year Progression of UARS to OSA in a Population-Based Cohort

S.B. Tufik¹, G. Natan Pires¹, L. Palombini¹, S. Tufik¹, M. Levy Andersen¹

¹Instituto do Sono, Sao Paulo, Brazil

Introduction: Upper Airway Resistance Syndrome (UARS) is a form of non-hypoxic sleep-disordered breathing characterized by increased inspiratory effort during sleep without overt apneas or oxygen desaturation. Although initially described as distinct from Obstructive Sleep Apnea (OSA), UARS remains controversial due to overlapping clinical features and a lack of consensus in diagnostic standards. Our previous analysis from the São Paulo Epidemiologic Sleep Study (EPISONO) reported a UARS prevalence of 3.1%, predominantly among young, non-obese females. In this longitudinal follow-up, we investigated the long-term trajectory of UARS over eight years and its potential progression to OSA, aiming to clarify whether UARS represents an early manifestation within the OSA spectrum.

Materials and methods: This study utilized a representative subset of adults from the EPISONO cohort who underwent comprehensive evaluations in both 2007 (baseline) and 2015 (follow-up). Inclusion required complete type-I polysomnography and validated symptom questionnaires. UARS was defined using strict criteria: apnea-hypopnea index (AHI) < 5 events/h, minimum SpO₂ ≥ 92%, airflow limitation (AFL) ≥ 5% of total sleep time (TST), and presence of either excessive daytime sleepiness (Epworth Sleepiness Scale (ESS) score > 10) or fatigue (Chalder Fatigue Scale (CFS) score > 3). OSA was classified according to AHI thresholds, with symptom criteria applied to mild cases. Follow-up involved reassessment with identical PSG and survey instruments. Multinomial logistic regression and generalized estimating equations were used to model diagnostic evolution and symptom trajectories over time, with covariates including age, sex, and body mass index (BMI).

Results: Among 571 eligible participants, 18 were diagnosed with UARS at baseline. At follow-up, 6 of these individuals developed OSA (incidence: 33.3%), 7 remained classified as UARS (persistence: 38.9%), and the remainder shifted into other categories. Among the 59 baseline controls, 5 developed OSA (8.5%), and 4 developed UARS (6.8%). UARS diagnosis at baseline conferred a 5.4-fold increased risk of OSA onset ($p = 0.014$), which rose to 11.75-fold after adjusting for sex and age ($p = 0.006$). UARS participants also exhibited significantly higher levels of depressive symptoms (Beck Depression Inventory: 12.89 vs 4.58), anxiety (Beck Anxiety Inventory: 10.5 vs 6.27), daytime sleepiness (ESS: 12.22 vs 7.32), and fatigue (CFS: 5.2 vs 2.42) than controls (all $p < 0.05$). Mean AFL increased markedly in persistent UARS cases, from 10.1% to 33%. Although both groups showed AHI increases over time, the change was more pronounced in the UARS cohort. GEE analyses confirmed UARS status as a significant predictor of worsening mood and fatigue symptoms, independent of age or BMI.

Conclusions: Our findings support the hypothesis that UARS may represent an early, milder phase within the broader spectrum of sleep-disordered breathing. The elevated risk of progression to OSA and persistent burden of sleepiness, fatigue, depression, and anxiety among UARS individuals reinforce the clinical significance of this diagnosis. Early recognition and targeted interventions for UARS may be critical in preventing the emergence of more severe forms of sleep apnea and associated neuropsychiatric morbidity.

Fusobacterium nucleatum mediates inflammatory effect in pediatric obstructive sleep apnea with adenoid hypertrophy

H. Xu¹, X. Zhang¹, J. Guan¹, H. Yi¹, S. Yin¹

¹Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Department of Otorhinolaryngology-Head and Neck Surgery, Shanghai, China

Introduction:

Adenoid hypertrophy (AH), a leading risk factor of pediatric obstructive sleep apnea (OSA), is associated with disturbance of oral microbiota, especially the microbial film on adenoids. However, precise microbial characteristics on adenoids and their role in pediatric OSA are unclear.

Materials and methods:

Fifteen polysomnography-confirmed pediatric OSA with AH, and twenty- two controls were enrolled (Approval no.2018-073 and 2019 R061-F01). Metagenomic sequencing was used to identify the microbial characteristics on surface of nasopharyngeal adenoids. Linear discriminant analysis was used to explore differential microbial characteristics and molecular biology techniques were used to assess how such microbial differences may participate in AH.

Results:

Significant differences in β diversity between pediatric OSA and controls indicate close relationships between changes in the bacterial community on adenoids and pediatric OSA. Enrichment of *Prevotella_pleuritidis*, *Porphyromonas_endodontalis*, and *Fusobacterium_nucleatum* were significantly associated with pediatric OSA, among which *Fusobacterium_nucleatum* infection could promote the production of IL1 β in mouse lymphocytes and adenoid primary cells through NLRP3 pathway activation.

Conclusions:

Changes in the microbial structure and function on adenoids may provide an important pathogenic factor for pediatric OSA induced by AH. In particular, *Fusobacterium_nucleatum* may promote inflammatory response that enhances the development of adenoid hypertrophy, thereby serving as potential therapeutic target.

Gender Differences in Changes in Sleep-Related Physical and Mental Symptoms and Quality of Life Following CPAP Treatment in Patients with OSA

Y.-C. Chen¹, C.-Y. Lin², Y.-H. Chen¹

¹National Sun Yat-sen University, School of Medicine, Kaohsiung, Taiwan, ²National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan, Tainan, Taiwan

Introduction: Poor sleep quality, memory impairment, emotional disorders, and reduced quality of life (QOL) are prominent symptoms among individuals with obstructive sleep apnea (OSA). Continuous Positive Airway Pressure (CPAP) therapy is widely recognized as the gold standard treatment for OSA. However, the diagnostic criteria and treatment approaches for OSA have historically been based on male-centric models, potentially overlooking gender-specific symptomatology. The objective of this study was to investigate gender differences in changes in sleep-related physical and mental symptoms, as well as QOL, after CPAP treatment among individuals with OSA.

Materials and methods: A prospective study with a repeated measures design was conducted at a sleep outpatient clinic within a medical center. Individuals diagnosed with OSA, defined by an apnea-hypopnea index (AHI) ≥ 5 events per hour as measured by polysomnography, were included. Daytime sleepiness, sleep quality, cognitive function, anxiety and depression, and QOL were assessed using the Epworth Sleepiness Scale (ESS), Pittsburgh Sleep Quality Index (PSQI), Mini-Mental State Examination (MMSE), Hospital Anxiety and Depression Scale (HADS), and the World Health Organization Quality of Life-BREF (WHOQOL-BREF), respectively. Measurements were collected at four time points: baseline (T0, before CPAP initiation), 1 month (T1), 3 months (T2), and 6 months (T3) after CPAP initiation. Repeated measures analyses were conducted to evaluate changes over time.

Results: A total of 121 participants were enrolled, with a mean age of 50.78 years. The male-to-female ratio was approximately 5.4:1 (19 females). Among them, 111 participants initiated CPAP therapy, and 69 completed the 6-month follow-up (T3). CPAP adherence over time did not significantly differ between genders. At baseline, females exhibited significantly poorer sleep quality compared to males ($p = .007$). Following CPAP initiation, improvements were observed in daytime sleepiness, sleep quality, cognitive function, anxiety, and QOL across participants, with notable gender differences. In the fully

adjusted repeated measures model, females consistently demonstrated poorer sleep quality ($\beta = -3.23$, $p < .0001$) and greater improvement in cognitive function ($\beta = 0.70$, $p = .025$) compared to males across all follow-up points. No significant gender differences were observed in changes in daytime sleepiness, anxiety, depression, or QOL.

Conclusions: This study demonstrated that CPAP treatment effectively improved daytime sleepiness, sleep quality, cognitive function, anxiety, and QOL among individuals with OSA. Notable females exhibited persistently poorer sleep quality but greater improvements in cognitive function compared to males following CPAP therapy. No significant gender differences were identified in changes in daytime sleepiness, anxiety, depression, or overall quality of life. These findings highlight the need for gender-sensitive approaches in the evaluation and management of sleep-related symptoms in OSA patients undergoing CPAP treatment.

Gender Effects on Surgical Outcome after Maxillomandibular Advancement for Obstructive Sleep Apnea in the East Asian Patient

C.S. Lee¹, C.-H. Lin²

¹Khoo Teck Puat Hospital, Dental Surgery, Oral & Maxillofacial Surgery, Singapore, Singapore, ²Chang Gung Memorial Hospital and College of Medicine, Chang Gung University, Craniofacial Center, Craniofacial Research Center and Sleep Center, Taoyuan, Taiwan

Introduction: Anatomical and physiological differences between genders may influence surgical outcomes in sleep apnoea treatments. Maxillomandibular advancement (MMA) is a common procedure for obstructive sleep apnoea (OSA) patients. Still, the impact of gender on surgical success in the East Asian patient has not been fully explored.

Aim:

This study aims to compare the post-operative outcomes of MMA in East Asian patients, specifically examining gender as an influencing factor.

Materials and methods: A retrospective matched cohort study was conducted on 36 OSA patients (18 males, 18 females) who underwent MMA at Chang Gung Memorial Hospital, Taiwan. Patients were matched by age and body mass index. Pre- and post-operative polysomnographic indices and cephalometric measurements were analysed to assess surgical outcomes. Logistic regression was used to evaluate gender as a predictor of outcomes, adjusted for baseline apnoea-hypopnoea index (AHI).

Results: Surgical success was observed in 83.3% of males and 66.7% of females, with cure rates of 44.4% and 50.0%, respectively. After adjusting for baseline AHI, gender was not a significant predictor of cure (OR 0.99; 95% CI: 0.24–4.17; $p = 0.984$) or success (OR 1.54; 95% CI: 0.28–9.43; $p = 0.619$). Males demonstrated greater improvements in AHI, oxygen desaturation index, arousal index, and wake after sleep onset. Females showed greater gains in rapid eye movement sleep and hyoid elevation.

Conclusions: Gender does not independently predict surgical success or cure following MMA in East Asian OSA patients. However, gender specific responses were noted in certain polysomnographic indices and cephalometric measurements. Further studies are warranted to explore underlying mechanisms influencing these differential responses.

Acknowledgments: I acknowledge the support and supervision of **Dr. Cheng-Hui Lin from Chang Gung Memorial Hospital, Taiwan**, the principal investigator of this research project.

Genetic Variants of High-density Lipoprotein Cholesterol on Insulin Resistance and Cardiovascular Diseases in Obstructive Sleep Apnea

X. Li¹, Y. Peng¹, H. Xu¹, J. Guan¹, S. Yin¹

¹Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China

Introduction: Obstructive sleep apnea (OSA) and its common comorbidities, including insulin resistance (IR) and cardiovascular diseases (CVD), are frequently manifested as alterations in high-density lipoprotein cholesterol (HDL-C) levels. This study aimed to explore the association between genetic variations of HDL-C and these conditions.

Materials and methods: 4,513 individuals suspected of OSA underwent anthropometric measurements, polysomnography assessments, and serum biochemical testing. Genetic variations of HDL-C were evaluated using 45 single nucleotide polymorphisms (SNPs). IR was assessed via the Triglyceride-Glucose (TyG) index, while CVD risk was determined by the 10-year Framingham CVD risk score (FRS). Inter-relationships among these factors were analyzed through linear regression, with results corrected employing the Benjamini-Hochberg (BH) method.

Results: After BH correction, the rs35950463 and rs10787431 variants positively correlated with the lowest oxygen saturation ($\beta = 0.48$, $P_{BH} = 0.023$; $\beta = 0.046$, $P_{BH} = 0.023$). The variants rs429358, rs328, and rs2980859 were significantly associated with the TyG index ($\beta = 0.056$, $P_{BH} = 0.001$; $\beta = -0.074$, $P_{BH} = 2.3 \times 10^{-6}$; $\beta = -0.084$, $P_{BH} = 1.2 \times 10^{-7}$), while the variants rs651821 and rs75198898 were significantly associated with FRS ($\beta = 0.031$, $P_{BH} = 0.001$; $\beta = -0.039$, $P_{BH} = 8.1 \times 10^{-6}$).

Conclusions: Several HDL-C SNPs significantly correlated with oxygenation status, IR, or CVD risk in OSA patients, suggesting potential targets for preventive and therapeutic interventions.

Higher Ambient Temperatures may Increase Sleep Apnea-Specific Pulse-Rate Response in obstructive sleep apnea

Y. Li^{1,2}, Y. Shi^{1,2}, D. Han^{1,2}

¹Beijing Tongren Hospital, Capital Medical University, Sleep Medical Center, Beijing, China, ²Capital Medical University, Key Laboratory of Otolaryngology Head and Neck Surgery, Ministry of Education, Beijing, China

Introduction: Obstructive sleep apnea (OSA) features repeated sympathetic activation, elevating cardiometabolic and neurocognitive risks. The heart rate response to respiratory events, measured by ΔHR (the difference between the lowest heart rate during the event and the peak following airway reopening), reflects sympathetic activity and correlates with adverse cardiovascular outcomes. Environmental temperature may influence autonomic function: lower temperatures may enhance baseline sympathetic tone and modify ΔHR , while higher temperatures could further elevate the heart rate response. We hypothesize that elevated ambient temperatures are associated with exaggerated post-apneic heart rate elevation in patients with OSA.

Materials and methods: We retrospectively analyzed data from 2,169 Chinese adult participants diagnosed with OSA using in-laboratory polysomnography between January 2017 and December 2024. Ambient temperature data were obtained from official sources. ΔHR was defined as the difference between the maximum and minimum heart rates within an event-related window around each respiratory event, calculated directly from the continuous heart rate recordings. This metric quantitatively reflects sympathetic activation during OSA events and has demonstrated predictive value for adverse cardiovascular outcomes. Associations between ΔHR , OSA severity, and ambient temperature were analyzed.

Results: 1,840 males and 329 females with a median age of 41.0 years (interquartile range [IQR]: 34.0–50.0) and a median body mass index (BMI) of 26.8 kg/m² (IQR: 24.6–29.4) were included in this study. Participants exhibited a median apnea-hypopnea index (AHI) of 32.5 events/hour (IQR: 14.9–59.1). Higher ambient temperatures were significantly associated with greater ΔHR . Specifically, the minimum, mean, and maximum temperatures over 1-day and 7-day periods all demonstrated statistically significant positive correlations with ΔHR ($p < 0.05$ for all comparisons). Stepwise linear regression analysis indicated that each 10°C increase in the 7-day average minimum temperature corresponded to a significant 0.96 bpm increase in ΔHR (95% confidence interval [CI]: 0.48–1.44). During the warmer season (defined as minimum temperature $\geq 4^\circ\text{C}$), ΔHR showed the strongest correlation with the previous 7-day minimum temperature ($\rho = 0.103$, $p < 0.001$). Conversely, no significant correlation was observed during the colder season (minimum temperature $< 4^\circ\text{C}$; with central heating utilized in 617 out of 1,018 days in Beijing) ($\rho = 0.010$, $p = 0.761$). The association between higher temperatures and greater ΔHR was more pronounced among those with BMI ≥ 28 kg/m² ($\beta = 0.109$, 95% CI: 0.024–0.194). No significant associations were observed between ambient temperatures and AHI, SpO₂, sleep latency, or sleep efficiency.

Conclusions: Higher temperature may modulate the compensatory autonomic response to respiratory events in OSA patients, especially among those with higher BMI and during warmer seasonal periods. Ambient factors might be considered as effect modifiers when evaluating OSA-induced pathophysiological consequences.

Higher Trend of Severe OSA in Normal BMI Patients: Analysis from Western Part of India

K. Jhala¹

¹Apollo International Hospital, Pulmonology and Sleep Medicine, Ahmedabad, India

Introduction: Obstructive Sleep Apnea (OSA) is a prevalent sleep disorder characterized by repeated episodes of partial or complete obstruction of the upper airway during sleep. This study aims to analyze the demographic, clinical, and comorbidity profiles of patients diagnosed with OSA, and treatment outcomes.

Materials and methods: Data from 42 patients (31 males and 11 females) diagnosed with OSA were analyzed. The patients were categorized based on Body Mass Index (BMI), history of sleep apnea, duration of symptoms, comorbidities, Apnea-Hypopnea Index (AHI), Oxygen Desaturation Index (ODI), and Epworth Sleepiness Score (ESS). Symptom prevalence and treatment outcomes were also recorded.

Results: A total of 42 patients enrolled, with a mean age of 56.1 ± 16 years; 31(73.8%) were males and 11(26.2%) were females. Regarding BMI, 11 (26.2%) patients had a BMI of less than 25, while the majority, 31 (73.8%) patients, had a BMI of 25 or higher. A history of sleep apnea was reported by 37(88.1%), with only 5 (11.9%) having no prior history.

The duration of symptoms varied, with the majority, 39 (92.9%) patients, experiencing symptoms for more than 6 months, and 3 (7.1%) patients for 1 to 6 months. Comorbidities were prevalent, with 11 patients having diabetes (26.2%), 33 patients having hypertension (78.6%), 10 patients having asthma (23.8%), 4 patients having chronic obstructive pulmonary disease (9.5%), 5 patients having ischemic heart disease (11.9%), and 9 patients having dyslipidemia (21.4%). Other comorbidities included post PTCA, chronic rhinosinusitis, severe eosinophilic asthma, asthma-COPD overlap, chronic severe asthma, and asthmatic bronchitis incidence were similar (1,2.4%).

The severity of OSA was categorized as mild for 6 patients (14.3%), moderate for 6 patients (14.3%), severe for 26 patients (61.9%), very severe for 2 patients (4.8%), moderate to severe for 1 patient (2.4%), and mild to moderate for 1 patient (2.4%). Majority of patients were treated with CPAP and outcomes showed that 26 patients experienced improvement (61.9%), while 16 patients remained stable (38.1%).

In current study we observed, out of 42 patients, 11 have **normal BMI** and still have OSA. This represents **26.19%** of the total patients, indicating significant proportion of patients with normal BMI also suffer from OSA.

In group of BMI >25, ODI showed 3% with normal, 16% with mild, 19% with moderate, and 61% with severe scores, compared to 18%, 27%, 18%, and 36% respectively in BMI<25 ($p = 0.262$). For, ESS 29% of the BMI>25 group were classified as normal, 32% mild, 6% moderate, and 32% severe, in BMI<25 group had 45% normal, 36% mild, 9% moderate, and 9% severe scores ($p = 0.48$). Regarding the STOP-BANG score, 77% of individuals with BMI>25 were at high risk and 23% at intermediate risk, compared to 82% and 18% respectively in the BMI<25 group ($p = 1$).

Conclusions: The analysis of the data indicates a high prevalence of severe OSA among the patients. Notable proportion of patients with normal BMI also suffer from OSA, highlighting the importance of considering OSA risk factors beyond BMI. Treatment outcomes showed improvement in more than half of the patients.

High night-to-night variability in OSA severity is associated with prevalent major adverse cardiovascular and cerebrovascular events

B. Lechat¹, L. Pinilla¹, K. Sansom¹, A. Vakulin¹, P. Escourrou², J.-L. Pepin³, S. Bailly³, S. Baillieux³, A. Reynolds¹, H. Scott¹, J. Manners¹, P. Catcheside¹, R. Adams¹, D.J. Eckert¹

¹Flinders University, Adelaide Institute for Sleep Health and FHMRI Sleep Health, Adelaide, Australia,

²Centre Interdisciplinaire du Sommeil, Paris, France, ³Univ. Grenoble Alpes, HP2 Laboratory, Grenoble, France

Introduction: High night-to-night variability in obstructive sleep apnoea (OSA) severity is associated with hypertension and increased likelihood of atrial fibrillation events independent of OSA severity.

However, impacts on cardiovascular and cerebrovascular events are unknown. This study aimed to examine the association of OSA severity and its night-to-night variability with cardiovascular disease prevalence.

Materials and methods: Multi-night apnoea-hypopnea index (AHI) data were collected from users of a validated, FDA-cleared under-the-mattress sensor (Withings Sleep Analyzer) who completed six-monthly questionnaires on demographics and physician-diagnosed health conditions including cardiovascular and cerebrovascular diseases. OSA severity (AHI) and OSA variability (root-mean square of successive differences in AHI) were calculated in the 6-months preceding the questionnaire entry. The primary outcome was a composite measure of non-fatal major adverse cardiovascular and cerebrovascular events (MACCE), including myocardial infarction or heart attack, stroke, angina pectoris or coronary artery disease, and congestive heart failure. Logistic models assessed associations between with MACCE prevalence adjusted for age, sex, body mass index, alcohol consumption, smoking status, average OSA severity and physician-diagnosed OSA. The logistic regression results are presented as odds ratios (OR) and 95% confidence intervals (CI), comparing the 75th percentile with the 25th percentile of the continuous exposure variable. Robust covariance was estimated using sandwich estimators by using participants IDs as a cluster variable to account for correlated responses within participants (for those with multiple questionnaire entries).

Results: Among 3,159 participants (mean age: 49±13 years; 19% female; mean BMI: 29±6 kg/m²), 139 (4.4%) instances of MACCE were reported based on the last questionnaire entry. The final dataset included 4,936 questionnaire entries. Among them, 1,982 participants completed a single questionnaire, 725 completed two, and 452 completed more than two entries. Average OSA severity was not associated with MACCE prevalence (moderate-to-severe OSA vs. no OSA: adjusted OR [95%CI]; 1.42 [0.89, 2.24]). However, high night-to-night OSA variability (75th vs. 25th; 11.0 vs. 3.8 events/h) was associated with a 33% increase in the odds of prevalent MACCE, independent of OSA disease severity (adjusted OR [95%CI]; 1.33[1.02, 1.74]). Among participants with mild OSA, high OSA variability (tertile 3 vs. tertile 1) was independently associated with an increased prevalence of myocardial infarction, heart attack and/or stroke events (adjusted OR [95%CI]; 3.93 [1.21, 12.6]). This association was not evidenced in participants with moderate-to-severe OSA, although these results should be interpreted with caution given the reduced number of events once stratified by OSA-severity category.

Conclusions: High night-to-night variability in OSA severity represents a novel clinical OSA phenotype linked to higher cardiovascular and cerebrovascular prevalence, which may be a better marker of risk than OSA severity in individuals with mild OSA. These findings underscore the importance of multi-night OSA assessments to adequately characterise OSA and improve patient management and outcomes.

Home monitoring of patients under continuous positive pressure by a non intrusive under-mattress sleep analyzer

P. Escourrou¹, R.-Y. Yang², A. Sabil³, O. Felix⁴

¹CIS, Paris, France, ²WITHINGS, Issy les Moulineaux, France, ³SOS oxygene, Montigny le Bretonneux, France, ⁴SomniPlanet, Courbevoie, France

Introduction: To determine the performance of the WITHINGS Sleep Analyzer (WSA) in the evaluation of sleep duration and respiratory events, we compared WSA data with CPAP use, residual events and polysomnographic data in patients with CPAP treatment.

Materials and methods: The WSA (CE medical and FDA certified) placed between the bed base and the mattress, records pressure variations and snoring. It was set up in the patient's home after one month of CPAP use. Simultaneous 7-daily reports from CPAP Airsense 11 (Resmed) and WSA were collected. In addition 14 patients had simultaneous recordings of CPAP and WSA under full PSG at home. Patients and home care providers did not receive feedback from the WSA during the protocol.

Results: 75 patients (17F) with a diagnosis of OSAS, mean age 55.1 years (SD 12.1), BMI 30.8 kg/m² (4.7), Epworth Sleepiness Scale 11.2 (5.4), AHI (Apnea-Hypopnea Index) 44.2/hr (20.5) had 480 nights of concurrent WSA and CPAP recordings. Time spent in bed was 8.1 hr (1.2) and sleep time 7.1 hr (1.2) for an average duration of CPAP use of 6.5 hr (1.7) (Wilcoxon test comparison of sleep time WSA vs

CPAP $p < 0.001$). The AHI determined by the WSA was 11.3/hr (12.4) vs 2.0 (1.9) for CPAP ($p < 0.001$). In the 14 patients recorded with PSG, AHI_{psg} was 10.9/hr (8.4) compared to AHI_{wsa} 8.8 (10.9) and AHI_{cpap} 2.9 (2.7) ($p < 0.05$ between PSG and WSA, WSA and CPAP; $p < 0.01$ between PSG and CPAP). **Conclusions:** In this highly adherent patient group, WSA allowed to evaluate Time in bed, Total sleep time and AHI_{wsa}. AHI_{wsa} was higher than AHI_{cpap} and close to AHI_{psg}. In the future WSA could improve CPAP follow-up with better therapy efficacy assessment particularly during the early phase of treatment. WSA may also increase patient empowerment.

Introduction: Obstructive Sleep Apnea (OSA) affects approximately 4 million people in Vietnam, with 2.3 million individuals suffering from moderate to severe conditions. Among these, people with existing cardiovascular diseases, hypertension, diabetes, and obesity are at high risk of developing OSA. Therefore, this study aims to assess the prevalence of Obstructive Sleep Apnea in this population group using a Level 3 diagnostic model at home.

Materials and methods: A cross-sectional multicenter survey was conducted from December 2024 to March 2025, involving population with different health problems across Vietnam. Collected data included age, sex, body mass index (BMI), STOP-BANG score, Epworth Sleepiness Scale (ESS), apnea-hypopnea index (AHI), oxygen desaturation index (ODI), and comorbid conditions. Selected participants for doing Home Sleep Testing (HST) were for those who had at the moment of study one of the following conditions: Cardiovascular diseases, Hypertension, Diabetes, or Obesity (CHDO). They completed questionnaires (STOP-BANG, ESS) and underwent Type III respiratory polygraphy using self-applied Apnea-Link Air devices at home. Trained technicians at the centers provided remote technical support, reviewed, and standardized these recordings. Statistical analyses included descriptive summaries, correlation assessments, univariate and multivariable linear regression models for AHI, and logistic regression models to identify factors associated with moderate (AHI ≥ 15) and severe OSA (AHI ≥ 30).

Results: Number of included study participants was 340 among 1500 subjects with current health problem across four different regions of Vietnam. Initial screening showed that 268 participants with CHDO problem, 268 subjects had cardiovascular-disease and hypertension, 107 had diabetes mellitus, and 56 were obesity. Participants had a mean age of 59.9 ± 15.1 years, mean BMI of 25.1 ± 3.5 kg/m². A STOP-BANG score ≥ 3 (4.2 ± 1.6) was present in 294 participants (88.0 %), and an mean of ESS: 7.1 ± 5.4 within ESS ≥ 11 was present in 91 participants (27%). Respiratory polygraphy using Apnea-Link Air devices identified OSA in 73% of the participants (28% mild, 24% moderate, and 21% severe). The prevalence of OSA in the Cardiovascular-disease – Hypertension group was 75% (40% mild, 32% moderate, and 28% severe); in the Diabetes mellitus group was 77% (39% mild, 29% moderate, and 32% severe), and in the Obesity group was 76% (23% mild, 37% moderate, and 40% severe). BMI and STOP-BANG scores demonstrated a moderate positive correlation with AHI ($r = 0.33$; $p < 0.001$), whereas ESS had a weak correlation ($r = 0.11$; $p = 0.43$). In multivariable regression, both BMI and STOP-BANG remained significant predictors of AHI, while ESS was not. Logistic models confirmed that both BMI and STOP-BANG significantly predicted the presence of moderate and severe OSA.

Conclusions: Compared to the general population, the prevalence of OSA in the population group with pre-existing cardiovascular diseases, hypertension, diabetes mellitus, and obesity is very high. OSA severity is closely linked with objective measures such as BMI and STOP-BANG scores, but not with subjective daytime sleepiness as assessed by the ESS. These findings underscore the importance of

structured screening tools in those with cardiovascular risk factors. Therefore, a level 3 HST model is effective and suitable for screening OSA in high-risk populations and in emerging countries.

Identification and validation of a novel autophagy-related biomarker in obstructive sleep apnea syndrome

Z. Li¹, H. Yi², F. Han², P. Guo¹

¹Peking University People's Hospital, Emergency Surgery, Beijing, China, ²Peking University People's Hospital, Sleep Medicine, Beijing, China

Introduction: Obstructive sleep apnea syndrome (OSAS) is implicated in tumor progression, with chronic intermittent hypoxia (CIH) driving autophagy and malignancy. This study investigates the role of autophagy in OSAS progression and its implications for colorectal cancer (CRC).

Materials and methods: We analyzed OSAS datasets (GSE135917, GSE38792) from the Gene Expression Omnibus to identify differentially expressed genes (DEGs) and autophagy-related DEGs. Functional enrichment was performed using Gene Ontology, Kyoto Encyclopedia of Genes and Genomes, and gene set enrichment analysis (GSEA). A protein-protein interaction network pinpointed hub genes. CRC datasets from The Cancer Genome Atlas were used for differential expression, survival, GSEA, and immune infiltration analyses. In Sprague-Dawley rats, CIH-induced autophagy and oxidative stress were assessed via reactive oxygen species (ROS) assays. Hub genes were validated in rat models and OSAS patient samples.

Results: GSEA revealed significant enrichment of autophagy-related genes in OSAS. Five hub genes (ATG5, CASP1, MAPK8, EIF4G1, TBK1) were identified, with ATG5 and TBK1 validated. Autophagy-related DEGs were predominantly upregulated in CRC tissues. Elevated TBK1 expression in CRC was associated with improved immunotherapy sensitivity and increased infiltration of CD8+ T cells, macrophages, and regulatory T cells, suggesting modulation of the immune microenvironment. In rats, CIH elevated ROS levels, supporting its role in autophagy activation. TBK1 expression was significantly higher in OSAS patients compared to controls, unaffected by continuous positive airway pressure therapy.

Conclusions: This study pioneers the identification of TBK1 as a key contributor to OSAS progression, highlighting its potential as a novel biomarker and therapeutic target. These findings underscore the interplay between CIH, autophagy, and tumor immunity, offering new avenues for OSAS management and CRC immunotherapy.

Acknowledgments: This research was supported by the National Key Research and Development Program of China (Grant No. 2023YFC2412005). We thank the Gene Expression Omnibus and The Cancer Genome Atlas for providing access to essential datasets, and the Animal Experiment Center of Peking University People's Hospital for their support with animal studies. The study involving human subjects and animal experiments was approved by the Ethics Committee of Peking University People's Hospital (2022PHB359-001).

Identification of the prevalence of Obstructive Sleep Apnea in the Cardiology and Neurology Semi-Intensive Units at a private hospital in Brazil

E.L. Brasil¹, P. Andrade Xavier¹, S. Hilger¹, R. Afonso Caserta Eid¹

¹Hospital Israelita Albert Einstein, Department of Critical Care Medicine, São Paulo, Brazil

Introduction: Sleep disorders are three times more prevalent in patients with cardiovascular disease compared to the general population. Obstructive Sleep Apnea (OSA) is the most common type of sleep-disordered breathing and is associated with a 70% relative increase in the risk of cardiovascular morbidity and mortality. OSA is a recognized risk factor for several cardiovascular conditions, including arterial hypertension, heart failure, stroke, coronary artery disease, metabolic syndrome, and cardiac arrhythmias. Polysomnography is considered the gold standard for diagnosing OSA. However, screening questionnaires such as the Berlin Questionnaire (BQ) and STOP-Bang can be utilized as practical tools to identify risk factors for OSA.

Materials and methods: In patients over 18 years of age admitted to the Cardiology and Neurology Semi-Intensive Units with a diagnosis of acute myocardial infarction, atrial fibrillation, systemic arterial

hypertension, stroke, complete atrioventricular block, and heart failure, the Berlin Questionnaire and STOP-Bang screening tools were applied to help identify those at high risk of OSA. After identifying patients at high risk for OSA, they were referred for polysomnography and/or in-hospital or outpatient treatment.

Results: The implementation of this screening allowed the team to effectively identify and manage patients at high risk for OSA, ensuring greater safety throughout hospitalization. Patients could be diagnosed during their stay and promptly begin appropriate treatment for sleep apnea. Furthermore, those scheduled for examinations or procedures involving sedation could be assessed for potential respiratory complications based on their OSA risk profile.

Conclusions: This approach significantly improved understanding and management of OSA risk, enabling the team to provide comprehensive care and reduce potential complications associated with the condition.

Identifying Obstructive Sleep Apnoea in Headache Clinics: Clinical Clues and Diagnostic Considerations

Y.-J. Tan¹, T. Gosavi², V. Thirunavukarasu³

¹SingHealth Duke-NUS Sleep Centre, Singapore, Singapore, ²National Neuroscience Institute, Neurology, Singapore, Singapore, ³Ng Teng Fong General Hospital, ENT, Singapore, Singapore

Introduction: Encounters with patients experiencing chronic headaches are common occurrences in neurology clinics. However, recognition of underlying obstructive sleep apnoea (OSA) in some of these patients remains limited amongst neurologists, potentially leading to suboptimal treatment with migraine medications and muscle relaxants, resulting in incomplete headache relief. Diagnostic clues from clinical features and ancillary test results are therefore essential to help neurologists identify these patients in a headache clinic and guide appropriate testing and treatment.

Materials and methods: Typical of a consecutive case series, patients who presented to a neurology clinic between June 2024 to June 2025 for the main complaints of chronic headaches (15 days or more, for at least 3 months) and with a STOPBANG score of 3 or more were included into this study. All patients subsequently undergo home sleep apnoea tests (WatchPAT device) or overnight polysomnographies. Clinical features and ancillary test data were retrospectively analyzed, regardless of the presence, absence, or severity of OSA on diagnostic testing.

Results: We studied 26 patients, of which most (73.1%) were women (females to males = 2.7:1). The median age was 54.5 years (inter-quartile range [IQR] 49–63), and the median body mass index (BMI) was 28.3 kg/m² (IQR 23.1–36.6). Over half (53.8%) were obese (BMI >27 kg/m²), 26.9% were overweight (23–27.4 kg/m²), and 19.2% had normal BMI. Nearly all (88.5%) had cardiovascular risk factors—69.2% had hypertension, 30.8% hyperlipidaemia, 30.8% diabetes, 11.5% prior strokes, and 11.5% ischemic heart disease. Half had two or more risk factors. Among those with hypertension, 55.6% (10/18) were diagnosed before age 50, and 27.8% (5/18) before age 40. Chronic bitemporal/bifrontal headaches resembling tension-type headaches were the most common presenting complaint (84.6%), worsening in the morning for most (92.3%). All patients reported snoring and having non-restorative sleep. Other sleep complaints included dry mouth on waking (92.3%), nocturnal micturition (57.7%), choking /coughing during sleep (53.8%), and apnoeic episodes (15.4%). The median STOP-BANG score was 4.5 (IQR 4–5). Less than 1/3 (30.8%) had neck circumferences of >40cm, or BMIs of > 35kg/m² (26.9%). Despite frequent reports of daytime sleepiness (84.6%), their median Epworth Sleepiness Scale score was only 9 (IQR 4–11.5), with half scoring below those of pathologic sleepiness. 23 and 3 patients underwent home sleep apnoea testing and overnight polysomnography respectively. Their median sleep parameters were: sleep latency of 17.5 minutes (IQR 9.5–20), REM latency of 67 minutes (IQR 42.5–90.3), sleep efficiency of 84.6% (IQR 82.5–90.6), overall apnoea–hypopnoea index (AHI) of 24.4 (IQR 16.9–47.7), non-REM sleep of AHI 23.9 (IQR 7.3–45.4), and REM sleep AHI of 34.9 (IQR 28.2–51.6).

Conclusions: Notwithstanding the methodological limitations, our findings highlight the need to consider OSA in patients with chronic tension-type headaches, particularly when they are overweight, or have multiple cardiovascular risk factors. Hypertension before age 50 is an important diagnostic clue, while high Epworth Sleepiness Scale scores appear less reliable. Clinicians should screen for

symptoms of sleep apnoea, and objective sleep assessments are recommended even in those with intermediate STOP-BANG scores.

Imaging features of upper airway in obstructive sleep apnea patients with epiglottic collapse

Y. Zhang^{1,2}, D. Zhao¹

¹Department of Otolaryngology, Second Affiliated Hospital of Zhejiang University, Hangzhou, China,

²Department of Otolaryngology, the First People's Hospital of Xiaoshan District, Hangzhou, China

Introduction: The epiglottic location is concealed, and airway collapse and obstruction in OSA patients only occur in sleep. Drug-induced sleep endoscopy (DISE) is a kind of real-time and dynamic laryngoscopy on the upper airway of patients induced to sleep through drugs, which can accurately locate the plane and degree of obstruction. Due to the limited medical resources, it is difficult to apply on a clinical basis and can not be promoted in primary hospitals. Upper airway Computed tomography (CT) It can initially determine the structural factors of nasopharyngeal, oropharyngeal, and glossopharyngeal stenosis during the waking period and has particular clinical guiding value. Therefore, this study aims to screen out OSA patients with epiglottic collapse through DISE examination and compare and analyze the upper airway CT with other OSA patients and people without OSA to summarize the imaging characteristics and rules of patients with epiglottic collapse.

Materials and methods: One hundred and four patients underwent physical examination, polysomnography (PSG), and a three-dimensional CT plain scan of the upper airway. In addition, all patients underwent drug-induced sleep endoscopy (DISE). According to DISE, all patients were divided into the epiglottic and non-epiglottic collapse groups. Eighteen patients with foreign bodies in the esophagus who received treatment in our hospital during the same period completed three-dimensional CT of the upper airway. They denied snoring history and were selected as a standard control group. Collected the relevant data and analyzed the differences among the groups.

Results: A total of 18 patients with foreign bodies in the esophagus were included as normal controls. One hundred four patients with OSA, 27 patients with epiglottic collapse, and 77 patients with non-epiglottic collapse were included. In this study, the incidence of epiglottic collapse was 25.96%. There were statistically significant differences in epiglottic length between patients with epiglottic collapse and the standard control group ($P < 0.05$). In the patients with epiglottic collapse, the epiglottic length ($t=2.162$, $P=0.033$) and the lymph tissue classification of the root of the tongue ($Z=-2.968$, $P=0.003$) were significantly greater than those in the patients with non-epiglottic collapse, and the epiglottis-root of tongue distance ($Z=-2.385$, $P=0.017$) was smaller than the latter. According to Logistic regression analysis, epiglottic collapse and epiglottic width (OR: 1.201; 95%CI: 1.009-1.430, $P=0.039$) were positively correlated, with epiglottic curvature (OR: 0.979; 95%CI: 0.961-0.998, $P=0.030$) was negatively correlated, and with the grade of lymph tissue of tongue root (OR: 1.936; 95%CI: 1.294-2.896, $P=0.001$) was positively correlated.

Conclusions: In patients with epiglottic collapse, the epiglottic length and lymphoid tissue grading of the root of the tongue are significantly greater than those of patients with non-epiglottic collapse, and the epiglottic root of tongue distance is smaller than the latter. CT examination in awake OSA patients with epiglottic collapse can reveal its characteristic indicators. The wider the epiglottic width, the smaller the epiglottic curvature, and the larger the lymph tissue grade of the base of the tongue were effective predictors of epiglottic collapse, and the lymph tissue grade of the base of the tongue was an independent predictor.

Impact of an early follow-up visit on adherence and adherence trajectories after initiation of continuous positive airway pressure therapy for obstructive sleep apnea

J.-L. Pepin¹, J. Texereau², S. Bailly³, J. Duval⁴

¹CHU de Grenoble, Laboratoire EFCR, Grenoble, France, ²Air Liquide Healthcare, Bagneux, France,

³Inserm U1300, HP2 Laboratory, Grenoble, France, ⁴Orkyn, Lyon, France

Introduction: Clinical outcomes during continuous positive airway pressure (CPAP) relate to therapy adherence. The impact of different/specific types of patient support on CPAP adherence is rarely

evaluated, meaning there is a lack of knowledge to inform the choice of follow-up strategy for individual patients. The study evaluates the impact of an early home visit on CPAP adherence/adherence trajectories in patients with obstructive sleep apnea, and which factors predict benefit of an early follow-up visit.

Materials and methods: This multicenter cohort study analyzed home service provider data. Participants were adults starting CPAP in 2019–2022 who had >90 days of telemonitoring data. Adherence was compared before and after the early visit, overall and in subgroups based on adherence over the 15 days after starting CPAP (<2 [low], 2–<4 [intermediate] or ≥4 [high] h/night). Adherence trajectories were also determined.

Results: 4,924 patients were included (62.3% male, mean age 59±13 years, apnea-hypopnea index [AHI] 40±17/h). The early follow-up visit took place 16±5 days after CPAP initiation. Change in adherence in the week after versus week before the early visit was 14±3 min/night overall, and -7±2, 60±4, 102±5 min/night in the high, intermediate, and low adherence subgroups, respectively (p<0.01). Adherence gradually decreased after therapy initiation, increased in the 1–2 days before the visit, then declined. Cluster analysis identified two profiles across all early adherence subgroups: responders and non-responders (those with or without better CPAP usage after the early visit, respectively). Responders were slightly older and had higher CPAP motivation than non-responders; higher leak and higher residual AHI predicted improved adherence after the early visit in the intermediate and low adherence subgroups, respectively.

Conclusions: These data highlight the need for deeper understanding of adherence trajectories and the impact of specific follow-up modalities to allow implementation of personalized CPAP therapy management pathways.

Impact of CPAP Treatment on Inflammatory Markers in Moderate-Severe Obstructive Sleep Apnea Patients: A 12-Month Follow-Up Study

P. Sirijanchune¹, B. Paihan¹, P. Panta², S. Chaikhan²

¹Chiangrai Prachanukroh hospital, Internal medicine, Meung, Chiang Rai, Thailand, ²Chiangrai Prachanukroh hospital, ENT, Meung, Chiang Rai, Thailand

Introduction: Obstructive Sleep Apnea (OSA) is characterized by intermittent upper airway obstruction, leading to chronic hypoxia and a pro-inflammatory state. The elevation of inflammatory markers, such as high-sensitivity C-reactive protein (hs-CRP) and erythrocyte sedimentation rate (ESR), is frequently observed in OSA and is associated with an increased risk of cardiovascular disease. Continuous Positive Airway Pressure (CPAP) is a well-established treatment for OSA; however, its effect on inflammatory biomarkers remains unclear. This study aimed to evaluate the impact of CPAP therapy on hs-CRP and ESR levels in patients with moderate-severe OSA, with good CPAP adherence, over a 12-month period.

Materials and methods: This prospective study was conducted at Chiangrai Prachanukroh Hospital from January 2023 to December 2024. A total of 120 newly diagnosed moderate-to-severe OSA patients were enrolled, all of whom had a minimum CPAP adherence rate of 70%. Participants were predominantly male (86/120, 71.66%) with a mean age of 49.3±15.5 years. The baseline assessment included polysomnography, measurement of hs-CRP, ESR, and metabolic parameters, along with the Epworth Sleepiness Scale (ESS) and STOP-BANG scores. CPAP therapy was initiated after diagnosis, and compliance was monitored through usage data. Follow-up assessments were performed 12 months after initiating CPAP therapy.

Results: At baseline, the mean apnea-hypopnea index (AHI) was 50.88 events/hour, and the mean ESS score was 9.17. After 12 months of CPAP therapy, the mean AHI decreased to 3.67 events/hour. Inflammatory markers, hs-CRP and ESR, showed a trend toward reduction after CPAP therapy, but the changes did not reach statistical significance (hs-CRP: 9.61 to 3.42 mg/L, p = 0.070; ESR: 19.58 to 13.64 mm/hr, p = 0.339). There was a statistically significant decrease in cholesterol levels from 179.17 mg/dL to 148.41 mg/dL (p = 0.036), but no significant changes were observed in blood pressure,

fasting blood sugar (FBS), or HbA1c levels. CPAP usage was adequate, with a mean daily usage of 5.77 ± 1.39 hours and an overall adherence rate of 87.5%.

Conclusions: This study indicates that while CPAP therapy in patients with moderate-severe OSA led to a reduction in inflammatory markers such as hs-CRP and ESR, these changes did not reach statistical significance. However, the reduction observed suggests a potential benefit of CPAP therapy in decreasing systemic inflammation. Despite the lack of statistical significance, these findings contribute to the ongoing debate regarding the role of CPAP in reducing inflammation and improving cardiovascular outcomes in OSA patients. Further studies with larger sample sizes and longer follow-up are needed to fully understand the effects of CPAP on inflammation in OSA patients.

Acknowledgments: We would like to acknowledge the Sleep Disorder Center team at Chiangrai Prachanukroh Hospital for their support and contribution to this study.

Impact of Insomnia and Periodic limb movements of sleep on Mortality in OSA: A High-Risk Phenotype Identified by A Cluster Analysis

Introduction: Obstructive sleep apnea (OSA) is a heterogeneous syndrome, which makes the Apnea-Hypopnea Index (AHI) insufficient in predicting clinical outcomes, including mortality. This study sought to identify novel OSA phenotypes through a cluster analysis of polysomnographic (PSG) data and to determine their association with all-cause and specific-cause mortality.

Materials and methods: We retrospectively analyzed the records of 3,380 patients with an AHI ≥ 15 /h who underwent PSG between January 1994 and December 2020 at the Center for Sleep and Chronobiology at Seoul National University Hospital, a tertiary medical center in the Republic of Korea. Seven principal components, which are the result of a principal component analysis (PCA) to reduce dimensionality, were associated with oxygen desaturation, sleep fragmentation, deep sleep, periodic limb movements of sleep (PLMS), REM sleep, hypopnea, and shallow sleep, respectively. Then, a K-means cluster analysis was performed to identify distinct OSA phenotypes. Mortality was ascertained from national death records provided by Statistics Korea through December 31, 2022. Using Kaplan-Meier survival analysis, we compared all-cause mortality and specific-cause mortality comprised of cardiovascular and cerebrovascular diseases. A Cox proportional hazards model was used for adjusting age, sex, BMI and comorbidities. The mortality risk of the identified phenotypes was then compared with that of typical AHI-based severity groups (moderate vs. severe OSA).

Results: Four distinct phenotypes were identified. Cluster 1 (n=1,956, 57.8%) was characterized as 'Severe OSA' (median AHI 31.3/h). Cluster 2 (n=674, 19.9%), termed 'Moderate OSA with stable sleep', had a moderate AHI (median 26.6/h) and preserved sleep architecture (median sleep efficiency [SE] 87.1%). Cluster 3 (n=427, 12.6%), termed 'Very severe OSA with hypoxemia', comprised the youngest (median age 49) and predominantly male (92.7%) patients, exhibiting a very severe AHI (median 69.4/h) and the most severe hypoxic burden (median time with $\text{SpO}_2 < 90\%$ 29.6%). Cluster 4 (n=323, 9.6%), described as 'Comorbid insomnia and sleep apnea with PLMS', included the oldest patients (median age 62) with the shortest sleep time (median total sleep time 399.5 min) and the highest PLMS (median 44.5/h). While moderate OSA and severe OSA showed no significant difference in all-cause (Log-rank $p=0.29$) or specific-cause mortality (Log-rank $p=0.09$), mortality rates showed a significant difference

among the cluster. For all-cause mortality (Log-rank $p < 0.001$), Cluster 4 showed the highest and Cluster 2 the lowest rates. After adjusting covariates, Cluster 3 (Hazard Ratio [HR] 1.95, 95% Confidence Interval [CI] 1.13–3.36, $p = 0.017$) and Cluster 4 (HR 2.10, 95% CI 1.43–3.08, $p < 0.001$) had significantly higher mortality risk than Cluster 1. For specific-cause mortality (Log-rank $p < 0.001$), only Cluster 4 showed a significantly higher adjusted risk compared to Cluster 1 (HR 3.19, 95% CI 1.36–7.50, $p = 0.008$).

Conclusions: This study identified distinct obstructive sleep apnea (OSA) phenotypes by cluster analysis using multiple polysomnography (PSG) variables that reflect underlying pathophysiology, which demonstrated superior prognostic value for both all-cause and specific-cause mortality compared to the typical AHI-based classification. Our findings suggest that for predicting the mortality of OSA, it is crucial to consider not only the severity of respiratory disturbance but also co-existing features such as sleep time and PLMS.

Impact of Obstructive Sleep Apnea on Daily Life by Disease Severity Level: Analysis from the SHINE Survey

A. Mendoza¹, M. Mallampalli², E. Cooksey³, J. Yee¹, E. Brouwer⁴, L. Bloudek⁴, R. Wu⁴, K.S. Yu¹

¹Apnimed, Inc., Cambridge, United States, ²Alliance of Sleep Apnea Partners, Ellicott City, United States, ³Project Sleep, Los Angeles, United States, ⁴Curta, Inc., Seattle, United States

Introduction: Obstructive sleep apnea (OSA) is a serious, chronic, sleep-related breathing disease characterized by intermittent airway blockage during sleep, leading to disrupted breathing, fragmented sleep, and reduced oxygenation. OSA is often underdiagnosed particularly in mild cases, despite its significant negative impact on daily functioning and quality of life. This analysis aimed to evaluate the impact of OSA on daily life of people living with OSA, based on self-reported OSA severity levels.

Materials and methods: The SHINE online patient survey, developed in consultation with patient advocates and OSA experts, was administered to 1,500 OSA patients in the United States. Data were analyzed using generalized linear models with a binomial distribution and logit link function, adjusted for age group, BMI category, race, region, income level, comorbidities, and time since diagnosis. Model outcomes included: (1) whether OSA limited patients' ability to engage in regular, non-work activities (rated 3, 4 or 5 on a 5-point scale), (2) whether OSA affected work productivity (rated 3, 4 or 5 on a 5-point scale), and (3) experienced ≥ 2 negative OSA symptoms in the past 30 days.

Results: Among respondents, 13% reported mild, 54% moderate, and 30% severe OSA. Results showed that patients at all levels of severity experienced symptoms and negative impact to daily activities and work productivity. The percentage of patients who reported ≥ 2 symptoms in the past 30 days was 84%, 91% and 86% ($p = 0.003$) among mild, moderate and severe patients, respectively. Mild (48%), moderate (64%) and severe (62%) patients also reported that OSA affected their non-work activities ($p < 0.01$). Among employed patients, 39%, 51%, and 48% of mild, moderate and severe patients, respectively, reported that OSA negatively impacted work productivity ($p = 0.002$). Comorbidities, including COPD, diabetes, and insomnia, were significantly associated with increased odds of OSA affecting work and non-work activities ($p < 0.05$).

Conclusions: Patients with OSA across the severity spectrum experienced daily life challenges, with severity generally correlating with greater impact. Surprisingly, even those with mild OSA experienced significant negative impact on their daily work and non-work activities. These findings emphasize the importance of early screening, diagnosis and treatment to delay the progression to severe OSA.

Impact of Obstructive Sleep Apnea on Nocturnal Ketone Metabolism: A Breath Acetone Analysis Study

Y.M. Chang¹

¹Taipei Medical University, Taipei City, Taiwan

Introduction: In recent years, ketogenic diets have gained popularity as effective strategies for weight loss and metabolic improvement. A key aspect of these approaches lies in the body's transition into a state of ketosis—shifting from glucose to fat as the primary fuel source, thereby promoting ketone

body production. However, poor sleep quality or sleep disturbances may impair ketogenesis, potentially reducing the expected metabolic benefits.

Obstructive sleep apnea (OSA) refers to sleep-disordered breathing caused by partial or complete airway obstruction. Despite its potential impact, empirical evidence on whether OSA disrupts overnight changes in ketone levels remains limited. Therefore, this study aims to investigate whether OSA influences overnight breath acetone fluctuations by comparing pre-sleep and post-sleep ketone levels, and to develop a predictive model based on sleep-related parameters.

Materials and methods: We conducted a cross-sectional study at Shuang-Ho Hospital to investigate the impact of obstructive sleep apnea (OSA) on overnight ketone metabolism. A total of 66 adult participants underwent overnight Polysomnography (PSG) and were categorized into two groups based on their Apnea-Hypopnea Index (AHI): the non-severe OSA group (AHI < 30, n = 42) and the severe OSA group (AHI ≥ 30, n = 24). Breath acetone levels were measured before and after sleep using a portable breath ketone meter. The change in breath acetone ($\Delta\text{Acetone} = \text{post-sleep} - \text{pre-sleep}$) was used as a marker of nocturnal ketogenesis. We performed Student's t-tests and Chi-Square tests to compare demographic and PSG variables between the groups. Spearman correlation analyses were used to assess associations between $\Delta\text{Acetone}$ and OSA-related variables. Finally, a logistic regression model was constructed to identify predictors of a negative overnight acetone change ($\Delta\text{Acetone} < 0$), using $\Delta\text{Acetone} > 0$ as the reference group.

Results: Among the 66 participants, those in the severe OSA group (n = 24) exhibited significantly higher age, weight, BMI, neck circumference, and waist circumference than the non-severe group (n = 42) ($p < 0.05$). PSG results showed that severe OSA patients had significantly lower mean SaO_2 , higher AHI, ODI, Arousal Index (Arl), and greater proportions of light sleep stages (N1 and Wake) ($p < 0.05$). The overnight change in breath acetone ($\Delta\text{Acetone}$) was significantly lower in the severe group (-0.52 ± 0.60) than in the non-severe group (-0.12 ± 0.57 ; $p = 0.01$). Spearman correlation revealed that AHI and ArI were negatively correlated with $\Delta\text{Acetone}$ ($r = -0.453$ and -0.454 , respectively; $p < 0.01$). Logistic regression analysis further identified AHI as a significant predictor of negative overnight acetone change (OR = 1.058, 95% CI: 1.003–1.117, $p = 0.04$), after adjusting for ArI, weight, and neck circumference.

Conclusions: This study provides preliminary evidence that obstructive sleep apnea (OSA), particularly with higher AHI levels, may impair overnight ketone metabolism. AHI was identified as a significant predictor for a negative overnight change in breath acetone. These findings highlight the potential metabolic consequences of untreated OSA and suggest a novel physiological link between sleep-disordered breathing and impaired lipid metabolism.

Impaired Cardiovascular Autonomic Regulation in Patients with Obstructive Sleep Apnea: A Heart Rate Variability-Based Analysis

J.-Y. Jeon¹

¹Department of Neurology, School of Medicine, Kyungpook National University, Daegu, Korea, Republic of

Introduction: Obstructive sleep apnea (OSA) is characterized by repeated airway obstruction during sleep, leading to hypoxia and sympathetic activation. These physiological changes may impair autonomic regulation, increasing cardiovascular risk. Heart rate variability (HRV) is a useful marker of autonomic function, but few studies have examined how OSA severity affects HRV before and after sleep. This study aimed to investigate the impact of OSA severity on heart rate variability (HRV), a marker of autonomic function, before and after sleep.

Materials and methods: We conducted a retrospective study of 34 adult patients (mean age 55.7 ± 13.5 years; 64.7% male) who underwent overnight polysomnography (PSG) between January and December 2021. Patients with previous cardiovascular, pulmonary, neurological, psychiatric diseases, or those on medications affecting HR were excluded. HRV was assessed using time- and frequency-domain indices from electrocardiography (ECG) recorded 1 hour after sleep onset and 1 hour before awakening. Participants were classified into mild, moderate, and severe OSA groups based on apnea-hypopnea index (AHI).

Results: The mean AHI was 29.9 ± 17.2 . Severe OSA patients showed significantly higher AHI (50.6 ± 13.1) and lower minimum oxygen saturation ($73.5 \pm 13.9\%$) compared to moderate and mild groups ($p < 0.05$). While time-domain HRV indices did not differ significantly among groups, a non-significant trend toward increased morning LF power (indicative of sympathetic activation) was observed in the severe

OSA group compared to others. A higher AHI was significantly associated with parasympathetic tone (HF power) in the morning, suggesting impaired recovery of autonomic balance.

Conclusions: No previous studies have directly compared heart rate variability complexity before and after sleep to investigate whether sleep apnea itself influences HRV complexity. OSA severity correlates with autonomic dysregulation, particularly reduced parasympathetic activity and sustained sympathetic activation during sleep. These findings underscore the importance of evaluating HRV in OSA patients as a potential marker for cardiovascular risk.

Implantable respiratory state detection in stimulation target-IPG ECG lead

M. Jiang¹, B. Ma¹

¹Tsinghua University, Beijing, China

Introduction: Hypoglossal Nerve Stimulation (HNS) has been developed as an effective treatment for moderate to severe Obstructive Sleep Apnea (OSA). Closed-loop stimulation is expected to significantly improve the efficacy of HNS by detecting the respiratory status of the patient, such as inspiration, expiration, hypoventilation and apnea. To realize implantable closed-loop HNS for OSA, a sensing system suitable for implantable application is required to collect physiological signals to detect the respiratory status.

Materials and methods: In this study, the standard lead ECG signals were first acquired by PSG for analysis, and the respiratory state information was obtained by parsing based on the principles of the QRS complex wave amplitude modulation effect caused by the oscillation of the electrocardiographic axis with respiration and respiratory sinus arrhythmia. Further based on the now widely used platforms of Vagus Nerve Stimulator (VNS) and Polysomnography (PSG), the ECG signals are collected and analyzed to obtain the respiratory status through its built-in implantable acquisition system. The VNS has a built-in ECG acquisition module to detect the onset of epilepsy and other patients, because the stimulation target of the VNS, the vagus nerve, is located in a similar position to the hypoglossal nerve, and its IPG is generally implanted 1-2 cm below the clavicle, which is the same as that of the IPG implantation of the HNS. The acquisition of stimulation target-IPG lead ECG signals by VNS can simulate the ECG signals acquired by HNS and detect the respiratory status based on the relationship between respiration and ECG. Similarly, in this study, the ECG signals of VNS stimulation target-IPG lead were collected by PSG in vitro and analyzed to obtain the respiratory status.

Results: By analyzing the standard-lead ECG signals acquired by PSG with the respiratory signals, the peak value of the electrocardiographic R-peak and the heart rate decreased during inspiration and increased during expiration; the rate of change of the peak value of the R-peak and the rate of change of the heart rate were significantly reduced in hypoventilation as well as in apnea, and the peak change of the R-peak and the change of the heart rate were strongly correlated with respiratory status. The peak R-peak changes in the stimulation target-IPG leads captured by VNS were also highly positively correlated and periodic with the heart rate variability, and the period was consistent with the respiratory cycle, which was the same as the characteristics of the changes in the standard PSG leads, and enabled the estimation of respiratory status.

Conclusions: The through-VNS neurostimulation target-IPG lead ECG signals enable effective detection of respiratory status, which in turn enables closed-loop HNS for OSA.

Improving Treatment Outcomes in Obstructive Sleep Apnea By Personalized Optimization of Mandibular Advancement Devices: Clinical Outcomes from a Prospective Cohort Study

S. Charkhandeh^{1,2}, S. Engelen^{1,2}, S. Op de Beeck^{1,2}, M. Braem^{1,2}, J. Verbraecken^{1,3}, M. Deltjens^{1,2}, O. Vanderveken^{1,2,3}

¹University of Antwerp, Faculty of Medicine and Health Sciences,, Antwerp, Belgium, ²Antwerp University Hospital, Belgium, Department of ENT, Head and Neck Surgery,, AntwerpBelgium, Belgium, ³Antwerp University Hospital, Belgium, Multidisciplinary Sleep Disorders Centre, Antwerp, Belgium

Introduction: Mandibular advancement devices (MADs) are an established treatment for obstructive sleep apnea (OSA), often titrated subjectively based on symptom relief. However, this subjective

approach may result in suboptimal outcomes and premature titration termination. This study evaluates whether objective polygraphy (PG)-guided optimization in combination with individualized clinical evaluation improves treatment efficacy.

Materials and methods: This sub-analysis of the First Line OSA Therapy (FLOSAT) study included moderate to severe OSA patients with apnea/hypopnea index (AHI) between 15 and 65/hour sleep. Other inclusion criteria were BMI <35 kg/m², obstructive AHI 15–65/h, central AHI <30% of total AHI, no prior MAD or CPAP. All patients initiated MAD therapy (ProSomnus EVO) at maximum comfortable protrusion minus 3 mm, followed by self-titration based on symptom relief. Post-titration efficacy was assessed via polysomnography (PSG). Responders were defined as AHI <10/h. Non-responders underwent additional PG-guided titration. Differences in respiratory parameters (AHI, and oxygen desaturation index (ODI)) between responders and non-responders were evaluated.

Results: Of 86 patients, 73 (85%) responded to subjective titration, while 13 (15%) required further PG-guided optimization. In the responder group, AHI and ODI improved significantly under MAD therapy: AHI from 23.9 (17.3; 31.3)/h to 6.7 (4.7; 10.2)/h and ODI from 18.7 (13.6; 26.5)/h to 8.8 (5.6; 12.5)/h. In the non-responders who needed additional titration, both respiratory parameters improved following optimization: AHI reduced from 29.8 (21.6; 40.6)/h at baseline to 15.9 (13.9; 19.6)/h after subjective titration to 12.8 (8.4; 20.9)/h after PG-guided titration, while ODI reduced from 26.3 (16.2; 32.0)/h at baseline to 15.4 (10.7; 17.8)/h after subjective titration to 9.6 (7.3; 14.2)/h after PG-guided titration. While personalized optimization enhanced outcomes overall, not all patients achieved similar therapeutic benefits. Moreover, the degree of improvement, varied depending on the respiratory index used.

Conclusions: Subjective titration alone may be insufficient for MAD therapy, at least in “non-responders”. Objective optimization improves efficacy but must be tailored to individual response variability. Standardized yet adaptable protocols may enhance outcomes. Furthermore, the degree of improvement can vary, depending on the respiratory index used. The results of this study are specific for the MAD used, and may not be generalizable to all MADs

Acknowledgments: This study was supported by ProSomnus Sleep Technologies, which provided MAD devices free of charge.

Increased urinary IgM excretion in patients with obstructive sleep apnea

M. Al-Houqani¹, A. Oulhaj², O. Bakoush³, M.A. Khan⁴, J. Pathan¹

¹UAE University, Internal Medicine, Al-Ain, United Arab Emirates, ²Khalifa University, Abu Dhabi, United Arab Emirates, ³UAE University, Internal Medicine, Al Ain, United Arab Emirates, ⁴UAE University, Family Medicine, Al-Ain, United Arab Emirates

Introduction: Obstructive sleep apnea (OSA) is characterized by intermittent hypoxia which results in systemic inflammation and oxidative stress. OSA is associated with albuminuria and chronic kidney disease. Elevated urinary immunoglobulin M (IgM-uria) levels are associated with a high rate of renal cardiovascular death. There is limited information regarding IgM-uria and albuminuria in patients with OSA. This study aims to assess the association between various OSA severity markers and the biomarkers IgM-uria and albuminuria

Materials and methods: This is a cross-sectional study in which 124 patients were enrolled and underwent overnight polysomnography. Patients' urine samples were collected in the morning, and urinary IgM and albumin levels were measured, along with other demographic and clinical characteristics.

Results: Multiple linear regression analysis, adjusting for age, sex, smoking status, body mass index and hypertension, revealed a significant association between IgM-uria and albuminuria and various OSA severity markers including mean SpO₂, ODI, and AHI. Among patients without diabetes, a one standard deviation (SD) decrease in mean SpO₂ was associated with a significant 0.65 SD increase in IgM-uria (p < 0.001) and a 0.5 SD increase in Albuminuria (p < 0.000). An increase in ODI by one SD was associated with an increase in IgM-uria by 0.29 SD (p = 0.014) and an increase in Albuminuria by 0.33 SD (p = 0.006). An increase in AHI by one SD was associated with an increase in IgM-uria by 0.24 SD (p = 0.034) and an increase in Albuminuria by 0.22 SD (p = 0.043). However, these associations were not found to be statistically significant among patients with diabetes.

Conclusions: Urinary IgM and albumin levels were associated with OSA severity and hypoxemia levels in non-diabetic patients, indicating that IgM-uria and Albuminuria are a potential biomarker for renal and cardiovascular complication in OSA.

Independent and dose-dependent effect of sleep apnea-specific hypoxic burden on hypertension in obstructive sleep apnea: results from Shanghai Sleep Health Study cohort

E. Zhou¹, W. Huang¹, H. Yi¹, Y. Leng¹

¹Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Otorhinolaryngology Head and Neck Surgery, Shanghai, China, ²University of California, Psychiatry and Behavioral Sciences, San Francisco, United Kingdom

Introduction: Obstructive sleep apnea (OSA)-specific hypoxic burden (HB) was recognized as a novel metric for quantifying OSA and its physiological consequences. This study aimed to evaluate the association between HB and incidence of hypertension among OSA in Chinese population.

Materials and methods: Suspected OSA subjects were examined in the sleep laboratory with standard polysomnography between February 2008 and January 2022. After identifying and adjusting potential confounders and covariates, the logistic regression model evaluated odds ratios (ORs) for hypertension incidence based on HB metric in three models. Furthermore, a stratified analysis was performed according to OSA severity.

Results: A total of 5108 subjects (4287 OSA and 821 simple snoring [PS] subjects) were included in the analysis. The incidence of hypertension in $32.4 < HB \leq 100.31$, $100.31 < HB \leq 251.02$, and $HB > 251.02$ was increased by 40.4%, 95.0%, and 115.6% compared to $HB \leq 32.40$, respectively (OR[95% confidence interval (CI)], 1.404[1.138,1.731], 1.950[1.586,2.397], and 2.156[1.748,2.659], all $p < 0.01$; linear trend, $p < 0.001$). In PS group, the hypertension incidence in $HB > 14.21$ was 1.201 times higher than that in $HB \leq 3.07$ (OR[95%CI], 2.201[1.111,4.358], $p < 0.05$; linear trend, $p = 0.03$). Compared to PS, the association between HB and hypertension incidence was significant in OSA, especially in moderate to severe OSA (linear trends, all $p \leq 0.001$).

Conclusions: HB in OSA is independently and dose-dependently associated with hypertension incidence. The study expounds on the advantages and clinical significance of HB in assessing hypertension incidence. HB may be a better predictor for hypertension in a hypoxia-affected population.

Acknowledgments: All of the authors are grateful to the staff in our sleep center and all of the subjects.

Independent association between sleep apnea-specific hypoxic burden and dyslipidemia in obstructive sleep apnea

E. Zhou¹, T. Zhou¹, J. Zhang¹, W. Huang¹, C. Li¹, H. Yi¹

¹Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China

Introduction: Obstructive sleep apnea (OSA) is associated with and contributes to lipid metabolism. Current researches assess hypoxic indicators and lipid metabolism without AHI stratifying based on the primary criteria. Our study aims to explore the advantages and threshold of sleep apnea-specific hypoxic burden (HB) in evaluation for OSA and lipid metabolism.

Materials and methods: This is a large-scale cross-sectional study enrolled subjects examined with standard polysomnography (PSG) from Jan 2011 to Jan 2022. Demographic, clinical, and sleep characteristics were collected. Confounders were adjusted by collinearity diagnosis before assessment. Multiple linear regression analyses were used to assess the association between HB and lipid profile. Furthermore, logistic regressions were used to evaluate the odds ratio (OR) of prevalent dyslipidemia among the HB quartiles stratified by apnea-hypopnea index (AHI).

Results: A total of 4312 subjects were included within 498 primary snoring (PS) and 3814 OSA (696 in mild, 747 in moderate, and 2371 in severe). The dyslipidemia prevalence was evidently increased with HB quartile both in the whole cohort and OSA group (p -value for trends, both $p < 0.001$). After stratified by AHI, compared with PS group, the dyslipidemia prevalence across the HB quartile in severe OSA

was increased from 58.0% to 98.6% (OR[95% confidence interval (CI)], 1.580[1.205,2.072], 1.664[1.263,2.193], 1.712[1.287,2.276], and 1.986[1.481,2.663], all $p < 0.01$; linear trend, $p < 0.001$). The hyper-low-density-lipoprotein cholesterolemia remained significance across the HB quartile in moderate OSA (linear trend, $p = 0.001$). Furthermore, positive increasing linear trends were presented among triglyceride (TG) level in severe OSA ($p < 0.001$), among total cholesterol (TC) level in moderate to severe OSA (both $p < 0.001$), and among low-density-lipoprotein cholesterol (LDL-C) level when AHI $\geq 5/h$ ($p = 0.021$ in mild OSA, $p < 0.001$ in moderate and severe OSA).

Conclusions: In this cross-sectional study, higher HB was associated with male, older, heavier individuals with worse PSG indexes and greater dyslipidemia prevalence, which appeared more sensitive in severe OSA. Furthermore, the HB performed as an independent factor for early warning of LDL-C level when OSA was diagnosed.

Inflammatory Biomarkers and Symptom Severity: The Role of Cytokines in Paediatric OSA

⁶Hong Kong Hub of Paediatric Excellence, The Chinese University of Hong Kong, Hong Kong SAR, China, ⁷Department of Paediatrics and Adolescent Medicine, Hong Kong Children's Hospital, Hong Kong SAR, China

Introduction: Obstructive sleep apnoea (OSA) affects 1-5% of primary school-aged children. While polysomnography (PSG) is the gold standard for OSA diagnosis, it has limitations in capturing the full spectrum of OSA symptoms. Therefore, parent-reported symptoms are also valuable. Snoring, the main symptom of OSA, is closely related to upper airway inflammation putatively driven by soft tissue vibrations within the upper airway. This study investigated the relationship between OSA symptoms and nasal inflammatory profiles.

Materials and methods: Children aged 5 to 11 years were recruited for clinical evaluation and underwent overnight PSG. OSA was diagnosed with an obstructive apnoea-hypopnoea index (OAHI) ≥ 1 . The Paediatric Sleep Questionnaire (PSQ) was used to measure OSA symptoms. Nasal epithelial lining fluid (NELF), sampled by three-day nasal strip tests in both morning and evening, was collected for each participant. Cytokine concentrations in NELF were measured by Cytometric Bead Array (CBA). The cytokine concentrations were averaged for each participant and natural log-transformed before being taken into a Generalised Linear Model (GLM). Potential confounders, including sex, age, body mass index (BMI) z-score, and the presence of allergic rhinitis, were adjusted for in the GLMs.

Results: Eighty children (31.2% girls) with a mean age of 8.76 years (SD = 1.65) were studied. Among them, 41 (51.3%) children had OSA. Seventeen (21.3%) children were overweight or obese with a BMI z-score larger than 1.036, and 58 (72.5%) children had allergic rhinitis. In adjusted GLMs, a higher PSQ score was significantly associated with a higher level of TNF- α [$\beta = 3.20$, 95% CI: (1.03, 5.37), $p = .004$]. It was also associated with a higher IL-10 despite not reaching statistical significance [$\beta = 3.02$, 95% CI: (-0.16, 6.21), $p = .067$]. Within the subgroup of children with OSA, both TNF- α [$\beta = 4.74$, 95% CI: (1.31, 8.16), $p = .01$] and IL-10 [$\beta = 5.12$, 95% CI: (1.51, 8.73), $p = .0086$] were significantly associated with the PSQ score, showing greater coefficients compared to the overall sample after being adjusted for confounders.

Conclusions: This study reveals a significant association between PSQ scores and nasal cytokine levels, highlighting the role of upper airway inflammation in the symptomatology of paediatric OSA. This potentially indicates a bi-directional interplay between OSA symptoms and upper airway inflammation. Combining PSG results, parent-reported symptoms and nasal inflammatory biomarkers may allow the identification of children with OSA in need of early attention.

Acknowledgments: We would like to thank all the children and their parents for participating in this study. The study is funded by the Commissioned Paediatric Research at Hong Kong Children's Hospital,

Health and Medical Research Fund, Health Bureau, The Government of the Hong Kong Special Administrative Region (reference number: PR-CUHK-4)

Influence of Respiratory Event Characteristics on Event-Specific Hypoxic Burden

H. MIN¹, S.W. Kim¹

¹Kyung Hee University Hospital, Department of Otorhinolaryngology-Head and Neck Surgery, Seoul, Korea, Republic of

Introduction: Obstructive sleep apnea (OSA) is a medical condition, characterized by repeated pauses and reductions in airflow during sleep. The prevalence of OSA is rising notably in high-income nations, a trend that is closely associated with increasing rates of obesity. Diagnosis and severity grading of OSA are predominantly based on the apnea-hypopnea index (AHI), which quantifies the frequency of apneic and hypopneic events per hour of sleep. Despite its widespread use, the AHI is limited in that it fails to capture the temporal characteristics and physiological impact of respiratory disturbances, such as the duration, depth, and corresponding oxygen desaturation burden. Recent studies have demonstrated that the OSA-specific hypoxic burden (HB)—which integrates the frequency, depth, and duration of desaturation events—shows strong associations with multiple adverse clinical outcomes. Calculating the HB for each respiratory event may serve as a tool for quantitatively analyzing the physiological characteristics and pathophysiological impact of apneas and hypopneas. Therefore, this study was designed to investigate how event-specific HB varies with the type and duration of respiratory events.

Materials and methods: Twenty-eight adult male subjects with complaints of snoring and suspected sleep apnea underwent polysomnography (PSG). PSG data were manually scored by a certified sleep technician in accordance with the 2012 American Academy of Sleep Medicine (AASM) scoring criteria. The pre-event baseline SpO₂ was defined as the maximum SpO₂ recorded within the 100 seconds preceding the termination of the event. The area between the baseline and the oxygen desaturation curve corresponding to each respiratory event is defined as event-specific HB. Violin plot, linear regression analysis, one-way ANOVA and subsequent pairwise comparisons were used for statistical analysis.

Results: A statistically significant difference in HB was observed between the two groups ($p < 0.001$), with apnea events demonstrating a higher HB compared to hypopnea events. A strong positive correlation was observed between HB and apnea duration ($R = 0.75$), indicating that longer apnea events are associated with greater HB. In contrast, the correlation between HB and hypopnea duration was minimal, suggesting that variations in hypopnea duration have limited influence on HB. An overall trend of increasing HB with longer event duration is observed, particularly in apnea events. Apneas accompanied by arousal (A-AR) exhibited a significantly higher HB compared to those without arousal ($p < 0.001$). In contrast, no significant difference in HB was observed between hypopnea events with and without arousal ($p > 0.05$).

Conclusions: Event-specific HB was higher in apneas than in hypopneas. In particular, within apneas, longer event duration and the presence of arousal were associated with a significantly greater HB.

Infrared Optical Gas Imaging for Sleep Apnea Diagnosis

H.J. Kim¹, J.K. Kim²

¹Ajou university School of Medicine, Otolaryngology, Suwon, Korea, Republic of, ²Konkuk University College of Medicine, Otorhinolaryngology-Head and Neck Surgery, Seoul, Korea, Republic of

Introduction: Polysomnography (PSG) is the standard method for diagnosing obstructive sleep apnea (OSA), but its use of multiple contact sensors can disrupt sleep and reduce test accuracy. Recent non-contact methods, such as audio and radar-based devices, offer convenience but cannot directly measure respiratory airflow. Infrared optical gas imaging, which visualizes exhaled carbon dioxide, may overcome these limitations by enabling direct, contactless monitoring of respiration during sleep. This study aimed to evaluate its feasibility as an alternative tool for OSA diagnosis.

Materials and methods:

We recruited 50 participants from Ajou University Hospital between June and August 2018. All participants underwent overnight polysomnography (PSG) and were simultaneously recorded using infrared optical gas imaging (FLIR GF343) to visualize exhaled CO₂. Standard sensors (oronasal thermistor and nasal cannula) were used during the first half of sleep and removed during the second half. Respiratory events were also measured using chest and abdominal belts. Infrared-derived airflow signals were extracted using a face-tracking and temperature-differential algorithm, allowing calculation of respiratory parameters such as AHI, RDI, and apnea/hypopnea indices. Data were scored based on AASM 2012 criteria.

Results: Respiratory parameters derived from infrared optical gas imaging showed strong positive correlations with those from standard PSG, both in the presence and absence of nasal cannula. Apnea-hypopnea index (AHI) values were particularly well-aligned ($p > 0.85$ with sensors, $p > 0.72$ without). Receiver operating characteristic (ROC) analysis confirmed the diagnostic validity of infrared imaging, with area under the curve (AUC) values exceeding 0.8. Although infrared imaging tended to slightly overestimate AHI, it reliably detected sleep-related respiratory events, even without contact-based sensors.

Conclusions: Infrared optical gas imaging accurately detected respiratory events during sleep; therefore, it may be employed as a screening tool for OSA.

"INNOVATING SLEEP APNEA SCREENING: TELE-OSA QUESTIONNAIRE- A NOVEL TELEPHONIC SCREENING TOOL FOR MODERATE TO SEVERE OBSTRUCTIVE SLEEP APNEA"

K.S. Kumar¹, S. Manwal², K. Rawat³, L.K. Saini⁴, R. Gupta⁵

¹AIIMS Rishikesh, Pulmonary Medicine, Rishikesh, India, ²AIIMS Rishikesh, Sleep Division, Department of Psychiatry, Rishikesh, India, ³AIIMS RISHIKESH, Pulmonary medicine, Rishikesh, India, ⁴AIIMS Rishikesh, Pulmonary Medicine and Division of Sleep Medicine, Rishikesh, India, ⁵AIIMS Rishikesh, Psychiatry and division of Sleep medicine, Rishikesh, India

Introduction:

- Prevalence of obstructive sleep apnea (OSA) varies between 6-17% in general adult population. Untreated severe OSA has 2-3-fold increased risk of all-cause mortality. Despite high prevalence, OSA often remains undiagnosed.
- Access to polysomnography (PSG), gold standard for diagnosis, can be limited in LMICs like India due to several factors like availability of sleep centers, geographical distribution (often concentrated in urban areas), cost of services, referral processes, awareness and workforce shortages.
- Consequently, sleep clinics often experience overwhelming patient loads and prolonged waiting times, underscoring urgent need to streamline screening and triage pathways.
- Drawbacks of existing screening questionnaires are usage of objective parameters (anthropometric measurements) and reliance on age, gender, and BMI which can introduce biases.

Materials and methods:
